Department of Medicine B, University of M\'fcnster, M\'fcnster, Germany*Introduction:* Activated monocytes with increased production of proinflammatory cytokines seem to play a major role IBD. The aim of our study was to determine the in vitro capacity of immunoregulatory cytokines (IL-4, IL-10 and IL-13) to down-regulate activated monocytes under various culture conditions and to examine the effect of a combined administration of these cytokines.*Methods:* Peripheral monocytes from patients with active IBD (CD, n = 27; UC, n = 27) were isolated over Ficoll and hypotonic Percoll gradient centrifugation and stimulated with Pokeweed mitogen (PWM, 10 \'b5g/ml). IL-4, IL-10, IL-13 and a combination of IL-4/IL-10 and IL-10/IL-13 were added at different concentrations (1–1000 U/ml) and different times. Secretion of IL-1{ b}, TNF-{ a} and IL-6 was assessed using sandwich ELISA-systems. 7-day cultured monocytes (stimulation with GM-CSF) were used as a model for matured macrophages.*Results:* The antiinflammatory cytokines IL-13, IL-4 and IL-10 were all capable to inhibit the monocyte secretion of the proinflammatory cytokine IL-1{ b} in a dose dependent manner in controls. With regard to IL-13 and IL-4, there was a diminished suppression of TNF-{ a} and IL-6 production from patients with active IBD compared with controls and patients with inactive IBD. The inhibitory effect of IL-13 on TNF-{ a} and IL-6 production in 7-day cultured, differentiated macrophages was also reduced in patients with IBD as well as in controls. In monocytes from disease controls we also observed a diminished inhibition of TNF-{ a} and IL-6 by IL-13. IL-10 plus IL-4 and IL-10 plus IL-13, respectively, inhibited the proinflammatory cytokine response of monocytes as well as matured macrophages much more than either IL-4, IL-10 or IL-13 alone in controls as well as in IBD-patients. Even at suboptimal concentrations for each cytokine alone, a combination of cytokines showed synergistic inhibitory effects.*Conclusion:* First, the hyporesponsiveness of activated and differentiated monocytes to IL-13 and IL-4 which is observed in patients with active IBD does not seem to be a disease specific phenomenon. Second, a combination of antiinflammatory cytokines is much more effective in down-regulating the response of activated and differentiated monocytes than using the cytokines alone and may have a potential therapeutic benefit for patients with IBD. OT10 0534**A Prospective Randomised Trial of Cimetidine Therapy in Gastric Cancer: An Interim Report**

*M.T. Hallissey, J.A. Dunn, P.G. Baker, J.G. Davis, L.J. Billingham, J.W.L. Fielding, M.J. Langman, British Stomach Cancer Group

CRC Trials Unit, University of Birmingham, Birmingham, UKCimetidine has been reported to improve the survival of patients with gastric cancer at all stages of disease. The aim of the fourth British Stomach Cancer Group trial was to assess the survival benefit of adjuvant cimetidine in gastric cancer.The study is a randomised double-blind trial comparing cimetidine at 2 dose levels, 800 or 400 mg twice daily with matching placebos. Eligible patients had biopsy proven gastric adenocarcinoma, with any stage of disease, were considered fit to enter the trial (life expectancy > 3 months) and were able to give informed consent. The study recruited 442 patients between February 1990 and March 1995 from 59 consultants in 39 hospitals throughout the UK. Analysis has been undertaken on an intention-to-treat basis. There is now 12 months follow up on all patients with a median follow up of 41 months.The treatment allocation was balanced for sex, age, and stage. The median age of the patients in the study population is 68 years, (range 23–88 years). The male to female ratio was 1:2.5. The majority of patients had stage III (31%) or stage IV (46%) disease, with 63 (15%) stage II and 36 patients (8%) stage I.The trial results demonstrate no survival benefit for cimetidine when comparing the survival for all patients receiving cimetidine against placebo ({ ?}^{2} = 1.77, p = 0.18). When adjustment is made for dose (400 vs 800 mg), stage (I/II, III, IV), age (< 68, 68+) and sex, there is no survival benefit for the use of cimetidine. The median survival is 11 months for the cimetidine group compared to 12 months for the placebo group. The median survival within the cimetidine group is 11 months (95% CI 6–16 months) for 800 mg BD and 12 months (95% CI 8–14) for 400 mg BD.The results of this trial do not support the use of cimetidine as an adjuvant therapy in gastric cancer. The need to continue trials of therapy in gastric cancer remains. OT10 0535**Use of Laparoscopic Ultrasonography (LUS) in the T-Stage Evaluation of Gastric Cancer. Preliminary Results**

*J. Durup Scheel-Hincke, M.B. Mortensen, C.P. Hovendal

Dpt. Of Gastroint. Surg. Odense University Hospital, Odense, -DenmarkThe most accurate method in the assessment of T-stage in gastric cancer is Endoscopic Ultrasonography (EUS). But evaluation is often compromised due to stenotic tumors. A new method for gastric cancer staging, LUS, have been introduced, but how accurate is this new method?15 consecutive patients with gastric cancer. (4 female 11 male, mean age 61 (37–76)) 11 Patients were histopathological evaluated. Four patients were not resected because of distal metastases. All patients underwent CT/eksternal ultrasonography, EUS and blinded; Laparoscopy with LUS.*Results:* n (%) CT/UL EUS LAP LUSCorrect 0 (0%) 9 (82%) 3 (27%) 9 (82%)Understaging 6 (55%) 1 (9%) 0 (0%) 0 (0%)Overstaging 0 (0%) 0 (0%) 0 (0%) 1 (9%)Insufficient 5 (45%) 1 (9%) 8 (72%) 1 (9%)There were no T1 tumors, 1 T2, 7 T3, and 3 T4 cancers. EUS understaged 1 patient with a stenotic non-traversabel tumor. LUS overstaged 1 patient with an absces located in cardiac region as having a T4 tumor.*Conclusion:* These preliminary results indicate that Laparoscopic Ultrasonography is a highly accurate method in T staging of gastric cancer. Larger blinded and prospective studies are needed. OT10 0536**Does the Addition of Cisplatin to High Doses of 5-Fluorouracile and Epirubicin in Advanced Gastric Cancer Results in Better Response to Therapy**

*A. Roth, K. Kolaric, D. Zupanc

University Hospital for Tumors, Zagreb, CroatiaThe aim of the study was to determine activity of high doses of 5-fluorouracile and epirubicin (FE) vs. the same combination + cisplatin (FEP) in advanced gastric cancer.From September 1991 to March 1996, 104 patients with advanced gastric cancer entered phase III clinical trial. Out of 104 patients 95 (65 males and 30 females) were evaluable ({\'b3} 2 cycles of chemotherapy). The range of patients age was 27–71 years (M = 55), and ECOG performance status was {\'a3} 3. The predominant metastatic sites were lymph nodes and liver. The treatment involved in FE arm 1000 mg/m^2 in 6-hour infusion of 5-fluorouracile on days 1, 2, 3, 4, 5 and 120 mg/m^2 of epirubicin i.v. on day 1; in FEP arm the same combination of cytostatics + cisplatin 30 mg/m^2 on days 2, 4 was administered. The cycles were repeated after 4 weeks.In FE arm 48 patients were evaluable with 1 complete and 14 partial remissions (31.25%), and in FEP arm out of 47 evaluable patients 2 complete and 17 partial remissions (40.42%) were observed. Median survival in FE group was 6.6 mos, and i FEP group 8.8 mos. The survival difference is statistically significant if Logrank test Statistica 4.0 Statsoft, 1993 is used (p = 0.02573), and is not statistically significant if Logrank test M. Peto, 1977 is used (hiq = 2.92) The most frequent toxic side effect was alopecia. Febrile neutropenia (grade IV) was observed in 3 patients in arm FE and in 5 patients in arm FEP. The treatment related death was not registered.The final results will provide a deffinite answer with regard to the value of cisplatin in combination with high doses of 5-fluorouracile and epirubicin in advanced gastric cancer. OT11 0537***H. Pylori Vac A* Gene Differences and *Cag A* Gene Existence in Patients with Duodenal Ulcer and Gastritis**

*J. Ostrowski, E. Hennig, J. Regula, K. Przytulski, I. Lazowska, E. Butruk

Dept. of Gastroenterology, Institute of Oncology, Warsaw, PolandThe purpose of this study was to compare the genetic divergence of *vacA* genes and the presence of *cagA* gene in *H. pylori*-infected patients.The study was carried out on 34 patients with duodenal ulcer (DU) and 33 patients with *H. pylori* associated chronic gastritis (GA). Patients were diagnosed histologically, by CLOtest and PCR amplified fragment of *urease A* gene in gastric mucosa lysates. Two other biopsy specimens were taken from the corpus and antrum. Lysates of these tissue samples were used for PCR amplifications of *vacA* gene fragments (with the primers described by Atherton et al., JBC 1995; 270: 17771) and *cagA* gene fragment.In DU patients *cagA* gene was found in 51% of biopsy specimens, and in GA patients in 31% of the samples. There were no differences in the frequency of *cagA* existence determined in biopsy specimens, taken from the antrum and corpus, in both studied groups. Amplification of the *vacA* middle region sequences revealed very similar DNA patterns among the studied patients. The predominant sequence type present was m2 (found in about 50% of the all samples), whereas m1 type was found in about 25% of biopsy lysates. In a few samples, both m1 and m2 fragments could be amplified, and in about 20% specimens neither m1 nor m2 was detected. The s2 signal sequence was found more frequently in GA than in DU patients (50% and 31%, respectively), whereas s1a and s1b sequences were shown more often in DU than GA patients (85% and 62% for s1a, and 15% and 2% for s1b, respectively). *VacA* amplification patterns for two different biopsy specimens from the same patient were identical in 64% GA and 47% DU patients.The results of this study suggest: 1) there is no single *vacA* gene type predominant in DU patients, 2) in most of our patients more than one *H. pylori* strain exists.Supported by grant 4 S402 034 07 from the National Research Committee Oesophageal gastric duodenal disorders: GD disorders, acid pepticOesophageal gastric duodenal disorders: Helicobacter PyloriHormones and receptors: Molecular biology }" "H. Pylori Vac A Gene Differences and Cag A Gene Existence in Patients with Duodenal Ulcer and Gastritis"

OT11 0538**Helicobacter Pylori (Hp) Genotyping: Association between Cytotoxic Strains and Peptic Ulcer****F. Navaglia, M.G. Piva, D. Basso, A. Toma, M. Scrigner, M. Rugge[1], F. Di Mario[2], M. Plebani**

Dept. of laboratory Medicine, University of Padova, Italy

[1] Dept. of Pathology, University of Padova, Italy

[2] Dept. of Gastroenterology, University of Padova, ItalyIt has been suggested that the cytotoxic strains of Hp play a major role in the pathophysiology of various gastroduodenal diseases, among which gastric and duodenal ulcer. Aims of the present study were: 1. to evaluate the genetic pattern of Hp infecting the gastric mucosa by the identification of urease gene A (UreA), cytotoxin associated gene A (CagA) and vacuolating cytotoxin gene (VacA); 2. to assess if there were any association between any genetic pattern of Hp and gastrodeuodenal diseases or the presence of intestinal metaplasia. A total of 129 patients were studied; 59 were affected by antral gastritis (AG), 10 by active (APU) or healed (HPU) (n = 27) peptic ulcer, 4 by chronic atrophic gastritis (CAG), 22 by duodenitis (DUO) and 7 by oesophagitis (OES). Gastric juice and gastric mucosal samples, obtained during endoscopy, were used for DNA extraction and further polymerase chain reaction (PCR) to identify the following genes: a) UreA with the primers: 5{\'a2}GACATCACTATCAACGAAGG3{\'a2} and 5{\'a2}TGAAAACCACGCTCTTTAG3{\'a2}; b) CagA with the primers: 5{\'a2}GATAACAGGCAAGCTTTTGAGG3{\'a2} and 5{\'a2}CTGCAAAAGATTGTTTGGCAGA3{\'a2}; c) the polymorphism of the mid region and of the signal peptide of VacA using the primers described by Atherton et al. [1], which identify cytotoxic (S1M1 or S1M2) and non cytotoxic (S2M2) genotypes. Hp infection, assessed by UreA, was found in 48% AG, 90% APU, 70% HPU, 100% CAG, 64% DUO and 57% OES. Three genotypes of VacA were found: S1M1, S1M2 and S2M2; the association S2M1 was never found. CagA was associated with S1M1 in 84%, with S1M2 in 72% and with S2M2 in 9% of the cases. CagA was significantly associated with both APU and HPU ($X2 = 4.9$, $p < 0.05$ and $X2 = 5.7$, $p < 0.05$). S1M1 VacA genotype was significantly associated with APU ($X2 = 7.5$, $p < 0.05$) but not with HPU ($X2 = 4.3$, p: ns). No association was found between Hp genotype and the presence of intestinal metaplasia in the gastric mucosa. In conclusion: 1. Hp infection was confirmed to be extremely frequent in patients with active or healed peptic ulcer; 2. the cytotoxic genotype of Hp was frequently, although not exclusively associated with CagA; 3. both VacA cytotoxic genotype and CagA were significantly associated with the presence of peptic ulcer disease, suggesting a key role of the vacuolating cytotoxin in the pathogenesis of this disease; 4. the vacuolating cytotoxin is probably not involved in the pathogenesis of gastric intestinal metaplasia.

OT11 0539**Effect of Macrolides on Gastric Acid Secretion under Basal and Stimulated Conditions**

*C. Landry[1], N. Vidon[1], J.A. Chayvialle[2], P. Sogni[3], J.P. Chauvin[4], D. Couturier[3], J.C. Chaumeil[1], S. Chaussade[3]

[1] Facult\'e9 de Pharmacie, Paris, France

[2] Hospital E. Herriot, Lyon, France

[3] Hospital Cochin, Paris, France

[4] Laboratoires Abbott France, FranceIn a previous study, we have shown that iv erythromycin (ERY) decreased gastric acid secretion during continuous enteral nutrition. This effect could be the consequence of the gastric emptying increase or a direct effect of ERY on gastric secretion. Clarithromycin (CLARI), in association with gastric acid secretion inhibitors, is an effective treatment for Helicobacter Pylori eradication. The *aim of the study* was to evaluate the effect of ERY and CLARI on gastric acid secretion under basal conditions and stimulated by pentagastrin. *Methods:* 8 healthy male subjects were studied. Each subject received in randomized order either iv ERY (150 mg/h for the 3 hours of the test period), oral ERY (500 mg), oral CLARI (500 mg) 1 hour before the test period or placebo. Gastric emptying and acid secretion were evaluated 1 h before and 2 h during pentagastrin perfusion (0.8 ug/kg/h). The method used has been described by Muller-Lissner (Dig Dis Sci 1986, 31: 807–10). Luminal somatostatin was measured during iv ERY and placebo. *Results* mean – SEM; * $p < 0.05$ compared to placebo. iv ERY Oral ERY CLARI Placebo*Secretion (mM/h)*Basal 1.8 – 0.3* 2.6 – 0.6 3.0 – 1.2 3.7 – 0.9Pentagastrin 1 h 16.5 – 3.7* 27.6 – 3.1 25.6 – 3.3 30.8 – 1.7Pentagastrin 2 h 14.5 – 3.6* 31.1 – 5.0 28.3 – 3.3 34.6 – 2.2*Emptying rate (%/min)*Basal 14.4 – 0.9* 11.7 – 0.8 12.2 – 0.5 10.8 – 1.3Pentagastrin 1 h 9.5 – 1.2* 4.8 – 1.0 5.0 – 1.2 4.4 – 1.0Pentagastrin 2 h 9.2 – 1.3* 4.3 – 1.2 5.5 – 1.1 4.0 – 1.4Luminal somatostatin was not statistically different.*Conclusions:* iv ERY decreases gastric acid secretions and increases gastric emptying under basal conditions as well as during pentagastrin perfusion. It would need further investigations to determine its mechanism of action. In our experimental conditions, oral ERY and CLARI did not modify gastric response. [2] Dept. of Gastroenterology, Athens, Greece

[3] 2nd and 3rd Dept. of Internal Medicine, ""ELPIS"" General Hospital of Athens, Greece

[4] Hellenique Pasteur Institute of Athens, Greece*The aim* of this study was to investigate the spread of the Hellicobacter Pylori (HP) infection amongst the members of the families of infected individuals, using a direct DNA amplification technique and restriction pattern analysis (REA-PCR).*Patients-Methods:* Eleven symptomatic index patients (7 children aged 6–14 years, 4 adults) seropositive for HP antibodies, and their 18 seropositive for HP antibodies family members were found to be HP positive by histology and culture. Biopsy specimens were taken from the duodenum, antrum and fundus of the above patients to assess the possibility of multiple HP strains infection. Amplification by PCR of UreA and UreB genes of HP, followed by restriction pattern analysis was used for the comparison of HP strains isolated in the index patients and their family members.*Results:* The results of our study were the following: 1) In 3 out of 6 families the children and their parents were infected by similar HP strains. 2) In 4 out of 8 couples, identical HP strains were harboured by each spouse. 3) In 5 out of 11 families (45%) at least two identical HP strains were found in each family. 4) In only one patient were two different HP strains isolated in the antrum and fundus.*In conclusion* vertical and/or horizontal transmission of HP within families is possible, although a common source of infection cannot be precluded. However, in 55% of the families, different sources of HP infection of the family members can be suspected. Infected individuals by multiple HP strains can be found but it is a rather rare phenomenon. OT11 0541**Comparison of Two Alternative Strategies for the Management of Duodenal Ulcer: An Economic Model**

*T. Lebrun[1], X. Lenne[1], B. Requin[1], M.A. Bigard[2], R. Colin[3], A. Cortot[4], P. Zeitoun[5]

[1] CRESGE (LABORES URA CNRS 362), France

[2] Nancy, France

[3] Rouen, France

[4] Lille, France

[5] Reims, FranceThis study aimed to compare two strategies for the management of duodenal ulcer 5 years after diagnosis with or without *Helicobacter pylori* eradication.*Methods:* A cost-effectiveness (C/E) and cost-benefit (C/B) analysis were performed using simulated Markovian modelling on 100,000 individuals. Revelant clinical data introduced to the model were obtained from published data or from a consensus of experts. The C/E analysis evaluated the cost of one additional unit of efficacy, either the number of patients healed after the initial 4 week treatment without recurrence at time t, or the mean number of months before the first recurrence. The C/B analysis (from a collectivity point of view) evaluated the costs avoided per French Franc (FF) invested. The costs taken into account were the costs of treatment (H_2 antagonists for the no eradication strategy, omeprazole plus two antibiotics, followed in case of failure by H_2 antagonists in eradication strategy), the cost of medical visits and the costs of gastroscopy. A sensitivity analysis was carried out to evaluate the effect of variations in clinical probabilities and costs, eg gastroscopy. The results presented are those where the strategy without eradication has a maximal efficacy (max) (recurrence without maintenance treatment: 50% within 2 years; with maintenance treatment: 17% within 2 years) and the treatment with eradication a minimal efficacy (min) (eradication: 55%) and maximal efficacy (max) (eradication: 95%).*Results:* 5-year figures: H1** H2**Cost-effectiveness Erad (max eff)/AH2 (max eff) 1048 FF 1375 FFratio* Erad (min eff)/AH2 (max eff) 3006 FF 3944 FFCost-benefit Erad (max eff)/AH2 (max eff) { -}5.28 FF { -}5.16 FFratio*** Erad (min eff)/AH2 (max eff) { -}0.51 FF { -}0.32 FF*patient without recurrence; **Depending on the mean cost of gastroscopy; ***Cost reduction per 1FF invested.*Conclusion:* The results support the eradication strategy option with maximal success of eradication as confirmed currently by triple drug regimens. This strategy gives a 5-year benefit of more than 5 FF for each franc invested (1$ = 4.90 FF). OT12 0543**The Costs of Crohn's Disease in Sweden**

*A. Lapidus, L. Bohman, R. L\'f6fberg[1], C.-H. Flor\'e9n, K. Sj\'f6berg[2], U. Johansson[3], A Danielsson[4], P. Hertzman[5]

[1] Department of Gastroenterology and Hepatology, Huddinge University Hospital, Sweden

[2] Department of Gastroenterology, University Hospital MAS, Malm\'f6, Sweden

[3] Department of Medicine S\'f6dert\'e4lje, Hospital, Sweden

[4] Department of Medicine Umea University Hospital, Sweden

[5] Astra Draco, Lund, Sweden*Background:* Crohn's disease (CD) is a chronic disease which mainly manifests in the early adulthood. It is characterized of either recurrent clinical flare-ups or chronic continuous disease. Patients therefore need regular medical attendance including visits, hospitalisation, endoscopies, pharmacological and/or surgical treatment. Swedish health care is predominantly public. With respect to the chronicity and early onset of the disease, the costs for medical service for these patients are not negligible.*Aim:* To evaluate the costs during the first 5-year period of CD with respect to extent of disease at diagnosis and type of medical measures.*Material & Methods:* From four different centres in Sweden, patients aged > 18 years who got the diagnosis of CD between 1983 and 1988 were included into the study. All CD related measures were registered and fixed the price of. The costs were related to different periods of disease, inpatient care, outpatient care, drugs and extent of disease at diagnosis.*Results:* 189 patients were included in the study. The mean costs per patient for the first 5-year period was 135540 SEK. (1 SEK = 0.15 US dollar) with the highest costs for the first year after diagnosis (52371 SEK.). Of the total costs, inpatient care accounted for 78.5%, outpatient care for 12.9%, costs related to time for diagnosis including the 6 preceding months for 3.7% and drugs for 4.8%. The mean costs for patients requiring surgery was twice as high as for the unoperated patients. Discontinuous ileocolonic disease accounted for the highest costs regarding extent of disease.*Conclusion:* The major costs of Crohn's disease are during the first year of diagnosis and mainly due to surgery and associated morbidity inpatient care. Pharmacological treatment and outpatient attendance account for minor costs and consequently frequent medical visits and treatment seem legitimated to avoid surgery as long as not deemed necessary. Intestinal disorders: IBD, basicClinical practice: Management strategy }" "The Costs of Crohn's Disease in Sweden"

OT12 0544**Optimisation of Diagnostic and Therapeutic Strategies before Laparoscopic Cholecystectomy (LC): A Decision Analysis StudyP. Burtin, S. Carpentier, J.P. Arnaud, G. Houbiers, C. Casa, B. Person, J. Boyer**

University hospital, Gastroenterology unit, 49033 Angers, FranceEndoscopic ultrasonography (EUS), and retrograde cholangiography (ERCP) have made complex the management of patients before LC.*Aim:* To select the best cost-effectiveness strategy before and after LC, taking into account the expected performances of endoscopists and surgeons.*Methods:* The expected results of EUS, diagnostic and therapeutic ERCP, and laparoscopic extraction of biliary stones (LCBDE) in the management of bile duct lithiasis were estimated according to the results of published data. Following primary LC, 3 different decision trees were built, using ERCP, LCBDE or open surgery to treat residual biliary stones. After selection of the more optimal surgical strategy, 3 other decision trees were also built, using respectively EUS only, ERCP only, and both EUS and ERCP before LC. Costs per patient were calculated for each strategy according to private practice (cost 1) or public practice (cost 2) in French Francs (1 ECU = 6.34 FF). The results of the 4 more relevant strategies are given below.*Results:* LC, then LCBDE, ERCP, then EUS, ERCP ERCP then ERCP LC and LCLow risk of biliary lithiasis (2.5%)Death rate (%) 0.32 0.40 0.53 0.33Hospital stay (days) 2.4 2.5 3.3 3.3Cost 1 (FF) 9,300 9,600 13,800 13,300Cost 2 (FF) 8,400 8,800 11,100 11,500Medium risk of biliary lithiasis (40%)Death rate (%) 0.63 0.86 0.72 0.60Hospital stay (days) 6.5 4.5 4.3 4.6Cost 1 (FF) 15,100 12,200 16,000 17,000Cost 2 (FF) 21,000 15,600 14,300 15,500In patients with high probability of stones (80%), the best strategy was primary ERCP, followed by LC or LCBDE according to the results of ERCP (death rate: 0.93%, hospital stay: 5.4 days).*Conclusions:* In asymptomatic patients, LC followed by eventual ERCP is the best cost-effective method to manage gallbladder lithiasis. In patients with a medium risk of biliary stone, it is preferable to perform EUS and ERCP before LC. OT12 0545**Comparison of the Cost-Effectiveness of Different Approved Dual Therapy Regimens for *H. Pylori* Eradication**

*L.F. Lacey[1], K. Claxton[2], A. Campbell[3], J. Phillips[1]

[1] Business Economics, Glaxo Wellcome plc, UK

[2] Dept. Economics and Related Studies, Univ. York, UK

[3] PA Consulting Group, London, UK*Purpose:* Dual therapies comprising an antisecretory agent plus an antibiotic are increasingly being used by primary care physicians to eradicate *H. pylori.* A decision tree model was built to compare the cost-effectiveness of different approved eradication regimens.*Methods:* The target patient population for the model are those patients who present to a primary care physician with symptoms and a previous history of duodenal ulcer (DU). The decision tree model caters for four different management strategies, which depend on whether DU diagnosis is determined by endoscopy or presumed based on symptoms/DU history and whether *H. pylori* status is determined. The model examines outcomes over a two year period. Each regimen involves co-prescription of an antisecretory drug and one antibiotic for 2 weeks to eradicate *H. pylori,* followed by a further 2 weeks of antisecretory treatment to ensure DU healing. The following regimens were compared: Regimen Eradication phase Healing phaseRBC + C Ranitidine Bismuth Citrate (400 mg bd) RBC (400 mg bd) + Clarithromycin (1–1.5 g daily)O + C Omeprazole (20 mg bd) + O (20 mg daily) Clarithromycin (1–1.5 g daily)O + A O (20 mg bd) + Amoxycillin (2 g daily) O (20 mg daily)*Results:* The results using UK cost data, for the case in which the presence of DU is confirmed and *H. pylori* status is tested, are: Regimen *Improvement in % *% Decrease in costscomparison relapse rate per treatment successRBC + C vs. O + C 10 20RBC + C vs. O + A 20 30*RBC + C has better health outcome, with lower costs in preventing DU relapse.*In conclusion:* RBC + C is more cost-effective than O + C or O + A in the treatment of DU. Clinical practice: Management strategyOesophageal gastric duodenal disorders: Helicobacter Pylori }" "Comparison of the Cost-Effectiveness of Different Approved Dual Therapy Regimens for H. OT12 0546**Choledochocholedochostomy with or without Drainage in Liver Transplantation**

*O. Boillot, S. Barcet, V. Frering, E. Fontaumard, P. Meeus, I. Mechet

Unit\'e9 de transplantation h\'e9patique, Pavillon D, Hospital Edouard Herriot, 69003 Lyon,
FranceBiliary complications following liver transplantation (LT) represents a high-frequency cause of morbidity. Choledochocholedochostomy (CC) with bile duct drainage through a T-tube represents the standard technique, but T-tube related complications are common after LT. The need for bile drainage remains questionable. In a retrospective study, we analysed the biliary complications following choledochocholedochostomy with or without T-tube in a series of 135 patients.*Patients and methods.* From october 1990 to october 1995, 214 LT were performed in 210 patients. Of them, 69 patients with hepaticojejunostmy and 10 with CC surviving less than 3 months were excluded from the study. Finally, 135 LT in 135 patients with a mean follow-up of 27.7 months were studied. There were 100 males and 35 females with a mean age of 44 years (range: 3 to 62). Mains indications for LT were viral (42%) and alcoholic cirrhosis (38%). Patients were divided in 2 groups according to the use (group I, n = 50) or not (group II, n = 85) of a biliary drainage. In group I, post-operative cholangiography through the T-tube was performed between day 10 and day 16 post-LT, then the drain was closed until a new control 3 to 4 months later before removal. The two groups were comparable for age, sexe, liver diseases, donor age, cold ischemic time and intra-operative blood products transfusions but different for operative procedure duration (GI: 382 mn vs GII: 312 mn; p = 0.001). Statistical analysis was made by ANOVA and chi-Square tests, differences were considered statistically different at $p < 0.05$.*Results.* After a mean follow-up of 38 months for GI and 21 months for GII, 44 (88%) and 83 (97.6%) patients were alive with their first graft. Seventeen (34%) and 6 (7%) patients experienced biliary complications in groups I and II respectively ($p < 0.05$), requiring operative management in 5 (10%) and 3 (3.5%) of them and endoscopic manoeuvres in 5 and 2 cases respectively. None of the deaths were related to biliary complications. In group I, 15 early complications were T-tube related (T-tube dislodgement leading to bile leak in 4 cases, bile leak at the T-tube site occuring after removal and responsible for peritonitis in 6 cases, heamobilia in 2 cases and symptomatic cholangitis in 3 last cases). During the late follow-up (at 4 and 7 months) 2 anastomotic stenoses were diagnosed. In group II, early biliary leaks happened in 2 cases at the end of the first week post-LT requiring urgent operative anastomotic biliary conversion to a successful hepaticojejunostomy. Later, 2 months post-LT an another patient experienced an anastomotic leak because of duodenum perforation and was treated using biliary stents. Late anastomotic stenoses (at 2, 4 and 8 months) occured in 3 patients.*Conclusions.* This study demonstrates the potential deleterious effects of the use of the T-tube which is responsible for the main biliary complications after LT. Our results underline the validity of choledochocholedocostomy without drainage which can be a safe and efficient technical option in liver transplantation. OT18 0547**Weekly High Dose of 5-Fluoruracil (5FU) 24 Hour Infusion + Oral L-Leucovorin (L-LV) in Advanced Colo-Rectal Cancer: A Phase II StudyM.C. Barzacchi, O. Sanguineti, M.T. Nobile,**

*P. Cognein, S. Bertoglio, P.M. Meszaros, P.L. Percivale, A. Lavarello, R. Rosso

National Institute for Cancer Research, Genoa, ItalyWe aimed at improving the clinical efficacy of the combination of 5-FU + L-LV for advanced colorectal cancer. We designed a phase II study based on a weekly outpatient regimen of oral L-LV and continuous 24 hr 5-FU infusion as follows: L-LV 100 mg/sqm by 4 hr i.v. infusion followed by 5-FU 2600 mg/sqm over 24 hr infusion combined with a fixed dose of oral L-LV (50 mg) every 4 hrs for 5 times. 57 pts (44 M, 13 F, mean age 63 yrs; mean performance status 1) were enrolled. All pts required subcutaneous port insertion and portable external infusion pump to allow outpatient regimen. All pts were evaluable. 37 pts did not receive any previous CT: 15 pts responded (7 CR and 8 PR, overall response rate: 40.5%). 20 pts received previous CT: no CR, 6 PR, overall response rate: 30%. The overall objective response was 35.5%, median duration of remission was 22 weeks. Major side effects were Hand-Foot Syndrome grade I–II 44.7%; Nausea-Vomiting grade I–II 42.5%; Fatigue grade I–II 34%; diarrhoea grade I–II 31.9% – grade III 17%; oral mucositis grade I–II 21.3%; Leukopenia grade I–II 8.5%. Concluding remarks: 1) high rate of objective responses, overall in those pts who did not respond to a previous chemotherapy; 2) acceptable toxicity rate; 3) feasibility in outpatient regimen. OT18 0548**Liposomal Versus Free Fluorouracil in the Treatment of Human Colon Carcinoma Cells: An In Vitro Ultrastructural and Cytotoxicity StudyJ.N. Giannios,**

*J.A. Karagiannis

Gastroenterology Unit, St. Savvas Anticancer Hospital, Athens, GreeceColorectal adenocarcinoma is an aggressive malignant tumour with high metastatic potential and poor response to conventional chemotherapy. The latter is mainly due to high expression of MDR-1 gene encoding a 170 kda plasma membrane P-glycoprotein, rendering malignant cells resistant to chemotherapeutic agents. On the other hand, quantitative studies have shown that colon malignant cells exert a high expression of low-density lipoprotein (LDL) receptors for the highly needed uptake of cholesterol compared to normal colon cells. Solid liposomal bilayers were prepared followed by 5-FU molecule entrapment in dehydration-rehydration vesicles so that 5-FU constituted part of their bilayers. The amount of 5-FU entrapped was approximately 86 \'b5g/liposome. Malignant colon adenocarcinoma cells were prepared after collagenase digestion of tissue specimen obtained after surgical excision from colon cancer patient. Malignant cells (2.06 {\'b4} 10^6/ml) were incubated (95% air, 5% CO2, 37\'b0C) with a) control liposomes, b) liposomal 5-FU bilayers and c) free 5-FU (10 mg/ml) for 10, 30 and 60 min. After incubation both cytotoxicity assays (trypan blue exclusion test, LDH activity, protein synthesis and colonies-forming capability) and electron microscopy (both transmission and scanning EM). Liposomal 5-FU treated malignant cells showed lower viability by trypan blue exclusion test (80% v. 95% at 10 min, 45% v. 90% 30 min, 5% v. 86% 60 min), higher LDH activity (25% v. 8% 10 min, 55% v. 10% 30 min, 96% v. 12% 60 min), decreased protein synthesis (79% v. 96% 10 min, 35% v. 95% 30 min, 8% v. 90% 60 min) and impaired colonies-forming capability (60% v. 93%, 20% v. 92% 30 min 6% v. 90% 60 min) compared to free 5-FU treated cells (% values refer to incubation with control liposomes). EM studies showed fusion of 5-FU loaded liposomes with cell surface and high granular cytoplasm breakdown of plasma and nuclear membranes while control liposomes didn't cause any damage to the tumour cells. Free 5-FU treated cells showed minimal structural changes.The above results suggest that liposomal 5-FU is capable of entering human colon adenocarcinoma cells resistant to conventional chemotherapeutic agents by circumventing the P-glycoprotein. [3] Unit\'e0 di Oncologia, IRCCS ""S. de Bellis"" Spec. in Gastroenterologia-Castellana G. (BA) ItalyCancer cells require more cholesterol than normal ones. A higher HMG-CoA reductase activity or a higher cholesterol uptake by the Low Density Lipoprotein Receptor (LDLR), whose expression have been also found in normal and neoplastic gastrointestinal mucosa [1,2], seem to satisfy this requirement. Since in breast cancer tissue the LDLR content has a prognostic significance [3], our *aim* was to verify whether the content of LDLR in neoplastic tissue could be of any prognostic value in patients with colorectal carcinoma (CRC). *Materials and Methods:* The LDLR content was detected in 93 patients (29 of whom had died) with CRC by ELISA method (using an anti-human LDLR mouse monoclonal antibody IgG-C8 – Oncogene Science, Uniondale, N.Y.). No patient was lost to follow-up (35 – 19 months, M – SD). Kaplan-Meier estimates and Cox proportional hazard model were performed to evaluate the survival time and the relative risk (RR) of prognostic factors. *Results:* Thirty-three of 93 cases (35%) were ELISA positive for LDLR, while 60 of 93 (65%) were LDLR negative. The survival of patients without LDLR expression in the neoplastic tissue was shorter than that of patients with LDLR one (log rank test, $P < 0.01$). By performing Cox model, only LDLR status (RR 0.40) and Dukes' stage (RR 5.02, 10.16) resulted statistically significant on the CRC-related death survival, after controlling for age, sex, tumour site and histological differentiation. *Conclusions:* These findings suggest an association between the LDLR absence in neoplastic mucosa and a shorter survival of CRC patients. This is probably due to an abnormally high endogenous HMG-CoA reductase activity with high levels of isoprenoid compounds. These substances could potentially confere a growth advantage to colorectal neoplastic cells.

OT21 0550**Auxiliary Liver Transplantation for Fulminant Liver Failure: Limits of an Attractive Concept**

*J. Belghiti, F. Zinzindohoue, F. Durand[1], R. Noun, A. Sauvanet, J. Bernuau[1]

Department of Digestive Surgery, University Paris VII, Clichy, France

[1] Department Hepatology, Hospital Beaujon, University Paris VII, Clichy, FranceAuxiliary liver transplantation (ALT) theoretically bridges the period of acute liver failure until the native liver (NL) recovers and immunosuppression can be discontinued. However, this attractive concept is burdened by technical problems and by the selection of candidates. We report our experience of ALT with special references to early and long term graft function in a prospective study including all patients who underwent emergency liver transplantation for acute liver failure from April 1993 to October 1995.*Patients:* Thirty patients aged from 16 to 62 years with acute liver failure were candidates for emergency liver transplantation according to Clichy criteria. Causal disease was drug toxicity (n = 10) including paracetamol in 3; hepatitis B (n = 6); hepatitis A (n = 2) and other (n = 12). We decided to perform OLT in 18 because of age > 60 years (n = 3), pre-existing chronic liver disease (n = 4), haemodynamic instability (n = 4), poor liver graft (n = 2) and poor neurological status with immediate risk of cerebral herniation (n = 5). Seven patients died postoperatively including 5 after ALT; in the latter group mortality was due to vascular thrombosis (n = 3) graft compression (n = 1) and sepsis (n = 1). With a follow up ranging from 3 to 31 months among the 7 surviving patients, graft was removed in 2 respectively after 1 and 7 months, immunosuppression was stoped in 2 respectively after 9 and 27 months. Liver biopsy demonstrated the presence of mild fibrosis in 3 respectively after 6 and 9 months.*Conclusion:* After auxiliary liver transplantation for fulminant hepatitis, there is no predictive value of the extent nor the delay of sufficient regeneration of the native liver. The higher operative risk associated with ALT suggests that this procedure should: (a) not be indicated earlier than standard OLT; (b) be restricted to patients < 50 years without haemodynamic instability and (c) be performed using good quality ABO compatible graft. Liver and bile ducts, 1: Liver transplantation }" "Auxiliary Liver Transplantation for Fulminant Liver Failure: Limits of an Attractive Concept"

OT21 0551**Cytokine Responses after Surgery in Obstructive Jaundice Indicate Endotoxin Tolerance**

*A.P.J. Houdijk, P.A.M. van Leeuwen

Department of Surgery, Free University Hospital, Amsterdam, The NetherlandsIn obstructive jaundice postoperative complications are related to gut derived endotoxemia and possibly mediated by cytokines like TNF and IL-6. This study investigated the course of IL-6 and TNF following surgery in bile duct ligated rats (BDL) treated with and without the enteral endotoxin binder cholestyramine. Endotoxin in rat plasma was determined by blocking cytokine production in human whole blood cell cultures stimulated by rat plasma using antibodies directed against the endotoxin (CD14) receptor. Rat and human TNF and IL-6 were measured using bioassays and specific ELISA's.Results showed that in saline treated BDL rats (BDL SAL) surgery elicited a significant IL-6 response (max 900 U/L). In these rats there was no increase in plasma TNF after surgery and values remained at their low preoperative levels ({ @} 20 U/mL). In cholestyramine treated BDL animals no TNF and IL-6 levels were measured prior to surgery but in contrast to BDL SAL rats both TNF (max { @} 300 U/mL) and IL-6 (max { @} 1500 U/mL) were significantly raised after surgery. BDL SAL plasma samples from all time points elicited significant TNF and IL-6 responses in human blood cell cultures (TNF max at t = 2 h { @} 630 pg/ml). These reponses could be inhibited by CD14 blockade ($p < 0.001$) indicating endotoxemia before and after surgery. In cholestyramine treated BDL rats only the plasma samples taken at t = 2 h after surgery elicited human blood cell TNF (max 290 pg/mL) and IL-6 responses that were significantly lower compared to BDL SAL responses. This response was also inhibited by CD14 blockade ($p < 0.01$) indicating low grade postoperative endotoxemia.The absent postoperative plasma TNF response in the BDL SAL group, in the continuous presence of endotoxin, indicates endotoxin tolerance for TNF production in postoperative BDL rats. Gut endotoxin neutralization prevented immune cells of BDL rats to develop endotoxin tolerance as was evidenced by the high plasma TNF levels in response to postoperative endotoxemia. OT21 0552**^{13}C-Galactose Breath Test: An Early Indicator of Liver Fibrosis in Hepatitis C Virus Infection**

*F. Mion, M. Rousseau, P. Paliard, Y. Minaire

F\'e9d\'e9ration des Sp\'e9cialit\'e9s Digestives, Hospital E. Herriot; CNRS UMR 5578; INBIOMED; Lyon, FranceSimple, non invasive tests are still needed to measure liver function mass. In cirrhotic patients, we have previously shown that the ^{13}C-galactose breath test (GBT) is well correlated to the severity of liver disease (Gastroenterology 1995; 108: A1124).*The goal* of this study was to measure liver function mass by GBT in patients with HCV chronic hepatitis and no cirrhosis, and to correlate the results of the GBT with the severity of fibrosis on liver biopsy specimens.*Methods.* GBT was performed in 6 healthy volunteers [mean age: 44 (range: 32–63), 4 men and 2 women] and 16 liver biopsy-proven chronic virus C hepatitis patients [mean age: 48, range: 25–64), 12 men and 4 women]. GBT was done after an overnight fast: galactose was given iv in less than 10 minutes (0.5 g/kg of body weight of unlabeled galactose + 5 mg/kg of body weight of ^{13}C-galactose). Breath samples were obtained before galactose administration (basal) and every 10 minutes thereafter until 210 minutes. ^{13}C/^{12}C isotopic ratio was determined in each breath sample by GC-IRMS, and the amount of galactose oxidized to CO_2 per unit of time (\'b5mol/min) was calculated. On liver biopsy specimens, the degree of inflammation, necrosis, and steatosis was assessed as mild, moderate or severe, while the intensity of fibrosis was measured according to the Knodell fibrosis score (1 or 3). Statistical analyses were performed by regression analysis and one-way ANOVA.*Results.* GBT was significantly lower in HCV patients compared to controls (85 – 5 vs 141 – 10 \'b5mol/min, p < 0.0001). In HCV patients, the results of GBT were independent from the levels of serum ALT and AST, the severity of hepatic steatosis, necrosis and inflammation. They were significantly lower in the group with a Knodell fibrosis score of 3 (11 patients) than in the group with a Knodell fibrosis score of 1 (5 patients): 77 – 5 vs 102 – 9 \'b5mol/min, p < 0.05.*In conclusion,* GBT is altered early in the course of HCV chronic hepatitis, and is significantly correlated to the degree of liver fibrosis. This test could thus be useful in monitoring the efficacy of anti-viral therapy in HCV chronic hepatitis. Liver and bile ducts, 1: Hepatitis viral, diagnosisClinical practice: Management strategy }" "13C-Galactose Breath Test: An Early Indicator of Liver Fibrosis in Hepatitis C Virus Infection"

OT22 0553**The Split Liver in Liver Transplantation: A Recent Experience**

*D. Azoulay, I. Astarcioglu, M. Johann, R. Adam, D. Castaing, H. Bismuth

Hepato-Biliary Surgery and Liver Transplant Center, Paul Brousse Hospital, Villejuif, FranceThe good results of liver transplantation (LT) have allowed its larger use. However this increased use of LT has uncovered a relative organ shortage. The split liver is one of the means to increase the number of available grafts. We report here our recent experience with this technique. From January to December 1995, a systematic proposal to perform a split was made to the French organ sharing network as often as possible. Ninety LT were performed using 61 whole grafts, 27 split liver grafts, 2 reduced size grafts. Twenty livers were splitted at our center generating 40 split liver grafts: 23 transplanted at our center in 23 patients and 17 shipped to other centers. We received 4 split liver grafts from 4 livers splitted in other centers. Our 27 patients were transplanted for cirrhosis in 19 cases, amyloid polyneuropathy in 6 cases and fulminant hepatitis in 2 cases. Operative mortality (< day 60 post-LT) occurred in one case of fulminant hepatitis and long term mortality (> day 60 post LT) occurred in 1 case of cirrhosis. One patient was retransplanted at day 6 for primary non function due to a too small graft (the lowest liver to recipient weight ratio = 0.87). Patient and graft actuarial survival are respectively 91.4 – 5.8% and 87.5 – 6.8%. Twelve technical complications occurred in 10 patients: 3 arterial complications (2 thrombosis and 1 dissection) of which 2 were successfully treated by urgent desobstruction; biliary fistula: 4 cases, biliary stenosis: 2 cases; hemoperitoneum: 2 cases, segment 4 necrosis: 1 case. Eight of these complications needed surgery to be controlled.*Conclusion:* 111 LT were performed with 87 livers realising an economy of 24/111 grafts (22%). During the same period, 16 proposals of split were refused in France. The graft economy would have been of 28%. When used for elective transplantation, the split LT gives good results comparable to those of whole LT. Our results promote the use of split LT every time it is possible. }" "The Split Liver in Liver Transplantation: A Recent Experience"

OT22 0554**Quadruple Versus Triple Initial Immunosuppression in Liver Transplantation**

*O. Boillot, E. Grandclement, Y. Bouffard, S. Barcet, P. Meeus, I. Mechet, D. Gille, P. Paliard

Unit\'e9 de Transplantation h\'e9patique, Pavillon D, Hospital Edouard Herriot, 69003 Lyon, FranceRejection following liver transplantation (LT) represents one of the main causes of morbidity, graft loss and patient death. Conventional triple immunosuppressive regimen using Cyclosporine (Cya), steroids and Azathioprine (AZA) is still responsible for high rate of rejection in the early post-operative period after LT, underlying the need for improved therapies. In a retrospective study, we compared the effects of standard triple immunosuppressive therapy versus an initial quadruple therapy using anti-thymocytes globulines in a series of 113 LT.*Patients and methods.* From September 1991 to March 1995, 155 LT were performed in 151 patients. Of them, 42 liver transplant cases were excluded from the study (29 children, 10 adults surviving less than 3 months and 3 adults who had prophylactic OKT3 immunosuppressive regimen). Finally, 113 LT in 113 adults patients were studied. There were 75 males and 38 females with a mean age of 44 – 9 years (range: 18 to 63). Main indications for LT were viral (49%) and alcoholic cirrhosis (32%). All LT were donor/recipient ABO group identical. Patients were divided in 3 groups according to the type of immunosuppressive regimen; group I (n = 37): standard triple therapy using Cyclosporine, steroids and Azathioprine, group II (n = 35): when introduction of Cya or AZA had to be delayed because of renal dysfonction or thrombopenia, a rabbit anti-thymocyte globulin (Thymoglobulines, Pasteur M\'e9rieux) was administrated intravenously at the dose of 2.5 mg/kg/day 1 to 5 days after LT for 10 to 14 days until the triple regimen could be applied, group III (n = 41): a quadruple immunosuppressive therapy was done with intraoperative induction of Thymoglobulines which was given furthermore for 9 days. The three groups were comparable for age, sex and liver diseases. Statistical analysis was made by ANOVA and chi-Square tests, differences were considered statistically different at $p < 0.05$.*Results.* A rejection episode occurred in 73%, 46% and 32% of patients in groups I, II and III respectively ($p < 0.05$ G II and G III versus G I). OKT3 therapy was needed in 32%, 18% and 7% of patients in groups I, II and III respectively ($p < 0.05$). The number of rejection episodes was significantly lower in G II and III than in G I, none of patients from G II and III experienced more than 3 and 2 episodes respectively. The date of rejection occurrence was different between the 3 groups, 75 to 85% of the first episode of graft rejection happened in the first two weeks in G I, in the first two months in G II and during months 2 and 3 in G III. Only 1 case of chronic rejection happened in G I and none in the other groups. Grafts and patients one year survival were 84%, 94% and 97% in groups I, II and III respectively ($p < 0.05$ G II and III versus G I).*Conclusions.* This quadruple regimen using initial anti-thymocytes globulines added to the three standard immunosuppressive drugs especially when given early intraoperatively allowed a decreased rate and severity of rejection episodes, an improved graft and patient survival without increased morbidity rate. Liver and bile ducts, 1: Liver transplantation }" "Quadruple Versus Triple Initial Immunosuppression in Liver Transplantation"

OT22 0555**Vitamin D Receptor Gene Polymorphism and Bone Loss after Liver Transplantation**

*J. Guardiola, X. Xiol, J.M. Escriba, J.M. Nolla, J. Figueras, R. Sallie[1]

Hospitales de Vilafranca and Bellvitge, Barcelona, Spain

[1] NIDDK, Bethesda, USABone loss is a frequent complication of orthotopic liver transplantation (OLT). A relationship between common allelic variants in the gene encoding the vitamin D receptor (VDR) and bone mineral density (BMD) has been demonstrated. *Aim and Methods:* To investigate the influence of VDR gene polymorphism on bone loss after OLT, 55 cirrhotic male patients who underwent OLT were studied. VDR polymorphism were assigned blind with respect to the BMD data following restriction enzyme (Bsm1) digestion of PCR amplified DNA extracted from formalin fixed tissue. To measure BMD, dual energy X-ray absortiometry at lumbar spine was performed before OLT, and repeated at 3 mo (n = 36), 6 mo (n = 33) and 12 mo (n = 22) and 24 month (n = 12) after OLT. Values of BMD are reported as Z score (standard deviations from the age and sex adjusted mean). Changes of BMD after OLT are expressed as percentage of the initial value. *Results:* Genotype bb was detected in 22 patients (40%), Bb in 27 (47%) and BB in 7 (13%). Before OLT, there were not differences between Z score of bb patients compared to the other genotypes (bb: { -}0.508 vs Bb + BB: { -}0.690, NS). Changes of BMD after OLT and p values between bb and Bb/BB groups are shown in the table below 3 mo (n) 6 mo (n) 12 mo (n) 24 mo (n)bb { -}1.2% (16) +0.4% (16) +4.1% (8) +11% (5)Bb/BB { -}4.3% (20)# { -}3.6% (17)# { -}1% (14) +1.5% (7) $p < 0.05$ $p = 0.11$ $p = 0.25$ $p = 0.05$(# = significant intragroup changes from baseline BMD). Both groups were similar in all other parameters studied.*Conclusions:* In male patients, VDR gene polymorphism influences BMD changes after OLT. Genotype bb protects against the rapid bone loss seen in the early months after OLT. OT22 0556**Liver Transplantation for Familial Amyloidotic Polineuropathy. Evolution of Peripheral Neuropathy**

*L. Tom\'e9, O. Mota, A. Mestre, J. Ferr\'e3o, R. Perdigoto, L. Furtado

Transplantation Unit, University Hospital, Coimbra, PortugalPeripheral neuropathy in familial amyloidotic polineuropathy (FAP) depends on the deposition of an abnormal transthyretin in the nervous system. Most of the abnormal protein is synthetized in the liver. Hepatic replacement should halt the progression of the disease and eventually correct established neurologic alterations.Our program transplanted 35 patients (35.8 sd 7.6 years old) suffering from FAP. The symptoms were known for 5.2 sd 3 years (from 1 to 12). The neurologic deficiency (Macedo, E. et al, 1988) reached 36.2 sd 10.6%. The time elapsed from the beggining of symptoms and the neurologic score correlated significantly (F: 13.87; r = 0.55; p = 0.0008). The neurologic score evaluated before transplantation (148 sd 99 days before) and the score observed at least 180 days after the operation (621 sd 321 days after) could be compared in 15 such patients. They were not significantly different (p = 0.68).We conclude that liver transplantation stops the evolution of familial amyloidotic polineuropathy but does not promote a resolution of established lesions at least in the short term. Liver and bile ducts, 1: Liver transplantation }" "Liver Transplantation for Familial Amyloidotic Polineuropathy. Evolution of Peripheral Neuropathy"

OT23 0557**Treatment of Malignant Liver Tumours by CryotherapyR. Adam, E. Akpinar, M. Johann, F. Kunstlinger, H. Bismuth**

Hepatobiliary Surgery and Liver Transplant Center, Paul Brousse Hospital, & U350 INSERM Centre Univ. Orsay, Villejuif, FranceThe use of cryotherapy for the treatment of liver tumours has been established as a therapeutic option when resection is not possible. The aim of this study was to determine the real place of this treatment in the therapeutic strategy of liver tumours.*Methods:* From Oct 1993 to July 1994, 41 patients (pts) have been treated by cryotherapy at our institution, either as a single treatment (Group 1–11 pts), as combined with partial resection (Group 2–19 pts) or as complementary to a complete resection with no sufficient margin of normal liver around the tumour (Group 3–11 pts). There were 7 hepatocellular carcinoma all with underlying cirrhosis, 25 metastases of colorectal cancer and 9 metastases of other malignant tumours. Mean number of tumours was 3.9 (Range 1–8) in Group 1, 3.8 (2–9) in group 2 and 5.9 (1–9) in Group 3. Mean maximum tumour size was 56 mm (20–130), 40 mm (10–100), and 48 mm (16–80) respectively for the same groups. We used the LCS 2000 device (Cryogenic Technology Ltd, Belper, UK) designed specifically for hepatic cryotherapy to deliver liquid nitogen to the tip of a triple lumen probe applied under ultrasound guidance to the lesion to be frozen.*Results:* There were 2 peroperative complications related to the procedure: one rupture of the tumour during the freezing process and one perforation of the liver capsule. Both complications were easily controlled by suture. Operative mortality within 2 months was 2.4% (1/41), unrelated to cryotherapy (cardiac infarct at day 3). Serum transaminases increased post operatively in relation to the duration of cryotherapy and the number of treated lesions. They normalized within 5 days. In Group 1 (Cryo alone), a reduction of tumour size was observed in 4 pts (36%), with disappearance of a treated lesion in one case. Tumour markers were decreased in 3/4 pts with preoperative increased levels. Four pts with huge multinodular lesions died of progression of the disease from 2 to 6 months after cryotherapy. Seven pts are alive of whom 2 were subsequently submitted to hepatic resection. In Group 2 (Cryo + Resection), a reduction in cryotreated tumour size was observed in 6 pts (32%). Decreased tumor markers were demonstrated in 4 cases (21%). One patient died at 9 months, of local and extrahepatic recurrence. The remaining 18 pts are alive of whom 5 with local recurrence and 4 with recurrence outside the cryotreated site. In Group 3 (""Adjuvant"" cryotherapy), one patient died 2.5 months after the procedure of sepsis unrelated to cryotherapy. All the other pts are alive without local recurrence. Overall, the main determinants of recurrence following cryotherapy were maximum tumour size > 5 cm and number of lesions > 3. Of 6 pts with both risk factors, 5 have currently recurred and 2 died of progressive disease.*Conclusion:* Cryotherapy is a simple and safe procedure that may be useful in the treatment of unresectable malignant liver tumours and as an adjuvant to liver resection. Objective criteria of anti tumoral effects are demonstrated but need confirmation with a longer follow-up. Selection of pts should exclude all those with large multinodular tumors. }" "Treatment of Malignant Liver Tumours by Cryotherapy"

OT23 0558**Percutaneous Ethanol Injection under General Anesthesia of Hepatocellular Carcinoma on Cirrhosis: Three Years Survivals in 107 Patients**

*A. Giorgio, L. Tarantino, N. Mariniello, G. de Stefano, A. Perrotta, V. Aloisio, F. Esposito

V Divisione, D. Cotugno Hospital, Naples, ItalyPercutaneous ethanol Injection (PEI) under general anesthesia (u.g.a.) is a new therapy for treatment of large and/or multiple Hepatocellular Carcinoma (HCC) by the injection of large amount of ethanol in the tumor. We report our results with 3 years survival rates in patients with HCC on cirrhosis treated with PEI u.g.a.*Patients and methods:* between october 1992 and december 1995, 112 cirrhotic patients (79 male; age: 45–80; mean: 64 years) with 215 HCC nodules (diam. = 0.6–14 cm; mean: 4.1 cm; median: 3.5 cm) underwent PEI u.g.a. 53 patients had one nodule (diam. = 3–14 cm; mean = 4.2 cm; median = 3.5 cm), 59 had 2 or more (2–5) nodules (diam. = 0.6–13 cm; mean = 3.9; median = 3.5 cm). Total ethanol injected per treatment ranged between 16–205 cc. Survival rates and statistical analisis were calculated according to Kaplan-Meier method and Wilcoxon test respectively.*Results:* 5 patients died within 7 hours–10 days after the treatment for rupture of aesophageal varices in 3 cases, rupture of subcapsular HCC in 1 case and liver failure in 1 case. In the remaining 107 patients, dynamic CT, performed 72 hours–one month after the treatment, showed complete necrosis in 76 (71%) cases and incomplete necrosis (although always > 50%) in 31.Survival rates at 1, 2, 3 years in all 107 patients were 88%, 76% and 76% respectively. Survival rates in Child class A patients were 100%, 92%, 92% and in class B patients were 84%, 72% e 72% at 1, 2, 3 years respectively; in class C were 100% e 50% at 1 and 2 years respectively (p = n.s.). Survival Rates in patients with one nodule were 80%, e 68% at 1 and 2 years, while in the patients with two nodules or more were 95%, 82% e 82% at 1, 2 and 3 years respectively (p = n.s.). Survival rates in patients with nodules < 5 cm were 88%, 73%, 73% while in patients with nodules > 5 cm were 89%, 77% e 77% at 1, 2 and 3 years respectively (p = n.s.). During the follow-up (5–46 months) 48 (45%) patients showed intrahepatic recurrences; 41 out of them were retreated with new sessions of PEI-u.g.a. or conventional PEI.*Conclusions:* PEI-u.g.a. is more aggressive than traditional PEI and can cause also the death of the patient. Moreover, it is an effective, fast and inexpensive therapy in patients with large and/or multiple HCC on cirrhosis. Although the treatment was performed on unselected patients, survival rates of PEI-u.g.a. seems similar to those obtainable by conventional PEI and even better than surgery. OT23 0559**Percutaneous Radiofrequency Interstitial Thermal Ablation of Hepatocellular Carcinoma**

*L. Buscarini, S. Rossi, M. Di Stasi, E. Buscarini

Gastroenterology Department, Hospital of Piacenza, Italy*Purpose:* To evaluate the long-term results of interstitial thermal ablation (RITA) of hepatocellular carcinoma (HCC).*Methods:* 27 men and 17 women (all cirrhotic but one), mean age 66.7 years (52–82), with 46 HCC nodules < 3.0 cm in diameter underwent monopolar and/or bipolar RITA procedure (using 15–18 G caliber electrode needles or modified electrode needles with retractable lateral exit jackhooks on the tip; exposed tip of 1.0–2.0 cm; temperature of 90\'b0C; 3–20 minutes/thermal lesion). The needles were placed into the tumor under US-guidance.*Results:* Tumor destruction was achieved in a mean of 3.1 RITA sessions, demonstrated by US-guided biopsies, dynamic CT and angiography. During a mean follow-up of 24.6 months (range 3–73), 2/44 patients showed local recurrences and 14/44 new lesions. Nine patients with a first and four patients with a second recurrence underwent new effective RITA treatment. 11/44 patients died: five from cancer and six from other causes. Histology on five treated HCCs showed total necrosis in four and subtotal in one. 5-year survival rate was 0.40. No complications were observed.*Conclusions:* RITA is a useful percutaneous treatment for HCC. OT23 0560**Hepatocellular Carcinoma (HCC) and Liver Transplantion: Evaluation of Diagnostic Accuracy of Lipiodol-CTA. Veltri, M. Grosso, D. Regge, M.C. Martina, M. Cogoni, P. Busolli**

Istituto di Radiologia, Universit\'e0 di Torino, Italy*Purpose*To assess the diagnostic accuracy of lipiodol-CT in the diagnosis of HCC based on the histopathological study of explanted livers.*Materials and Methods*The results of lipiodol-CT in 66 cirrhotic patients were retrospectively examined and compared to histopathological findings, which demonstrated 41 lesions (diameter range: 0.8 to 4.0 cm, mean: 2.1 cm) in 33 patients*Results*Lipiodol-CT correctly diagnosed 32/41 nodules (78%) in 27/33 patients (81.8%). The specificity was 66.6%; the diagnostic accuracy was 74.2% with 16 false positive nodules in 12 patients. The positive predictive value for the presence of a lesion was 66.6%; the negative predictive value was 78.6%.*Conclusions*Based on our experience, the results obtained indicate a poor diagnostic accuracy of lipiodol-CT. In particular, only the patient-based sensitivity (> 80%) appears acceptable, while the number of lesions detected, the specificity and the diagnostic accuracy were inferior in comparison to traditional integrated imaging methods (sonography, CT, and angiography).The results, in accordance with some recently reported data, suggest not to include lipiodol-CT in the diagnostic-staging work-up of HCC while awaiting liver transplantation. OT24 0561**Overexpression of p53 Protein Correlates with Enhanced Aggressiveness of Pancreatic Cancer**

*U. Boggi, P.C. Giulianotti, G. Di Candio, A. Pietrabissa, F. Sbrana, D. Campani[1], D. Cecchetti[1], F. Ceccarelli[1], A. Veracini[1], G. Fornaciari[1], F. Mosca

Istituto di Chirurgia Generale e Sperimentale, Universit\'e0 di Pisa, Italy

[1] Istituto di Anatomia Patologica, Universit\'e0 di Pisa, ItalyThe aim of this study was to ascertain the frequency and the prognostic significance of p53 overexpression in pancreatic cancer.Paraffin embedded specimens from 70 pt.s operated on for ductal adenocarcinoma of the pancreas were analysed. Using the monoclonal Ab D07, the nuclear overexpression of the mutated p53 protein was immunohistochemically determined in both the primary tumor and its lymph node metastases (LNM). T and N status, tumor stage, histological grade (HG) and proliferation index (PI) were also recorded. Minimum follow-up was 12 months and complete data were available in all cases. Survival curves were constructed by Kaplan-Meier method.Fifty-seven percent of our cancers showed p53 overexpression of either focal or diffuse patterns. No relationship was discovered between p53 overexpression and T status, HG or PI respectively. Thirty-two cases (46%) had histologically documented LNM. 28 out of 38 N0 tumors (74%) were p53 negative while 20 out of 32 N1 cancers (63%) were p53 positive ($p = 0.005$). LNM were significantly related to reduced survival times ($p = 0.02$). Moreover, comparing pt.s with p53 negative LNM with those of the same stage bearing p 53 positive metastases a wide difference became clearly evident ($p = 0.003$) (figure 1).

Nuclear overexpression of p53 in pancreatic cancer seems to correlate with increased lymphatic spread and poor prognosis. In particular, the occurrence of lymph node metastases overexpressing the mutated p53 protein, seems to imply a dreadful prognosis. The possibility of improving these results by treating these cases with new adjuvant therapies, such as the newly proposed treatment with antisense oligonucleotides directed against p53 oncogene, adds further interest to this observation. Oncology, specific: Pancreas }" "Overexpression of p53 Protein Correlates with Enhanced Aggressiveness of Pancreatic Cancer"

OT24 0564**Enhanced Expression of Plasminogen Activators in Pancreatic Cancer is Associated with Poor Prognosis**

*H. Friess, M. Schilling, D. Cantero, A. Zimmermann, M. Korc, M.W. B\'fcchler

Departments of Visceral and Transplantation Surgery and Pathology, University of Bern, Switzerland

Departments of Medicine and Biological Chemistry, University of California Irvine, Irvine USAuPA (urokinase plasminogen activator) is a serine proteinase which plays an important role in cancer invasion and metastasis. It binds to a specific cell surface receptor which is called uPA receptor (uPAR). uPA activates plasminogen to form plasmin, which, like uPA, participates in tissue degradation and proteolysis. Binding of uPA to its receptor accelerates UPA's own activation from pro-uPA, enhancing the activity of the uPA/uPAR cascade.*Patients:* Pancreatic cancer samples were obtained from 30 patients (12 women, 18 men) with a median age of 66.5 years (range: 32–79 years) undergoing pancreatic resection. Pancreatic tissue samples obtained from 30 previously healthy organ donors (14 women, 16 men, median age: 41 years) served as controls.*Methods:* Tissues destined for RNA extraction were frozen in liquid nitrogen immediately upon surgical removal. In addition, freshly removed tissue samples were fixed in Bouin solution and paraffin embedded for histological analysis. Expression of the uPA and uPAR was analysed by Northern blot analysis using specific cDNA probes. In addition, immunohistochemical analysis using specific monoclonal antibodies was performed. The Northern blot data were correlated with the survival periods of the patients.*Results:* Immunohistochemical analysis demonstrated moderate to strong immunostaining of both factors in most pancreatic cancers. Cancer lesions with signs of invasion exhibited the strongest immunohistochemical signals for both factors. In addition, in desmoplastic areas adjacent to the cancer cells, moderate uPA and uPAR immunoreactivity was detectable. Northern blot analysis revealed a 6-fold and a 4-fold increase in uPA and uPAR mRNA levels in pancreatic cancer, respectively, in comparison with normal controls ($p < 0.01$). Correlation of the Northern blot data with the clinical parameters of the patients indicated that patients with concomitant overexpression of uPA and uPAR had a shorter postoperative survival (median: 9 months; mean – SD: 10.2 – 3.6 months) than patients in whom only one or none of these factors were overexpressed (median: 18 months; mean – SD: 20.3 – 8.7 months) ($P < 0.002$).*Conclusion:* Our data suggest that uPA and uPAR may serve as prognostic markers in human pancreatic cancer and that the marked overexpression of both factors may create an environment that enables pancreatic cancer cells to invade surrounding tissues. Support: SNF 32-39529. OT25 0565**Immediate and Long-Term Results of Pancreatic Ductal Drainage in Severe Painful Chronic Pancreatitis**

*P.L. Bittencourt, M. Delhaye, J. Deviere, O. Le Moine, M. Baize, C. Matos, A. Vandermeeren, M. Cremer

Department of Gastroenterology, Erasme Hospital, Brussels, BelgiumThe aim of the present study is to evaluate the symptomatic improvement of 119 chronic pancreatitis patients (93 men, 26 women, median age 45 y, median disease duration 3 y) submitted to different endoscopic drainage procedures and extracorporeal shock wave lithotripsy (ESWL). The inclusion criteria of the patients were: 1) history of recent severe acute pancreatic pain, 2) no previous pancreatic surgery; 3) demonstration of main pancreatic duct (MPD) obstruction (stenosis or stones) with upstream ductal dilatation on endoscopic pancreatography or CT scan.Deep MPD cannulation was possible in 96% of the patients. Fifty-three patients (group 1) underwent pancreatic sphincterotomy alone or in combination with ESWL. Sixty-one patients with MPD distal stricture (group 2) also required pancreatic stents. Complications occurred in 4% of the patients and none needed surgical intervention. No mortality was observed.Sixty-nine patients had a minimal 2 y follow-up (FU) (median: 64 m, range: 24–100 m). Eighty-six percent of them experienced a dramatic improvement (58%) or complete relief (28%) of pain. Worsening of endocrine and exocrine functions was observed in only 13 and 5 patients respectively over the FU period. Ten patients (14%) did not improve and eight of them were surgically treated.The following observations were seen with the same frequency in groups 1 and 2: successful ductal stone clearance and MPD drainage, immediate and long-term pain relief, median number of recurrent pain attacks and surgical requirement. However, complete pain relief tended to be more frequent in group 1 (37% vs 21%, p = 0.14).It is concluded that endoscopic MPD drainage is an effective treatment of painful chronic pancreatitis. It causes immediate and long-term pain relief in 91% and 86% of the cases, respectively, and preserves endocrine and exocrine functions in most cases. OT25 0566**Fecal Elastase-1: Not Helpful in Diagnosing Chronic Pancreatitis with Slight to Moderate Exocrine Pancreatic Insufficiency**

*I. Schmidt, H. K\'f6nig, M. L\'f6hr[1], R. Knollmann[1], S. Liebe[1], P.G. Lankisch

Department of Internal Medicine, Municipal Hospital of L\'fcneburg, Germany

[1] University of Rostock, GermanyPreliminary studies on the value of fecal elastase-1 to estimate exocrine pancreatic insufficiency (EPI) were controversial but mostly favorable (Gastroenterology 106: A290, A300, A325, 1994; Gastroenterology 108: A341, 1995). For a definitive evaluation, elastase-1 estimations were compared with fecal chymotrypsin results in patients categorized according to grades of exocrine pancreatic function using the gold standard tests, the secretin-pancreozymin test (SPT) and fecal fat analysis, and to grades of morphological changes, the presence and absence of calcifications and duct changes.*Patients and Methods.* An SPT and fecal fat analysis as well as fecal chymotrypsin and fecal elastase-1 estimations were performed in 64 patients in whom EPI was suspected. Grading categories for EPI were *slight* (enzyme secretion reduced, bicarbonate concentration and fecal fat excretion normal), *moderate* (SPT abnormal, fecal fat excretion normal), and *severe* (SPT abnormal plus steatorrhea). Patients were further staged for calcifications and duct changes according to the Cambridge classification.*Results.* Exocrine pancreatic function was normal in 34 (53%) patients (group 1) and abnormal in 30 (47%) patients (group 2). In group 1, fecal chymotrypsin was normal in 27 (79%) and elastase-1 in 32 (94%) patients. In group 2, both tests were abnormal in 17 (57%) and 16 (53%), respectively. When group 2 was split into slight (n = 10), moderate (n = 9), and severe EPI (n = 11), chymotrypsin was abnormal in 30%, 44% and 91%, respectively, and elastase-1 in 40%, 33% and 82%, respectively. Pancreatic calcifications were present in 12 (40%) of all patients and duct changes in 62% of 13 investigated patients. The percentage of abnormal chymotrypsin and elastase-1 estimations was the same in patients with and without calcifications/duct changes.*Conclusion.* Fecal elastase-1 estimation is not superior to traditional fecal enzyme estimation and helpful only in detecting severe, but not slight to moderate EPI which is the more frequent and difficult clinical problem and does not correlate significantly with severe morphological changes of chronic pancreatitis. Clinical practice: Management strategyIntestinal disorders, absorption: Pathophysiology of diarrheaPancreas: Pancreatitis, chronic }" "Fecal Elastase-1: Not Helpful in Diagnosing Chronic Pancreatitis with Slight to Moderate Exocrine Pancreatic Insufficiency"

OT25 0567**Results after 5 and 10 Years Following Surgery for Chronic Pancreatitis: Long Term Survival Is Unrelated to Surgical Technique**

*G. Spiliopoulos, B. Chareton, C. Stasik, M.A.C. Machado, J.P. Campion, B. Meunier, B. Launois

Department of Digestive Surgery and Transplant Unit, CHR Pontchaillou, Rue Henri Le Guilloux, 35033 Rennes, FranceIn papers published by Leger [1] and Moreaux [2] in 1974 and 1984 it was suggested that pancreaticoduodenectomy should be banned from the surgical arsenal of chronic pancreatitis because of the disappointing long-term results. The aim of the present study was to review long-term outcome of patients having undergone surgery in our Department.*Patients and methods:* between 1972 and 1994, 381 patients underwent surgery for chronic pancreatitis at a referral centre. There were 322 males and 59 females with a mean age of 45 – 12.3 years. Alcohol abuse was the prevailing etiological factor (89.7%). Surgical procedures included 153 resections (87 Whipple procedures, 62 distal pancreatectomies, 4 total pancreatectomies), 113 bypasses (40 pancreatic + biliary and/or digestive bypasses, 73 biliary and/or digestive bypasses) 89 cystoenteric anastomoses, 4 splenectomies and 22 exploratory laparotomies.*Results:* Operative mortality was 7.8% for resections, 5% for pancreatic bypasses, cystoenteric anastomoses and exploratory laparotomies. Morbidity was 17% for resections and cystoenteric anastomoses and 7.5% for pancreatic bypasses, 5 and 10 years survival was 92% and 76% for resections, 79.7% and 53.8% for cystoenteric anastomoses, 85% and 66% for pancreatic bypasses. (n = N.S.). Diabetes mellitus developed in 39% of patients who underwent resections and 37.5% of patients having bypasses. Persistent pain was present in 24% of patients following resection and bypass.*Conclusion:* the long-term outcome of patients with chronic pancreatitis is unrelated to the type of surgery.

OT25 0568**Effects of Ethanol (EtOH) on Neutrophils in the Pancreas**

*P.U. Reber, A.G. Patel, M.K. Schilling, W. Uhl, H.U. Baer, H.A. Reber, M.W. Buchler

Depts of Surgery, Inselspital Bern, Switzerland, UCLA Los Angeles, CAAlthough EtOH is a common cause of pancreatitis, the mechanisms by whitch it damages the pancreas remain poorly understood. Studies in other systems suggest that neutrophils may cause tissue injury in a variety of conditions. Here we studied the effects of EtOH on neutrophil activation and extravasation in an in vivo pefused cat pancreas.*Methods:* The pancreata of adult cats (2.5–3 kg) were isolated and perfused at a constant flow rate with various concentrations (0.2–2 mg/dl) of EtOH in an oxygenated physiological perfusate. The control group received perfusate without EtOH. Neutrophil activation and extravasation were assessed by measuring pancreatic tissue myeloperoxidase activity (MPO) by the oxidation of tetramethylbenzidine with hydrogen peroxide.*Results:* Perf. time Control (6) EtOH (0.25 mg/dl) (6) EtOH (2 mg/dl) (6)0 1.1 – 0.3 U 1.3 – 0.4 U 1.4 – 0.3 U60 min 1.6 – 0.2 U 1.7 – 0.9 U 9.1 – 0.7 U\'86120 min 1.9 – 0.2 U 3.2 – 0.8 U* 11.8 – 1.4 U\'86*$p < 0.05$ vs control, \'86$p < 0.05$ vs EtOH (0.25 mg/dl) and control.*Conclusions:* EtOH perfusion of the pancreas at concentrations of 0.25 mg/dl or more, caused a time dependent neutrophil activation, which was directly related to [EtOH]. EtOH (0.2 mg/dl) had no effect (data not shown). This suggests a new mechansim by which EtOH, in physiologically relevant concentrations, and independent of its effects on pancreatic blood flow, may cause pancreatic injury. OT26 0570**Severe Acute Pancreatitis: Initial and Evolutive Bioclinical Prognostic Evaluation on 234 Patients. A Multicenter, Prospective Study of the French Associations for Surgical Research**

*N. Rotman, S. Chevret, D. Pezet, P.L. Fagniez, French Associations for Surgical Research

Centre Hospitalo-Universitaire Henri-Mondor, 94010 Cr\'e9teil, FranceDuring the past 25 years many studies were carried out to appreciate the best methods to differentiate between mild and severe pancreatitis. Nonetheless, within the group of patients with severe acute pancreatitis some will have a relatively uneventful course and others will have local and general complications. In order to identify the patients at risk of developing complications, the French Associations for Surgical Research began a multicenter prospective study including 234 patients with a first episode of severe AP. The purpose of this study was firstly to compare the predictive value of bioclinical data and specific and non specific bioclinical scoring systems at admission and to define, during the course of pancreatitis, the parameters indicating the occurrence of local infection (pancreatic abscess or infected necrosis) and death.Nineteen bioclinical parameters were recorded on admission, on day 3 and then every 4 days as well as preexisting diabetes mellitus, respiratory, cardio-vascular and hepatic disorders. Specific and non specific scoring systems (Ranson, Imrie, Simplified Acute Physiologic Score, Organ System Failure) were also assessed. To summarize prognostic information multivariate analysis used the Cox's model.Bioclinical data collected at admission and indicating local infection occurrence were: age > 55 years, systolic pressure < 120 mmHg, hematocrit < 30%. Bioclinical data collected at admission and predictive of survival were: age > 55 years and serum urea > 9 mmol/l. Ranson score and SAPS were predictive of survival while SAPS and OSF were predictive of local infection. Multivariate analysis of bioclinical data collected during the course of pancreatitis showed that pulse rate > 100/mn, systolic pressure < 120 mmHg, hyperthermia were significantly associated with survival. Increased pulse rate, hyperthermia and septicemia were significantly associated with local infection occurrence.This study confirms the predictive value of Ranson scoring system and SAPS. Some easily collected prognostic parameters, at admission and during the course of the disease were also identified. Pancreas: Pancreatitis, acute }" "Severe Acute Pancreatitis: Initial and Evolutive Bioclinical Prognostic Evaluation on 234 Patients. OT26 0571**Pancreatic Tissue Penetration of Amikacin, Amoxycillin/Clavulanic Acid, Piperacillin and Ofloxacin in Acute Experimental Pancreatitis**

*J. Spic\'e1k, J. Mart\'ednek[1], F. Z\'e1vada, J. Mor\'e1vek, V. Melenovsk\'fd

Clinic of Hepatogastroenterology and Diabetology, IKEM, Prague, Czech Republic

[1] Gastroenterology Department CHUV, Lausanne, Switzerland*Background & Aims:* Pancreatic infection is an often lethal complication of acute necrotic pancreatitis. The tissue/serum (T/S) ratio is an important criterion in deciding on antibiotic treatment but an influence of pancreatic inflammation on the tissue concentration and on the T/S ratio of antibiotics has not yet been evaluated. *The aim* of our study was to evaluate pancreatic tissue penetration and T/S ratios of amikacin, amoxycillin/clavulanic acid (augmentin), piperacillin and ofloxacin in normal (NR) and acute pancreatitis (AP) rats.*Methods:* Bolus of antibiotics was administered via the external jugular vein. In NR, the antibiotic concentrations were evaluated in blood and pancreatic tissue 90 min after antibiotics administration. In AP, severe necrotic acute pancreatitis was induced by infusion of 2 ml of 5% sodium taurocholate into the pancreaticobillary duct, and 3 hours thereafter the antibiotics were administered.*Results:* Amikacin Augmentin Piperacillin OfloxacinNR AP NR AP NR AP NR APn = 11 n = 11 n = 11 n = 11 n = 11 n = 11 n = 11 n = 11Serum concentration 1.9 2.2 14.7 23 29.5 20.4 1.1 1\'b5gram/ml [0.7] [4.3] [25.1] [15.2] [4.4] [7.2] [1.1] [1.0]Tissue concentration 0.3 0.2 4.8 6.5 7.6 6.3 0.8 0.5\'b5gram/g [0.1] [0.3] [2.3] [4.2] [2.3] [3.0] [0.4] [0.7]Tissue/serum ratio 0.16 0.07 0.24 0.23 0.27 0.26 0.59 0.52 [0.04] [0.06] [0.15] [0.11] [0.12] [0.13] [0.56] [0.21](NR-normal rats, AP-acute pancreatitis rats, data are medians [IQ distance])All antibiotic concentrations in serum were higher than in tissue ($p < 0.05$). In AP, tissue concentrations were not different as compared to NR for each antibiotic. In both, NR and AP, the highest T/S ratio was observed during ofloxacin as compared to the other antibiotics ($p < 0.003$). T/S ratios for piperacillin and augmentin were similar and higher as compared to amikacin ($p = 0.016$). Pancreatic tissue concentrations as well as T/S ratios were similar in NR and AP except for amikacin where the T/S ratio was lower in AP than in NR ($p = 0.02$).*Conclusion:* Ofloxacin showed the best pancreatic tissue penetration of the four antibiotics tested. The penetration of ofloxacin, augmentin and piperacillin was not influenced by pancreatic inflammation, while the penetration of amikacin was diminished by inflammation. Pancreas: Pancreatitis experimental }" "Pancreatic Tissue Penetration of Amikacin, Amoxycillin/Clavulanic Acid, Piperacillin and Ofloxacin in Acute Experimental Pancreatitis"

OT28 0572**The Mouse Model of Infection with Cytotoxin Expressing Strain of *Helicobacter Pylori* (Hp) in Studying the Pathogenesis of Chronic Gastric Ulcer**

*T. Brzozowski, P.Ch. Konturek, E. Karczewska, P. Ghiara, E.G. Hahn, S.J. Konturek

Inst Physiol, Univ Sch Med, Krakow, Poland

Dept Med I, Univ Erlangen-Nuremberg, Erlangen, Germany*Purpose:* Hp infection in humans is known to be responsible for gastritis and peptic ulcers but studies on the pathogenesis of Hp infection and peptic ulceration is limited by the absence of adequate animal model.*Methods:* We studied the effects of inoculation of conventional BULB/c mice with bacteria expressing both cytotoxin-associated gene A (CagA) and vacuolating cytotoxin (VacA) (SPM 326 type I) and non-cytotoxic Hp strain (SPM 314 type II), obtained from fresh clinical isolates, on the course of healing of chronic ulcers induced in the stomachs by serosal application of acetic acid. Inoculation of type I or II strain (2 {\'b4} 10^9 CFU) or vehicle saline was made at day 2, 4 and 6 upon ulcer production and the mice were killed at day 7 and 14. The ulcer area was measured by planimetry, the mucosal blood flow was determined by laser Doppler and mucosal biopsy samples were taken for histology and Hp culture.*Summary of results:* General condition of all animals subjected to Hp was fine and their weight increased normally. Hp infection was positive at 1 and 2 wk both by histology and cultural status. Neutrophil infiltration mainly at the submucosa was apparent in type I strain infected mice indicating the occurrence of gastritis. After 1 and 2 wk upon ulcer formation in vehicle-treated mice, the ulcer area was reduced by – 46% and 93%, respectively, and similar rate of healing was observed in type II Hp strain infected mice. In contrast, in type I strain infected mice no tendency of ulcer healing was observed after 1 and 2 wk. Blood flow was significantly lower in the ulcer area in type I strain than in type II strain infected or vehicle treated mice.*Conclusions:* Conventional mice can be successfully colonized by Hp strain expressing CagA and VacA and this infection delays healing of chronic gastric ulcers, at least in part, due to reduction in gastric blood flow. OT28 0573**Helicobacter Inhibits Directly Acid Secretion by H_3 Receptor Mediator PathwayB. Alchepo, I. Sobhani, L. Moizo, J.P. Laigneau, M. Mignon, A. Labigne, M.J.M. Lewin, A. Bado**

INSERM U10, Hospital Bichat & Institut Pasteur, Paris-FranceHelicobacter modifies gastric acid secretion interfering with gastrin, somatostatin and histamine. It increases N-{ a}methylhistamine a known H3 selective receptor agoniste. Previous study from us and others have shown that activation of H3 receptor reduces stimulated gastric acid secretion. The *aim* of the present study was to investigate H3 receptor pathway *in vivo* in cat before and after eradication. *Materials.* Six adult cats (Iffa Credo) provided with a fistula in the stomach were examined for the presence of Helicobacter using biopsies submitted to CLO test, histology, culture and/or PCR analysis. Meal-, histamine (20–160 \'b5g/kg/hr)- and gastrin (G5 1–32 or G17 0.5 \'b5g/kg/hr)-stimulated H+ outputs were analysed after 18 hr fasting before and 5 weeks after Helicobacter eradication (15 days PPI + 2 antibiotics therapy). The effect of thioperamide, R{ a}methylhistamine (H3 receptor antagonist) on the G17-stimulated acid secretion and serum gastrin (RIA) level (4 {\'b4} 15 min) in response to meal were analysed before and after eradication. *Results:* Before eradication histology did not show mucosal inflamation. Before eradication CLO test was positive and *H. felis* (n = 4) and *Heilmanni* (n = 2) were characterized; after eradication no bacterium was found and CLO tests were negative. Meal-stimulated gastrin level remained unchanged by eradication therapy. Acid secretion increased (40%) significantly ($p < 0.01$) after eradication in a dose-dependent manner in response to pentagastrin or histamine and to G17 (i.e. 1580 + 300 \'b5Eq/15 min vs 940 + 190 \'b5Eq/15 min). The level of gastric acid output under ""thioperamide + G17"" before eradication was similar to that observed under ""G17 alone"" after eradication. *Conclusion.* These results demonstrate that Helicobacter but no inflammatory cells inhibits acid secretion in cat. Since thioperamide reversed this inhibition, we suggest that *Helicobacter* inhibits acid secretion *via* an H_3 receptor mechanism. }" "Helicobacter Inhibits Directly Acid Secretion by H3 Receptor Mediator Pathway"

OT28 0574**Role of Selectins in the Formation of Leukocyte-Platelet Aggregates Elicited by *H. Pylori* Infection**

*J.I. Elizalde, J. Pan\'e9s, J. G\'f3mez, M. Casadevall, A. Salas, D.N. Granger[1],

*J.M. Piqu\'e9

Dept Gastroenterology, Hospital Cl\'ednic, Barcelona, Spain

[1] Dept Physiology, LSU Med Center, Shreveport, LAExtracts of *Helicobacter pylori* have been shown to induce leukocyte adhesion in mesenteric venules, but the effect of this chronic infection in the gastric microvessels is still unknown. The objective of the present study was to characterize the effects of *H. pylori* infection on leukocyte-endothelial cell interactions in the gastric microcirculation, and to assess the role of selectins in such interactions.Mice were orally inoculated with fresh clinical cagA+ vacA+ *H. pylori* isolates 3 times at 2-day intervals. Infection was assessed by culture and/or urease test of gastric specimens obtained at the end of the experiments. Controls included mice inoculated with *E. coli* or saline. Leucocyte-endothelial cell interactions were characterized in the stomach using intravital microscopy after fluorescent labeling of leukocytes and platelets with acridine orange.In non infected animals the number of rolling leukocytes in the gastric venules was low (2 – 0.8 cells/min). Infection with *H. pylori* induced a marked increase in rolling both at one (11.2 – 3.6) and two weeks (8 – 0.2) after inoculation. In addition, in these animals leukocyte-platelet aggregates were observed both at one (19.6 – 3.0) and two weeks (10.8 – 5.8 aggregates/min) after inoculation. By contrast, aggregates were never observed in non-infected controls. In animals inoculated with *E. coli,* the number of rolling leukocytes in gastric venules (2 – 0.7) was the same as in controls, and platelet-leukocyte aggregates were rarely observed (1.2 – 0.7 aggregates/min).To assess the role of selectins in the formation of aggregates, anti L-, P-, and E-selectin mAbs were iv given after basal observation. Whereas anti E- selectin didn't exert any effect in the number of aggregates, they markedly decreased following anti L- (from 21 – 3 to 4 – 2 aggregates/min) or anti P-selectin (from 19 – 4 to 1.5 – 0.5 aggregates/min) mAbs administration.The results of the present study indicate that infection with *H. pylori* induces leukocyte rolling and elicits the formation of L- and P-selectin dependent leukocyte-platelet aggregates in the gastric microvasculature. These microvascular alterations may contribute to the pathogenesis of mucosal damage in H. pylori infection.

OT28 0575**Helicobacter Heilmanil Type 1 (Hh1) Infection Induces Increased Gastric Emptying of Liquids in RatsI. Duval-Ara\'fajo,**

*D.M.M. Queiroz, C.J.S. Simal, V.S.P. Marino, A.G.P. Magnago,, S.D. Carvalho, L.A.S. Machado

Laboratory of Research in Bacteriology & Post-Graduate Surgery Laboratory, Fac. Medicina, UFMG, BrazilThe association between H. pylori and gastric motilily abnormalities is not well evaluated and is still controversial due in part by the lack of an appropriate animal model. It was recently demonstrated that (Hh1), a spiral bacterium that infects the stomach of both humans and pig, easily colonizes and induces an inflammatory response in the gastric mucosa of rodents. For these reasons, we aimed to study the relationship between gastric motility in rats experimentally infected by Hh1 correlating the results with serum gastrin and gastric somatostatin concentration, since these hormones seem to be involved in the gastrointestinal motility. Twenty Wistar female rats were divided in two experimental groups: A, 10 non-infected animals (control group) and B, 10 animals inoculated *per os* with 0.2 ml of gastric mucus of a Hh1 positive swine. After 56 days of inoculation, the animals were anesthetized with ketamine chloride (50 mg/Kg body weight) and gastric emptying was studied by scintigraphy after oesophageal administration of 0.2 ml 99mTc-fitate diluted (1:1) in 2.5% peptone solution. After the scintigraphic study, the animals were sacrificed, blood samples were collected for serum gastrin contents measurement and fragments of the gastric antrum were obtained for somatostatin contents evaluation and Hh1 diagnosis. The results were analysed by the Kruskall-Wallis test and the level of significance was set at $p < 0.05$. All animals of the group B were Hh1-positive by carbolfuchsin stained smears and urease test and all group A animals were Hh1-negative. There was an increase in the gastric remnant in group A when compared to the group B (72.7 – 17.7% vs. 47.7 – 13.9%, $p = 0.01$). Serum gastrin levels of group B were higher than in the group A (median 64.3 pg/ml; range 26.7 to 197.5 vs. 30.3 pg/ml; range 20.9 to 84.1, $p = 0.03$) and gastric somatostatin levels were lower in the group B when compared to group A (0.9 ng/mg; range 0.7 to 3.2; and 2.9 ng/mg; range 1.2 to 5.2, $p = 0.01$). In conclusion, gastric motility is altered in rats infected by Hhl. This abnormality could be related to the concurrent abnormalities of gastrin and somatostatin secretion. Oesophageal gastric duodenal disorders: Helicobacter PyloriMotility, general: Functional GI disordersMotility, specific: Stomach }" "Helicobacter Heilmanil Type 1 (Hh1) Infection Induces Increased Gastric Emptying of Liquids in Rats"

OT29 0576**Referral for Anorectal Function: The Dutch Experience**

*R.J.F. Felt-Bersma, A.C. Poen, M.A. Cuesta[1], S.G.M. Meuwissen[2]

[1] Dept. of Surgery, University Hospital ""Vrije Universiteit"", Amsterdam, The Netherlands

[2] Dept. of Gastroenterology, University Hospital ""Vrije Universiteit"", Amsterdam, The Netherlands*The purpose of the study* was to evaluate the impact of Anorectal Function Evaluation (AFE) on patients and referring specialists.*Methods.* In one year 135 patients (fecal incontinence 31%, constipation 17%, fistula 16%, pain 14%, other 22%) were referred for AFE. AFE consisted of proctoscopy, anal manometry, rectal compliance, anal mucosal sensitivity and anal endosonography. From 128 patients an address was available; 100 returned the questionnaire (78%). The response of the referring specialists was 91%.*Results.* Forty-one patients (30%) were referred from other hospitals. In 70% there was total agreement about the referring and final diagnosis. (R 0.76 ($p < 0.0001$)). Patients questionnaire: The visual analogue scales (VAS, 0–10) for the experience of referral for AFE were for embarrassment 4.4 (SD 3), pain 3.6 (SD 3.6) and traveling time 2.4 (SD 3.2). The sex of the investigator did not matter in 87% of the patients. Of the women, 13% preferred a female investigator. Fifty-nine patients answered that they had received (another) treatment: surgery (32), medication (16), diet (5), physiotherapy (1), combination of the above (7) or otherwise (4). Of the 41 patients who did not receive (another) treatment), 29 were reassured and 12 said to have had no benefit from the visit. The medical situation before AFE and at follow-up (VAS 0–10) improved overall from before 4.4 (SD 3.8) to after 6.3 (SD 3.6) ($p < 0.0001$), caused by the treated group (58) with an improvement from 4.1 (SD 3.9) to 6.9 (SD 3.4) ($p < 0.0001$). Specialists questionnaire: The advice was followed by the referring specialist in 84% of the patients. Physiotherapy was followed in only 67%, while surgery, depending of the type, was followed up to 100%. The quality of the advice was considered good in 84%. The possibility for referral for AFE was considered useful in 93% patients. In 71 patients information of both specialist and patient was obtained. Three patients had therapies that were not advised, 19 patients did not follow up their (mainly diet) advice. In the 135 patients, AFE changed the management in 34 (25%) patients. In the other 101 patients, mainly endosonography was of value, by determining size of sphincter defects or fistula tracts.*Conclusion:* AFE is well tolerated and changed management in 25% of patients. Treatment advised after AFE improved the clinical condition significantly. Specialists considered referral useful in 93%. Dietary advices and physiotherapy were less frequently followed by both patient and specialist. Anal endosonography seems the most valuable test.

OT29 0577**Validation of a Questionnaire for Functional Dyspepsia (FD) in a Multicenter Setting**

*V. Stanghellini, The Italian Dyspepsia Study Group (IDySG)

1st Medical Clinic, S. Orsola Hospital via Massarenti 9, 40138 Bologna, Italy*Purpose:* Whether symptom questionnaires can be applied in multicenter studies on FD has not been validated. We tested intra- and inter-centers reproducibility, responsiveness to changes (i.e. to treatment), and validity (i.e. capability of distinguishing FD from health) of a symptom questionnaire, in 7 gastroenterological Italian centers. *Methods:* Based on the clinical judgment of experienced gastroenterologists and the negative findings at upper GI endoscopy (and of other appropriate tests when deemed), 43 pts (M/F: 19/24; age 34.6 – 9.8 yrs, m – SD) were diagnosed as having FD. Each patient was administered a visual analogue scale of general well being (VAS: 0–100) and a symptom questionnaire, both being relative to the 2 wks preceding the interview, on different occasions: 0L) at entry (by a local interviewer: L); 1L) 1 wk later (by L); 1R) immediately after 1a (by a reference interviewer: R, VAS was not administered in this occasion), 6) at the end of a 5 wk treatment period (by L): lansoprazole 30 mg bid + clarithromycin 250 mg bid + amoxicillin 1 g bid for 1 wk, followed by cisapride 10 mg tid for 4 wks, in HP+ve pts; cisapride 10 mg tid for 5 wks, in HP{ -}ve pts. Multiple point adjectival scales were used to grade 0–4 severity (S) and frequency (F) of 9 symptoms (epigastric pain/burning/bloating, cardiac pain/burning, postprandial fullness, early satiety, nausea, vomiting). VAS and questionnaire were also administered to 50 healthy controls (HC, M/F: 21/29), 36.4 – 12.4 yrs), at time 0 (by L). 0L-HC 0L-FD 1L-FD 1R-FD 6L-FDVAS 83.7 – 11.1 41.7 – 17.0{[a]} 52.3 – 22.8{[?]} – 67.4 – 23.7{[d]}S 0.06 – 0.30 0.77 – 1.15{[a]} 0.62 – 1.06{[b]} 0.67 – 1.15 0.18 – 0.57{[e]}F 0.04 – 0.20 0.85 – 1.32{[a]} 0.71 – 1.23{[g]} 0.76 – 1.36 0.24 – 0.74{[e]}m – SD; {[a]}p < 0.001 vs 0-HC (Mann-Whitney U-test); {[b]}p < 0.01 vs 0-FD; {[g]}p < 0.05 vs 0-FD; {[d]}p < 0.01 vs 1a-FD; {[e]}p < 0.001 vs 1a-FD (Wilcoxon matched pairs test); {[?]}p = 0.086 vs 0-FD.A good agreement was found as to symptom S and F between 1L-FD and 1R-FD (S: K = 0.70; F: K = 0.62), while a fair agreement was found between 0L-FD and 1L-FD (S: K = 0.48; F: K = 0.43).*Conclusion:* The questionnaire we tested presents high responsiveness and validity and is reproducible in a multicenter setting. The weaker intra-center reproducibility is likely due to the design of this protocol which did not correct for the spontaneous -fluctuations of the syndrome. OT29 0578**Academic Gastroenterology in Western Europe in the Past 5 Years: Publications in Specialty Journals**

*D. Sorrentino, International Committee of the Italian Society of Gastroenterology, F. De Biase, A. Trevisi, E. Bartoli

GI Unit, Department of Internal Medicine, University of Udine, Udine, Italy*Aims:* To evaluate publications in gastroenterology, hepatology and digestive endoscopy in Belgium (B), Denmark (DK), France (F), Germany (D), Great Britain (GB), Holland (NE), Italy (I), Spain (ES), Sweden (S), Switzerland (CH). *Methods:* The nine top-rated specialty journals i.e. Am. J. Gastroenterol, Dig. Dis. Sci, Endoscopy, Gastroenterology, Gastrointest. Endoscopy, Gut, Hepatology, J. Hepatology and Scand. J. Gastroenterol, years 1991–95, were screened by Silver Platter' for full articles and reviews/editorials bearing the name of the above countries as the site of the first institution. Papers were rated according to the the Impact Factor (IF) – Institute of Scientific Information' – 1994. Linear regression was used to analyze the past 5 years behaviour of each country IF. This survey does not take into account non-specialty journals and small changes in journals IF in the last few years. A more comprehensive search is under way. *Results:* As randomly tested, the computer search had an error of – 5%. Total number of papers, total IF and average IF per single paper (in parenthesis) were: GB: 1473–5020 (3.4), F: 668–2787 (4.2), D: 751–2726 (3.6), I: 770–2695 (3.5), ES: 418–1740 (4.2), NE: 409–1389 (3.4), B: 176–1072 (6.1), S: 386–1072 (2.8), DK: 253–679 (2.7), CH: 165–677 (4.1). Fifty-two percent of the IF for GB was from Gut, while thirty percent of IF for S came from the Scand. J. Gastroenterology. For comparison, equivalent figures for the United States (U.S.) were 3806–15072 (4.0) and for Japan (J) 1337–4689 (3.5). Sixty-one percent of total IF for the U.S. came from Gastroenterology and Hepatology. Total IF in the past five years (percent per year) increased substantially for ES (+17.9) and CH (+14.9) and less for I, D and F (+7.3, +4.1 and +6.9 respectively) with no change for the others and a small decrease for DK ({ -}3.3). For the U.S., IF decreased by 4.4% while for J it increased by 17%. *Conclusions:* GB totalled the highest total IF and the highest number of papers published in gastroenterology specialty journals in the past five years. Without the publications in Gut and given the small error of this search, figures are virtually identical for F, D, GB and I. As defined in this study, scientific production in gastroenterology appears on the rise in western Europe and Japan and slightly declining in the U.S. Clinical practice: Epidemiology (non cancer) }" "Academic Gastroenterology in Western Europe in the Past 5 Years: Publications in Specialty Journals"

OT31 0580**Stimulation of Antral Motility by the New Motilide ABT-229**

*M.A.M.T. Verhagen[1], M. Samsom[1], J.M. Kroodsma[2], A.J.P.M. Smout[1]

[1] Gastrointestinal Motility Unit, University Hospital Utrecht, The Netherlands

[2] U-Gene Research, Utrecht, The NetherlandsABT-229 is a recently developed erythromycin derivate with motilin agonist activity, but devoid of antibiotic activity. We studied the effects of ABT-229 on postprandial antroduodenal motility.The effects of an oral dose of 4 mg, 16 mg ABT-229 and placebo were studied in 9 healthy male volunteers, using a double-blind randomized 3-period cross-over design. A water-perfused catheter, with 4 antral sideholes (A1–A4; spaced 1 cm) and 4 duodenal sideholes (D1–D4; spaced 10 cm) was introduced transnasally. Transmucosal potential difference was measured between the distal antral (A4) and proximal duodenal (D1) sidehole (spaced 5 cm) to monitor the position of the catheter. The drug (Abbott Laboratories, IL, USA) was given in enteric coated granules during phase II. 45 min later a solid meal (bread and egg, 150 ml water; 250 kcal) was taken, after which postprandial activity was recorded for 4 h. Thereafter, a second, identical meal was consumed and recordings continued for another 4 h. The number of pressure waves (P) and their mean amplitude were calculated. During the first 2 postprandial hours after the first meal the propagation of PWs over antrum and duodenum was studied.After the 1st meal ABT-229 dose-dependently increased both the number of antral PWs (mean – SEM; placebo; 4 mg; 16 mg; 162 – 16; 212 – 20; 279 – 23; $p < 0.01$) and their mean amplitude (7.3 – 0.7; 10.0 – 0.9; 13.3 – 0.7; $p < 0.01$). ABT-229 selectively increased PWs propagated over the antrum (A1{’}A4; 5.4 – 1.8; 18.7 – 3.1; 34.5 – 4.6; $p < 0.01$) and PWs propagated over the antrum onto the duodenum (A1{’}D1; 18.0 – 5.6; 32.3 – 3.7; 39.2 – 4.4; $p < 0.01$). No effect was seen after the 2nd meal. No changes were found in the number and amplitude of duodenal PWs after both meals. Phase III-like activity increased after 16 mg ABT-229 (2.3 – 0.6; 2.6 – 0.4; 4.2 – 0.4; $p < 0.01$) and originated more often in the antrum (43%; 70%; 92%; $p < 0.01$).*Conclusion:* The new motilin agonist ABT-229 increases the strength and length of the antral pump by increasing the number, amplitude and the propagation of antral PWs and induces antral phase III-like activity. ABT-229 bears the potential of becoming a new prokinetic drug for gastric motility disorders. OT31 0581**Second Report of a Multicenter Study on Electrical Stimulation for the Treatment of GastroparesisThe GEMS Study Group**

The University of Tennessee, Memphis, TN, USA

Universitaire Ziekenhuizen Gasthuisberg, Leuven, Belgium

Centre Hospitalier Regional et Universitaire de Nantes, Nantes, France

University of G\'f6teborg, G\'f6teborg, Sweden

Medizinische Klinik der Universit\'e4t M\'fcnster, M\'fcnster, Germany

McMaster University, Hamilton, Canada

Bakken Research Center B.V., Maastricht, The Netherlands*Introduction:* Patients with severe gastroparesis (GP) are often refractory to medical therapy. Although gastric electrical stimulation (GES) has been advocated as therapy for GP, results of previous trials have been inconclusive. This is a preliminary report of a prospective multicenter study of GES for GP.*Methods:* 21 patients (16 M and 5 F) mean age 36 (18–49) with drug refractory GP (5 IDDM, 16 Idiopathic) were enrolled using entry criteria of delayed gastric emptying (GE), Vomiting (V) and Nausea (N). The study consisted of two phases – I percutaneous temporary stimulation (TS) and II permanent stimulation using an implantable pulse generator. Stimulation parameters were 12 bpm (0.2 Hz), 5 mA and pulse width 330 \'b5s. GE, as well as frequency of N and V were measured at baseline, end of TS, and 3 months post permanent implantation.*Results:* Of the 21 pts 18 were selected for PS. The weekly frequency of V and N, median (range), after solid food were significantly reduced (* p < 0.05 sign test) with pacing at end TS and 3 M post implant. Baseline # pts End TS # pts 3 months # ptsVomiting 21 (0–210) 19 0 (0–2)* 17 0 (0–7) 9Nausea 21 (7–168) 18 2 (0–21)* 17 3 (0–14)* 9GE data were considered improved ({\'ad}) or deteriorated ({\'af}) if changed {\'b3} 30% from baseline. Lower differences were considered as no change (=). End TS # pts 3 Months # ptsGET T50 solid 2 {\'ad} 3 {\'af} 13 18 0 {\'ad} 0 {\'af} 6 = 6GET T50 liquid 8 {\'ad} 0 {\'af} 7 15 5 {\'ad} 0 {\'af} 1 = 6*Conclusions:* Gastric pacing with a fully implantable system is feasible and has an important antiemetic effect. GET T50 liquid improves in more than half of the patients while the result is inconclusive for GET T50 solid. OT32 0582**Lack of Compensatory Hyperphagia in HIV-Infected Patients with Malabsorption**

*F. Carbonnel, L. Beaugerie, A. Abou Rached, H. d'Almagne, W. Rozenbaum, J.P. Gendre, J. Cosnes

Dept of Gastroenterology and Infectious Diseases, Hospital Rothschild, Paris, FrancePatients with malabsorption due to the short bowel syndrome (SBS) have adaptive hyperphagia that tends to compensate their absorptive handicap. Thus, many of them maintain a normal nutritional status in spite of marked malabsorption. Whether compensatory hyperphagia occurs in malabsorption due to other causes remains unknown. *Methods.* Daily food intake and simultaneous measurement of fecal weight, fat and nitrogen were performed in postsurgical patients (10 with ileal pouch anal anastomosis, IPA; 75 with SBS), patients with small bowel diseases (SBD; 26 celiac disease, 4 unexplained enteropathy, 12 others) and HIV-infected patients with chronic, intractable diarrhea [cryptosporidia (n = 22), microsporidia (n = 18), no detectable enteropathogen (n = 26)] or without diarrhea (n = 13). Patients were stratified according to the level of fat malabsorption (fecal fat/fat intake). *Results.* (mean) IPA (n = 10) SBD (n = 9) HIV (n = 13) P*Fat malabsorption 0–5%Energy intake (kcal/IBW/d) 30.5 34.8 23.5 0.004Fat malabsorption 18–31% SBS (n = 22) SBD (n = 16) HIV (n = 34)Energy intake (kcal/IBW/d) 29.2 30.9 23.7 0.0004Fat malabsorption > 31% SBS (n = 53) SBD (n = 13) HIV (n = 32)Energy intake (kcal/IBW/d) 35.6 27.6 21.5 < 10{ -6}IBW: ideal body weight. * differences between groups assessed using Kruskall-Wallis test. In postsurgical patients (but not in others), energy intake increased at the higher levels of malabsorption (p = 0.046). *Conclusion.* HIV-infected patients have a reduced energy intake at all levels of malabsorption comparatively with SBS and SBD patients. There is no compensatory hyperphagia such as in SBS patients. These results suggest that reduced energy intake has a prominent role in body weight loss of HIV-infected patients with malabsorption. Nutrition: Nutrients and gut functionImmunology and microbiology: GI infections in adultsIntestinal disorders, absorption: Malabsorption syndromes }" "Lack of Compensatory Hyperphagia in HIV-Infected Patients with Malabsorption"

OT32 0583**Plasma Amino Acid Metabolism in Asymptomatic HIV Infected PatientsJ. Ockenga, U.J.F. Tiedge, U. S\'fcttmann, M.J. Bahr, A. M\'fcgge, K.H.W. B\'f6ker, M.P. Manns**

Gastroenterology and Hepatology and Clinical Immunology, Medical School Hannover, FRGMalnutrition and wasting are known features of human immunodeficiency virus (HIV) infection and are associated with a predominant loss of body protein. Malnutrition can develop from undernutrition or from disease-induced alteration in metabolism. We could show, that a positive protein balance is possible in symptomatic, malnourished HIV infected patients by a protein intake > 1.2 g/kg/day using parenteral nutrition [Metabolism 44; 9: 1159–65]. But there is only limited information about about nutritional status, protein intake and amminoacid (AA) metabolism in asympt. HIV infected patients.Therefore we studied in 15 asymptomatic HIV infected patients (CDC < III, temperature < 38\'b0C, C-reactive protein < 6 mg/l) and in 30 age and sex matched patients AA concentrations by liquid chromatography. In 10 of these HIV patients we investigated body composition (bioelectric impedance analysis, anthropometry), albumin, malabsorption (D-xylose test and serum vitamin B12 serum concentration), resting energy expenditure (indirect calorimeter), food intake (7-day record), soluble TNF receptor p55 + 75, and CD4 count.8/21 AA levels are significant decreased to the control group: LEU (108.3 vs. 145.6, p < 0.001), ILE (58.3 vs. 73.3, p < 0.01); VAL (202.2 vs. 241.3, p < 0.01); PHE (54.5 vs. 70.3, p = 0.01); LYS (182.3 vs. 214.8, p < 0.05); MET (19.8 vs. 27.5, p = 0.001), CYS (21.7 vs 50.7, p < 0.001) and TAU (62.8 vs 78.5, p < 0.05). REE is 1775 – 174 and the mean difference to predicted REE (Harris Benedikt) is 9.24 – 5.9%. Energy intake is 2670 – 381 kcal/d [= 1.52 (range 1.15–1.90) {\'b4} REE]. Protein intake is 91.46 – 13.4 g/d (= 1.35 – 0.31 g/kg/d). REE/kg body cell mass is 57.24 – 3.38 kcal/kg/d and is negatively associated with Plasma concentrations of PHE (R = { -}0.91, p < 0.01), VAL (R = { -}0.87, p < 0.01), LEU (R = { -}0.82, p < 0.01), and GLU (R = { -}0.82, p < 0.05). Changes in AA concentrations are indepent from total calory intake, protein intake, body composition, CD4 count, and soluble TNF receptors.The significant decrease of the essential aminoacids LEU, ILE, VAL, PHE, LYS, and MET are not related to a lower protein intake. Our data suggest that these changes reflect the altered metabolism with a probably higher protein turnover in asymptomatic HIV infected patients. In addition the decrease of natural antioxidants like CYS and TAU may be due to chronic oxidative stress in these patients. Nutrition: MetabolismImmunology and microbiology: GI infections in adults }" "Plasma Amino Acid Metabolism in Asymptomatic HIV Infected Patients"

OT32 0584**Does Anal Mucosal Immunity Prevents Anal Dysplasia? Results of a Prospective Study**

*I. Sobhani, E. Gervaz, Ch. Vissuzaine, F. Potet, J. Vilotte, M. Mignon, G. Benhamou

FAMA MST and FAMA Coloproctologie Bichat Hospital; 75877 Paris Cedex 18, France
(ANRS support)*Introduction:* The incidence of anal dysplasia is increased in patients suffering from AIDS. The aim was to investigate prospectively the incidence of anal dysplasia and cancer and to assess immunologic characterization of anal mucosa in patients examined in coloproctology departement in 1995. *Patients and methods:* All consecutive AIDS patients suffering from anal ulcerations and/or condyloma (n = 79; 70 men; mean age 36 yrs), 45 HIV negative patients (32 men; mean age 45 yrs with hemorroids (n = 30) or fissuration (n = 15)) and 25 HIV negative homosexual men (mean age 31 yrs, with intra anal condyloma) were included. Anal biopsies were obtained for immunohistochemistry using CD1a, CD3 and CD4 antibodies, and HPV, EBV and HSV detection by in situ hybridization. Blinded histology examination was performed to detect dysplasia and/or cancer. When HPV failed to be detected by ISH, PCR was performed on stains. Percentage of Langerhans' cells and lymphocytes was calculated for each patient (45 controls, 25 VIH negative patients with condyloma and 27 patients with AIDS). The t test and correlation tests were used for statistical analysis. *Results:* 65% of patients with AIDS had CD4 lymphocytes < 50/ml in serum. Two moderate dysplasia and two anal carcinomas were observed in this subgroup of AIDS patients *vs* no dysplasia nor carcinoma in all other groups. Percentage of Langerhans' cells and mucosal lymphocytes (5 – 1 and 27 – 7, respectively) were significantly inferior in anal mucosa of AIDS patients compared to controls (17 – 2 and 64 – 27) or negative HIV patients with condyloma (20 – 8 and 53 – 10 respectively). HPV typing and PCR to detect oncogenic HPV in anal mucosa are in progress.*Conclusion:* Incidence of anal dysplasia or carcinoma is higher in AIDS patients compared to negative VIH patients. This may be related to the alteration of anal mucosal immunity. Intestinal disorders: Anorectal disordersOncology, general: Proliferation, carcinogenesisOncology, specific: Colon, rectum }"

OT36 0585**Regulation of Mucin Secretion in Human Gallbladder Epithelial Cells: Predominant Role of Calcium and Protein Kinase CN. Dray-Charier, A. Paul, M. Bouin, M. Mergey, D. Veissiére, P. Balladur, J. Capeau,**

*C. Housset

INSERM U. 402, Facult\'e9 de. M\'e9decine St Antoine, Paris, France*Background/Aims:* Mucins are major compounds of bile. They are secreted in the biliary tract, predominantly although not exclusively in the gallbladder. Their main attributed function is to ensure the cytoprotection of the biliary epithelial cells which are exposed to highly concentrated bile acids. Under pathological circumstances, biliary mucins contribute to the formation of gallstones and supposingly to that of bile plugs in diseases such as cystic fibrosis. Despite the important biological role of biliary mucins, the mechanisms regulating their secretion in humans are unknown. To address this question, we used human gallbladder epithelial cells in primary culture. *Methods:* [1-^{14}C]-glucosamine-labeled glycoproteins secreted *in vitro* were analysed, and quantified after exposing cells to activators and inhibitors of the main transduction pathways, and to potential biologically active secretagogues. *Results:* Secreted glycoproteins exhibited the characteristics of biliary mucins. Activators of cyclic AMP-dependent pathway as well as secretin and VIP did not significantly modify mucin secretion. By contrast, ionomycin and PMA increased mucin secretion by 292 – 48% and 134 – 19% over basal level, respectively. The effects of these two agents were additive and were respectively mediated, by a calcium-dependent pathway implicating Ca^{2+}/calmodulin-dependent protein kinase II (Ca^{2+}/CaM-kinase II), and by the action of protein kinase C (PKC), as ascertained by the use of inhibitors. In addition, mucin secretion was stimulated by extracellular ATP via P_{2U} receptors and PKC, and by taurochenodeoxycholic acid via intracellular calcium increase and Ca^{2+}/CaM-kinase II. *Conclusions:* Mucin secretion in human gallbladder is regulated predominantly by calcium-dependent pathways implicating Ca^{2+}/CaM-kinase II and PKC. Constituents of bile such as extracellular ATP and bile acids may play a major role in the regulation of biliary mucin secretion, by activating these different signalling pathways. OT36 0586**Cisapride Reverses the Effects of Octreotide (OT) on Intestinal Transit and the Proportion of Deoxycholic Acid (% DCA) in Bile and Serum**

*M.J. Veysey, S.R.D. Arraton, A. Mallet[1], P. Jenkins[2], G.M. Murphy, J.A.H. Wass, R.H. Dowling

Gastroenterology Unit, UMDS of Guy's & St Thomas' Hospitals, London

[1] Mass Spectrometry, UMDS of Guy's & St Thomas' Hospitals, London

[2] Dept of Endocrinology, St Bartholomew's Hospital, London

[3] Dept of Endocrinology, The Radcliffe Infirmary, Oxford, UK*Background:* We showed recently that, in addition to its effect on gallbladder (GB) emptying, OT prolongs intestinal transit and increases the % DCA and the cholesterol saturation of GB bile — factors important in the pathogenesis of OT-induced GB stones (GBS). It seemed important, therefore, to see whether the prokinetic drug, cisapride, might overcome these effects.*Methods:* Therefore, in 8 acromegalic patients (age range 22–69; 4 women) receiving long-term OT (LTOT; 100–200 \'b5g tds), we used a randomised, double-blind, placebo-controlled, cross-over design to study the effect of cisapride (10 mg qds for 2 weeks) on; (i) mouth-to-caecum transit time (MCTT), measured by the breath hydrogen technique, (ii) large bowel transit time (LBTT), measured using marker shapes, and (iii) the % DCA in fasting serum (since there is an exchange, and ultimately an equilibrium, between bile acids in serum and bile). We then compared these results with those obtained in 8 acromegalics (age range 30–69; 3 women) untreated with OT.*Results:* Mean values – SEM Acromegalic patients no OT LTOT + placebo LTOT + cisaprideMCTT (min) 171 – 14.7** 268 – 18.3 183 – 17.1**LBTT (h) 39 – 4.9* 54 – 4.3 30 – 4.4**%DCA 15 – 1.8* 24 – 2.9 13 – 4.5**p < 0.05, **p < 0.005 compared to LTOT + placebo. There was a linear relationship between LBTT and % DCA for all 3 groups (n = 24, r = 0.76, p < 0.005).*Summary/Interpretation:* These results clearly show that cisapride reverses the effects of OT on both small and large bowel transit and prevents the rise in the % DCA in serum, and by implication, in bile. If changes in intestinal transit are rate-limiting in the pathogenesis of OT-induced GBS, cisapride should prevent their formation. Liver and bile ducts, 2: Gallstones, formation, treatmentLiver and bile ducts, 2: Bile acids synthesisMotility, specific: Colon, anorectum }" "Cisapride Reverses the Effects of Octreotide (OT) on Intestinal Transit and the Proportion of Deoxycholic Acid (% DCA) in Bile and Serum"

OT36 0587**Biliary Lipid Determinants of Bile Lithogenicity and Cholesterol Gallstone Formation**

*G. Galatola[1], R.P. Jazrawi[2], G. Corrao[3], M. Fracchia[1]

[1] Division of Gastroenterology, Ospedale Mauriziano, Torino, Italy

[2] Division of Biochemical Medicine, St George's Hospital Medical School, London, UK

[3] Istituto di Scienze Statistiche ""Marcello Boldrini"", University of Milan, ItalyIncreased cholesterol saturation index (CSI) of gallbladder bile is a prerequisite for cholesterol gallstone (CGS) formation. It is calculated from the relative molar concentrations of cholesterol (C), phospholipid (P) and bile acid (BA), thus it does not give information on the absolute modification of biliary lipids in gallbladder bile. It is still debated whether enrichment of bile with deoxycholic acid (DCA) is associated with CGS formation. Our aim was to assess the independent biliary lipid determinants of lithogenic bile and CGS formation in a consecutive series of 79 subjects, 22 of whom had CGS. We used an already validated method of nasoduodenal bile sampling and cholescintigraphy in order to measure biliary lipid masses within the gallbladder. Bile acid composition was measured by high performance liquid chromatography. Subjects were initially stratified according to CSI {\'a3} 1 (N = 35; 21 M) and CSI > 1 (N = 44; 22 M). Between the two groups respectively, there was no difference in age, mass of P and BA, whereas C mass was 169 – 32 vs 397 – 49 \'b5mol ($p < 0.001$) and % DCA was 13 – 2 vs. 22 – 2 ($p < 0.001$). CSI was significantly associated with C mass. % DCA was significantly associated with CSI, age, C mass and P mass. By fitting a multiple linear regression model, % DCA ($p < 0.01$) and P mass ($p < 0.001$), but not age, gender and BA mass, were independent determinants of an increased C mass in gallblader bile. In order to assess the determinants of CGS formation, we then stratified the 44 subjects with CSI > 1 according to the absence (GS{ -}; N = 22; 11 M) or presence (GS+; N = 22; 11 M) of gallstone disease. CSI was similar in the two groups. The GS+ group was older (54 vs 39 years, $p < 0.001$) and had increased % DCA in bile (26 – 2 vs. 18 – 3; $p < 0.05$). No significant difference was observed for the biliary lipid masses between the two groups, although GS+ had a trend towards lower BA mass (2.4 – 0.3 vs. 3.2 – 0.4 mmol) and increased P mass (1.1 – 0.2 vs. 0.7 – 0.1 mmol). To test the hypothesis that CGS formation occurs in supersaturated bile with time and is favoured by a reduction in biliary BA, we fitted a logistic regression model using the absence or presence of CGS as dependent variable and age, mass of biliary lipids and % DCA as independent variables. Decreased BA mass was the only significantly independent determinant of CGS ($p < 0.05$). We conclude that lithogenic bile is due to an increased mass of C in gallbaldder bile, which in turn is associated with biliary enrichment with DCA. Formation of CGS seems to depend on a superimposed reduction of BA mass occurring with time in patients with bile supersaturated with cholesterol. An increase in percent biliary DCA seems to occur with time, and in subjects with supersaturated bile a further increase in % DCA may play a role in the process of CGS formation. Liver and bile ducts, 2: Gallstones, formation, treatment }" "Biliary Lipid Determinants of Bile Lithogenicity and Cholesterol Gallstone Formation"

OT38 0588**Effect of Insulin on Pancreatico-Biliary Secretion During Hyper- and Normoglycemia**

*H.A.J. Gielkens, W.F. Lam, M. Coenraad, I. Biemond, C.B.H.W. Lamers, A.A.M. Masclee

Dept. of Gastroenterology, University Hospital Leiden, The NetherlandsAcute hyperglycemia (HG) is known to inhibit gastrointestinal motility and secretion. In non-diabetic subjects acute HG stimulates endogenous insulin release. It is not known, however, whether hyperinsulinemia contributes to the inhibitory effect of HG on gastrointestinal function. Therefore we have investigated the effect of hyperinsulinemia (aimed at 200 mU/l) both during normoglycemic clamping (blood glucose 5 mmol/l, plasma insulin 200 mU/l; hyperinsulinemic normoglycemic clamp; HI) and during hyperglycemic clamping (blood glucose 15 mmol/l, plasma insulin 200 mU/l; hyperglycemic hyperinsulinemic clamp; HG) on pancreatico-biliary secretion in healthy subjects and compared with the results obtained during normoglycemia (NG). Nine healthy subjects (age 22–52 yr) were studied on 3 separate occasions during HI, HG and NG. Pancreatico-biliary secretion was measured under basal conditions (60 min) and during cholecystokinin infusion (CCK 0.25 IDU.kg{ ˉ1}.h{ ˉ1}) for 60 min. Plasma CCK and pancreatic polypeptide (PP) levels were determined.*Results:* (p * < 0.05) NG HG HIBasal trypsin (U/h) 24 – 5 7 – 2* 8 – 3*bilirubin (\'b5mol/h) 13 – 4 5 – 2* 3 – 1*CCK trypsin (U/h) 39 – 10 20 – 7* 55 – 14bilirubin (\'b5mol/h) 64 – 22 29 – 14* 40 – 7Plasma CCK levels was not sign. different between the 3 experiments. Plasma PP secretion during HG (0.2 – 0.06 nM.120 min) and HI (0.8 – 0.2 nM.120 min) were sign. (p < 0.05) reduced compared to NG (1.5 – 0.2 nM.120 min). *Conclusions:* HG inhibits basal and CCK stimulated pancreatico-biliary secretion. HI inhibits basal but does not affect CCK stimulated pancreatico-biliary secretion. Hyperinsulinemia contributes to the inhibitory effect of hyperglycemia on basal pancreatico-biliary secretion. The impaired PP secretion points to vagal cholinergic inhibition both during HG and HI. Pancreas: Secretion, regulationNutrition: MetabolismNutrition: Nutrients and gut function }" "Effect of Insulin on Pancreatico-Biliary Secretion During Hyper- and Normoglycemia"

OT38 0589**In vivo and in vitro Antagonist Properties of a New Peptide Bombesin Derivative**

*C. Nagain, J. Azay[1], M. Llinarés[1], J.A. Fehrentz[1], J. Martinez[1], C. Roz\'e9

INSERM U 410, 75870 Paris Cedex 18, France

[1] LAPP, ESA CNRS 5075, 34060 Montpellier Cedex, FranceBombesin (BN) elicit a broad spectrum of biological activities including stimulation of exocrine pancreatic secretion and mitogenic effect on human small cell lung carcinoma. These results increased the interest for obtention of potent and specific BN receptor antagonists. Various BN related peptides with C-terminal modifications display antagonist properties on rat pancreatic acini in vitro.Among these, JMV 736 (D-Phe-Gln-Trp-Ala-Val-Gly-His-NH-CH[CH2-CH(CH3)2]-*CHOH-CH2-CH-(CH3)2; * 50% S, 50% R) has been used. Its agonist and antagonist properties were studied in vitro on amylase secretion by isolated rat pancreatic acini and in vivo on external pancreatic secretion in anaesthetized rats. Its ability to inhibit BN-induced proliferation was also measured on Swiss 3T3 cells in vitro.BN (pGlu-Gln-Arg-Leu-Gly-Asn-Gln-Trp-Ala-Val-Gly-His-Leu-Met-NH2) stimulated amylase secretion in vitro with an EC 50 of 0.07 – 0.03 nM and total protein output in vivo with an ED 50 of 0.36 – 0.07 nmol/kg.h. JMV 736 had a high affinity for BN acinar receptors with a Ki of 0.67 – 0.08 nM. JMV 736 did not stimulate amylase secretion from isolated acini but inhibited stimulation induced by 1 nM BN with an IC 50 of 1.6 – 0.3 nM. In vivo, JMV 736 did not stimulate pancreatic secretion but inhibited the stimulation induced by 10 nmol/kg.h BN with an ID 50 of 10.5 – 2.15 nmol/kg.h on total protein output.BN dose dependently stimulated Swiss 3T3 cell proliferation. JMV 736 had a high affinity for BN Swiss 3T3 cell receptors with a Ki of 0.56 – 0.11 nM. JMV 736 did not stimulate 3T3 cell proliferation even at high doses (up to 10 \'b5M) but inhibited proliferation induced by 100 nM BN with an IC 50 of 88 – 11 nM.These results indicate that the reported modification of the C-terminal end of the BN molecule produced a potent antagonist which displayed ID 50 in vivo and IC 50 in vitro in the same dose range as the maximally effective dose of BN on pancreatic secretion. This antagonist was also very effective to inhibit Swiss 3T3 cell proliferation induced by BN. The high potency of this antagonist associated with its good in vivo tolerance suggest that it may become an useful tool to analyze the role of BN in physiological and pathological processes.

OT38 0590**Comparative Clinical Evaluation of ^{13}C-Starch Breath Test as a Novel Indirect Pancreatic Function Test**

*Chr. L\'f6ser, A. M\'f6llgaard, S. Aygen[1], O. Hennemann[1], U.R. F\'f6lsch

I. Medical Department, Christian-Albrechts-University, Kiel, Germany

[1] INFAI Institute, Bochum, GermanyThe clinical relevance of the ^{13}C-starch breath test was evaluated in comparison to the secretin-caerulein test (SCT), fecal elastase and fecal chymotrypsin in 30 patients with mild (n = 15) or severe (n = 15) exocrine pancreatic insufficiency, 23 patients with gastrointestinal diseases of non-pancreatic origin and 31 healthy controls. As ""gold standard"" the SCT was performed in all patients to define or exclude exocrine pancreatic insufficiency. 50 g of normal starch of maize were orally administered and breath samples were taken before and in 30 min intervals for 6 hours after oral ingestion and the increase of the relation of ^{13}C/^{12}C-isotopes was analysed by mass spectrometry. Furthermore, various correlation studies were performed with the different parameters of the SCT. ^{13}C-starch breath test Fecal elastase Fecal chymotrypsin Max. value AUC 180 min 240 min. (< 200 \'b5g/g) (< 3 U/g)*Sensitivity*Mild 53% 53% 60% 47% 87% 47%Severe 87% 87% 87% 87% 100% 73%Total 73% 73% 77% 70% 93% 60%*Specificity* 74% 72% 74% 69% 93% 93%Significant correlations ($p < 0.001$) were found between duodenal lipase activity (SCT) and the maximal value (r = 0.626) as well as AUC (r = 0.668) of the ^{13}C-starch breath test.*Conclusions:* Using naturally occurring starch of maize, the ^{13}C-starch breath test reveals in comparison to chymotrypsin higher and to fecal elastase lower sensitivity. As known from the other indirect pancreatic function tests (exception: fecal elastase 87%), insufficient low sensitivity was found for patients with mild exocrine pancreatic insufficiency during the ^{13}C-starch breath test. With regard to the evaluation in comparison to the SCT as ""gold standard"" fecal elastase determination is superior compared to ^{13}C-starch breath test and fecal chymotrypsin and remains to be the most reliable and practical indirect pancreatic function test available today. Pancreas: Pancreatitis, chronicPancreas: Pancreas, cystic fibrosisClinical practice: Management strategy }" "Comparative Clinical Evaluation of 13C-Starch Breath Test as a Novel Indirect Pancreatic Function Test"

OT38 0591**RNA Expression of Immunoregulatory Cytokines and Polymeric Immunoglobulin Receptor in Pancreatic Duct Cell Lines**

*J. Emmrich, G. Sparmann, M. L\'f6hr, L.H. Vu[1], Z. Moldoveanu[1], J. Mestecky[1], S. Liebe

Dept. of Medicine, Univ. of Rostock, Germany

[1] Dept. of Microbiology, Univ. of Alabama, Birmingham, AL, USA*Introduction:* Chronic pancreatitis is histologically characterized by infiltration with inflammatory cells as well as an extended fibrosis. It was suggested that cytokines are involved in this inflammatory process, Therefore, we investigated the cytokine RNA expression by pancreatic duct cell lines. In addition, we monitored the RNA expression of polymeric immunoglobulin receptor (pIgR) indicating epithelial cell activation. *Methods:* RNA expression of cytokines and pIgR were demonstrated in 6 pancreatic epithelial duct cell lines (AsPC-1, BxPC-3, Capan 1, Capan 2, PANC-1, and PaCa 44) and SV 40 immortalized human pancreatic duct cells. RNA was extracted from cultured cells and RNA expression was analyzed using RT-PCR with specific primers for pIgR, IL-1, IL-2, IL-4, IL-6, IL-7, IL-8, IL-10, IL-12, IL-13, TGF{ b}1, TNF{ a}, IFN{ g}, and GM-CSF. *Results:* All cell lines and immortalized pancreatic duct cells expressed message for TGF{ b}1, IL-7, and IL-8. pIgR expression was found in all cell lines except PANC-1. In PANC-1 and AsPC-1, the IL-6 and the GM-CSF RNA could not be detected.. Capan 2 cells were negative for IL-1 and IL-6 RNA. All other cell lines and immortalized cells expressed in addition to TGF{ b}1, IL-7, and IL-8 also GM-CSF, IL-1, and IL-6. No RNA expression was found for IL-2, IL-4, IL-10, IL-12, IL-13, IFN{ g}, and TNF{ a}. *Conclusion:* Pancreatic duct epithelial cells are able to produce TGF{ b}1, IL-1, IL-6, IL-7, IL-8, and GM-CSF which can affect lymphocytes and macrophages as well as fibroblasts in panceatic tissue. Based upon this ability, epithelial cells copuld play an important role influencing the cytokine network in inflamed pancreatic tissue. pIgR is also expressed to allow transport of polymeric IgA and IgM across the epithelial cell layer.Supported by BMBF, FKZ 01/ZZ/9102 and NIH, DK 28537. Pancreas: Acinar, duct cell functionImmunology and microbiology: Host defense mechanismsImmunology and microbiology: Inflammation }" "RNA Expression of Immunoregulatory Cytokines and Polymeric Immunoglobulin Receptor in Pancreatic Duct Cell Lines"

"P P 21 0592"P 21 0592**Apoptosis in Barrett's Oesophagus**

*U. Halm[1], C. Marx[2], M. Breidert[2], B. Wohlgemuth[3], S.R. Bornstein[2], J. M\'f6ssner[1]

[1] Department of Internal Medicine II, University of Leipzig, Germany

[2] Department of Internal Medicine III, University of Leipzig, Germany

[3] Institute of Pathology, University of Leipzig, Germany*Background:* Barrett's epithelium is known as the most important risk factor for adenocarcinoma of the oesophagus. In the metaplasia, dysplasia, adenocarcinoma sequence of Barrett's oesophagus the expression of mutated p53 protein or proliferations indices as proliferating cell nuclear antigen is well-known, whereas the role of apoptotic cell death in this sequence is uncertain. Therefore, we determined the frequency of apoptosis in different stages of Barrett's oesophagus.*Methods:* We investigated paraffin embedded tissue sections from patients with Barrett's oesophagus (gastric metaplasia n = 8, intestinal metaplasia n = 4, dysplasia n = 3, adenocarcinoma n = 3, and controls with normal fundic epithelium n = 3) by in situ DNA-labelling technique (Apoptag, Oncor, USA). The apoptotic labelling index (LI) was calculated after counting 2000 nuclei.*Results:* The LI was 1.6% (range: 0.8–2.8%) for gastric metaplasia, 1.6% (0.7–2.8%) for intestinal metaplasia, 0.9% (0.5–1.4%) for dysplasia, 0.8% (0.6–1.0%) for adenocarcinoma and 6.8% (2.8–13.1%) for normal fundic epithelium, respectively.*Conclusions:* Our results suggest that the rate of apoptosis in Barrett's oesophagus with gastric and intestinal metaplasia may be different from epithelium with dysplasias and adenocarcinoma. Our preliminary data have to be confirmed by larger series of patients. Thus, studies on apoptosis may improve our understanding of the metaplasia, dysplasia, adenocarcinoma sequence in Barrett's oesophagus. "P P 21 0593"P 21 0593**Evaluation of CD44 Protein Expression in the Progression of Barrett's Mucosa to Invasive CancerC. Lagorce, S. Dubois, C. Degott, D. H\'e9nin,**

*J.F. Fl\'e9jou

Service d'Anatomie et de Cytologie Pathologiques, Hospital Beaujon, Clichy, France*Background, aims and methods:* Barrett's adenocarcinoma develops by a multistep process in which the specialized metaplastic columnar epithelium progresses to dysplasia and eventually to adenocarcinoma. CD44 is a surface adhesion molecule that can be expressed in the form of various splice variants in human tumours, including colorectal carcinoma. It has been suggested that CD44 molecules have a role in tumor progression and metastasis. This study investigated the expression of CD44H (hematopoietic form), V4 and V6 by immunohistochemistry on tissue samples of Barrett's mucosa (34), and Barrett's adenocarcinoma (35) obtained from surgical resection specimens from 35 patients.*Results:* CD44H and V6 expression was found in 56% and 48% of Barrett's specialized mucosa negative for dysplasia. CD44H expression was found in 68% of low grade dysplasia, 80% of high grade dysplasia and 84% of Barrett's adenocarcinoma. CD44V6 expression was found in 57% of low grade dysplasia, 68% of high grade dysplasia and 78% of Barrett's adenocarcinoma. CD44H and V6 variant were expressed at the deeper part of the crypts in Barrett's metaplasia negative for dysplasia and at the upper part of the crypts in high grade dysplasia. CD44V4 was not expressed in Barrett's &diphtong;sophagus.*Conclusion:* These data indicate that both CD44H and CD44V6 protein are frequently expressed in Barrett's &diphtong;sophagus. The increasing rate of expression that we observed from mucosa negative for dysplasia to adenocarcinoma suggests that CD44H and V6 may be involved in the carcinogenesis of Barrett's esophagus. Whether or not patients with CD44 protein expression are at increased risk for progression to adenocarcinoma should be determined by prospective endoscopic biopsy analysis. "P P 21 0594"P 21 0594**Spatiotemporal Reflux Characteristics in Gastro-Oesophageal Reflux Disease (GORD), with and without Barrett's Metaplasia**

*E.C. Niemantsverdriet[1], R. Timmer[1], R. Breumelhof[1], A.J.P.M. Smout[2]

[1] St. Antonius Hospital, Nieuwegein, The Netherlands

[2] University Hospital, Utrecht, The NetherlandsPrevious studies have shown that in GORD distal oesophageal acid exposure increases with increasing mucosal injury. To investigate the characteristics of reflux at more proximal oesophageal levels in GORD patients with various stages of the disease, we studied 16 patients (age: 53.1 – 12.2 yr; mean – SD) with endoscopy-negative GORD, 14 patients (46.8 – 16 yr) with oesophagitis grade I and II and 15 patients (64.4 – 10.4 yr) with Barrett's oesophagus (> 3 cm). Multichannel ambulatory 24-hr pH measurements were performed using a pH-catheter (Sentron) with 5 ISFET sensors at intervals of 3 cm, (distal sensor at 3 cm above the LOS) and a portable data logger (MMS). Acid inhibiting agents were discontinued at least 5 days before measurements.At 3 cm above the LOS 24-hr acid exposure was significantly higher ($p < 0.01$) in patients with oesophagitis (pH < 4: 8.6 – 5.9%; mean – SD) than in endoscopy-negative reflux patients (5.4 – 6.9%). In patients with Barrett's oesophagus distal oesophageal acid exposure was much higher (36.0 – 19.0%; $p < 0.001$). These differences were largely determined by differences in nocturnal reflux. Significant differences in oesophageal acid exposure were also found at 6 and 9 cm above the LOS. However, at the more proximal levels the differences between patient groups faded out; at 15 cm above the LOS 24-hr acid exposure was similar in the 3 patient groups (resp. 2.9 – 9.8%, 4.2 – 4.0% and 3.2 – 2.1%). Other reflux variables (number of reflux periods, episodes > 5 min and duration of the longest episode) showed similar differences in spatiotemporal characteristics between the groups. *Conclusions:* In GORD increasing mucosal damage is associated with increasing acid exposure at distal oesophageal levels, however at more proximal levels acid exposures are similar in all grades of the disease. "P P 21 0596"P 21 0596**Intestinal Metaplasia of the Cardia Epithelium in Light Esophagitis: Histochemical and Ultra Structural Study**

*M.M. Tolentino, J.G. Faifer, E.A. Trentini, A.C.M. Stipp

Unigastro Rua Antonio Garcia N° 2–21, Bauru, BrasilThirty consecutive subjects with gastro-oesophageal reflux disease (GORD) were studied without hiatus hernia or classical Barrett esophagus, who had showed light esophagitis at endoscopic examination (Savary-Miller grade 1). The presence of one or two digitiform prolongations of the columnar epithelium above the Z line was not an exclusion criterium. A group of 9 asyntomatic volunteers was used as control group. Four Z line biopsies were taken (level 1), followed by other four biopsies 5 mm below Z line (level 2 – cardia). The biopsies were dyed with hematoxylin-eosin, PAS + Alcien-Blue and Alcien-Blue pH 2.5. Extra fragments at level 2 were taken from the 12 first cases for transmission electron microscopic study. The findings were analysed as a group and individually taking into consideration: the biopsy level and the type of epithelium in which changes were detected (lining or glandular). In 22 cases (73.3%) at least 1 of the fragments showed any metaplastic changes cells such as globets cells or lining cells with thin acid mucins deposits. Dyeing with PAS- Alcien-Blue improved much the viewing of light metaplasia foci ($p < 0.01$). Among 10 out of 22 positives (45.5%) changes appeared in only 1 of the fragments. Metaplastic changes at level 1 were found in 17 subjects (56.6%) and level 2 in 14 subjects (46.6%) without statistical difference. In 5 cases (16.7%) the changes occurred only at level 2. The comparison of positivity between the two levels demonstrated some statistical difference ($p < 0.05$) when the exclusive changes of the glandular epithelium were considered (mainly level 1) and the lining epithelium (mainly at level 2). The remaining comparisons were not significant. The electron microscopy showed the presence of epithelium cells with suggestive ultrastructural changes of metaplastic transformation in 7 out of 12 subjects (58.3%). Such a finding is a meaningful coincidence with a positivity to PAS + Alcien-Blue ($p < 0.05$). It has been concluded that the cardia epithelium (lining as well as glandular) demonstrate meaningful changes at GORD. Multiple biopsies conducted at different levels of Z line and the analysis of the biopsies through PAS + Alcien-Blue coloring are fundamental for the diagnosis of early metaplasia. The incidence of metaplastic changes is high (histochemical and ultrastructural) in the cases of light esophagitis. Oesophageal gastric duodenal disorders: EG RefluxEndoscopy, specific: Oesophagus }" "Intestinal Metaplasia of the Cardia Epithelium in Light Esophagitis: Histochemical and Ultra Structural Study"

"P P 21 0598"P 21 0598**DNA Ploidy and p53 Overexpression as Markers of Malignant Potential in Barrett's Oesophagus**

*M. Robaszkiewicz, A. Volant, E. Hardy, J.M. Cauvin, J.B. Nousbaum, J.P. Metges, H. Gou\'e9rou

CHU de la Cavale Blanche, 29609 Brest Cedex, FranceAbnormal nuclear DNA-content and TP53 gene mutations are early events during neoplastic progression of Barrett's oesophagus. The aim of this study was to investigate the value of DNA-ploidy and p53 immunostaining in an endoscopic surveillance protocol of patients with Barrett's oesophagus.*Patients – Methods:* 45 patients with Barrett's oesophagus participated in the study. Endoscopic follow-up was obtained for all patients. Multiple biopsy samples were taken using a rigorous protocol. Dysplasia was graded according to Riddell criteria. Flow cytometric DNA content analysis was performed according to the method described by Vindelov. Immunohistochemistry was performed with DO7 monoclonal antibody.*Results:* The mean follow-up was 27 months. Initial diagnosis n p53 (+) DNA-aneuploidyNo dysplasia or indefinite for 38 1 3dysplasia (ND/I)Low grade dysplasia (LGD) 6 3 2High grade dysplasia (HGD) 1 1 1Total 45 5* 6**4 patients had simultaneously p53 overexpression and aneuploidy.Of the 38 patients who were graded initially ND/I, 1 patient progressed to LGD; he had p53 overexpression and increased G2M fraction. A cancer developed in 1 of the 6 patients with LGD: the patient had p53 overexpression and DNA-aneuploidy; among the 5 other patients, LGD was not confirmed during subsequent follow-up. The patient with HGD progressed to a carcinoma. Among the patients who were p53 ({ -}) and had a normal DNA content, no progression was noted. Both adenocarcinomas were diagnosed at an early stage.*Conclusion:* These results confirm the difficulty of histologic assessment of dysplasia in Barrett's oesophagus. Although the follow-up is still too short, they suggest that combination of p53 immunostaining and flow cytometric evaluation might be useful in managing the cancer risk in patients with Barrett's oesophagus. Oncology, general: Proliferation, carcinogenesisOncology, specific: OesophagusOesophageal gastric duodenal disorders: EG Reflux }" "DNA Ploidy and p53 Overexpression as Markers of Malignant Potential in Barrett's Oesophagus"

"P P 22 0599"P 22 0599**Outcome Research in GORD: Retrospective Analysis of Prescription Data (Mediplus' UK) on Cisapride (CIS), Ranitidine (RAN) and Omeprazole (OME)A. Eggleston[1], A. Wigerinck[1], A. Haycox[2]**

[1] Janssen Research Foundation, B-2340 Beerse, UK

[2] Dpt Pharmacol Ther, University of Liverpool, UKClinical trials often represent a highly selective patient sample. Little is known about the use of and response to antireflux agents in a real life situation. The database MediPlus was used to collect information on drug use in patients (pts) with a first diagnosis of GORD treated with CIS, RAN or OME, as an hypothesis generating exercise, addressing initial success and relapse rates in pts.*Methods.* Pts with a first diagnosis of GORD occurring after 1.1.1993 and treated initially (antacids excluded) with either CIS, RAN or OME were identified. A random sample from each treatment group was selected for screening. \lquoteSuccess\rquote was arbitrarily defined as reflux medication prescribed for a period of {\'a3} 3 months (mo). Treatment was considered a \lquotefailure\rquote in case of switch of prescriptions to another antireflux agent in the first 3 mo or if subsequent reflux prescriptions were given for > 3 mo. Among successfully treated pts, the relapse rates in the subsequent 6 mo period were evaluated. Pts with a recurrent diagnosis of GORD, H_2-refractory GORD, or an index indicative of referral prior to the first Rx were excluded.*Results.* 279 of 790 pts were elegible. \lquoteSuccess\rquote rates for the different drugs tested were 70% in the CIS group, 79% in the RAN group, 75% in the OME group. In each group, – half of the pts received medication for {\'a3} 1 mo. Among the failures, switch of medicaton occurred after the first prescription in almost all pts of the CIS group, but was temporally dispersed in the other groups. The failures continuing the initial medication > 3 mo accounted for 12% of the CIS and RAN pts vs 21% in the OME group. Relapse rates at 6 months were 23% for CIS, 52% for RAN, 37% for OME. At the end of the observation period, 21% of the CIS group, 31% of the RAN group and 39% of OME group took regular or continued medication (respectively 7%, 5% and 34% took OME).*Conclusion.* There is little evidence to support a hypothesis of differences in response rates in pts presenting with a first episode of GORD in primary care. However, a hypothesis of lower relapse rates with CIS is supportable, to be confirmed in a randomised study. Treatment and outcomes in primary care, therefore, appear to differ from that previously generated in clinical trials from specialist centres. Oesophageal gastric duodenal disorders: EG RefluxMotility, general: Functional GI disordersClinical practice: Management strategy }"

"P P 22 0600"P 22 0600**Cost of Gord-Medication in Clinical Practice in Patients with a First Diagnosis of Gord Based on Prescription-Data Analysis (Mediplus UK)A. Eggleston[1], A. Wigerinck[1], A. Haycox[2]**

[1] Janssen Research Foundation, B-2340 Beerse, Belgium

[2] Dpt Pharmacol Ther, University of Liverpool, UKCost calculations of anti-reflux medication so far have been based on outcome measures obtained in controlled clinical trials. Such calculations do not take into account real drug use and interventions in real life, nor may they apply to primary care.*Objective:* To describe from a primary care perspective, based on a retrospective prescription database analysis, the cost of outpatient treatment associated with GORD during the first 6 treatment months, in patients, initiated on treatment with either cisapride (CIS), ranitidine (RAN) and omeprazole (OM) for their first diagnosis of uncomplicated GORD.*Method:* Calculation of all anti-reflux medication (antacids inclusive) and interventions linked to the index diagnosis of GORD among patients (pts) with a first episode of GORD. Pts with initial referral (< 13%) were excluded.*Results:* The costs over 6 months per CIS, RAN and OME patient were respectively \'a3137, \'a3178 and \'a3189. The number of one-month-equivalent treatments of the comparator drugs were respectively 1.85, 2.56 and 2.96, leading to costs of \'a349, \'a367 and \'a3105 per patient respectively. Antacid and alginate/antacid use was higher in CIS and RAN group (1 Rx of 500 ml or 56–60 tabs per patient versus 0.4 for OME), but their contribution to the total cost per patient was low (< 2%). The number of consultations varied between 2.4 and 2.9 per patient (CIS: 2.4 (\'a360.3), OME: 2.6 (\'a365.5) and RAN: 2.9 (\'a373.0)). The total number of referrals, endoscopies, Barium or X-rays, outpatient visits were the highest in the RAN group (0.034 versus < 0.02 in the CIS and OME group), their cost being respectively \'a323.8, \'a39.6 and \'a311.1 per patient. Their contribution to costs in the RAN group was offset by the lower cost of medication, when compared to the OME group.*Conclusion:* The data from this retrospective analysis indicate that the \lquotestep up\rquote approach starting with CIS, combined with antacid/alginate use, is the least costly approach of the 3 comparators in primary care patients with uncomplicated GORD. The calculations do not support a lower cost of the \lquotestep-down\rquote approach using OME initially in these patients. "P P 22 0601"P 22 0601**Gastroesophageal Reflux Disease in Children. Usefulness of Scintigraphic StudiesA.I. Santos,**

*A.I. Lopes, T. Martins, C. Rodrigues, P. Magalh\'e3es Ramalho, F. Godinho

Instituto de Medicina Nuclear, FML, Lisboa,- Portugal

Unidade de Gastrenterologia do Servi\'e7o de Pediatria, HSM, Lisboa, PortugalNowadays, it is known that gastroesophageal reflux (GER) may be part of a complex disease, where other disturbances of the digestive tube may exist.Our purpose was not only to compare pHmetry with the scintigraphic detection of RGE, but also to study if there was any gastric emptying abnormality that correlated with the presence of gastroesophageal reflux. We have performed 21 studies in 18 children, all of them with symptoms that required pHmetry. Four of these children had negative pHmetry and no other known disease, 2 had only gastroesophageal reflux and 12 were neurologically impaired children. The pHmetry was performed with a DIGITRAPPER MKIII and, for purposes of comparison with the scintigraphic studies the following parameters were considered: Reflux Index (refl/hour) and Esophageal Clearance (min/refl). The scintigraphic study was performed with a milky meal, adapted to the age and habits of the child, with a lipid content > 20% and labelled with Tc-99m-stannous colloid. Immediately after the ingestion, a dynamic study was started with 180 frames of 20 seg each, in a 64 {\'b4} 64 matrix. Planar images of 60 seg each were also acquired at 90 min, 2, 3 and 4 hours. The following parameters were calculated: Gastroesophageal Reflux Index (%) and Gastric Retentions of the meal at 15, 30, 45, 60 and 90 min and 2, 3 and 4 hours (%). To statistically compare the values obtained we used linear regression.We found a positive strong correlation between scintigraphic gastroesophageal reflux index and esophageal clearance ($r = 0.91$; $p < 0.001$). This same scintigraphic parameter and gastric retention at 4 hours also correlated ($r = 0.64$; $p < 0.05$), as well as the latter and esophageal clearance ($r = 0.61$; $p < 0.05$).Although the true pathological meaning of these correlations is still to be elucidated, it does seems that the gammagraphic detection of GER is associated with esophageal disturbances and eventually with slow gastric emptying. Oesophageal gastric duodenal disorders: EG RefluxMotility, specific: Oesophagus }" "Gastroesophageal Reflux Disease in Children. Usefulness of Scintigraphic Studies"

[2] Krankenhaus Buch, Berlin, Germany

[3] Krankenhaus Friedrichstadt, Dresden, Germany

[4] Weizenkamp 1, Damme, Germany

[5] Byk Gulden, Konstanz, Germany*Aim:* The safety and prophylactic efficacy of pantoprazole (40 mg per day) was assessed in an open, 1-year, multicenter trial in Germany, in 222 patients whose Stage II or III reflux oesophagitis had been healed after 4 or 8 weeks of treatment with pantoprazole or omeprazole.*Methods:* Patients with symptoms of reflux oesophagitis for at least 3 consecutive days underwent endoscopy, and those with endoscopically confirmed disease were classified as having relapsed. Efficacy was assessed by Kaplan Meier survival analysis for all patients who provided data by returning to the first 3-months follow-up visit.*Results:* In the per-protocol group, including only endoscopically confirmed relapses as treatment failures (n = 10), estimated cumulative rates of confirmed relapse were 2% at 6 months and 6% at 12 months. Median serum gastrin levels rose from 52 ng.l{ ¯1} at the start of the acute trial to 108 ng.l{ ¯1} at 6 months, but showed no further increase in the next 6 months. There were no other changes in laboratory variables. Adverse events occurred in only 24% of patients, which is similar to the rate with placebo [1]. 15 patients withdrew with adverse events. Serious adverse events were reported for 12 patients, including 6 who withdrew (with lumbago, skin carcinoma, gastrointestinal carcinoma, brain tumour, pulmonary embolus, and an orthopaedic operation). These adverse events were not considered to be related to study treatment.*Conclusion:* Pantoprazole is highly effective with a good safety profile in the long-term prophylaxis of reflux oesophagitis.

[1] Department of Medicine and Gastroenterology, University of Byk Gulden, Germany

Department of Medicine and Gastroenterology, University of Konstanz, Germany*Aim:* The prophylactic efficacy and safety of pantoprazole (PAN; 40 mg/day) was assessed in an open, 1-year, multicentre, follow-up trial in South Africa.*Methods:* 157 outpatients (pts), 64 female/93 male, median age: 46 years, with healed stage II or III reflux oesophagitis (Savary-Miller classification) were included in the study after an initial healing phase of 4 or 8 weeks with either 40 mg or 80 mg PAN in 8 study centres. Pts were seen after 3, 6, 9 and 12 months or whenever symptoms occurred on more than 3 consecutive days. An endoscopy was done in these cases and routinely at the beginning of the trial and after 12 months. Endoscopically confirmed relapses were evaluated as treatment failures. During the study period 30 pts were lost to follow-up due to e.g. protocol violation.*Results:* The 12-months' remission rate was 87.4% (111/127 pts; 95% confidence interval 80–93%). The pts experienced 11 possible drug related adverse events (AEs) as judged by the investigators. These AEs were: increase in liver enzymes (n = 2) or alkaline phosphatase (n = 2), diarrhoea, nausea, dry mouth, headache, weight gain, rash, eructation of air (n = 1 each). Four pts were withdrawn due to unrelated AEs. One pt who had increased his alcohol consumption concomitantly, was withdrawn due to possible drug related moderate increase in liver enzymes.*Conclusion:* This study proved that PAN is a safe and efficacious treatment for the long-term prophylaxis (one year) of reflux oesophagitis. "P P 22 0604"P 22 0604**Comparison of Cisapride Plus H-2 Antagonist Vs. H-2 Antagonist Monotherapy in the Prevention of Reflux Esophagitis RelapsesS. Gullini, S. Anna, CIS-ITA-24 Study Group**

Gastroenterol. Div. Arcispedale, Ferrara, ItalyThis study (controlled, double-blind, randomised and in parallel groups) was carried out in 34 Italian centers in order to evaluate the efficacy and tolerability of the association cisapride 20 mg/die plus H-2 antagonist (cimetidine 400 mg/die; ranitidine 150 mg/die; famotidine 20 mg/die) vs. H-2 antagonist monotherapy (cimetidine 400 mg/die; ranitidine 150 mg/die; famotidine 20 mg/die) in the prevention of reflux esophagitis relapses. 198 patients previously suffering of esophagitis, after treatment with a drug therapy, were enrolled in the study (24-weeks long) and treated, by oral route, win the association cisapride/H-2 antagonist or H-2 antagonist in monotherapy for relapse prevention. All patients, at the enrolling visit, did not show any endoscopic sign of pathology. Severity of symptoms [reflux symptoms (frequency, time, intensity and duration) (reflux score) and associated symptoms (epigastric pain/burning, disphagy, pain on swallowing, early satiety, bloating, epigastric distention, anorexia, nausea, vomiting, nocturnal coughing and shortness of breath)] were arbitrarily scored, on a 4-point scale, at each control examination. In addition, patients, at each visit completed two visual analogue scales related to general conditions and severity of the reflux occurred in the previous 7 days. Instrumental evaluation was performed through esophago-gastroduodenoscopy at baseline and at the end of the study (or before, in case of symptomatic relapses): results were expressed by a 5-point analogue severity scale. Finally 174 patients (87 treated with the association cisapride/H-2 antagonist and 87 with H-2 antagonist in monotherapy) were included in statistical analysis (both parametric and no -parametric).Results demonstrated the efficacy and tolerability of cisapride/H-2 antagonist combined treatment. All patients in this group reported a clear and progressive improvement (0.001 {\'a3} p {\'a3} 0.05 et week 24) in reflux score compared to the baseline score. On the contrary, the treatment with H-2 antagonist in monotherapy did not produce any significant improvement of reflux score. A significant and progressive reduction of associated symptoms and severity of reflux and improvement of general conditions compared to those at baseline was also observed in all patients treated with cisapride/H-2 antagonist and, only in a lesser extend, in patients treated with the monotherapy of H-2 antagonist. Even though no statistically differences between the two treatments were observed, the overall efficacy assessed by both physicians and patients ranged from excellent and good in 78.5% (association) and 66.6% (H-2 monotherapy) of the patients. Eight patients (8.7%) in the association group and 12 patients (12.8%) in the H-2 group showed endoscopic relapses. Five patients (3 in association group and 2 in H-2 group) reported adverse effects. "P P 22 0605"P 22 0605**Comparison of Two-Dose-Regimens of Cisapride in the Prevention of Reflux Esophagitis RelapsesA. Del Genio, CIS-ITA-20 Study Group**

[1] Gastroenterol. Surg., II Univ. of Naples, Naples, ItalyThis study (controlled, randomised and in parallel groups) was carried out in 36 Italian center in order to evaluate the efficacy and tolerability of two dosing regimens of cisapride (20 mg u.i.d. vs. 10 mg b.i.d.) in the prevention of reflux esophagitis relapses. 203 patients suffering of esophagitis, after treatment with a drug therapy, were enrolled in the study (24-weeks long) and treated, by oral route, with cisapride 10 mg b.i.d. (n = 96) or 20 mg u.i.d. (n = 107) for relapse prevention. All patients, at the enrolling visit, did not show any endoscopic sign of pathology. Severity of symptoms [reflux symptoms (frequency, time, intensity and duration) (reflux score) and associated symptoms (epigastric pain/burning, disphagy, pain on swallowing, early satiety, bloating, epigastric distention, anorexia, nausea, vomiting, nocturnal coughing and shortness of breath)] were arbitrarily scored, on a 4-point scale, at each control examination. In addition, at each visit, patients completed two visual analogue scales related to general conditions and severity of the reflux occurred in the previous 7 days. Instrumental evaluation was performed through esophago-gastroduodenoscopy at baseline and at the end of the study (or before, in case of symptomatic relapses): results were expressed by a 5-point analogue severity scale. Finally 177 patients (85 treated with 10 mg b.i.d. cisapride and 92 with cisapride 20 mg u.i.d.) were included in statistical analysis (both parametric and no -parametric).Results demonstrated the efficacy and tolerability of both cisapride treatments. All patients reported a clear and progressive improvement (p {\'a3} 0.001 at week 24) in reflux score compared to the score reported at the enrolling examination. No significant differences were observed between cisapride 10 mg b.i.d. and 20 mg u.i.d. A significant and progressive reduction of associated symptoms and severity of reflux and improvement of general conditions compared to those reported in enrolling examinations were also observed in patients treated with both cisapride dosing regimens. The overall efficacy assessed by both physicians and patients was comparable and ranged from excellent and good in 91% (10 mg b.i.d.) and 80.5% (20 mg u.i.d.) of the patients. Furthermore, only 5 patients (5.2%) in the 10 mg b.i.d. group and 7 patients (6.5%) in the 20 mg u.i.d. group showed endoscopic relapse. Five patients (4 in the 20 mg u.i.d. group and 1 in the 10 mg b.i.d group) reported adverse effects. The endoscopic relapse percentages obtained with cisapride in our study seem to be lower than those usually reported after pharmacological treatments for reflux esophagitis relapse prevention. Futher studies to confirm our results should be performed. "P P 22 0606"P 22 0606**Efficacy of Omeprazole 20 mg or 10 mg in the Long-Term Management of Symptomatic Reflux Complicated by Confluent or Circumferential Erosive Esophagitis**

*J. Laurent, P. Cassan, J.F. Rey, T. Helbert, A. Caekaert, P. Barth\'e9l\'e9my

Cregg, Angh. Essey les Nancy, Vichy, Saint Laurent du Var, Marseille, Astra FranceThis study aimed to evaluate a treatment regimen using several doses of omeprazole in the management of symptomatic reflux complicated or not by esophagitis. The results observed in patients with simple reflux or low grade esophagitis have already been presented (Laurent, Gastroenterology 1995, A145). We report here the symptomatic and endoscopic results observed in patients with esophagitis grade {\'b3} 2 followed for 1 year.*Methods:* Patients with confluent erosive esophagitis (Savary-Miller grade 2–3) were treated by omeprazole 20 mg (O20) or 40 mg (O40) (in case of a severe concomitant disease) for 4 months (period 1, P1). At the end of this period, patients healed (absence of erosion) and relieved were treated for 8 months (period 2, P2) by omeprazole 10 mg (O10) or 20 mg, depending on the dose administered during the fourth month (M4). Endoscopy was repeated after 12 months (M12). Symptoms of reflux were assessed by the heartburn severity score (HSS) on a scale of 1 to 4 (1 = absent, 4 = severe) and the Spechler activity index (Spechler, N Engl J Med 1992). At M4 and M12, success was defined as the absence of erosion at endoscopy and a HSS {\'a3} 2. Early study withdrawals other than lost to follow-up (P1: n = 10; P2: n = 12) were considered as failures.*Results:* 196 patients (58 – 14 years; M/F 143/53; grade 2/3: 125/71) were included in the study. 160 patients took part in P2. P1 (n: 196, O40: 21%, O20: 79%) P2 (n: 160, O20: 12%, O10: 88%) M0 M4 M4 M12Endo success – 83% – 71%Sympt. success – 94% – 87%Complete success – 82% – 70%Spechler 112 – 20 78 + 8 78 – 7 79 – 9Complete success was identical for grades 2 and 3.*Conclusion:* After healing of severe esophagitis by omeprazole, reduction of the dose after 4 months of induction treatment maintained endoscopic and symptomatic remission in 2/3 of patients. Oesophageal gastric duodenal disorders: EG Reflux }" "Efficacy of Omeprazole 20 mg or 10 mg in the Long-Term Management of Symptomatic Reflux Complicated by Confluent or Circumferential Erosive Esophagitis"

"P P 22 0607"P 22 0607**Treatment of Patients with Esophagitis and Laryngitis**

*M. Tuncer, A. Dobrucali, I. Yurdakul, S. Tuncer, F. Hamsioglu, A. \'c7elik, K. Bal, H. Uzunismail, E. Oktay

Gastroenterology Department of Cerrahpasa Medical Faculty of Istanbul University, Istanbul, Turkey*Aim:* Despite the varied classic symptomatic presentation of gastroesophageal reflux disease (GERD), some patients have atypical presentation. Sometimes, chronic persisting cough or hoarseness may be caused by GERD. Esophagitis is increasingly suggested as a cause of chronic laryngitis and there is some evidence that GERD is more common in patients with laryngitis. The purpose of the study was to evaluate if patients with esophagitis and laryngitis benefit from ranitidine medication.*Patients and Methods:* 68 patients with endoscopically proven GERD were asked for laryngeal symptoms (sore throat, cough, hoarseness) and underwent laryngoscopy. In case of association between reflux esophagitis and laryngitis, patients received 4 weeks of ranitidin 600 mg per day. The questionnaire and endoscopy were repeated at 2 and 4 week.*Results:* Eighteen patients (26%) had both esophagitis (grade II and III. Savary-Miller classification) and symptomatic laryngitis. After ten days administration of ranitidine, esophageal and laryngeal symptoms had improved in all patients. No patient suffered from drug induced side effects. Endoscopically, the healing rate of esophagitis and laryngitis was 72% resp. 33%. At four weeks control, all patients were free of complaints and no sign of esophageal and laryngeal inflammation could be found.*In Conclusion;* Patients who have esophageal and laryngeal symptoms should have adequate anti-reflux therapy. The findings and symptoms of associated esophagitis and laryngitis improve with the treatment of ranitidine suggesting that esophageal reflux is the underlying etiology. "P P 22 0608"P 22 0608**Cisaprid and its Effect at Severe Forms of Reflux Esophagitis**

*T. Hildebrand, J. Podrack\'fd, M. Zakuciov\'e1, L. Sokol, M. Fedurco, P. Dedina, F. Reme&nbreve;\'e1r

I. Clinic of Internal Medicine, Faculty Hospital Kosice, SlovakiaCisaprid as an effective prokinetic agent is a drug of choice in the treatment of moderate and medium severe forms of reflux esophagitis (r.e.). It increases the resting pressure of the lower esophageal sphincter (LESP), reduces the frequency and duration of its transitory relaxations and increases the amplitude of peristaltic contractions. The aim of our study was to find out wether this effect is also similar in severe forms of r.e. (stage III by the Savary-Miller classification) accompanied by severe lower sphincter incompentecy.74 patients with the endoscopy findigs of r.e. were examined. On the basis of the achieved values of LESP the patients were devided into three groups: *Group A:* 22 patients, LESP < 5 mm Hg; *B:* 24 patients, LESP 5–12 mm Hg; *C:* 28 patients, LESP > 12 mm Hg. Ambulatory manometry was performed under basal conditions and 1 hour after the administration of 10 mg of cisaprid orally. After the triple registration of LESP values (rapid pull through method), the amplitude of three peristaltic contracions before and after the drug administration was measured.A significant increase of LESP after the administration of cisaprid was found only in the patients of Group B and C ($p < 0.02$). In Group A with a predominantly severe degree of esophagitis there was an insignificant increase in the LESP (3.9 – 0.8 mm Hg to 7.1 – 2.9 mm Hg, $p < 0.05$). There was a significant increase in the amplitudes of peristaltic contractions also in this group (72.5 – 14 mm Hg to 91.3 – 12 mm Hg, $p < 0.02$)*Conclusions: 1)* In r.e. with a severe incompetence of the lower sphincter with LESP < 5 mm Hg the basal pressure is not affected more significantly by cisaprid. However, in some patients (15% from our sample) there was a significant increase. *2)* In severe forms of r.e. the effect of cisaprid on the amplitudes of peristaltic contractions is retained. *3)* Cisaprid can be used as a pharmalogical test of severe sphincter incompetency. Clinical practice: Management strategyOesophageal gastric duodenal disorders: EG RefluxMotility, specific: Oesophagus }"

"P P 22 0609"P 22 0609**A Multicenter Randomized Clinical Trial of Sodium Alginate Versus Cisapride in Patients with Non-Severe Oesophagitis****T. Poynard, C. Richard-Berthe[2], A.L. Knellwolf[2], H. Agostini[3], Multicenter Group**

[1] Service d'H\'e9pato-Gastroent\'e9rologie, Hopital Piti\'e9-Salp\'eatriére, Paris, France

[2] Laboratoires Smith-Kline Beecham, Paris, France

[3] Quanta-M\'e9dical, Rueil Malmaison, France*The aim* of this trial was to compare the efficacy of a non-expensive treatment, sodium alginate (GAV), to cisapride (CIS) in the treatment of reflux symptoms in patients with non-severe oesophagitis. *Patients and methods:* Patients with severe oesophagitis or with motor-like dyspepsia were not included. 353 patients, mean age 40 years, 51% males, 33% smokers, 43% drinkers were randomized, 180 treated by GAV (4 sachets/day) and 173 by CIS (5 mg q.i.d) for 1 month. They were followed every 2 weeks. The main end point was the intensity of reflux estimated by an analogic visual scale (AVS) at 4 weeks (range 0–100). Secondary endpoints were the score at 2 weeks, the number of patients considered as failure, the impact of reflux on activity and sleep, the number of pain episodes, the adverse events, and the direct costs. Univariate and multivariate analyses have been performed without knowledge of treatments received according to the intention to treat method. *Results:* At randomization there was no difference between groups according to epidemiological factors or symptoms (AVS: 74 – 18, m – sem, in GAV vs 73 – 20 in CIS). There was a difference in favor of GAV vs CIS, for AVS at 2 weeks (29 – 35 vs 35 – 25, $p = 0.01$) and at 4 weeks (12 – 17 vs 20 – 23, $p = 0.001$), for the number of episodes at 4 weeks (2 – 2 vs 3 – 4, $p = 0.001$), the pain associated to activity impairement (3% vs 10%, $p = 0.009$), pain associated to sleep impairement (3% vs 14%, $p = 0.004$) and patients considered as failure (11% vs 24%, $p < 0.001$). Adverse events occured in 13 patients treated by GAV vs 23 treated by CIS ($p = 0.06$). Compliance was similar in both groups (97% s 96%). Mean cost was lower for GAV (130 FF) than for CIS (175 FF, $p < 0.001$). Sensitivity analyses conducted according to per-protocole gave same results. *Conclusion:* Sodium alginate has a greater efficacy and a lower cost than cisapride for the treatment of symptoms in patients suffering from non-severe oesophagitis. }" "A Multicenter Randomized Clinical Trial of Sodium Alginate Versus Cisapride in Patients with Non-Severe Oesophagitis"

"P P 22 0610"P 22 0610**Omeprazole Is More Effective than Cimetidine in the Prevention of Recurrence of GORD-Associated Heartburn and the Occurrence of Underlying Oesophagitis**

*C.M. Bate, J.R.B. Green, A.T.R. Axon, G. Tildesley, F.E. Murray, S.M. Owen, C.E. Emmas, M.D. Taylor

Gastroenterology units in Wigan, Stoke-on-Trent, Leeds, Hartlepool, Dundee and Astra Pharmaceuticals Ltd., Kings Langley, U.K.There is a paucity of data on the use of omeprazole 10 mg o.d. and cimetidine in the prevention of recurrence of symptoms in GORD patients, a group which includes the large number of patients with symptoms but no oesophagitis. This study compared omeprazole 10 mg o.d. with cimetidine 800 mg nocte in the prevention of recurrence of GORD-associated heartburn.Patients who had symptomatic non-ulcerative oesophagitis (81%) or symptoms without oesophagitis (19%), achieved symptomatic remission (no more than mild heartburn on 1 out of 7 days) following 4 weeks of omeprazole 20 mg o.d. (66%; 74/112) or cimetidine 400 mg q.d.s. (31%; 34/109) ($p < 0.0001$) and, if required, a further 4 weeks of omeprazole 20 mg o.d. (67%; 54/81). Patients in symptomatic remission (100 male, 56 female) aged 48 – 14 years (mean – SD) were then randomised to receive, double-blind, either omeprazole 10 mg o.d. ($n = 77$) or cimetidine 800 mg nocte ($n = 79$) for 24 weeks.A greater proportion of patients receiving omeprazole, compared with those receiving cimetidine, were in symptomatic remission after 12 (69% vs 27%) and 24 weeks (60% vs 24%) (each $p < 0.0001$). The median time to symptomatic relapse was longer for patients receiving omeprazole (169 vs 15 days) ($p = 0.0001$). Analysis of prognostic factors identified treatment with omeprazole ($p = 0.0001$), increased age ($p = 0.001$) and shorter duration of the patient's most recent episode of heartburn prior to entry ($p < 0.01$) as increasing the probability of maintaining symptomatic remission. Of patients leaving the study in symptomatic remission, a greater proportion receiving omeprazole, compared with cimetidine, were free of oesophagitis at endoscopy (84% vs 53%; $p < 0.05$).A greater proportion of patients receiving omeprazole were satisfied with their medication after 12 (69% vs 45%) and 24 weeks (68% vs 45%) (each $p = 0.005$). Doctor satisfaction with the treatment was also greater for omeprazole after 12 (74% vs 55%; $p < 0.05$) and 24 weeks (76% vs 58%) (each $p < 0.05$).In conclusion, omeprazole 10 mg o.d. is more effective than cimetidine 800 mg nocte in the prevention of recurrence of GORD-associated heartburn. Patients in symptomatic remission are more likely to be free of oesophagitis following treatment with omeprazole 10 mg o.d. than cimetidine 800 mg nocte. Oesophageal gastric duodenal disorders: EG Reflux }" "Omeprazole Is More Effective than Cimetidine in the Prevention of Recurrence of GORD-Associated Heartburn and the Occurrence of Underlying Oesophagitis"

"P P 22 0611"P 22 0611**Comparison of Two Dosing Regimens of Cisapride (CIS) in the Treatment of Reflux Oesophagitis**

*K. Sch\'fctze, M.A. Bigard, L. Van Waes, J. Hinojosa, G. Bedogni

Medical Dep. I, Hanusch Krankenhaus, Vienna, Austria

Hospital de Brabois, Vandoeuvre les Nancy, France

Aalsters Sted. Ziekenhuis, Aalst, Belgium

Hospital de la Seguridad Social, Valencia, Spain

Arciospedale S. Maria Nuova, Reggio Emilia, Italy*Objective:* The aim of this international multicentre, double-blind trial was to document the therapeutic equivalence of two dosing regimens of CIS on endoscopic healing and symptom improvement in patients with proven reflux oesophagitis grade I or II (Savary-Miller).*Methods:* 407 patients (256 M/151 F) between 18 and 75 years of age were randomly allocated to treatment with either CIS 10 mg qid or CIS 20 mg bid for 8 to 12 weeks depending on whether complete healing was found at endoscopy. The primary parameters of efficacy were cure of oesophagitis and improvement of the reflux symptom score (frequency, time, intensity, duration of heartburn and regurgitation). Secondary efficacy parameters included Visual Analogue Scales for reflux symptoms, general well-being and severity of oesophagitis as well as global evaluation by the investigator and severity of associated symptoms.*Results:* 326 patients were included in an on-protocol analysis. The healing rates at endpoint were 85% and 87% in the CIS 10 mg qid and 20 mg bid group respectively. The mean total reflux symptom score decreased from baseline to endpoint from 8.0 to 1.2 (CIS 10 mg qid) and 7.9 to 1.5 (CIS 20 mg bid). Both treatment groups showed also a reduction of associated symptoms and an improvement in the patient's feeling of general well-being. Both treatment regimens were well tolerated. The most frequently reported adverse event (diarrhoea) can be explained by the pharmacological action of CIS.*Conclusions:* The results of the study demonstrated that CIS 10 mg qid and 20 mg bid were highly statistically equivalent in efficacy and safety in the treatment of reflux oesophagitis. "P P 22 0612"P 22 0612**Pantoprazole is Superior to Famotidine in the Treatment of Reflux Esophagitis — A Multicenter Study**

*H.G. Dammann, E.G. Hahn, G. Adler, M. Schlander

Hamburg, Erlangen, Ulm and Konstanz, Germany*Objective:* Pantoprazole is a new, precise proton pump inhibitor. It was the aim of the present study to compare the efficacy and tolerability of pantoprazole and famotidine in outpatients with acute gastro-esophageal reflux disease (grade II and III according to Savary/Miller).*Methods and patients:* Open, 2:1 randomized, controlled, multicenter trial. 129 Investigators enrolled 734 outpatients to receive pantoprazole (P; $n = 495$) 40 mg o.a.d. (morning) or famotidine (F; $n = 239$) 40 mg o.a.d. (evening) for 4 weeks, or 8 weeks if healing was incomplete by 4 weeks. Demographic data and severity of disease at baseline were comparable in both study groups.*Results:* Endoscopically proven healing rates (primary study endpoint, *intent-to-treat* analysis [per protocol]): 4 weeks 8 weeksPantoprazole 69% [80%] 83% [93%]Famotidine 48% [57%] 62% 72%] $p < 0.001$ [$p < 0.001$] $p < 0.001$ [$p < 0.001$]Patients with pain prior to treatment achieved complete relief of principal symptoms (i.e. heartburn, acid regurgitation, pain on swallowing) after 4 weeks in 78% with P compared to 53% with F ($p < 0.001$). Pantoprazole and famotidine were equally well tolerated.*Conclusions:* Pantoprazole (40 mg o.a.d.) was significantly superior to famotidine (40 mg o.a.d.) in terms of healing rates and symptom relief in patients with reflux esophagitis, grade II and III. Both treatments were well tolerated. Oesophageal gastric duodenal disorders: EG RefluxOesophageal gastric duodenal disorders: Secretion: mechanism, regulation }"

"P P 23 0616"P 23 0616**Selective Antireflux Surgery in the Repair of Paraoesophageal Hiatus Hernia**

*A. Francis, C. Duignan, J.G. Temple, M.T. Hallissey

Dept of Surgery, Queen Elizabeth Hospital, Birmingham, UKThe management of paraoesophageal, type II, hiatus hernia is surgical and has centred on the anatomical repair of the hernia and associated gastric volvulus. Review of the results of this procedure in 23 patients showed that 17% had significant gastro-oesophageal reflux post-operatively. All had experienced gastro-oesophageal reflux symptoms prior to surgery. A policy of the selective addition of an antireflux procedure was adopted and the impact of this approach on post operative symptoms has been assessed.All patients undergoing repair of a paraoesophageal hiatus hernia under the care of 2 consultants at a single institution over a 15 year period have been studied. During the first 10 years, surgery consisted of an anatomical repair of the hiatal defect with a fundopexy. For the remaining 5 years of the study, in addition to the anatomical repair, a Nissen's fundoplication was performed in patients with pre-operative symptoms of gastro-oesophageal reflux.A total of 51 patients have undergone surgery. In three patients, the paraoesophageal hiatus hernia developed following antireflux surgery and these patients will not be considered further. During the initial 10 years, twenty-three patients had an anatomical repair alone. Of the 25 patients operated on in the last 5 years, 15 underwent anatomical repair alone and in 10 anatomical repair was combined with a Nissen's fundoplication. In the initial period, 4 of the 23 patients had symptomatic gastro-oesophageal reflux requiring medical management. No patient in the second period has developed symptomatic reflux and there have been no symptoms attributable to the fundoplication.Gastro-oesophageal reflux symptoms following anatomic repair of paraoesophageal hiatus hernia can be troublesome. The incidence can be reduced by the use of pre-operative symptoms to select a group for antireflux surgery. This approach is not associated with additional morbidity or post-operative symptoms. Clinical practice: Management strategyOesophageal gastric duodenal disorders: EG RefluxOesophageal gastric duodenal disorders: Oesophageal disorders, non reflux }" "Selective Antireflux Surgery in the Repair of Paraoesophageal Hiatus Hernia"

"P P 23 0618"P 23 0618**The Effect of Anti-Reflux Surgery on Esophageal Motility in Patients with Reduced Clearance**

*H. Van der Walt, J.B. Van den Bogaerde

Department of Surgery, & Gastroenterology, University of Pretoria, South Africa*Purpose:* The purpose of this study was to determine whether anti-reflux surgery improved motility in patients with reduced pre operative clearance.*Methods:* A prospective study was undertaken in patients suffering from gastro-esophageal reflux disease, refractory to medical therapy, who received either a floppy Nissen fundoplication or a modified Toupet operation. Patients who consented to pre- and post-operative manometry were entered into the trial. Those with reduced esophageal clearance, defined as a distal pressure of less than 40 mm Hg. or propagation of less than 60%, were selected pre-operatively. Post-operative manometry was then performed. The results of the pre- and post-operative manometric studies were then compared. Statistical analysis was performed using Microsoft Excel'. Data were compared using the two tailed T test. Significance was defined as a p value of less than 0.01. The null hypothesis read as follows: ""Anti-reflux surgery does not improve esophageal motility in patients with reduced clearance.""*Summary of Results:* Fifty nine patients were assessed. All had reduced clearance pre-operatively. Post-operative clearance improved in 29 out of 59 patients. The mean distal pressure pre-operatively was 30.4 mm Hg. (Standard deviation 21.6) Post-operative manometry (performed on average 44 days after surgery) produced a mean value of 44 mm Hg. (Standard deviation 7.57). This represents a significant difference ($p < 0.01$). On the basis of these data the authors reject the null hypothesis.*Conclusion:* These data suggest that anti-reflux surgery may improve clearance in a cohort of patients with reduced pre-operative clearance. "P P 23 0619"P 23 0619**Postoperative Dysphagia after Laparoscopic Nissen Repair: An Univariate and Multivariate Analysis in 198 Patients**

*A. Fingerhut, E. Blezel, J.C. Etienne, B. Millat, B. Vinson-Bonnet, J.M. Hay, A.R.C.

8, Avenue des Peupliers, 92270, Bois Colombes, France*Purpose:* to determine which, if any, operative steps in laparoscopic Nissen repair could be held responsible for postoperative dysphagia.*Methods:* Between July 1994 and March 1996, 198 patients (115 males and 83 females) underwent a laparoscopic Nissen or Nissen-Rosetti repair for gastroesophageal reflux disease (GERD).*Results:* Mean age of patients was 44.8 years old (21–82), the mean duration of operation was 230 minutes (70–480). The mean duration of hospital stay was 4.8 (2–25) days. 60 patients (30%) had dysphagia during the first postoperative month. Only two lasted more than one month and underwent pneumatic dilatation. One was in fact associated with peptic ulcer disease. Through univariate and multivariate analysis we showed that neither calibration (40 French) before suture, ligation of the short vessels, nor closure of the crus (steps performed or not) were contributing factors to dysphagia.*Conclusion:* Laparoscopic Nissen repair associated with crura closure corrects GERD effectively without persistent dysphagia and should be proposed as a gold standard of treatment for this disease. "P P 23 0621"P 23 0621**Laparoscopic Modified Toupet Operation for the Treatment of Gastro Esophageal Reflux Disease**

*H. Van der Walt, J.B. Van den Bogaerde

Department of Surgery, & Gastroenterology, University of Pretoria, South Africa*Purpose:* The purpose of this study is to present the authors' experience with the laparoscopic Modified Toupet procedure.*Methods:* Patients presenting with gastro-esophageal reflux disease (GERD) refractory to medical therapy, underwent laparoscopic modified Toupet anti-reflux surgery. Pre-operative work up included: clinical examination, symptom scoring, endoscopy, esophageal manometry and 24 hour Ph study. Post-operative work up included: symptom scoring, endoscopy, and manometry where possible. A defective lower esophageal sphincter (LES) was defined as a mean pressure of less than 6 mm Hg., intra-abdominal length of less than 1 cm, or a total length of less than 2 cm. Reduced esophageal clearance was defined as a distal pressure of less than 40 mm Hg. or propagation of less than 60%.*Results:* The laparoscopic Modified Toupet procedure was performed on 343 patients. Mean age was 41 years (range 12 to 78). Mean hernia size was 3 cm. Pre-operative LES pressure was 4.29 mm Hg. Of the 343 patients, 296 had defective LES. Reduced clearance was found in 103 patients. Theater time was 52 minutes. There was minimal morbidity and no mortality. Symptom scoring improved post operatively in all patients. Post-operative manometry was performed on 215 patients. Mean post-operative LES pressure was 12.1 mm Hg. Mean abdominal LES length was 2.7 cm. Four patients had defective LES post-operatively. Gasbloat or dysphagia occurred in less than 5% and resolved in all but one patient. Non-fatal pulmonary embolism occurred in two patients in the immediate post operative period.*Conclusion:* The data presented here confirm that the laparoscopic Modified Toupet operation is both safe and effective in the treatment of refractory GERD. Post operative LES function normalised in virtually all patients who were evaluated. "P P 23 0622"P 23 0622**The Results of Aggressive Surgery for Gastrooesophageal Leaks after Oesophagectomy**

*M.T. Hallissey, J.G. Temple

Dept of Surgery, Queen Elizabeth Hospital, Birmingham UKThe mortality following gastro-oesophageal leakage after oesophageal resection is recognised to be high with rates of over 50% being reported. From 1991, a policy of immediate surgical intervention has been adopted by our unit, the aim being to re-operate on all cases within 12 hours of evidence of leakage. This study assesses the results of this approach on mortality and the success rate for re-establishing gastrointestinal continuity.Between July 1991 and April 1996, 10 patients have developed clinical evidence of a GI tract leak in the chest. All had undergone potentially curative oesophageal surgery, stage I–III. Primary surgery was an Ivor-Lewis resection in 7 cases and a 3 stage McKeown's resection in 3 cases. The cause of leakage was necrosis of the gastric staple line in one case, gastric remnant necrosis in 2 cases and anastomotic leakage in 7 cases. The gastric staple line leakage was treated by resection and primary repair with thoracic lavage. The remaining cases were all treated by exteriorisation, forming a cervical oesophagostomy and gastrostomy, with thoracic lavage. There was a single death from multi-system failure following salvage surgery in a patient undergoing exteriorisation. Reconstruction was attempted 3 months following discharge after salvage surgery. Reconstruction with a substernal colonic interposition was successful in 7 of the 8 cases. The failure was a result of necrosis of the colonic graft at 10 days. There were no deaths in this group. There have been 2 deaths during follow up, one at 11 months and one at 18 months following salvage surgery, both from recurrent disease. The remaining patients are well at a follow up of between 6 and 34 months.Aggressive surgical intervention can salvage 90% of patients following leakage after oesophagectomy. Gastrointestinal continuity can be restored in 88% of survivors. This supports the value of early intervention in patients with leakage following oesophageal surgery. Clinical practice: Management strategyOncology, specific: Oesophagus }" "The Results of Aggressive Surgery for Gastrooesophageal Leaks after Oesophagectomy"

"P P 23 0623"P 23 0623**Posterior Hemifundoplication for Gastro-Oesophageal Reflux — Comparison of Laparoscopic and Open Approach**

*P. Jagot, A. Sauvanet, B. Maignien, G. Cargill, J. Belghiti, F. F\'e9k\'e9t\'e9

Digestive Surgery, Hopital Beauton, 100 Bd Du Gal Leclerc, 92110 Clichy, FranceIn experienced hands, laparoscopic fundoplication can be performed with safety and with good immediat results. Some authors reported an higher rate of postoperative dysphagia after laparoscopic approach. The aim of this study was to compare results of 270\'b0 posterior fundoplication after laparoscopic and open approach.*Patients and Methods:* Sixty-three patients operated for a laparoscopic posterior hemifundoplication from 1992 to 1995 were compared retrospectively with 118 patients operated through laparotomy from 1989 to 1991. These 2 groups had similar clinical, radiological, endoscopic, pH-metric and manometric features. Of 63 laparoscopic procedures attempted, 53 (84%) were completed laparoscopically and were analysed for functional results.*Results:* Operating time was significantly longer in the laparoscopic group (142 – 48 min vs 112 – 51 min, $p < 0.05$). No patient died postoperatively. Postoperative course was uneventful in 60/63 (95%) patients after laparoscopy and in 99/118 (84%) after laparotomy (NS). The period of hospitalization was shorter for the laparoscopic group (4.5 – 2 vs 10 – 4 days, $p < 0.05$). The median follow-up was superior to 12 months in both groups. Two patients (4%) after laparoscopy and 5 patients (4%) after laparotomy showed clinical or pH-metric evidences of reflux recurrence. More than one month after the procedure, 7/53 patients (13%) in the laparoscopic group and 4/118 patients (3%) in the laparotomy group complained dysphagia ($p < 0.05$).*Conclusion:* these results suggest that laparoscopic 270\'b0 posterior fundoplication is as effective to treat the gastro-oesophageal reflux as the open procedure, shorten the hospitalization period but is more frequently associated with postoperative dysphagia. Longer follow-up and reduction of incidence of postoperative dysphagia are mandatory before considering laparoscopic approach as the gold standard for anti-reflux surgery.

"P P 24 0625"P 24 0625**Corrosive Esophagitis and Esophageal Cancer. Definitions of Predictive Signs of Cancer by Long-Term Endoscopic and Pathologic EvaluationE.G.H. Moura,**

*F. Maluf Filho, R.S. Azzam, P. Sakai, S. Ishioka, K. Iriya, I. Cecconello, H.W. Pinotti

Department of Gastrointestinal Endoscopy and Digestive Surgery, Hospital das Cl\'ednicas, S\'e3o Paulo University, S\'e3o Paulo, Brasil*Purpose:* Corrosive esophagitis is a well-known high-risk condition for squamous cell carcinoma of the esophagus. The prognosis of this association is commonly poor due to difficult and late diagnosis. We sought to establish predictive signs of epidermoid cancer occurence at caustic esophageal stenosis.*Method:* Thirty-seven patients with a previous history of lye ingestion dating from ten or more years were prospectively evaluated by a five-year protocol. They underwent to yearly upper GI series, endoscopic examinations associated to chromoscopy with a 3% Lugol solution. Exfolliative cytology and biopsies were oriented to all negative and low stained areas. Mucosal abnormalities and dilation difficulty were graded by the same operator. The cytologic smears were considered negative or positive for malignant cells. Pathologic findings were described as chronic esophagitis, suprapapilar atrophy and squamous cancer by the same pathologist.*Results:* During the five-year follow-up period, cancer was found in 6 patients (16.2%) staged as early in two and advanced lesions in four cases. The longer the postingestion period (11 to 57 years, mean = 31.6 y), the greater the chance of cancer occurrence. Some endoscopic and histopathologic findings were statistically proved to be preditive for cancer occurrence: I – a difficult dilation of a stenosis covered by an irregular mucosa and II – the finding of suprapapilar atrophy.*Conclusions:* The endoscopic and histopathologic findings above mentioned at stenotic caustic esophageal area aging ten or more years demand close follow-up. These findings rise again the question of preventive surgical approach for these group of patients. "P P 25 0629"P 25 0629**RIBA Positive, PCR Negative Irish Anti-D Hepatitis C Patients have Minimal Liver Inflammation and Fibrosis, Not Predicted by Number of Positive RIBA Bands****N. Kieran, G. Clarke, P. MacMathuna, A. Sullivan, G. Callagy, J.C. O'Keane, J. Crowe**

Liver Unit, Mater Misericordiae Hospital, Dublin 7Of 1013 RIBA positive anti-D associated chronic hepatitis C (CHC) Irish women, 438 were PCR positive and have surprisingly mild disease. However, the disease status of the RIBA positive, PCR negative patients is thus uncertain (? immune, carriers or low grade inflammation with silent fibrosis) and was the subject of this investigation. 23/74 RIBA positive persistently PCR negative CHC patients referred to our unit were biopsied because of elevated ALT (4) or florid symptoms dating from inoculation (23).*Results:*Histologic activity index* (Range 1–18) RIBA 1 5, 1, 0, 1BANDS 2 3, 2, 2 (F), 0, 4 (F), 2 (F), 0, 4 (F), 1, 2, 0 3 0, 2, 1, 2, 2, 5 (F), 2 4 2, 3, 2, 3No bile duct damage, lymphoid follicles or aggregates were observed. Only 3/23 patients had mild peri-portal fibrosis (F), 2 of these had steatohepatitis with obesity (1) and impaired glucose tolerance (1) suggesting dual pathology.*Conclusions:* (1) RIBA positive, PCR negative anti-D/CHC patients have minimal inflammatory activity and fibrosis. (2) Elevated ALT and fibrosis may be associated with dual pathology (non-alcholic steato hepatitis) in CHC, possibly a synergistic effect. (3) Number or type of RIBA bands positive is not a predictor of inflammatory activity. Liver and bile ducts, 1: Hepatitis viral, diagnosis }" "RIBA Positive, PCR Negative Irish Anti-D Hepatitis C Patients have Minimal Liver Inflammation and Fibrosis, Not Predicted by Number of Positive RIBA Bands"

"P P 25 0630"P 25 0630**Interferon-Ribavirin Combination Therapy for Chronic Hepatitis C, Type 1b in a Unique Irish Cohort 18 Years Post InoculationG. Clarke, A. Sullivan, P. MacMathuna, G. Callagy, P. Kelly, J. Crowe**

Liver Unit, Mater Misericordiae Hospital, Dublin 7*Introduction:* In 1977 anti-D serum contaminated by Hepatitis C was given to women subsequently identified by a national screening programme which revealed 438 to be PCR positive for RNA of Hepatitis C Type 1b. Ninety four were referred to this institution, of these ten had moderate inflammatory activity (Modified Knodell Activity Index (KAI) 8 – 1.4) bridging fibrosis and mean ALT of 77 (42–176) and were selected for treatment.*Methods:* We chose 6 months dual therapy consisting of Interferon 3 Mu {\'b4} 3 weekly and Ribavirin 400 mgs {\'b4} 2 daily, in an attempt to increase efficacy over interferon monotherapy in this group with adverse prognostic indicators (Genotype 1b and long disease duration).*Results:* Two of ten withdrew because of hyperthyroidism (1) and depression (1). Seven of eight patients (88%) responded with normalisation of ALT and negative PCR. All eight showed improved histology (KAI 4 – 1.5), fibrosis was unchanged. Adverse reactions in treated group included marrow suppression (1) and thyrotoxicosis (1). At six months follow up 4 of 7 patients remain in remission with negative PCR and normal ALT. Three have relapsed (PCR positive, mean ALT 87 (50–150).)*Conclusions:* Despite adverse prognostic indicators in this homogenous group with CHC genotype 1b and long disease duration, dual therapy with Ribavirin and low dose Interferon achieved therapeutic responses comparable to prolonged high dose Interferon therapy in patients with more susceptible genotypes Liver and bile ducts, 1: Hepatitis, viral, treatment }" "Interferon-Ribavirin Combination Therapy for Chronic Hepatitis C, Type 1b in a Unique Irish Cohort 18 Years Post Inoculation"

"P P 25 0631"P 25 0631**Absence of Correlation between HCV NS5A Mutations and Response to Alpha Interferon in French Patients with Chronic Hepatitis CGio Squadrito, F. Leone, B. Nalpas[2], P. Berthelot[2], S. Pol[2], C. Brechot**

[1] INSERM U370, Paris, France

[2] Liver Unit, CHU Necker, Paris, France

[3] Dept. Internal Medicine, University of Messina, Italy

[4] Dept. Internal Medicine, University of Novara, Italy*Objectives.* It has been recently suggested that in patients with chronic HCV-1b infection there is a correlation between response to IFN and mutations in $NS5A_{2209–2248}$ gene. The aim of our study was to examine whether the NS5A amino acid sequence before treatment could be correlated to response to IFN in patients infected with genotypes associated to both low (1b) and high (3a) response rates. *Methods.* We retrospectively analyzed 37 patients with chronic HCV infection, 19 infected with genotype 1b and 18 with 3a, who had received from 3 to 6 MU of IFN for 6 to 12 months. Eleven patients were long term responders (LTR) and 26 were non-responders (NR). We amplified and directly sequenced, from pretreatment serum samples, the amino acid sequence of NS5A that was compared with the published sequence for HCV-J and NZL1. HCV RNA quantitation was analyzed by Branched DNA assay (Quantiplex' 2.0). *Results. Genotype 3a:* One of 7 LTR and none of 11 NR showed amino acid mutations in NS5A. *Genotype 1b:* All 4 LTR and 10 of 15 NR showed mutations in NS5A. Among the 14 patients with mutation in NS5A, 9 had 1 mutation and 5 had 2 mutations. Thirteen of 19 amino acid changes occurred at codon 2218. There was no significant difference of baseline serum HCV RNA levels between patients infected with the HCV 1b wild type and the NS5A mutated genome (49.3 – 62.37 and 31.47 – 36.55 {\'b4} 10^5 genomes eq/ml, respectively). *Conclusion.* In contrast with previous studies in Japan there is no apparent correlation in our patients between NS5A sequence and response to IFN; among patients infected with genotype 1b, mutation at codon 2218 is the most prevalent but its implication is unclear; NS5A mutations do not correlate with viral load. }" "Absence of Correlation between HCV NS5A Mutations and Response to Alpha Interferon in French Patients with Chronic Hepatitis C"

"P P 25 0632"P 25 0632**Tauroursodeoxycholic Acid for the Treatment of HCV-Related Chronic Hepatitis: A Multicenter, Placebo-Controlled Study**

*A. Crosignani, G. Budillon, C. Del Vecchio Blanco, F. Fatti, G. Ideo, G. Raimondo, R. Stabilini, M. Podda

Milano, Monza, Napoli, Messina, Mantova, ItalyTauroursodeoxycholic acid (TUDCA) has physicochemical and metabolic properties which favour its use as an alternative to ursodeoxycholic acid for chronic cholestatic liver disease. TUDCA may prove of benefit also for necroinflammatory liver disease, especially for HCV-related chronic hepatitis in which bile duct damage is frequently seen at histology.To evaluate the effects of TUDCA administration on serum liver enzymes related to cytolysis and cholestasis, 150 patients with HCV-related chronic hepatitis were selected in 6 different centers and randomly allocated to double-blind treatment with placebo, TUDCA 500 mg/day or TUDCA 750 mg/day for 6 months. Blood samples were taken at entry and after 30, 90 and 180 days of treatment and serum liver biochemistry was evaluated in the same laboratory.Patient characteristics (gender, age, severity of the disease at histology) were comparable in the three groups. A consistent and progressive decrease in serum liver enzymes was observed in patients treated with TUDCA. Values (means – S.D.) at baseline and after 180 days of treatment are reported in the table. Baseline Treatment Placebo 67 – 33 79 – 43AST TUDCA 500 mg 68 – 34 47 – 18*(IU/L) TUDCA 750 mg 75 – 33 47 – 20* placebo 88 – 49 103 – 41ALT TUDCA 500 mg 83 – 42 52 – 28*(IU/L) TUDCA 750 mg 90 – 39 56 – 31* placebo 71 – 52 73 – 54{ g}-GT TUDCA 500 mg 68 – 50 47 – 38*(IU/L) TUDCA 750 mg 66 – 41 41 – 20**p < 0.001 vs. placebo.In conclusion, TUDCA may be beneficial in patients with HCV-related chronic hepatitis. Long-term studies with clinically relevant end-points are warranted. "P P 25 0633"P 25 0633**Comparison Between Two Different Regimens of Alfa INF Treatment in Chronic Hepatitis C**

*B. Paris, M. Bonelli, F. Negrini, E. Marzo, S. Signorelli, M. Girola

Gastroenterology and Third Department of Internal Medicine, Ospedali Riuniti, Bergamo, ItalyINF alfa recombinant is the drug of choice for treatment of chronic hepatitis C. However a sustained biochemical and virological response to standard therapy (3 MU thrice weekly – TIW – for six months) is seen in no more than 20–25% of patients. Predictors of poor response appear to be presence of cirrhosis, genotype 1b infection and high levels of viraemia pretreatment, but doubts concerning influence of dosage and duration of treatment still remain.*Aim of the study.* To assess the efficacy of two schedules (3 vs 6 MU) of INF 2a in the treatment of chronic hepatitis C.*Patients and methods.* 46 pts. (32 men mean age 46 + 5 years) were randomized to receive 3 or 6 MU of INF TIW for six months. All cases had chronic hepatitis histologically proven without cirrhosis. Sustained response (SR) was defined as normalization of ALT levels and disappearance of HCV-RNA by PCR 12 months after stopping therapy.*Results.* The 2 groups of pts. were homogeneous concerning age, sex, ALT levels, distribution of genotype 1b and histologic lesions. The follow-up was at least 12 months for all patients. In the group A (23 pts. 3 MU INF) we had a SR in 5/23 (21.7%) while in group B (23 pts. 6 MU INF) we found a SR in 9/23 (39%) ($p < 0.05$). In both groups INF was well tolerated and all pts. completed the study.*Conclusion.* The sustained response to INF is statistically more effective in pts. treated with 6 MU for 6 months than with 3 MU for the same period. }" "Comparison Between Two Different Regimens of Alfa INF Treatment in Chronic Hepatitis C"

"P P 25 0634"P 25 0634**The Influence of Antiviral Therapy with Interferon Alfa-2A on the Levels of Oncomarker CA 19-9 in Chronic Viral Hepatitis CV.V. Gorbakov, O.V. Rumyantsev, S.V. Plyusnin, V.T. Ivashkin**

Burdenko Main Military Hospital, Moscow, Russia*Aim of the study:* to assess the levels of oncomarker CA 19-9 in patients with chronic viral hepatitis C (HCV) and their changes during the treatment with interferon { a}-2a. *Patients and methods:* 53 patients with HCV have undergone clinical, laboratory and morphological (liver biopsy) examination. All patients received antiviral treatment with interferon { a}-2a (Roferon-A, Hoffmann-La Roche, Switzerland) during 6 months (6 mln ME intramuscularly tiw during the first 3 months, 3 mln ME tiw during consequent 3 months). *Results:* Blood levels of the oncomarker CA 19-9 were increased in 52.8% patients with HCV (normal – 37 U/ml). The carbohydrate antigen CA 19-9 is used for laboratory diagnose of pancreatic malignancies. In patients with benign pancreatic neoplasm, CA 19-9 is increased only in 12% of cases. Mean (\'b1 SD) level of CA 19-9 in HCV patients was 101.0 – 11.0 U/ml that is over 3-fold higher than the upper normal range. In patients with morphologically verified chronic persistent hepatitis (CPH) (n = 25) the mean CA 19-9 level was 65.2 – 10.3 U/ml, in those with chronic active hepatitis (CAH) (n = 23) 145.0 – 20.6 U/ml, in those with CAH and cirrhotic transformation and liver fibrosis (n = 25) 119.0 – 34.3 U/ml. Treatment with Roferon-A resulted not only in normalisation of ALT levels and other liver test, but also led to changes of CA 19-9 levels. From 1 to 4 months after the start of the treatment the increased levels of carbohydrate antigen were found only in 18.9% of patients (mean, 54.6 – 16.7 U/ml). Patients with CPH had the mean CA 19-9 level of 60.3 – 33.1 U/ml, those with CAH – 43.9 – 6.6 U/ml, those with CAH and cirrhotic transformation – 62.3 – 14.1 U/ml. *Conclusions:* 1. Increased blood levels of CA 19-9 are characteristic for 52.8% of patients with chronic viral hepatitis C. 2. The increase of carbohydrate antigen levels correlates with activity of pathological process in the liver. 3. Treatment with interferon { a}-2a (Roferon-A) results in normalisation or significant reduction of CA 19-9 levels in most of patients with all morphological types of hepatitis. Liver and bile ducts, 1: Hepatitis, viral, treatment }" "The Influence of Antiviral Therapy with Interferon Alfa-2A on the Levels of Oncomarker CA 19-9 in Chronic Viral Hepatitis C"

"P P 25 0635"P 25 0635**Interferon Gamma Deficiency in Pathogenesis of Chronic Hepatitis C (CHC)**

*N. Osna, G. Silonova, M. Ponomareva, N. Vilgert, L. Viksna, D. Gardovska, A. Sochnev

Latvian Medical Academy, Riga, LatviaTHE AIM of our work is to study IFNg production capacity of peripheral blood cells in CHC and to analyse the influence of rIFNa therapy on this parameter.Twelve adult patients and 10 children (anti HCV+, with clinical, biochemical and morphological features of CHC) were treated by rIFNa (2–3 MU thrice a week, 24 weeks). IFNg was induced at pre- and posttreatment level in whole peripheral blood culture by PHA (24 and 96 hours of incubation) and tested in ELISA.It was shown that IFNg production capacity was decreased in CHC patients versus healthy donors ($p < 0.05$). After three months of IFNa therapy we saw an enhancement of spontaneous and early (24 hours) induced IFNg only in responder group (patients that have respondered to rIFNg therapy by ALT normalisation). This effect was prolonged till 6 months of the therapy and did not concern IFNg induced in 96 hours. We did not find such dynamics in the non-responder group. If we accept that 24 h induced IFNg is the predominant product of natural killers (NK) cells, and 96 h induced IFNg are produced by T-cells, our results means that rIFNa therapy activates IFNg production mainly at NK cells level, and this factor corresponds to the therapy outcome. We have analysed possible causes of defect 96 h induced IFNg production. In children but not in adult group impaired IFNg level was restored by combination of PHA with rIL-2. We also have found that autoserum possessed IFNg downregulative properties especially after rIFNa treatment course.We conclude that IFNg deficiency is of pathogenic meaning, and activation of IFNg production by NK cells during rIFNa treatment is an important factor in responder status establishment in CHC. "P P 25 0636"P 25 0636**Response to HBV Vaccine in Relation to Anti-HCV and to Anti-HBc Positivity: A Study in Drug Addicts**

*F. Minniti, L. Di Furia[1], R. Bricolo[1], R. Trivello[2], L. De Marzi[3], M. Miolo[3], M. Chiaramonte

Dpt. of Gastroenterology, University of Padova, USSL 16 Padova

[2] Dpt. of Hygiene, University of Padova, USSL 16 Padova

[1] SERT, USSL 16 Padova

[3] Public Health Laboratory, USSL 16 PadovaDrug addicts is the group of young adults with the lowest response to HBV vaccine. It is, therefore, a good model to study the factors affecting the decrease of the response to HBV vaccine. HCV infection had been suggested to lower the vaccine response (Clin. Nephrol. 1994; 41: 113–116) while the role of antiHBc positivity is still debated.We studied 110 i.v. drug addicts (90 male, 20 female, mean age 29.5 – 6.3), all HIV negative, HBsAg and antiHBs negative and all vaccinated with the following protocol: Recombivax 10 \'b5g i.m. at month 0, 1, 2. AntiHBs test was done between month 4 and 6. As usual, response to vaccine was considered positive when antiHBs was over 10 IU/L.Out of the 110, 73 were antiHCV+ve and 37 antiHBc+ve; 32 subjects were positive for both.The overall prevalence of the response to vaccine was 66.4%. We correlated the response either to positivity of antiHCV or antiHBc. Response in antiHCV+ve was 63.0% vs 72.9% in antiHCV{ -}ve (p = n.s.), response in antiHBc+ve was 51.4% vs 74.0% in antiHBc{ -}ve ($p < 0.05$) and in anti HCV+/antiHBc+ve was 50.0% vs 73.2% in anti HCV+/antiHBc{ -}ve ($p < 0.05$).*Conclusions.* In drug addicts we found an overall low response to vaccine. According to previous results, the fast protocol, used to increase the compliance, can affect the antiHBs titer but not the response. The response seems to be affected by positivity of antiHBc but not by HCV infection. These results suggest that antiHCV positive subjects can be successfully vaccinated, while the low response observed in some cases can be due to a latent HBV infection reflected by antiHBc positivity.

[2] Unit\'e9 INSERM U417, Paris, France

[3] Laboratoire de Virologie M\'e9dicale Mol\'e9culaire-Facult\'e9 de M\'e9decine de Grenoble, France*Introduction:* Nonsteroid antiinflammatory drugs are cyclooxygenase inhibitors, which could increase IFN efficacy by an activation of the arachidonic acid metabolism pathway (epoxygenase).*The aim* of this study was to evaluate the changes of 2{\'a2}5{\'a2} AS levels on peripheral blood mononuclear cells (PBMC) in patients treated by the association of interferon and nonsteroid antiinflammatory drugs (tenoxicam) by comparison to IFN alone. The 2{\'a2}5{\'a2} AS is an intracellular enzyme induced by IFN. Double blind prospective study concerned 28 patients (20 males, 8 females) with histologically proved chronic hepatitis C. Mean age was 34.3 – 11.1 years. Patients were randomly divided in 2 groups: group 1 (n = 13): IFN a 2a 3 MIU/TIW/6 months plus Tenoxicam 20 mg Po per day; group 2 (n = 15): IFN a 2a 3 MIU/TIW/6 months. The 2 groups were similar for age, sex, basal ALT level, mode of contamination, duration of disease, serotype, quantitative viremia (MONITOR), Knodell score, response to therapy, and basal 2{\'a2}5{\'a2} AS levels. 2{\'a2}5{\'a2} AS activity was measured in PBMC by a radio active assay and expressed in UI/10^7 cells at D0, M3, M6, and M12.*Results:* In group 1, 2{\'a2}5{\'a2} AS level was not significantly increased at M3 (2.85 – 3.48 vs 1.13 – 2.26 at D0), M6 (2.19 – 2.85) and at M12 (0.82 – 0.81); on the other hand, in group 2, 2{\'a2}5{\'a2} AS level was significantly increase at M3 (6.08 – 5.44 vs 1.13 – 2.26 at D0: $p < 0.05$) but not at M6 (2.33 – 1.85) and M12 (1.09 – 0.77). Serotype and HCV RNA levels were not predictive parameters of 2{\'a2}5{\'a2} AS levels increase.*Conclusion:* Our results suggest that in patients with chronic hepatitis C, IFN therapy significantly increased 2{\'a2}5{\'a2} AS levels. This increase is temporary and not find with IFN/nonsteroid antiinflammatory drugs combination. Liver and bile ducts, 1: Hepatitis, viral, treatmentLiver and bile ducts, 1: Hepatitis viral, diagnosisImmunology and microbiology: Host defense mechanisms }" "Interferon (IFN) Therapy Combined with Nonsteroid Antiinflammatory Drugs (AINS) Does Not Induce a Significant Increase of 2'5' Oligoadenylate Synthetase (2'5' AS) Activity in Patients with Chronic Hep"

"P P 25 0639"P 25 0639**How Do Patients with Mild Chronic Hepatitis C Respond to Interferon (IFN) Therapy?**

*L. Serfaty[1], O. Chazouill\'e9res[1], J.M. Dauchot[1], A. Loria[1], C. Legendre[2], R. Poupon[1]

[1] Unit\'e9 d'H\'e9patologie, Hospital St-Antoine, Paris, France

[2] Service d'anatomopathologie, Hospital St-Antoine, Paris, FranceThe influence of histological activity on efficacy of IFN in patients with non cirrhotic chronic hepatitis C is debated. The aim of this study was to compare biochemical and virological responses to IFN in patients with mild hepatitis or with moderate to severe hepatitis.*Methods:* Between 1990 and 1993, 192 patients with non cirrhotic chronic hepatitis C were treated with IFN alfa 2 recombinant 3 MU {\'b4} 3/week for 6 months in our institution. 57 had mild hepatitis (MiH), defined by Knodell score {\'a3} 4, 135 had moderate to severe hepatitis (SH). Biochemical response was classified as non response (NR) (i.e., elevated ALT at the end of treatment), response with relapse (RR) (i.e., normal ALT at the end of treatment and elevated ALT thereafter) or sustained response (SR) (i.e., ALT still normal one year after the end of treatment). Virological response was defined as PCR negativity. HCV genotype was determined in 67 patients using InnoLipa technic. Mean follow-up was 21 – 12 months.*Results:* Pretreatment characteristics of patients with MiH or SH were as follows: age (37 – 10 vs 43 – 13 yrs, $p < 0.05$), sex ratio (1.1 vs 1.3), history of blood transfusion (32% vs 43%) or IVDU (41 vs 35%), ALT levels (73 – 46 IU/1 vs 101 – 98 IU/1, $p < 0.05$), HCV genotype (1a, 1b, 2a, 3a, others: 29, 29, 6, 18, 18 vs 18, 36, 8, 18, 20%). Biochemical response was not significantly different between the 2 groups: NR, RR, SR = 37, 37, 26% in the MiH group vs 45, 40, 15% in the SH group. Virological response was also identical at 3 and 6 months of treatment (53 vs 48%, 40 vs 42%). Among the 35 patients with a sustained biochemical response, the percentage of patients with negative PCR one year after the end of treatment was not significantly different in patients with MiH or SH (55% vs 83% respectively, $p > 0.05$).*Conclusion:* this large cohort study shows that biochemical or virological responses to IFN are not significantly better in patients with mild hepatitis than in patients with moderate to severe hepatitis. Taken together with the generally good prognosis of the natural course of mild hepatitis C, this relatively low efficacy makes questionable the standart IFN therapy in these patients. }" "How Do Patients with Mild Chronic Hepatitis C Respond to Interferon (IFN) Therapy?"

"P P 25 0640"P 25 0640**Prevalence of Anti-Thyroid Autoantibodies before and after Interferon Treatment in Patients with HCV Infection and B-Thalassaemia Major in GreeceK. Mimidis,**

*K. Goritsas, P. Matsouka, V. Margaritis, C. Lambropoulou-Kar\'e0tza

Department of Internal Medicine, University Hospital of Patras, Patras, GreeceThe prevalence of anti-thyroid autoantibodies varies in reports from different countries. A high prevalence of antithyroid antibodies in chronic hepatitis C especially after IFN treatment is already reported. We studied the prevalence of antimicrosomal antibodies in Greece in multitransfused thalassaemic patients and in otherwise healthy patients with chronic hepatitis C. Epidimiologic data in general population of our region (SW Greece) report a prevalence for anti-thyroid antibodies of 12%.*Patients-Method:* 25 patients with chronic HCV infection (9 males and 16 females; age 54 – 2 years, mean – SD) and 24 patients (9 males and 15 females; 24 – 2.1 years, mean – SD) with chronic HCV infection and { b}-thalassaemia major, transfused regularly in monthly intervals were included in the study. All patients were treated with ra2{ b} IFN 3 MU three times/week for at least 6 months. HCV diagnosis was made by ELISA-3 Abbot for HCV and RT-PCR for HCV. Liver biopsy was performed in all patients. Thyroid function and anti-thyroid peroxydase antibodies were measured by RIA in all patients at diagnosis, every three months during IFN therapy and 6 months after withdrown of IFN.*Results:* Before IFN treatment 4 patients (3 females, 1 male) out of total 49 (8.16%) presented with an increased autoantibody titer (NS compared with the prevalence in general population in our region). None of those 4 patients was thalassaemic. After IFN treatment only one female patient with thalassaemia (4.1%) and the previous 4 patients presented an increased autoantibody titer. Subclinical hyperthyroidism after IFN therapy presented only one non thalassaemic patient.*Conclusion:* 1) Prevalence of autoantibody in Greek patients with HCV infection does not differ from that observed in general population.2) Patients with { b}-thalassaemia major had a nihil prevalence of anti-thyroid antibodies probably because of their young age.3) IFN treatment did not influance the thyroid function in anti-thyroid autoantibody negative patients. Liver and bile ducts, 1: Hepatitis, viral, treatment }" "Prevalence of Anti-Thyroid Autoantibodies before and after Interferon Treatment in Patients with HCV Infection and B-Thalassaemia Major in Greece"

"P P 25 0641"P 25 0641**Udca, Alone or in Combination with Interferon-{ a}, in the Management of Chronic HCV InfectionH. Senturk, O. Uzunalimoglu, Y. Batur, I. Simsek, A. Mert, H. Cetinkaya, G. Ersoz, F. Tabak, H. Akbaylar, M. Akdogan, A. Dokmeci, A. Sonsuz, S. Ozenirler, E. Avsar, N. Tozum**

Hepatitis Study Group, TurkeyUrsodeoxycholic acid (UDCA) has a controversial role in the treatment of chronic hepatitis C virus (HCV) infection. We studied its impact, alone or in combination with Interferon-alpha (Ifn-{ a}) 2b (Intron, Schering & Plough), on chronic HCV infection. The diagnosis was based on: 1-The presence of ALT elevation, in the preceding six months, 2-Presence of Anti-HCV antibodies and HCV-RNA by PCR in the circulation, 3-Chronic hepatitis in liver biopsy. Response was defined as complete normalization of ALT. Sustained meant no flare in the six months period following treatment. In total, 107 patients were randomized into three treatment arms: 1-UDCA alone 250 mg bid (14), 2-UDCA 250 mg bid + Ifn-{ a} 3 MU tiw (45), 3-Ifn-{ a} alone 3 MU tiw (49). The treatment was continued for six months. At the end of six months the responders continued the same treatment for another six months. The nonresponders of the groups were crossed-over as following: 1-UDCA was replaced by Ifn-{ a} 3 MU tiw. 2-The dose of Ifn-{ a} was increased to 6 MU tiw. 3-UDCA 250 mg bid was added to the treatment. All the nonresponders received these alternative treatments for six months. All the responders to any type of treatment were followed-up for another six months untreated. The enrollment to UDCA group was stopped early, because only 1/14 patient normalized ALT at the end of three months. However 12/14 from this group completed six months and then crossed-over as planned. 39/45 from the second and 45/49 from the third group completed treatment. 1/12 of UDCA patients responded which was not sustained. Overall sustained response rate did not differ between Ifn-{ a} and Ifn-{ a} + UDCA groups (7/39, 18% vs. 9/45, 20%.) None of the Ifn-{ a} nonresponders achieved sustained response with switch to combination treatment. Only 1/15 nonresponders from combination group achieved sustained response with the dose escalation of Ifn-{ a}.It was concluded that UDCA alone is ineffective in chronic HCV infection. Combination with Ifn-alfa is not additive to the latter. Liver and bile ducts, 1: Hepatitis, viral, treatment }" "Udca, Alone or in Combination with Interferon-alpha, in the Management of Chronic HCV Infection"

"P P 25 0642"P 25 0642**Chronic Hepatitis C And Autoimmunity. Good Response to Immunosuppressive Treatment****A. Tran[1], S. Benzaken[2], G. Yang[1], P. Rampal[1]**

[1] Liver Unit, Archet Hospital, Nice, France

[2] Department of Immunology, Archet Hospital, Nice, FranceThe link between autoimmunity and hepatitis C virus infection remains controversial. Some rare patients with chronic active hepatitis C present features of autoimune liver disease. The choice of treatment is very difficult: Interferon-alpha may exacerbate the autoimmune component while corticoids may enhance viral replication. We describe 3 patients with chronic hepatitis C and features of autoimmune liver disease treated by azathioprine (2 mg/kg/day) and prednisone (1 mg/kg/day). The dose was then adjusted. The follow-up was 4, 2 and 1 years in patients 1, 2 and 3, respectively. Treatment was safe and efficacious (See table). Data Patient 1 Patient 2 Patient 3Age (yrs) 67 69 70Sex female female maleHCV RNA (RT-PCR) positive positive positiveContamination transfusion transfusion unknownGenotype 3a 3a 1bLiver biopsy cirrhosis cirrhosis cirrhosis Before After Before After Before AfterALT (5–40 IU/l) 52 17 68 17 110 25Gammaglobulin (9–17 g/l 23.5 15.3 29.2 10.8 24.9 17.4Anti-LKM antibody (ab) Neg Neg Neg Neg Neg NegAnti-nuclear ab Neg Neg Neg Neg 1/10^4 1/10^{3}Anti-mitochondrial ab Neg Neg 1/10^3 1/200 Neg NegAnti-smooth muscle ab 1/600 1/50 Neg Neg Neg NegKnodell's score 12 8 17 12 16In conclusion, we recommend that these patients with chronic hepatitis C and features of autoimmune liver disease be treated by immunosuppressive therapy first. Interferon therapy should be reserved for those patients who fail to respond. Liver and bile ducts, 1: Hepatitis, viral, treatment }" "Chronic Hepatitis C And Autoimmunity. "P P 25 0643"P 25 0643**Interferon Therapy in HBV Precore Mutant Related Chronic Liver Disease in IndiaR.C. Guptan, V. Thakur,**

*S.K. Sarin, V. Malhotra

Dept. of Gastroenterology, Pathology, G.B. Pant Hospital, Delhi*Background:* About 15% of Indian patients with HBV related chronic liver disease (CLD) have infection with precore mutant forms. These patients have an aggressive course. Some success with interferon (IFN) therapy is reported from the West. IFN was found effective by us (J. Hepatol. April, 1996) in Asian Indians with CLD due to wild type HBV. IFN therapy has not been evaluated in CLD due to mutants in Asian patients. *Material and Methods:* 18 biopsy proven CLD patients (age 38.2 – 12 yr, M:F:: 17:1) with mutations at 1896 and 1898 position, HBsAg+ve, HBeAg { -} ve, HBeAb+ve, HBVDNA+ve), ALT levels > 2 {\'b4} N and negative for hepatitis C and auto immune markers were included. IFN (INTRON-A) was given as 3 MU, AD, for 4 mo. Serial serology and repeat liver biopsy was done after completion of therapy and hepatic activity index (HAI) was calculated. HBVDNA was done by both Dot-Blot Hybridization (detection limit < 1 pg/ml) and PCR at base line and 4 mo. Success of IFN was defined as normalization of ALT and loss of HBVDNA by dot-blot. *Results* INF therapy was successful in 12 (75%) patients. The mean ALT decreased from baseline in responders (36.5 – 12 vs. 82.6 – 22 IU/L, $p < 0.05$), while it remained high (72.2 – 26 IU/L) in non-responders. HAI decreased insignificantly (15 – 6 vs. 11 – 8.4). 12 patients became HBV DNA negative by dot blot at 4 mo but none became PCR negative. During 13.2 – 6.2 mo follow-up, 7 (58.3%) responders relapsed. 2 (11.1%) patients died; 1 of hepatoma and the other of coma. In 3 (16.6%) patients, IFN was rescheduled due to thrombocytopenia. *Conclusions* (i) IFN therapy is beneficial in precore mutant related CLD (ii) Despite HBVDNA clearance by dot-blot in 75% patients, low level viremia (PCR+ve) persists leading to high relapse. Combination of drugs needs evaluation. Liver and bile ducts, 1: Hepatitis, viral, treatment }" "Interferon Therapy in HBV Precore Mutant Related Chronic Liver Disease in India"

"P P 25 0644"P 25 0644**Clinical Study of the Efficacy of Interferon Therapy for Chronic Hepatitis C****M. Takase, Y. Ishizuka, K. Uchiyama, H. Mutsukawa, T. Kawai, M. Nakagawa, Y. Nishizato[1], T. Saito[2]**

[1] Dep. of Gastroenterology, Hachioji Medical Hospital, Tokyo Medical College

[2] The Fourth Dep. of Internal Medicine, Tokyo Medical College*Objectives:* The therapeutic effects of interferon (IFN) therapy for chronic hepatitis C were investigated according to hepatitis C virus (HCV) subtype, HCV-RNA quantity, and histodiagnosis. HCV core antibody (C22-3) level was quantitatively determined before and after IFN therapy to investigate the correlation of the level with HCV-RNA and the usefulness of the antibody level for evaluating the efficacy of IFN therapy.*Methods:* The subjects were 35 patients who had tested positive in a blood HCV-RNA determination. Three periods of administration of r-IFN a 2a at a daily dose of 9 MU were used (total dose, 774, 846 and 918 MU). The case in which alanine amino transferase (ALT) was normalized within 6 months after the administration period and the ALT level remained normal for at least the next 6 months was regarded as complete response (CR). Viral fluctuation (fate) was also investigated by determining HCV-RNA at the end of administration and 6 months after the administration period. HCV subtypes were determined according to the method of Okamoto et al., and HCV-RNA quantity according to the competitive RT-PCR method. The histodiagnosis followed the European classification.*Results:* CR was observed in 48.6%. As a result of assessing the background factors in the CR group, HCV-subtypes 2, 3 and 4 were observed in 33.3%, 77.8% and 50.0%, respectively. The HCV-RNA quantity was 10^5/50 ul or more in 31.6% and less than 10^5/50 ul in 68.8%. According to histodiagnosis, CAH2A and CAH2B were observed in 54.5% and 38.5%, respectively, in the CR group. The C22-3 antibody titer decreased to 68.2% and 56.8% at the end of administration and at 6 months after the administration period, respectively, as compared with the level before IFN therapy, in the patients who showed a change in HCV-RNA to a negative level at the end of administration and 6 months after the administration period. In the patients who showed no change in HCV-RNA to a negative level, the antibody titer decreased to 78.7% at the end of administration, and it tended to increase thereafter.*Conclusions:* 1. IFN therapy showed low efficacy in the patients with HCV-subtype 2, HCV-RNA quantity of 10^5/50 ul or more, and who showed advanced histological findings of the liver. 2. The quantitative level of C22-3 antibody is useful as an indicator for estimating viral fluctuation (fate), and the continuous decrease in the C22-3 antibody level starting from the end of administration, which suggested the elimination of HCV-RNA. Liver and bile ducts, 1: Hepatitis, viral, treatment }" "Clinical Study of the Efficacy of Interferon Therapy for Chronic Hepatitis C"

"P P 25 0645"P 25 0645**HCV Carriers with Normal ALT: Response to Interferon (IFN) Treatment**

*A. Rossini, A. Ravaggi[1], L. Biasi, F. Callea[2], E. Agostinelli[3], G.B. Gazzola[3], E. Cariani[1], E. Radaeli

III Dept. of Internal Medicine, Hospital of Brescia, Italy

[1] III Laboratory, Hospital of Brescia, Italy

[2] I Dept. of Pathology, Hospital of Brescia, Italy

[3] Blood Transfusion Service, Hospital of Chiari, ItalyThe efficacy of interferon treatment in HCV carriers with normal ALT levels is still debated. *Methods:* 19 consecutive subjects with normal ALT, positive for anti-HCV and HCV-RNA (mean age 50.8 – 9.5; M:F 11:8) underwent monthly monitoring of ALT activity for 8–18 months. ALT levels were persistently normal (< 40 IU/I) in 12 cases, whereas occasional elevations < 1.5-fold N.V. were detected in 7 cases. Liver biopsy detected CAH in 18 and CLH in 1 (median Knodell score = 6, range 2–8). Patients were randomized to receive IFN alpha 2b 3 MU t.w. for 12 months (n. 10, group 1) or no treatment (n. 9, group 2). The response treatment was monitored with monthly ALT and HCV-RNA determinations. In case of HCV-RNA persistence treatment was suspended after 6 months. Subjects of group 1 and 2 did not differ significantly for age, sex, Knodell score (median 5 vs 6), HCV genotype (type 1 n. 2, type 2 n. 8; vs type 1 n. 5, type 2 n. 4), HCV-RNA titer (median 8.15 log copies/ml vs 7.5). n. of subjects with occasional ALT elevation (4 vs 3). *Results:* during IFN therapy 5 patients in group 1, but none in group 2, cleared serum HCV-RNA. ALT flare-up was observed in 2 patients, but ALT levels returned normal in few months. After stopping therapy 3/5 had immediate re-appearance of viremia and transient ALT increase. The 2 remaining patients were still HCV-RNA negative after 9 months of post-treatment follow-up. They had a pretreatment viral titer of 7.1 and 5 log copies/ml and were infected with genotype 2c. Total Knodell score were 4 and 8. These results show that in HCV carriers with persistently normal or near normal ALT: 1) interferon treatment induced clearance of HCV-RNA until 9 months post-IFN in 2/10 patients, both infected with genotype 2; 2) transient ALT flare-up may be detected 3) clearance of HCV-RNA during treatment is not predictive of sustained response. Liver and bile ducts, 1: Hepatitis, viral, treatment }" "HCV Carriers with Normal ALT: Response to Interferon (IFN) Treatment"

"P P 25 0646"P 25 0646**Hepatitis C Virus-Positive (HCV) Chronic Active Hepatitis (CAH): A Randomized, Controlled Trial of IFN – Colchicine**

*P. Trande, P. Esposito, S. Marchi[1], A. Grottola, P. Buttafoco, P. Ciccorossi[1], A. Ricchiuti[1], S. Petruccelli[1], A. Ferrari, I. Ferretti, N. Nardella, F. Manenti, E. Villa

Cattedra di Gastroenterologia, Universit\'e0 di Modena Italia

[1] Cattedra di Gastroenterologia, Universit\'e0 di Pisa, ItaliaFibrosis in pts with CAH is a frequent occurrence also in long term responders to IFN; colchicine (C) has been used as antifibrillogenetic drug. We have therefore planned a randomized trial of IFN – C [IFN 6 MU {\'b4} 3 months, 3 MU {\'b4} 3 months (Roferon A, Roche) – C 1 mg for 5 days/week for 1 year] trying to improve the overall outcome of IFN alone. We report the results at 2 years of the 85 pts with antiHCV+ CAH enrolled (IFN: 42; IFN + C: 43). *Results:* the 2 groups were balanced for all parameters (age, sex, ALTs levels, duration of disease) except than more severe CAH (HAI > 9), more genotype 1b and baseline higher PIIIP (indirect index of collagen deposition) were present in IFN + C group. Longterm response (LTR) was significantly higher in IFN (9.5%) vs IFN + C (4.5%) treated pts. PIIIP decrease in both groups was significant at month XII vs baseline ($p < 0.05$) but not between the 2 groups. HAI decrease at month XII in both groups was not significant. Presence of genotype 1b was the only parameter associated, at multivariate analysis, with non response.Comparison of the subgroup, in the IFN + C (n. 14), characterized by more severe cases with the totality of IFN-treated patients demonstrated a rate of LTR in IFN + C pts similar to that of IFN-treated patients (IFN vs IFN + C: 9.5 vs 7.0%) and a significantly higher decrease of HAI score ($p < 0.05$).*Conclusions:* 1. genotype 1b is a strong predictor of non response to IFN; 2. PIIIP decrease may be a consequence of the antiviral-antiinflammatory activity of IFN; 3. the association with colchicine does not improve the overall response of IFN in unselected CAH; however, it improves the rate of long term response and the histological activity score in patients with more severe disease.(Supported by grant 40% Virus).

"P P 25 0649"P 25 0649**Pretreatment Low Serum HCV-RNA Levels with a Branched DNA Assay Predict Response to Interferon-Beta Treatment in Chronic Hepatitis C**

*T. Fukutomi[1], M. Fukushima[1], Y. Tanabe[1], K. Hiroshige[1], H. Sakai[2], H. Nawata[2]

[1] Department of In¯ternal Medicine, Fukuoka City Hospital, Fukuoka, Japan

[2] Third Department of Internal Medicine, Faculty of Medicine, Kyushu University, Fukuoka, JapanThe aim of this study is to evaluate whether initial HCV-RNA titer, HCV genotype and histological findings predict response to natural IFN-beta in chronic hepatitis C (CHC). *Method:* Thirty six patients with CHC (male 19 and female 17, mean age 46.4 years) were treated with natural IFN-beta 6 MU/day for 8 weeks. Complete response (CR) was defined as persistence of normal ALT levels after the end of treatment and as clearance of HCV RNA (by RT-PCR) at the end of treatment, 3 month and 6 month after the cessation of the treatment. HCV-RNA genotyping was performed using specific PCR primers according to the method of Okamoto, and HCV-RNA quantitation was performed using branched DNA (b-DNA) assay. Liver biopsy specimens were scored according to the Desmet's grading method. *Results:* HCV genotype 1b 2a 2bCR rate 23% (3/13) 58% (11/19) 50% (2/4)HCV-RNA (mEq/ml) < 0.5 0.5–1.0 1.0 <CR rate 84% (14/19) 0% (0/4) 15% (2/13)Grading minimal mild moderate severeCR rate 50% (5/10) 53% (9/17) 25% (2/8) 0% (0/1)Staging score 0 score 1 score 2 score 3 score 4CR rate 0% (0/0) 58% (7/12) 39% (7/18) 33% (2/6) 0% (0/0)Analysis of the 19 patients with low serum HCV-RNA levels (< 0.5 mEq/ml) were as follows: HCV genotype 1b 2a 2bCR rate 75% (3/4) 77% (10/13) 50% (1/2)Staging score 0 score 1 score 2 score 3 score 4CR rate 0% (0/0) 86% (6/7) 67% (6/9) 66% (2/3) 0% (0/0)*Conclusions:* These data suggested that pretreatment low serum HCV RNA levels (< 0.5 mEq/ml) determined by b-DNA assay were regarded as most important predictor of response to IFN-beta treatment in chronic hepatitis C. Consideration of this factor will provide more rational criteria to select patients for IFN-beta treatment. Liver and bile ducts, 1: Hepatitis, viral, treatment }" "Pretreatment Low Serum HCV-RNA Levels with a Branched DNA Assay Predict Response to Interferon-Beta Treatment in Chronic Hepatitis C"

"P P 25 0650"P 25 0650**Interferon (IFN) Therapy in HCV Chronic Liver Disease: Is Old Age a Contraindication?**

*U. Lorenzoni, A.R. Floreani, A. Vian, S. Lobello, R. Naccarato, M. Chiaramonte

Dept. of Gastroenterology, Padua University, ItalyElderly people are considered poor candidate for IFN treatment, because of a suspected higher risk of adverse effects and/or a higher prevalence of non responders.*Aim:* To evaluate the response to IFN in a selected population of old patients compared to adult controls.*Material and Methods:* We retrospectively evaluated 166 chronic HCV hepatitis patients enrolled in IFN treatment protocols since 1990: a) N. 25 were > 60 yr old (14 M, 11 F; mean age 61.6, range 60–67); b) N. 141 were < 60 yr. old (104 M, 37 F; mean age 43.2, range 24–59). The following variables were correlated to the response: gender, serum ferritin, { g}GT, ALT, HCV genotype and liver histology. The statistical analysis was done by T-Student's test for unpaired data.*Results:* Sustained response (12–48 months of follow-up after the therapy) was observed in 7/25 (28%) of aged compared to 43/141 (30.4%) of adult patients (p = n.s.). Short term response (with relapse after treatment) was observed in 6/25 (24%) of aged and in 48/141 (34%) of adults (p = n.s.).Univariate analysis demonstrated that liver cirrhosis and high levels of both ferritin and { g}GT were correlated with non-response to treatment in both groups. However, liver cirrhosis was more frequent in aged compared to adults (13/25, 52.0% vs 26/141, 18.4%; p < 0.001), while { g}GT, ferritin and 1b genotype were not statistically different in the two groups.Major side effects were more frequent in older patients than in adults (28.0% vs 14.2%, p < 0.01).*Conclusions:* Selected elderly subjects with HCV chronic hepatitis, in spite of the higher prevalence of cirrhosis, might have the same probability of sustained response compared to adults. However, attention must be paid in monitoring the major adverse effects. Liver and bile ducts, 1: Hepatitis, viral, treatment }" "Interferon (IFN) Therapy in HCV Chronic Liver Disease: Is Old Age a Contraindication?"

"P P 25 0651"P 25 0651**Can Pretreatment Characteristics Predict Short Term Non-Response to Interferon Therapy in Chronic Hepatitis C?**

*R. Testa, E. Giannini, A. Picciotto, S. Caglieris, D. Risso[1], P.B. Lantieri[1], L. Arzani, S. Alvarez, G.L. Guido, N. Campo, L. Faraldi[2], G.C. Icardi[2], G. Lapertosa[3], G. Celle

Gastroenterology Unit, DIMI, Italy

[1] Institute of Medical Statistics, University of Genoa, Italy

[2] Institute of Hygiene, University of Genoa, Italy

[3] Institute of Pathological Anatomy, University of Genoa, ItalyPredictors of a sustained response to interferon (IFN) therapy in chronic hepatitis C were identified in several trials. About 50% of patients have no response during IFN therapy and this failure is very expensive. Aim of our study was to identify possible predictors among biochemical, virological, pharmacokinetic and histological pretreatment variables of a non-response during IFN therapy. 50 patients (41 M and 9 F, mean age 46 – 12) with chronic hepatitis HCV RNA positive were treated with IFN { a}2b recombinant or lymphoblastoid (9 MU weekly for six months). Pretreatment were evaluated ALT, AST, { g}GT, alkaline phosphatase, bilirubin, albumin, protrombin activity, gammaglobulin (GGL), prolylhydroxylase, procollagen III peptide, bile acids, viral genotype, monoethylglycinexylidide formation (MEGX, lidocaine metabolite), histological activity index (HAI) with partial scores (fibrosis, necrosis + inflammation, biliary duct damage, steatosis) and were related to short term response (ALT and AST normalization both at 3rd and 6th month). 24 patients were responders and 26 non responders. Significant differences between responders and non responders were found for { g}GT (mean – SD U/l 37 – 18 vs 78 – 61, p = 0.0007), GGL (g/dL 1.4 – 0.4 vs 1.7 – 0.7, p = 0.042), HAI (6.5 – 3.0 vs 9.5 – 4.2, p = 0.0075), necrosis + inflammation (5.5 – 2.4 vs 7.5 – 3.1, p = 0.0109) and fibrosis (0.5 – 0.8 vs 1.2 – 1.2, p = 0.05). Multivariate logistic analysis showed that only increased { g}GT is an independent predictor of non-response (p = 0.0254), and that in combination with decreased MEGX formation at 60 min, high HAI and genotype 1 allows to calculate a probability index of non response (0.26 error, p = 0.0008). Non response probability {\'b3} 0.50 showed a 0.75 SP, 0.73 SS and 0.76 PPV, while a probability {\'b3} 0.70 showed a 0.92 SP, 0.50 SS and 0.87 PPV. A high pretreatment risk of non response can suggest to modify IFN dose or to combine it with other drugs. Liver and bile ducts, 1: Hepatitis, viral, treatment }" "Can Pretreatment Characteristics Predict Short Term Non-Response to Interferon Therapy in Chronic Hepatitis C?"

"P P 26 0652"P 26 0652**Apolipoprotein E Polymorfism in Primary Sclerosing Cholangitis (PSC)**

*M.A. F\'e4rkkil\'e4, A.-L. Karvonen, P. Pikkarainen, H. Nurmi, H. Nuutinen, P. K\'e4rkk\'e4inen, M. Taavitsainen, T. Miettinen

Department of Medicine Helsinki, Tampere and Turku University Hospitals, Finland

Department of Pathology, University of Helsinki, Finland

Department of Radiology of Helsinki University Hospital, FinlandPSC is a non-suppurative inflammation of intra- and extrahepatic bile ducts of uncertain origin leading to chronic cholestatic liver disease. No effective medical treatment has so far been available. Ursodeoxycholic acid (UCDA) has widely been used in patients with PSC, although there is no proven efficacy of the treatment. Apolipoprotein E (Apo E) polymorfism has been shown to regulate the absorption of intestinal cholesterol and bile acids. Moreover, apo E polymorfism has been demostrated to affect the treatment response to UCDA in primary biliary cirrhosis.*Aim of the study.* To evaluate the apo E polymorfism in PSC patients and compare it in healthy finnish population.*Patients and methods.* The study population consisted of 67 patients with PSC. The diagnosis was based on ERCP and liver histology. Apo E phenotyping was determined by isoelectric focusing. Liver enzymes and bilirubin were measured by routine lab methods.*Results.* The relative frequencies of apolipoprotein E phenotypes in healthy controls (n = 615), in PSC (n = 67) and in primary biliary cirrhosis (n = 88) are shown in the table 1. The apo E2 phenotype was 4.6 times higher in PSC than in controls and about two times higher than in PBC. The effect of apo E phenotype on the clinical manifestations (extent of the disease judged by ERCP, S-ALP, S-bilirubin and bile acids) of PSC was further analyzed, showing no clinically significant differences between the different apo E phenotypes, although patients with apo E2 tend to have more cholestatic disease.Table 1. Apolipoprotein E polymorfism in PSC Apo E2 Apo E3 Apo E4Controls 4.1% 73.3% 22.7%PSC 18.8%* 59.4%* 21.7%PBC 9.7%* 73.3% 17.0%*p < 0.01*Conclusions.* Apo E2 phenotype is significantly higher and apo E3 lower in PSC than in healthy controls or in PBC. Patients with apo E2 tend to have more cholestatic disease. The effect of apo E phenotype on the treatment response to UDCA is to be determined. Liver and bile ducts, 2: Bile formation, cholestasis }" "Apolipoprotein E Polymorfism in Primary Sclerosing Cholangitis (PSC)"

"P P 26 0653"P 26 0653**Antiendomysial and Antigliadin Antibodies in Patients with Autoimmune Liver Diseases**

*U. Volta, L. De Franceschi, N. Molinaro, F. Cassani, L. Muratori, M. Lenzi, C. Tetta, A.J. Czaja[1], F.B. Bianchi

Medicina Interna 2, Bologna, Italy

[1] Division of Gastroenterology, Mayo Clinic, Rochester, Minnesota, USASerum antiendomysial (EmA) and antigliadin antibodies (AGA) proved to be reliable markers of coeliac disease (CD). The reported association of CD with autoimmune hepatitis (AIH) and primary biliary cirrhosis (PBC) prompted us to perform an antibody screening for gluten sensitive enteropathy in a large series of patients with autoimmune liver disorders. Sera from 181 patients with AIH (157 type 1 – ANA/SMA+ – and 24 type 2 – LKM/LC1+) and 62 with PBC were tested for IgA EmA on human umbilical cord (EmA-HUC) by IFL and for IgG and IgA AGA by ELISA. As control group, sera from 80 patients with HCV chronic hepatitis (CH) (of whom 53 LKM/LC1+) and from 30 with HBV CH were studied. IgA EmA-HUC were positive only in 8 AIH patients (5 females and 1 male with AIH type 1 and 2 females with AIH type 2). IgA AGA were detected in 6 out of the 8 EmA-HUC positive cases, but were also present in other 2 cases of AIH type 2 and in one with HCV CH. IgG AGA were positive in 15% of the 243 patients with autoimmune liver disorders (16 AIH type 1 and 9 type 2 and 11 PBC) and in 13% of the 110 with HCV and HBV CH. It is generally acknowledged that IgA EmA-HUC display a 100% positive predictive value for CD, whereas IgA and especially IgG AGA can be also found in patients without a gluten-induced intestinal damage. The 2 women with AIH type 2, positive for both IgA EmA-HUC and AGA, underwent duodenal biopsy showing a subtotal villous atrophy consistent with the diagnosis of CD. On the basis of these data at least 2 (8.3%) of the 24 patients with AIH type 2 are affected by CD, but we can also presume that the results of duodenal biopsy, which is still in progress, will definitely confirm CD diagnosis in the 6 (3.8%) AIH type 1 cases with IgA EmA-HUC. The high prevalence of IgG AGA in both autoimmune and viral liver diseases is likely to be related to an impaired hepatic clearance of dietary antigens which, passed through the intestinal barrier, evoke an enhanced IgG class antibody synthesis. Therefore, AIH type 1 and 2 can be regarded as a high risk condition for CD and all AIH patients should be screened by means of IgA EmA-HUC and AGA for excluding the coexistence of gluten-sensitive enteropathy. Intestinal disorders, absorption: Gluten enteropathyIntestinal disorders, absorption: Malabsorption syndromesLiver and bile ducts, 1: Chronic non viral hepatitis }" "Antiendomysial and Antigliadin Antibodies in Patients with Autoimmune Liver Diseases"

"P P 26 0654"P 26 0654**Hydroxylysylpyridinoline in Bile — A Marker for Primary Sclerosing Cholangitis and Primary Biliary Cirrhosis?**

*A. Gillessen[1], Y. Acil[2], J. Brinckmann[3], P.K. M\'fcller[2], W. Domschke[1]

[1] Dept. of Medicine B, University of M\'fcnster, M\'fcnster, Germany

[2] Dept. of Med. Molecular Biology, University of L\'fcbeck, L\'fcbeck, Germany

[3] Dept. of Dermatology, University of L\'fcbeck, L\'fcbeck, GermanyHydroxylysylpyridinoline (HP) is a non-reducible cross-link molecule of mature collagen. This degradation product is found in serum and urine and has been evaluated as a marker for the catabolism of collagen fibres mainly from sceletal tissues. Recently a possible value of HP as measured in serum for the assessment of fibrotic liver diseases was described. In primary biliary cirrhosis (PBC) and primary sclerosing cholangitis (PSC) fibrogenesis takes place next to the bile ducts. Consequently it was tempting to investigate concentrations of HP in the bile.We analyzed bile samples from 10 patients with PBC (5) or PSC (5) and 10 controls. The bile was obtained free of contrast medium during ERCP examination. The total amount of HP was measured by fluorometry after reversed-phase high-performance liquid chromatography (HPLC) of hydrolyzed bile.Bile of normal controls contained no measurable HP in 9 of 10 cases. fifty-five pmol HP/ml bile were found in one normal patient. HP concentrations in bile of all patients with PBC were measured to be between 34–75 pmol/ml (mean 52.6 pmol/ml). In bile of 4 PSC-patients, HP values between 20–98 pmol/ml (mean 51.25 pmol/ml) were obtained. One patient suffering from mild PSC had no detectable HP concentrations in bile. There was no significant difference between HP concentrations in any of these diseases.Hydroxylysylpyridinoline is only detectable in bile of patients with PBC or PSC, while normal controls have no measurable bile HP content. This clear difference was found in 9 of 10 patients in each group indicating a possible role of this marker for assessment of fibrotic activity in these diseases. "P P 26 0655"P 26 0655**Clinical Significance of Different Antinuclear Antibody Patterns in the Course of Primary Biliary Cirrhosis**

*T. Remmel, A. Piirsoo, A. K\'f4iveer, R. Uibo, V. Salupere

University of Tartu, Estonia*Aims:* The purpose of this study is to investigate the clinical significance of antinuclear antibodies (ANA) in primary biliary cirrhosis (PBC) patients.*Methods:* 69 patients with PBC were investigated. Control groups included 21 patients with autoimmune hepatitis, 26 with alcoholic liver disease, 13 with systemic connective tissue disease and 27 healthy persons. ANA was detected by an immunofluorescence method on rat liver tissue sections and HEp-2 cells at serum dilution 1/40.*Results:* In 48 out of 69 PBC patients (70%) ANA was positive in HEp-2 cell line, but in rat liver tissue sections only 29% of patients had positive ANA reactions. Most frequent patterns were multiple nuclear dots (MND) in 42% and perinuclear in 16%. ANA were found in all five AMA negative PBC cases. AMA negative-ANA-positive (5 patients) and AMA positive PBC patients (64 patients) did not differ in clinical, laboratory and histological features from each other ($p > 0.05$).ANA-negative patients had higher sedimentation rate ($p < 0.05$), more frequently ascites ($p < 0.05$) and variceal haemorrhages ($p < 0.05$), but other clinical and laboratory features were similar ($p > 0.05$). There were no more associated autoimmune diseases in ANA-positive group ($p > 0.05$).Survival from the moment of developing first symptom(s) attributable to liver disease was longer in the ANA positive patients than ANA negative ones ($p < 0.02$). There were no statistically significant differences in histological stages at the beginning of the study and in treatment regime and doses during the course of disease, between ANA-negative and ANA-positive patients group ($p > 0.05$).*Conclusion:* In PBC patient's incidence of ANA, especially MND-ANA is a frequent immunological abnormality. All AMA-negative patients had ANA, but clinical, histological and laboratory features were similar. ANA positive patients have significantly better survival. "P P 26 0656"P 26 0656**High Prevalence of Coeliac Disease among Patients with Primary Biliary Cirrhosis**

*W. Dickey, S.A. McMillan, M.E.C. Callender

Altnagelvin and Royal Victoria Hospitals, Regional Immunology Laboratory, Belfast City Hospital, Northern Ireland*Introduction:* Many published case reports describe coeliac disease (CD) in association with primary biliary cirrhosis (PBC). However, as CD is common (1:250–300 by screening) the link may be coincidental. We screened our PBC patients for CD to clarify the situation.*Methods:* Sera from patients with PBC (serum antimitochondrial antibodies and typical liver histology) were tested for IgA endomysial antibodies (EmA) by indirect immunofluorescence. No patient studied was taking a gluten-free diet (GFD) or immunosuppression. Patients who had EmA were invited to undergo endoscopic small bowel biopsy.*Results:* We studied 57 patients (52 female), aged 30–79 years (mean 57). Six (11%) had EmA. Four (7%) agreed to undergo small bowel biopsy which showed villous atrophy and inflammatory cells consistent with CD. Three patients were treated with GFD for at least 12 months with no improvement in liver biochemistry.*Conclusions:* The prevalence of CD among patients with PBC is at least 1:14. Although, as reported elsewhere, the liver disease does not respond to GFD, screening for CD is worthwhile. Both conditions are potent risk factors for metabolic bone disease and some of the symptoms reported by individual patients may be gluten sensitive. Intestinal disorders, absorption: Malabsorption syndromesIntestinal disorders, absorption: Gluten enteropathyLiver and bile ducts, 2: Bile formation, cholestasis }" "High Prevalence of Coeliac Disease among Patients with Primary Biliary Cirrhosis"

"P P 26 0657"P 26 0657**Primary Biliary Cirrhosis (PBC) in Poland: Demography and Survival Model**

*A. Habior, P. Krzeski, E. Butruk

Department of Gastroenterology, Medical Center for Postgraduate Education, Oncology Center, Warszawa, PolandThe incidence of PBC in Poland is not known. The aim of this study was to analyse the incidence and course if this disease in a representative group of the Polish population.*Material and methods:* The incidence and prevalence of PBC during the period of 1983–1995 were investigated in four distant provinces of Poland representing 1/5 of the total Polish population. The data were collected by means of mail survey of specialist physicians and a review of clinical records of seven gastroenterology departments located in these provinces. The observed survival of PBC patients was compared with the predicted survival using Mayo model.*Results:* Over 13-ys period, PBC was diagnosed in 136 patients. No case was diagnosed in a provincial or district hospital. The female:male ratio was 13:1. The familial incidence of PBC was 1.4%. There were only six asymptomatic cases of PBC. The mean annual incidence in four Polish provinces was 1.24/l mln (range: 0.79–1.70). In two urban provinces (Warszawa and Katowice) the incidence of PBC was higher than in predominantly rural provinces of Gdansk and Szczecin. The point of prevalence (Dec. 1995) for the whole analysed group was 10.82/l mln. The Mayo model used for our patients did not correlate with their actual survival.Therefore, we constructed our own model in which the age, serum bilirubin and serum cholesterol were selected for calculation of prognostic index.*Conclusions:* 1. The incidence and prevalence of PBC in Poland is the lowest ever recorded. 2. The Mayo survival model could not be applied to our patients, an observation which suggests that an individual survival model should be constructed for each population. Clinical practice: Epidemiology (non cancer)Liver and bile ducts, 2: Bile formation, cholestasis }" "Primary Biliary Cirrhosis (PBC) in Poland: Demography and Survival Model"

"P P 26 0660"P 26 0660**Autoantibodies in Chronic Hepatitis. Importance of the Autoimmune Etiology**

*J.M. Pascasio, I. Narv\'e1ez, M. Garc\'eda-D\'edaz, J. Saenz de Santamar\'eda, M. Alcalde, L. Vargas, A. Soria, E. Doblar\'e9

University Hospital ""Infanta Cristina"", Badajoz, Spain*Aims:* To investigate the presence of serum autoantibodies (AB) and viral markers in chronic hepatitis (CH) and to evaluate autoimmune etiology in our area.*Methods:* 225 patients with CH by histological assessment were evaluated retrospectively. Age, sex, history of alcoholism (in males > 80 g/daily, in females > 60 g/daily), past transfusion, intravenous drug use, liver enzymes, gammaglobulin, immunoglobulins, hepatitis B and C viral markers, antinuclear (ANA), antimitochondrial (AMA), smooth muscle (SMA) and liver/kidney microsomal type 1 (LKM1) antibodies were studied. Anti-HCV was determined by ELISA 2nd-3rd generation in 193 patients (85.78%) and by ELISA-1st generation in the others. HCV-RNA was done in 69 cases. AB were positive at titres {\'b3} 1:40. Scoring System for diagnosis of *Autoimmune Hepatitis (AIH)* defined by *The International Autoimmune Hepatitis Group (IAHG)* was applied in 170 patients.*Results:* The mean age of patients was 44.62 – 15.39 years and 148 (65.78%) were male. A history of alcoholism was found in 21.33% of patients, past transfusion in 32.89% and intravenous drug use in 9.33%. There were: 17.33%, HBsAg (+); 74.67%, anti-HCV (+); 1.33%, both markers (+) and 6.67%, neither. In 31.9% (67/210) there was at least one AB (+): ANA, 8.57%; AMA, 1.43%; SMA, 24.29% and LKM1, 1.18% (2/170). Only 7 cases (3.33%) had two AB (+). Titres {\'a3} 1:80 were found in 77.78% of ANA (+), 75.56% of SMA (+) and in 66.67% of AMA (+). Of patients with AB (+), 80.60% were anti-HCV (+); 11.94%, HBsAg (+) and 1.49% had both markers (+), without differences in relation to patients with AB ({ -}). Only one patient (0.59%) had score of *definite* and two (1.18%) of *probable AIH.* In 3 patientes (1.76%) score was close to a probable AIH and one of these with LKM1 (+) and RNA-HCV (+) was diagnosed of AIH after a bad response to interferon and a good response to steroids when other autoimmune disease was appeared.*Conclusions:* 1) AIH are rare in our area. 2) 95% of CH with AB (+) had positive viral markers, predominantly of HCV (> 80%). 3) Titres {\'a3} 1:80 were found in almost 80% of patients with AB (+). 4) No differences were found between AB (+) and AB ({ -}) and positive and negative viral markers. 4) The criteria defined by IAHG for the diagnosis of AIH are very strict and may exclude cases which behave like AIH. This indicates that better diagnostic criteria of AIH are required. Liver and bile ducts, 1: Chronic non viral hepatitisLiver and bile ducts, 1: Hepatitis viral, diagnosis }" "Autoantibodies in Chronic Hepatitis. Importance of the Autoimmune Etiology"

"P P 27 0661"P 27 0661**Incidence of Viral Replication in Chronic Infection with Hepatitis B Virus in Children**

*P. Grigorescu-Sido, R. Manasia, C. Lazar, L. Jebeleanu, P. Florescu, C. Skorka

1st Pediatric Clinic, ""Iuliu Hatieganu"" University of Medicine and Pharmacy, Cluj, Romania*The purpose of the study* was to ascertain the incidence of the cases with chronic HBV infection in their phase of viral replication in order to select them for interferon treatment. *Patients and methods.* The authors investigated 73 children (3–15 years) with: chronic active and persistent hepatitis (27 and 28 cases respectively); liver cirrhosis (9 cases) and persistent glomerulonephritis associated with HBV infection (9 cases). The diagnosis was made based on: clinical examination, the biochemical functional liver and/or renal tests, ultrasonography and liver and/or renal biopsy. Depending on the duration of the disease 4 groups were delimited: group I (< 1 year), group II (1–3 years), group III (3–5 years) and group IV (> 5 years) In all cases HBsAg, HBcAb, HBeAg and HBeAb were determined using the Elisa enzymatic method.*Results.* The first two markers were present in all cases. HBeAg — a marker of viral replication — was present in 38.3% of the cases showing an incidence dependent on the length of the course of the disease: 85%; 57% and 23% in groups I, II and III and absent in group IV. HBeAb were present in 56.1% of the group, their incidence increasing progressively with the duration of the disease: 10%; 36%; 78% and 100% respectively in the 4 groups; 5.5% of the cases (negative HBeAg, HBeAb) probably presented mutant forms of hepatitis B virus. *Conclusion.* The results obtained indicated spontaneous onset in time of seroconversion. However the persistence of HBsAg — indicating its inclusion in the liver cell genoma — pleads for the institution of interferon therapy in all children with chronic HBV infection and with viral replication, from the moment the diagnosis is made. Liver and bile ducts, 1: Liver diseases, children }" "Incidence of Viral Replication in Chronic Infection with Hepatitis B Virus in Children"

[1] Internal Medicine, University of Bologna, Italy

[2] Dep. of Clinical Pathology, S. Orsola Hospital, Bologna, Italy*Aim of the study:* to assess the prevalence of non organ (ANA, SMA, anti-LKM1, anti-LC1) and organ specific autoantibodies (anti-thyroid peroxidase and anti-thyroglobulin) in a retrospective series of children with HCV-related chronic hepatitis. *Patients and Methods:* 31 patients (15 males, 16 females) with a median age of 8.9 years (range 2–15) were evaluated. Eighteen patients had received blood or plasma transfusion, 10 were born from anti-HCV positive mothers, one had had major surgery and in two the way of infection was unknown. All patients were anti-HCV and HCV RNA positive, had abnormal ALT values and in 19 liver biopsy showed a picture of chronic hepatitis. Twelve patients were treated with alpha Interferon (3 MU thrice weekly for 12 mo). Sera were tested at a dilution of 1:40 on liver, kidney and stomach cryostat sections and on Hep-2 cell. Anti-LC1 antibody was tested by CIE with rat liver cytosol as source of antigen. Anti-thyroid peroxidase and anti-thyroglobulin antibodies were tested by a commercially available RIA. *Results:* non organ-specific autoantibodies were detected in 9 out of 31 patients (29%). Four had low titre SMA antibodies (13%) with non-actin specificity, 1 had ANA (3%) (speckled pattern), 4 had anti-LKM1 antibodies (13%) (all positive for 50 kD peptide in immunoblotting) and none of the 21 tested had anti-thyroid antibodies. No clinical and biochemical differences were present between autoantibodies positive and negative patients. No specific association was found between HCV genotypes and a particular autoantibody. Four out of the 12 patients who underwent interferon therapy developed low titre autoantibodies (3 SMA, 1 ANA) under treatment. *Conclusions:* these results demonstrate that the overall prevalence of non organ specific autoantibodies associated with HCV-related chronic hepatitis in children is similar to that observed in adults. The autoantibodies specificities typical of autoimmune hepatitis were never observed in these patients. However differently from what observed in adults anti-LKM1 reactivity was more frequently observed than other autoantibodies. "P P 27 0663"P 27 0663**The Role of Dendritic Cells in the Bile Duct Destraction of Primary Biliary Cirrhosis**

*T. Tamai, T. Shiro, T. Nakagawa, M. Wakabayashi, M. Imamura, T. Itou, A. Nishimura, T. Seki, K. Inoue, A. Okamura[1]

The third Dept. of Int. Medicine, Kansai Medical University, Moriguchi, Osaka 570, Japan

[1] The Dept. of Clinical Pathology, Kansai Medical University, Moriguchi, Osaka 570, Japan*Aim:*Primary biliary cirrhosis (PBC) is an immune-mediated liver disease. Histopathologically, chronic non-suppurative destructive cholangitis (CNSDC) involving small intrahepatic bile ducts is the fundamental lesion in PBC. In this study, we investigated whether interdigitating cells (IDCs) or follicular dendritic cells (FDCs) could act as antigen presenting cells to induce CNSDC in PBC.*Materials and Methods:*The frozen tissues obtained from fifty cases of clinicopathologically confirmed PBC, by needle liver biopsy. Earch sections were immunostained using a modification of the avitin-viotin-preroxidase complex method. To recognize dendritic cells was used both of the monoclonal antibodies, against FDCs (Dako) and IDCs (Serotec Ltd.).*Results:*In this study, FDCs were not found in the portal areas with and without lymphoid follicles in PBC. In contrast, IDCs infiltrated around the damaged bile ducts characterized by CNSDC within the portal areas. And IDCs within the portal areas were observed most frequently in the sections showing an earlier stage of the disease. Further some of these IDCs were observed to be in direct contact with the biliary epithelial cells. On the other hand, many of inflammatory cells infiltrated within the portal area were T lymphocytes, and the average number of CD4-positive and CD8-positive T cell subsets was almost even. Furthermore, CD8-positive T cells were found inside the basement membrane between biliary epithelial cells of damaged bile ducts.*Conclusion:*These results suggested that IDCs infiltrated around the bile ducts were considered to played an important role in a immune process induced CNSDC, at the initial stage of PBC. "P P 27 0664"P 27 0664**Peroxide Oxidation of Lipids and Prostanoids in Pathogenesis of Functional Disorder of Biliary System in Children and AdolescentsL.K. Parkhomento,**

*L.A. Strashok

Department of Therapy of Adolescents Kharkov Post Graduate Medical Studies Institute, UkraineAt present the study of endogenic biologically active substances — prostanoids and their corralation with the starting mechanism of most pathological processes — by means of free radical oxidation of lipids is one of prospective directions of basic research in medicine. The goal of our research was the study of prostacyclin and thromboxan, general TBA active products of peroxide oxidation of lipids in children and adolescents with prime dyskinesia of biliary system. We have investigated 15 boys and 15 girls (10–18 years old). All the patients underwent thorough anamnestic, physical, endoscopic, ultrasonic, radioisotope, biochemical research with the aim of exclution of accompanying organic pathology of digestive system. Prostanoids were under study with help of standart radioimmunologic sets of Hungarian Academy of Science Products of free radical oxidation in erythrocytes and plasma were defined with help of thiobarbituric acid test. All the patients regardless of sex had hightened contents of products of peroxide oxidation of lipids: in erythrocytes (14.94 – 1.81 nmol/mg of albumin, $p < 0.01$), in plasma (6.73 – 1.08 nmol/mgof albumin, $p < 0.01$) that testifies to the fact that penetrability of cytomembranes has increased. In boys changes in prostanoid system didn't reach statistically significant quantities. In girls there was revealed decrease of contents of prostacyclin (34.73 – 2.72 pg/ml, $p < 0.01$) and increase of thromboxan level (243.76 – 76.28 pg/ml, $p < 0.01$). There is an intimate relationship between the state of prostacyclin–thromboxan system and intensity of free radical oxidation of lipids that coincides with the data obtained. More clear-cut changes of prostanoids in girls are possibly piculiarity of proceeding of biliary pathology in adolescents and probably they are responsible for more frequent and clear-cut manifestation of biliary disorder exactly in females. Spectrum of changes of peroxide oxidation of lipids and prostanoids during biliary dyskinesia coincides with the one during atherosclerosis, hypertonicity and gallstones disease that probably reflects general biological reaction to a stress. Our results point to expediency of application of antioxidants and membrane stabilizers for functional disorder in biliary system, too. Liver and bile ducts, 2: Gallstones, formation, treatment }" "Peroxide Oxidation of Lipids and Prostanoids in Pathogenesis of Functional Disorder of Biliary System in Children and Adolescents"

"P P 27 0665"P 27 0665**Immunological Status of Children with Chronic Hepatitis C**

*T. Wozniakowska-Gesicka, D. Dworniak, J. Kups, M. Wisniewska, L. Bak-Romaniszyn, K. Zeman, I. Planeta-Malecka

Department of Pediatrics Polish Mother's Memorial Hospital, L\'f3dz, Poland

Department of Infectious Diseases and Gastroenterology Military Medical University, L\'f3dz, PolandHCV infection evokes a number of cellular and humoral immunological phenomena. Their effectiveness decides on the virus elimination and protects from chronic forms of HCV.The purpose of the study was the evaluation of immunological system in children with chronic hepatitis C.*Methods:* Investigations were performed in 20 children (8 girls, 12 boys) aged 3–6 years (mean 5.5 years) with anti-HCV antibodies and HCV-RNA in blood serum. ALT activity, total bilirubin level, leucoaggregation test, total complement activity (CH50) and C3, C4 components, T-lymphocytes subsets: CD3, CD4, CD8, CD19, CD4/CD8 ratio, NK cells (CD16), were estimated, moreover, IL-1, IL-2, IL-4 and TNF- alpha levels were determined.*Results:* ALT activity was increased significantly (185 – 96.65). Leucoggregation test value was decreased statistically insignificantly (2.02 – 0.67%). Total complement activity was statistically significantly decreased (37.63 – 10.14) and so were C3 component (60.11 – 12.55) and lymphocytes subsets: CD3 (60.0 – 6.25) and CD4 (34.25 – 6.78).Percentage of CD8 lymphocytes, NK cells and CD4/CD8 ratio were statistically significantly decreased. Mean IL-1 values showed significant increase (4.48 – 4.17 pg/ml). In 15 from 20 children concentration of IL-2 were below detectability threshold and in 5 from 20 of them TNF-alpha level was increased.*Conclusions:* The study results point to a potential engagement of the immunological system into processes to chronic hepatitis C. The observed changes may speak for immunological mechanisms defect. "P P 27 0666"P 27 0666**Cholelithiasis in Children: Clinical Analysis and Results of Bile Acids TherapyF. Iwanczak,**

*A. Stawarski, B. Iwanczak

II Clinics of Pediatrics and Gastroenterology, Medical University, Wroclaw, PolandThe purpose of our study was clinical analysis of 24 children aged from 10 months to 16 years with gallbladder stones and 3 children aged 3, 5–12 years with choledochal stones. Next we analysed results of bile acids therapy in 15 children treated with ursodeoxycholic and/or chenodeoxycholic acids.In all children health and family history were collected, physical examination, biochemical tests (aminotransferase and alkaline phosphatase activity, cholesterol and bilirubin concentration in blood serum), ultrasonography and postprandial gallbladder emptying were done. Children with mild clinical symptoms, with cholesterol radiolucent stones no bigger than 20 mm in diameter, with normal anatomy and motility of the gallbladder and without inborn errors of the lipid metabolism were qualified to the therapy. Bile acids were administered in a daily dose of 10–15 mg/kg body weight twice a day or just once in the evening. The therapy lasted from 2 to 12 months. During therapy children were controlled every other month.In 20% of patients no symptoms were observed in the course of the disease. The following symptoms were observed for the remaining group of patients: abdominal pain (85%), nausea (78%), vomiting (64%), meteorism and constipation (50%). The symptoms of the disease were observed for a period from 1 month to 8 years. After bile acids therapy in 6 children gallbladder stones dissolved, in 7 patients stones did not dissolve. However, complete or partial recovery of clinical symptoms was observed and higher values for the activity of aminotransferase and the concentration of serum bilirubin were back to normal. Bile acids were well tolerated.Our own experience confirms good therapeutic effects of bile acids in children with gallstones. Therapeutic results depend on the appropriate selection of patients. Liver and bile ducts, 2: Gallstones, formation, treatment }" "Cholelithiasis in Children: Clinical Analysis and Results of Bile Acids Therapy"

"P P 27 0667"P 27 0667**Long-Term Follow-Up of Low Dose Versus High Dose Ursodeoxycholic Acid (UDCA) in Cholestasis Related to Cystic Fibrosis (CF)**

*P.C. Van de Meeberg, G.P. VanBerge Henegouwen, Dutch CF-UDCA trial group

Department of Gastroenterology, University Hospital Utrecht, The NetherlandsUDCA improves liver biochemistry in CF related cholestasis. Since bile salt malabsorption may complicate the disease, high dose UDCA has been recommended. We studied the long-term biochemical response during low dose and high dose UDCA. CF patients with cholestasis (GGT > 150% normal), aged > 5 yrs were randomized for low dose (10 mg/kg/day, n = 16, 18.3 – 2.0 yrs, M/F = 11/5) or high dose (20 mg/kg/day, n = 15, 18.5 – 2.7 yrs, M/F = 11/4) UDCA. In both groups 1 patient was classified as child B, all others as Child A. Improvement of biochemical parameters was evaluated after 3 (n = 31) and 12 months (n = 21: 12 low dose, 9 high dose). Liver enzymes were comparable between groups at base-line, whereas the majority of patients had a normal bilirubin level. In both groups, 1 patient dropped out because of severe pruritus. One patient (low dose) died from liver failure, 7 patients have not yet completed 12 months follow-up. *Results:*Decrease from base-line (mean – SEM) 3 months 12 months 10 mg/kg 20 mg/kg 10 mg/kg 20 mg/kgAPh* 38.6 – 9.7 42.9 – 7.0 39.1 – 8.4 44.5 – 8.7GGT 50.3 – 5.0 68.4 – 4.1[\'86] 54.7 – 4.5 69.8 – 6.8[\'86]AST 25.5 – 5.8 33.8 – 6.5 35.5 – 8.3 36.1 – 7.5ALT 41.1 – 7.1 46.2 – 9.0 48.1 – 6.2 45.7 – 17.7*APh: only patients older than 18 yrs included. [\'86]p < 0.02 (high dose vs low dose, Mann-Whitney-U test).*Conclusion:* During long-term treatment liver enzymes improve slightly better with high dose UDCA in CF-related cholestasis. Liver and bile ducts, 2: Bile formation, cholestasisLiver and bile ducts, 1: Liver diseases, children }" "Long-Term Follow-Up of Low Dose Versus High Dose Ursodeoxycholic Acid (UDCA) in Cholestasis Related to Cystic Fibrosis (CF)"

"P P 27 0668"P 27 0668**Polyunsaturated Fatty Acid Status of Cholestatic Infants in a Longitudinal Study**

*P. Socha, B. Koletzko, J. Pawlowska, E. Swiatkowska, A. Stolarczyk, J. Socha

Child Health Centre, Warsaw, Poland

Kinderpoliklinik, L-M University, Munich, GermanyNo information is available on the development of polyunsaturated fatty acid (PUFA) status in children with cholestasis with increasing age. Therefore, we performed a long term follow up study in 28 infants (initial age 2.15 – 0.98 months, mean – SD) with cholestasis (12 extrahepatic and 16 intrahepatic). We determined fatty acid composition of plasma phospholipids [% wt/wt] at baseline and then twice at random time intervals (about 1.7 mon.): at the age of 3.8 – 1.8 mon. in all infants and at the age of 5.6 – 1.5 mon. in a subgroup of 14 patients. The total bilirubin levels decreased during the course of the disease: from 10.6 – 4.4 to 6.1 – 4.8 at the 1st control ($P < 0.001$) and to 5.3 – 5.4 at the 2nd control ($P < 0.05$). Compared to the fatty acid profile of 12 age matched controls, low levels of PUFA were detected in cholestatic patients already at the beginning of the study (29.2 vs. 37.2 in controls, $P < 0.001$). Changes of linoleic acid (LA, 18: 2{ w}-6),), { a}-linoleic acid (ALA, 18: 3{ w}-3), ratios arachidonic acid (AA, 20: 4{ w}-6)/LA and docosahexaenoic acid (DHA, 22: 6{ w}-3)/ALA during the study are shown in the table (values expressed as means): Baseline Mean age 3.8 Baseline Mean age 5.6 (N = 28) mon. (N = 28) (N = 14) mon. (N = 14)LA 14.6 16.9, $P < 0.05$. 13.2 17.2, $P < 0.05$ALA 0.11 0.17, $P < 0.01$ 0.12 0.23, $P < 0.05$AA/LA 0.6 0.5, n.s. 0.61 0.40, $P < 0.05$DHA/ALA 22.9 11.6, $P < 0.01$ 18.0 9.6, $P < 0.05$AA, DHA and PUFA content did not change significantly during the study. *Conclusions:* 1. Cholestatic infants have a high risk of essential fatty acid deficiency. 2. ALA and LA levels increase during the course of the disease which can be explained by therapeutic intervention with improved bile flow and reduced bilirubin levels. 3. Hepatic conversion of LA and ALA to AA and DHA, respectively, seems to be increasingly impaired with progressive liver dysfunction. Liver and bile ducts, 1: Liver diseases, childrenNutrition: Nutrition: childrenLiver and bile ducts, 2: Bile formation, cholestasis }" "Polyunsaturated Fatty Acid Status of Cholestatic Infants in a Longitudinal Study"

"P P 27 0669"P 27 0669**High Infection Rate with Hepatitis E Virus among Young Children****Rakesh Aggarwal, Hansa Shahi, Sita Naik, S.K. Yachha,**

*S.R. Naik

Departments of Gastroenterology and Immunology, Sanjay Gandhi Postgraduate Institute of Medical Sciences, Lucknow 226 014, India*Objective:* Hepatitis E virus (HEV) infection is common in India. However the frequency of HEV infection among healthy adults and children in different age groups is not known. Such information is necessary to better understand the epidemiology of HEV infection in endemic areas.*Methods:* Sera from 20 healthy adults and 75 children in different age groups were tested for IgG anti-HEV antibodies using an enzyme immunoassay (Abbott Laboratories).*Results:* Age (yr) n Anti-HEV +ve Anti-HEV { -}ve % +ve0–5 28 18 10 64%6–10 22 13 9 59%11–18 25 16 9 64%Adults 20 10 10 50%*Conclusions:* Our data show that IgG anti-HEV antibodies were present in 64% of children in the 0–5 year age group and that their prevalence did not increase with age even upto adulthood. These prevalence rates are higher than those in other geographic areas. No such data have been reported from other endemic areas. Thus our data suggest that in endemic areas, HEV infection is common in children and occurs quite early in life. Occurrence of large epidemics despite frequent exposure in childhood may suggest that infection in early childhood may not provide lifelong immunity as occurs with hepatitis A. Clinical practice: Epidemiology (non cancer)Liver and bile ducts, 1: Hepatitis viral, diagnosisLiver and bile ducts, 1: Liver diseases, children }" "High Infection Rate with Hepatitis E Virus among Young Children"

"P P 27 0670"P 27 0670**Serum Insulin-Like Growth Factor II in Children with Chronic Liver DiseasesA. Abdalla, F. El-Shennawy, A. Shaltout, H. Shafeik**

Paediatric Gasteroenterology Unit and Clinical Pathology Department, Mansoura University, Mansoura, Egypt*Aims:* our aims were to assess the serum levels of insulin-like growth factor II (IGF-11) in children with chronic liver diseases and to find if there is any correlation between such levels and clinical, laboratory and pathological parameters.*Methods:* 28 patients and 15 controls were the material of this study. Patients were classified histopathologically into: group I (15 cases with liver cirrhosis) and group 11 (13 cases with chronic active hepatitis, CAH). Serum IGF-11 was measured in all patients and controls using immunoradiometric assay.*Results:* Serum levels of IG-II was found to be significantly decreased in children with chronic liver diseases compared to controls (group I Vs control, $P < 0.05$ and group II Vs control $P < 0.05$). However, no significant difference was found between cirrhotic and CAH cases ($P > 0.05$). No significant correlation was found between serum levels of IGF II and clinical, laboratory or pathological features of children with chronic liver diseases. Cirrhotics and CAH cases could be correctly classified (100%), according to discriminating functional analysis utilising some of the clinical and laboratory variables assessed.*Conclusions:* serum IGF-II levels was found to be decreased significantly in children with chronic liver diseases. However, no significant correlation was found between serum IGF-II levels and clinical, laboratory or pathological feature of those children. "P P 28 0679"P 28 0679**Study of the Role of Direct Intra-Variceal Pressure Measurement in Prediction of Variceal BleedingS. Sheir Baddar,**

*M. Osman, S. Shalaby, T. Zaki

Internal Medicine Department, Ain Shams University, Cairo, EgyptThis study included fifty patients with portal hypertension and oesophageal varices, proved by clinical examination, ultrasonography, and laboratory investigations. There were 28 patients with history of upper gastrointestinal bleeding (bleeders) and 22 patients non-bleeders. According to Child's classification, there were 22 patients of Child A, 11 patients of Child B and 17 patients of Child C. Intra-oesophageal variceal pressure (IOVP) was measured for all patients and it was found to be significantly higher in bleeders than non-bleeders and IOVP >/18 mmHg was found to be ""risk value"" for predicting variceal bleeding. IOVP was found to be significantly higher in patients with large varices (3rd-degree) than those patients with 2nd-degree varices and in 80.7% in those with 3rd- degree varices. IOVP was found to be significantly higher in patients with endoscopic red color sign and in Child C than Child B and A. Serum bilirubin was significantly higher in bleeders than non-bleeders and there was significant correlation between serum bilirubin and IOVP. Serum albumin, prothrombin time, platelet count and ascites were not significantly correlated to IOVP or variceal bleeding. The congestion index of the portal vein (measured by Color Doppler) was significantly correlated with IOVP. We concluded that IOVP is considered a very reliable and accurate parameter in predicting variceal bleeding in portal hypertensive patients. }" "Study of the Role of Direct Intra-Variceal Pressure Measurement in Prediction of Variceal Bleeding"

"P P 28 0681"P 28 0681**Hemodinamic Changes in Intrahepatic Portal Vessels after Percutaneous Ethanol Injection of Hepatocellular Carcinoma under General Anesthesia**

*L. Tarantino, A. Giorgio, G. de Stefano, A. Perrotta, V. Aloisio, F. Esposito

US Department, D. Cotugno Hospital, Naples, Italy*Background:* Thrombosis of intrahepatic portal vessels (IPV) and ischemic necrosis of liver parenchima after Percutaneous ethanol injection (PEI) of Hepatocellular Carcinoma (HCC) have been reported. We evaluated intrahepatic hemodinamic changes in HCC patients treated with PEI.*Patients and methods:* From January to april 1996, 35 patients (21 male; age 49–80) with 62 HCC nodules underwent 42 sessions of PEI under general anesthesia (u.g.a). Amount of ethanol injected per session ranged 7–55 ml (mean: 29 ml). A baseline echo-color-doppler the day before treatment and a control examination within 6–10 days after the treatment were performed on all fasting patients and in supine position. Patency and blood flow direction were evaluated in main, right and left portal vein, in segmental portal vessels and in hepatic veins.*Results: Baseline echo-doppler examination* showed: absence of thrombosis in all patients; hepatopetal flow in IPV in 33/35 patients; reverse flow in the segmental portal branch related to the segment were the tumor were located (VII and VI respectively) in 2/35 (5.7%) patients; patency of paraumbilical vein with hepatofugal flow in 3/35 (8.5%) patients; continuous flow in hepatic veins in 28/35 (80%) patients and triphasic flow pattern in 7.The *post-treatment echo-color-doppler* showed: partial non neoplastic thrombosis (proved by fine needle biopsy) of right portal vein in one patient; reverse flow in the segmental portal branch related to the segment were the treated tumor were located in 5/35 (14.3%; 3 more than before PEI treatment) in one case there were clear evidence of periferic artero-portal shunt at echo-color-doppler. In another patient (who received 40 ml ethanol and had already been treated with 70 ml ethanol 35 days before) echo-color doppler showed reverse flow in right portal vein, in all portal vessels of the right lobe and in segmental portal vessels of the left lobe together with hepatopetal flow in main portal vein and in left portal vein which drained in a large patent paraumbilical vein with hepatofugal flow; this last patients started showing a severe liver failure 5–10 days after the treatment and died one month later.In the other patients echo-color-doppler dit not show any change in hepatic vein flow and in portal vessels.*Conclusions:* PEI of HCC can cause reverse flow in intrahepatic portal vessels probably due to diffuse thrombosis of the thin intralobular vessels or periferic portal vessels. Moreover, already pre-existing peritumoral and/or intrahepatic (cirrhosis-related) artero-portal shunts can play a role. "P P 28 0682"P 28 0682**Changes of Portal Hemodynamics in Patients with Liver Cirrhosis**

*T. Nakajima, H. Yoshioka, K. Ohnishi, K. Fujiwara, M. Nakajima[1]

The Third Department of Internal Medicine, Saitama Medical School, Moroyama, Japan

[1] Department of Clinical Laboratory, Saitama Medical School, Moroyama, JapanWe evaluated at regular interval changes in portal hemodynamics by Doppler's methods in patients with liver cirrhosis.The subjects consisted of 45 patients with liver cirrhosis in whom portal blood flow was could by Doppler's methods for 5 years. None of them had bleeding of esophageal varices, operation of the abdomen and treatment of portal hypertension. Blood flow was measured in the main portal vein (MPV), left branch (LPV) and right branch (RPV) at 12-month intervals. At each site, mean velocity, cross section area (CSA) and flow volume were measured.The CSA in the MPV was 1.03 – 0.32 cm^2 at the beginning of observation but significantly increased to 1.11 – 0.30 after 2 years ($p < 0.05$). The velocity in the MPV was 15.8 – 4.4 cm/sec at the beginning but significantly decreased to 14.9 – 4.4 after 1 year ($p < 0.05$). The flow volume in the MPV was 931 – 265 ml/min at the beginning but significantly decreased to 899 – 187 after 1 year ($p < 0.05$) with significantly changes in the subsequent year ($p < 0.01$). Similar findings were obtained at the other sites in terms of CSA, velocity and flow volume.The patients with liver cirrhosis showed an increase in the CSA, a decrease in the velocity and a decrease in the flow volume of portal system with the course. Liver and bile ducts, 1: Cirrhosis: portal hypertensionRadiology and ultrasound: Diagnosis }" "Changes of Portal Hemodynamics in Patients with Liver Cirrhosis"

"P P 28 0683"P 28 0683**The Impact of Spironolactone on Portal Vein Pressure and Portal-Systemic Shunt in Cirrhotic Dogs Induced by Common Bile Duct Ligation**

*J.Y. Wang, X.F. Lin, F.Z. Chen, X.F. Chen

Shanghai Medical University, Shanghai, China*Aim:* The impact of spironolactone on portal vein pressure and portal-systemic shunting were assessed in cirrhotic dogs induced by common bile duct ligation in order to investigate the effects of this drug on reducing portal hypertension and its mechanism.*Material and Methods:* 20 dogs were studied. Eight weeks after common bile duct ligation, blood sample was collected for testing plasma renin activity (PRA), plasma concentration of aldosterone, and AT-II. A cannula was inserted through mensenteric vein into portal vein to measure portal vein pressure. After injection of Indocyanine green (ICG) (0.6–0.8 mg/kg) into femoral vein, blood sample was collected in 5, 8, 11, 14, 17 sec. from femoral artery and hepatic vein to measure the ICG concentration and calculate extraction rate (ER), intrinsic clearance estimated hepatic blood flow (EHBF) and plasma volume (PV). Heart to Liver ratio (H/L) was tested by using 99mTc-MIBI per rectum to estimate the degree of portal-systemic shunt. After administration of spironolactone for 4 weeks (2 mg/kg/day), the above studies were repeatedly performed.*Results:* After eight weeks ligation, cirrhosis developed and confirmed pathologically. The portal vein pressure was 0.1368 – 0.37, 2.587 – 0.51 and 2.42 – 0.47 Kpa respectively before ligation, 8 weeks after ligation and 4 weeks after given spironolactone. H/L was decreased from 0.33 – 0.06 to 0.30 – 0.08, while the liver experienced a progressively pathological change. There was a significant reduction in plasma volume (from 569 ml to 549 ml), but no remarkable change in EHBF. The PRA and aldosterone level elevated.*Conclusion:* The results suggest that chronic administration of spironolactone could reduce portal vein pressure, relief portal-systemic shunt. It is effective in treating portal hypertension. Liver and bile ducts, 1: Cirrhosis: portal hypertension }" "The Impact of Spironolactone on Portal Vein Pressure and Portal-Systemic Shunt in Cirrhotic Dogs Induced by Common Bile Duct Ligation"

"P P 28 0684"P 28 0684**Reverse Flow in Intrahepatic Portal Vessels and Liver Function Impairment in Cirrhosis**

*L. Tarantino, A. Giorgio, G. de Stefano, N. Mariniello, A. Perrotta, V. Aloisio, F. Esposito

US Department, D. Cotugno Hospital, Naples, ItalyPrevalence of Reverse Flow (RF) in extrahepatic portal vessels has been reported in 8.3% of cirrhotic patients and a significative correlation has been found with Child class. Few report has been published about RF in intrahepatic portal vessels (IPV). We evaluated the prevalence of RF in IPV patients with different chronic liver diseases and its correlation with Child class and short term survival.*Patients and methods:* 45 patients with chronic active hepatitis (ECA) (17–56 years; 30 males) and 134 cirrhotic patients (26–72 years; 109 males) underwent Echo-Color-Doppler for evaluation of flow direction in segmental IPV, right and left portal vein (RPV, LPV) portal vein (PV), splenic vein (SV), superior Mesenteric Vein (SMV) and porto-sistemic shunts (paraumbilical, spleno-renal, left gastric vein). Patients with hepatocellular carcinoma and complete thrombosis of portal vein were excluded. All patients were followed-up for 3–8 months.*Results:* ECA: epatopetal flow in all portal vessels without portosistemic shunts in 44/45 patients. 1/45 (2.3%) showed RF in the SV with spontaneous spleno-renal anstomosis. Cirrhosis: 1) 111/134 (82.8%) cases (32 Child A, 59 Child B, 20 Child C) showed hepatopetal flow in all portal vessels. 9/111 (8.1%) showed a patent paraumbilical vein with hepatofugal flow. 2) 9/134 (6.7%) patients (2 Child A, 6 Child B, 1 Child C) showed RF only in the SV together with splenorenal anastomosis. 3) 2/134 patients (1 Child B, 1 Child C) showed alternating (""back and forth"") flow only in IPV, RPV and LPV with continuous hepatopetal flow in PV. 4) 9/134 (6.7%) showed RF in IPV (3 Child B, 4 Child C): in 4 cases RF was limited to LPV and related segmental portal vessels or to 1–2 segmental portal vessels together with hepatopetal flow in PV; the other 5 patients showed RF in all IPV and in main PV associated with hepatofugal flow through a large left gastric vein and large esophageal varices in 2 cases and through the splenic vein with splenorenal anastomosis in 3 cases. In no case RF in SMV were observed.3/9 (33%) patients died for liver failure in group 4 (all Child C) and 1/111 0.9%) patient died for rupture of esophageal varices in group 1 within 2, 4, 4 and 4 months respectively ($p < 0.001$).Prevalence of RF in 1 or more portal vessels in Child C patients (8/29: 27.5%) were significantly higher than in Child B patients (9/67: 13.5%) and in Child A patients (2/34: 6%) ($p < 0.02$). Prevalence of RF only in IPV was significantly different between Child B patients (4/61: 6.5%) and Child C patients (7/28: 25%) ($p < 0.05$).*Conclusions:* RF in IPV is a late event in cirrhosis whith advanced liver function impairment and often indicates a poor prognosis. RF only in extrahepatic portal vessels can be observed in well compensated cirrhotic patients and also in non cirrhotic patients. "P P 28 0685"P 28 0685**""Congestion Index"" of the Portal Vein Determined in Patients with Different Stages of Chronic Liver Disease**

*M. Trajkovska, V. Serafimoski, M. Neshkovski, M. Miloshevski, D. Trajanovski, D. Orovchanec, V. Chalovska

Clinic of Gastroenterohepatology, Medical Faculty, Skopje, Republic of MacedoniaTo evaluate the portal blood flow in different stages of chronic liver disease, we used the ""congestion index"" – CI. Congestion index is used to determine the ratio between the cross-sectional area (cm^2) and the blood flow velocity (cm/sec) of the portal vein, detected by Duplex-Doppler system. We studied a portal blood flow of 34 pts with liver cirrhosis (LC), 11 pts with chronic active hepatitis (CAH), 7 pts with chronic persistent hepatitis (CPH) and in 21 healthy normal volunteers (HV). The cross sectional area (CSA) of the portal vein in pts was as follows: LC 1.09 – 0.40, CAH 1.03 – 0.44, CPH 0.98 – 0.42 and in HV 0.71 – 0.19. There was a statistically significant difference between the CSA of the control group, and the CSA of the pts with LC ($p < 0.005$) and pts with CAH ($p < 0.005$). Mean blood flow velocity was as follows: 10.67 – 3.17 in pts with LC, 11.88 – 4.44 in pts with CAH, 13.9 – 3.51 in pts with CPH and 21.26 – 5.12 in HV. There was a statistically significant difference between the mean blood flow velocity of the control group and the pts with LC ($p < 0.005$), pts with CAH ($p < 0.005$) and pts with CPH ($p < 0.005$). The CI was as follows: 0.132 – 0.145 cm {\'b4} sec in pts with LC, 0.104 – 0.075 cm {\'b4} sec in pts with CAH, 0.073 – 0.031 cm {\'b4} sec in pts with CPH and 0.030 – 0.01 cm {\'b4} sec in HV. There was a statistically significant difference between the CI from the normal subjects and the indices obtained from patients with CPH, CAH and LC. Our results showed that the ""congestion index"" is very sensitive in detecting the changes of the portal blood flow in terms of pathophysiological haemodynamics in pts with different stages of chronic liver disease. "P P 28 0686"P 28 0686**Monitoring of Hepatic Hemodynamics by Pulsed Doppler in Hepatic-Portoentero-Stomied Children for Biliary Atresia****M. Sugai, R. Hada, M. Endoh, H. Kobori, D. Seito, Y. Toyoki, M. Konn**

Department of Surgery, Hirosaki University School of Medicine, Hirosaki, Japan*Aim:* To examine the hepatic hemodynamics in hepatic-portoenterostomied biliary atresia (BA) patients to predict the prognosis.*Methods:* The patients consisted of 5 boys and 5 girls who had undergone either Kasai original or Suruga-II hepatic portoenterostomy at the age of 36 to 81 day. Age- and gender-matched children without hepatobiliary diseases were served as normal controls. At a fasted condition, flow velocity and Doppler wave form in the right hepatic vein, portal venous trunk and splenic vein were determined with a duplex Doppler equipment (TOSHIBA-270A) with a 3.75 MHz transducer (convex or sector).*Results:* Wave forms were classified according to follows: *type 1,* pulsatile flow with reversed phase; *type 2,* pulsatile flow without reversed phase; and *type 3,* continuous flow with/without fluttering. The mean portal venous flow velocity was 16.6 – 3.7 for the patients versus 19.4 – 4.4 cm/s for the controls. The portal venous flow was hepatofugal with *type 3* wave form in all patients, while it was hepatofugal but with *type 1* wave form in the controls. The mean hepatic venous flow velocity was 17.7 – 2.9 for the patients versus 22.7 – 6.7 cm/s for the controls ($p < 0.01$). The hepatic venous flow was hepatofugal in all patients and the wave forms recorded were *type 3* for 4 patients (2/4 with a minimal fluttering) and *type 1* or 2 for 6 patients. Of the 4 patients with *type 3* hepatic venous wave form, 2 had portal hypertension featured with hepatomegaly, splenomegaly and hypersplenism. The splenic venous flow velocity determined in 4 patients, in whom the vein was dilated to more than 10 mm in diameter, ranged form 12 to 13 cm/s.*Discussion and Conclusion:* Flow velocity in the portal or right hepatic vein slightly decreased in the postoperative patients with BA. The direction of flow was hepatofugal in both veins. Wave form of right hepatic venous flow may be of a clinical importance in estimating the hepatic parenchymal condition for *type 3* wave form (continuous flow pattern with a minimal fluttering) indicating decreased compliance of the vein was registered in 2 of 4 patients with portal hypertension. Duplex Doppler can be a non-invasive method to estimate hepatic hemodynamics in the follow-up of postoperative patients with BA.

"P P 28 0687"P 28 0687**Expression and Distribution of Nitric Oxide Synthase in Patients with Portal Hypertensive Gastropathy (PHG)**

*K.B. Hahm, K.J. Lee, Y.S. Moon, Y.S. Kim, H.K. Kang, J.H. Kim, S.W. Cho

Department of Gastroenterology, Ajou University School of Medicine, Suwon, KoreaNitric oxide (NO) is associated with hyperdynamic circulation and development of collaterals in portal hypertension. However, still controversies exist in the involvement of NOS in the pathogenesis of PHG The distribution and expression of NO synthase (NOS) have not been explored in detail in patients with portal hypertension. The aim of this study was to investigate whether NOS ia activated in the PHG. The subjects composed of 19 patients, admitted due to complications of PHG; hematmesis or melena, and 19 normal controls showing normal looking gastric mucosa at endoscopy (*H. pylori* ({ -})). Obtaining 4–5 pieces of mucosal biopsied tissues, cNOS and iNOS activities were measured by measuring the conversion of ^{14}C-arginine to ^{14}C-citrulline, respectively. Western blotting and immunohistochemical staining were performed using antibody, eNOS and iNOS from Affinity Bioreagent Co. (1:250, 1:500 dilutions). MPO activities were measured according to the method by Bradley. The cNOS activities were significantly elevated as compared to those of normal controls (0.98 – 0.14 vs. 0.12 – 0.02, P < 0.01). However, iNOS activities were not differed each other between PHG and normal controls. MPO activities were significantly elevated in PHG than normal controls (0.06 – 0.03 vs. 0.018 – 0.009, P < 0.001). The cNOS activities were correlated with Child classification grade and total bilirubin levels. In 80% of the PHG, strong cNOS staining was noted in the endothelium of congested, dilated lamina proprial capillaries and gastric glands, whereas positive iNOS staining was observed in only 20% of PHG. The results of immunostaining were correlated with the results of western blottings. In conclusion, NOS didn't show causative role in the development of PHG in portal hypertension. Increased cNOS activities and expressions seemed to be the consequence of shear forces of portal hyperdynamic circulation. Liver and bile ducts, 1: Cirrhosis: portal hypertension }" "Expression and Distribution of Nitric Oxide Synthase in Patients with Portal Hypertensive Gastropathy (PHG)"

"P P 28 0688"P 28 0688**Evaluation of Haemodynamic Parameters of Portal Vein as Indicators of Portal Hypertension — An Echo Doppler Study**

*O. Chira[1], R. Badea, A. Ban, A.S. Chira

[1] Inst of Hyg&Public Hlth, Hlth Serv and Management, 3rd Medical Clinic, Cluj, RomaniaOver the past few years special attention has been paid to the haemodynamic parameters of the portal vein in the assessment of portal hypertension. The aim of this study was to evaluate the maximum velocity in the portal vein and the congestion index of the portal vein, recorded by duplex-doppler ultrasonogaphy, in patients with various degrees of liver fibrosis.In 75 patients with liver disease who underwent liver biopsy, the cross sectional area, mean and maximum velocity in the portal vein were recorded with Toshiba Sal 140. The congestion index of the portal vein was calculated (CI = cross sectional area/mean velocity). Based on a semiquantitative evaluation of hepatic fibrosis according to Knodell's scoring system, we divided the patients into two groups: one with mild fibrosis (grade 1) and another with severe fibrosis (grade 3–4). We compared the above mentioned haemodynamic parameters in these two groups.The patients with extensive fibrosis: grade 4 (cirrhosis) had the maximum velocity in the portal vein which was significantly lower than patients with mild fibrosis (16.7 – 3.5 cm/s vs 25.7 – 7 cm/s; p = 0.001) and the congestion index of the portal vein was significantly higher (0.08 – 0.02 cm {\'b4} s vs 0.03 – 0.01 cm {\'b4} s; p = 0.001). When we compared patients with grade 1 fibrosis to those with grade 3 (bridging fibrosis) the difference remained statistically significant: 25.7 – 7 cm/s vs 18.6 – 3.7 cm/s; p = 0.001 for maximum velocity and 0.03 – 0.01 cm {\'b4} s vs 0.06 – 0.02 cm {\'b4} s; p = 0.001 for congestion index of the portal vein.We think that this haemodynamic parameters of portal vein could be good predictors for extensive fibrosis. Liver and bile ducts, 1: Cirrhosis: portal hypertensionRadiology and ultrasound: Diagnosis }" "Evaluation of Haemodynamic Parameters of Portal Vein as Indicators of Portal Hypertension / An Echo Doppler Study"

"P P 28 0690"P 28 0690**Postprandial Portal and Splenic Flow is Related to the Severity of Portal Hypertension in Chronic Liver Disease**

*D. Ludwig, C.M. Korbel, B. Schiefer, K. Schwarting, E.F. Stange

Dept. of Medicine I, University of L\'fcbeck, GermanyThe purpose of this study was to determine if the combined analysis of portal and splenic flow in the postprandial state is related to the severity of portal hypertension in cirrhotic patients.In 113 patients with chronic liver disease portal and splenic flow were measured by Dopplersonography. Flow and cross-sectional area were assessed before and 30 minutes after a standardized liquid meal (Fresubin 5 ml/kgbw). Measurements were compared to parameters reflecting the severity of liver disease (Child-Pugh-Score) and portal hypertension (esophageal varices (EV), stigmata of bleeding (BS), portal hypertensive gastropathy (PHG)). Healthy volunteers (n = 12) and patients without liver disease (n = 8) served as controls.Baseline portal (BPF) and splenic (BSF) flow were equal in the control group (BPF 13.8 – 4.2 cm/s, BSF 13.8 – 3.4 m/s). The postprandial increase of portal flow (PIPF) exceeded the increase of splenic flow (PISF) significantly (PIPF 1.65 – 0.29, PISF 1.15 – 0.2; $p < 0.05$). BPF was lower in cirrhotic patients but not significantly different compared to the control group. In most patients with esophageal varices (82.5% with I–II, 100% with III) BSF exceeded BPF whereas in 90% of controls BSF was lower than BPF. PIPF was inversely related to the severity of liver disease (Child's score, $p < 0.002$) and portal hypertension (esophageal varices, $p < 0.02$; bleeding vs. non-bleeding, $p < 0.0005$; PHG, $p < 0.002$). In contrast to the controls, postprandial splenic flow decreased in most cirrhotic patients. The maximal reduction of splenic flow was observed in severe cirrhosis (Child C, $p < 0.005$; EV III\'b0, $p < 0.005$; severe PHG, $p < 0.001$).Patients with chronic liver disease and a splenic flow exceeding portal flow have a high prevalence (> 80%) of esophageal varices. The postprandial increase in portal flow is related negatively, the decrease in splenic flow positively to the severity of liver cirrhosis and portal hypertension. Liver and bile ducts, 1: Cirrhosis: portal hypertensionRadiology and ultrasound: Diagnosis }" "Postprandial Portal and Splenic Flow is Related to the Severity of Portal Hypertension in Chronic Liver Disease"

"P P 28 0691"P 28 0691**Hemodynamic Alterations in Decompensation of Liver Cirrhosis and Portal HypertensionK. Boulanov**

Institute of Clinical and Experimental Surgery, Kiev, UkraineAlterations in splanchnic hemodynamics play key role in the natural course of liver cirrhosis and portal hypertension. The aim of the study was to evaluate results of serial determination of hemodynamics in 90 cirrhotic patients subjected to surgical treatment. Measurements were performed using duplex system, dynamic scintigraphy, venous phase of superior arteriomesentericography and direct portomanometry and included the following parameters: splenic arterial flow (SAF), splenic venous flow (SVF), portal venous flow (PVF), hepatic arterial flow (HAF), portal congestive index (PCI), hepatoportal index (HPI), degree of portal perfusion (DPP), portal pressure (PP). Results given in the table are means. Normal Child A Child B Child CN 30 30 30 30SAF ml/min 189.5 349.8* 283.8$^{*\#}$ 232.3$^{\#}$SVF ml/min 206.2 949.0* 616.8$^{*\#}$ 595.0$^{*\#}$PVF ml/min 916.8 883.3 542.2$^{*\#}$ 459.0$^{*\#}$HAF ml/min 210.0 174.0 100.3$^{*\#}$ 69.9$^{*\#}$PCI cm.s 0.04 0.10* 0.16* 0.18$^{*\#}$HPI % 66.2 45.5 30.5* 18.5$^{*\#}$PP mmHg 8.7 32.8* 25.3$^{*\#}$ 21.4$^{*\#}$DPP 1.0 1.3 2.7$^{*\#}$ 3.2$^{*\#}$*P < 0.05 compared with normal, $^{\#}$P < 0.05 compared with group AThese results suggest, that major hemodynamic alterations responsible for decompensation of liver cirrhosis and deterioration of functional hepatic reserve are the following: change of hyperdynamic state of splenic circulation into congestive, gradual reduce of total and effective hepatic inflow and decrease of portal pressure. Liver and bile ducts, 1: Cirrhosis: portal hypertensionRadiology and ultrasound: Diagnosis }" "Hemodynamic Alterations in Decompensation of Liver Cirrhosis and Portal Hypertension"

"P P 28 0693"P 28 0693**Role of Sensory Neurons and Nitric Oxide in the Control of Hepatic Blood Flow**

*K. Czarnobilski, R. Sendur, M. Zejc-Bajsarowicz, J. Biernat, W.W. Pawlik

Inst. of Physiol., Jagiellonian Univ. Med. School, Krakow, PolandAn evidence exists that sensory nerve terminals (C-fibers) which contain different vasodilator peptides are found in the liver vasculature. In the present study the acute utilizing of neurotoxin-capsaicin (CAP) was used to explore the role of C-fibers in the maintenance of hepatic blood flow. The mediatory role of endogenous nitric oxide (NO) in the regulation of hepatic vasculature tone was also determined. Experiments were performed on rats under nembutal anesthesia. Hepatic blood flow (HBF) was registered continuously by Laser Doppler flowmeter (Periflux 4001 Master). Portal blood flow (PBF) was measured ultrasonically (Transonic System 206T). Systemic arterial pressure (AP) was measured with a strain gauge transducer. Topical application of CAP (0.5 mg) to periarterial nerves located in the hepatic porta evoked an initial vasodilation (at 8 minute HBF and PBF increased 77 – 6 and 48 – 4% respectively, while blood pressure decreased (19 – 3%). The apparent vasodilation was succeeded by vasoconstriction (at 30 min, HBF and PBF were decreased 31 – 5 and 55 – 3% respectively from control). Inhibition of NO synthase by N-nitro-L-arginine (L-NNA) (15 mg/kg i.v.) decreased HBF by 38 – 7 and PBF by 29 – 7% respectively and increased AP by 28 – 4%. Pretreatment of the animals with L-arginine (L-Arg) (100 mg/kg i.v.) was without any hemodynamic effects. However L-Arg reversed all circulatory effects of L-NNA. We conclude that acute responses to CAP of the hepatic circulation reflect release of peptide neurotransmitters (initial vasodilation) and their subsequent depletion (late vasoconstriction). These findings also suggest that primary sensory afferent nerves are physiological modulators of blood flow and vascular tone in the liver. The results presented also emphasize an important role of endogenous NO as a tonic vasodilator of hepatic vasculature.

"P P 28 0696"P 28 0696**Evaluation of Portal System by Color Doppler Ultrasonography in Patients with Liver CirrhosisVedat G\'f6ral, Fesih Araz, Arslan Bilici, Fikri Canoru\'e7**

Dicle University School of Medicine, Division of Gastroenterology, Diyarbakir, TurkeyPortal hypertension is the most important complication of liver cirrhosis. The development of portal hypertension usually becomes evident by the appearance of splenomegaly, ascites, encephalopathy, and/or esophageal varices.*Aim:* In this study, portal system was evaluated by color Doppler ultrasonography in liver cirrhosis.*Methods:* All patients were postnecrotic (HBV, HDV, HCV) cirrhosis. Portal system was evaluated by color Doppler ultrasonography (Toshiba SSA-270) in 40 cases (13 female, 27 men, mean age 42.7 years) with decompansated liver cirrhosis. 30 healthy persons were taken as control groups (9 female, 21 men, mean age 40.2 years). In both groups, diameter of portal and splenic vein, portal vein flow direction (hepatopedal or hepatofugal), portal vein thrombosis were investigated. In addition, all collateral veins were investigated in patients with liver cirrhosis.*Results:* Portal vein diameter was between 7–23 mm (mean 13.5 mm) in all cases and portal vein thrombosis couldn't find in any cases. PV flow direction was hepatopedal in 39 cases. Paraumblical vein (PUV) was established in 22 cases (55%), left gastric vein was established in 11 cases (45%). Retroperitoneal collaterals in 17 cases (40.5%), LGV in 11 cases (27.5%), renal vein collaterals in 15 cases (37.5%), peripancreatic collaterals in 1 case (2.5%), perigastric collaterals in 4 cases (10%) were established in cases with liver cirrhosis. At the 30 healthy persons, PV diameter was between 7–12.5 mm (mean 9.5 mm), splenic vein diameter was between 3–12.5 mm (mean 5.5 mm). There was a meaningful different between liver cirrhosis and healthy persons ($p < 0.001$).*Conclusion:* These results conclude that ultrasonography gives very useful informations about portal hypertension. Liver and bile ducts, 1: Cirrhosis: portal hypertensionRadiology and ultrasound: DiagnosisClinical practice: Management strategy }" "Evaluation of Portal System by Color Doppler Ultrasonography in Patients with Liver Cirrhosis"

"P P 28 0697"P 28 0697**Pulmonary Circulation Time in Patients with Chronic Liver Disease**

*M. Ohsuga, H. Homma, X.J. Zhang, T. Nagano, H. Komeichi, H. Terada, T. Sekiyama, K. Satomura, Y. Katsuta, T. Aramaki

First Dept. of Int. Med., Nippon Medical School, Tokyo, JapanThe hepatopulmonary syndrome (HPS) is an clinical entity characterized by abnormalities of arterial oxygenation in patients with chronic liver disease without cardiopulmonary disorders. The pathophysiology of this syndrome is thought to involve intrapulmonary vascular dilatation. We measured pulmonary circulation time (PCT) using contrast echocardiography and evaluated the relationship between PCT and arterial pO_2 (p_aO_2).*Patients and Methods:* 21 patients with chronic liver disease (cirrhosis n = 14, chronic hepatitis n = 7, age 27–77 yrs) were studied. PCT was measured by contrast-enhanced echocardiography using Albunex' (human serum albumin-micro air bubble complex, mean diameter 4 \'b5m). PCT was defined as the time lag of opacification between right and left atrium observed in video-records. Cardiac output (CO) was also determined by doppler echocardiography. P_aO_2 was measured insupine and sitting position.*Results:* Patients were devided into two groups; PCT < 4 sec. (S-PCT, n = 7, mean – S.D. 2.8 – 1.0 sec.) and PCT {\'b3} 4 sec. (NS-PCT, n = 14, 5.2 – 0.6 sec). P_aO_2 in supine position in S-PCT was significantly lower than in NS-PCT (83.9 – 5.6 mmHg vs 95.6 – 12.4, $p < 0.05$). In S-PCT, p_aO_2 in sitting position was significantly decreased than in supine position (77.8 – 8.0 vs 83.9 – 5.6, $p < 0.05$). No significant change in p_aO_2 was observed between two positions in NS-PCT. PCT significantly correlated with p_aO_2 in sitting position (r = 0.56, $p < 0.01$). PCT also significantly correlated with CO (r = { -}0.62, $p < 0.01$).*Conclusion:* Orthodeoxia was observed in patients with S-PCT. Thus PCT may detect potential HPS. "P P 28 0698"P 28 0698**Portal Hypertensive Colopathy — A Prospective Study**

*A.P. Oliveira, M.I. Cremers, M. Gon\'e7alves, J. Freitas

Gastroenterology Unit. Hospital of S. Bernardo, Set\'fabal, PortugalThe term Portal Hypertensive Gastroenteropathy was choosen to describe the spectrum of gastrointestinal mucosal changes associated with Portal Hypertension (PH). The aims of our study were: to detect the prevalence of Portal Hypertensive Colopathy (PHC) in patients with PH; to describe the colonoscopic and histological features and to correlate such findings with a variety of clinical, biochemical and endoscopic parameters.*Patients and methods:* thirty patients with PH and with clinical indication for colonoscopy were studied prospectively. The study included anamnesis, laboratory data, abdominal ultrasonography, upper gastrointestinal endoscopy, colonoscopy and biopsies, when possible.*Results:* nineteen of the 30 patients (63%) with PH had colonoscopic findings suggestive of PHC. Seven of these 19 patients had also varices of the rectum and/or sigma. We didn't find any correlation between the severity and extension of the lesions and Child-Pugh classification. We performed biopsies in 16 patients and in 15 dilatation and capilar congestion were found, associated with a chronic inflammatory infiltrate in 12. PHC was associated with Portal Hypertensive Gastropathy (PHG) in 13 patients, with esophageal varices in 15 and with gastric varices in 5. Thirteen patients had had upper gastrointestinal hemorrhage, but only 3 had been previously submitted to variceal sclerotherapy.*Conclusions:* PHC is found in approximately 2/3 of patients with PH and it is not always associated with PHG or with esophageal varices. This entity must be included in the differential diagnosis of lower gastrointestinal hemorrhage and ferropenic anaemia in patients with PH. The gravity and extension of lesions have no correlation with the severity of hepatic insufficiency. Liver and bile ducts, 1: Cirrhosis: portal hypertensionEndoscopy, specific: Colon, rectum }" "Portal Hypertensive Colopathy / A Prospective Study"

"P P 28 0699"P 28 0699**Plasma Interleukin-8 Levels in Patients with Post-hepatitic Cirrhosis: Relationship to Severity of Liver Disease, Portal Hypertension and Hyperdynamic Circulation**

*H.J. Liu, C.P. Li, F.Y. Lee, Y.T. Tsai, H.C. Lin, R.H. Lu, H.M. Cheng, T.F. Wang, S.S. Wang, S.D. Lee

The 807 Military General Hospital and Division of Gastroenterology, Veterans General Hospital-Taipei, Taiwan, ROC*Background/Aims:* This study investigated plasma interleukin-8 (IL-8) levels in patients with post-hepatitic cirrhosis and correlated it with the severity of liver diseases and hemodynamic parameters. *Methods:* Plasma IL-8 levels were determined by ELISA and hemodynamic studies were performed using Swan-Ganz catheterization. *Results:* Plasma IL-8 levels were significantly higher in 57 post-hepatitic cirrhotic patients (7.5 – 1.8 pg/ml, p < 0.005) than those in 41 healthy subjects (2.0 – 0.2 pg/ml). Elevated plasma IL-8 levels (plasma IL-8 level > 5 pg/ml) were found in up to 30% of the cirrhotic patients. In cirrhotic patients, the plasma IL-8 levels progressively increased in relation to the severity of liver dysfunction (Pugh's class A/B/C = 4.5 – 1.0/4.9 – 1.4/20.5 – 8.3 pg/ml, p < 0.005). A significant correlation was observed between plasma IL-8 levels and serum bilirubin levels (r = 0.72, p < 0.001). There were no differences in the hepatic venous pressure gradient (15.4 – 1.1 vs 15.1 – 0.9 mmHg, p > 0.05) and systemic vascular resistance (1119 – 118 vs 1199 – 54 dyne{\'d7}s{\'d7}cm{ -5}, p > 0.05) between cirrhotic patients with and without elevated plasma IL-8 levels. In addition, plasma IL-8 levels did not correlate with hepatic venous pressure gradient (r = 0.26, p > 0.05) and systemic vascular resistance (r = { -}0.24, p > 0.05). *Conclusions:* These results demonstrate that plasma IL-8 levels are increased in patients with post-hepatitic cirrhosis. The severity of liver cirrhosis is an important factor for the occurrence of enhanced IL-8 levels. IL-8 does not play a role in the hyperdynamic circulation observed in patients with post-hepatitic cirrhosis. Liver and bile ducts, 1: Cirrhosis: portal hypertension }" "Plasma Interleukin-8 Levels in Patients with Post-hepatitic Cirrhosis: Relationship to Severity of Liver Disease, Portal Hypertension and Hyperdynamic Circulation"

"P P 28 0700"P 28 0700**Long-Term Follow-Up of Intrahepatic Portal Flow Change in Normal Volunteers and Patients with Chronic Liver Diseases**

*Z.Y. Lin, J.H. Wang, M.L. Yu, S.N. Lu, S.C. Chen, W.L. Chuang, M.Y. Hsieh, J.F. Tsai, L.Y. Wang, W.Y. Chang

Department of Internal Medicine, Kaohsiung Medical College Hospital, Kaohsiung City, TaiwanThe summation of portal blood flow (SPBF), measured from the left umbilical portion and the right anterior branch by Doppler, was applied to investigate the long-term intrahepatic portal flow change in normal volunteers and patients with chronic liver diseases.Serial SPBF measurements were performed in 14 normal volunteers and 25 patients with chronic liver diseases. The duration of follow-up for patients and volunteers were 13.9 – 6.36 months and 17.89 – 4.51 months (mean – SD) respectively. The SPBF result obtained when both AST and ALT were within their normal limits was used as a baseline to compare with the subsequent data. Each SPBF result was compared with baseline and the coefficient of variation (CV) > 11% was defined as significant change of the SPBF.All volunteers and 20 patients showed constant or decreased SPBF results. The remaining 5 patients showed increased SPBF on serial follow-up. Among them, one with cirrhosis and one with chronic hepatitis C showed mild increase of the SPBF (CV range: 11–14%), one with chronic hepatitis B underwent seroconversion of HBeAg (+) to anti-HBe (+) showed moderate increase of the SPBF (CV = 18.65%), one with acute exacerbation of chronic hepatitis B during follow-up showed fluctuant increase of SPBF (CV range: 14.24–20.65%), and the remaining one chronic hepatitis C patient with persistent elevation of both AST and ALT for 22 months showed most remarkably progressive increase in SPBF (CV value increased from 17.47% to 49.25%).In conclusion, Doppler SPBF measurement can be applied in long-term follow-up study. Persistent inflammation of the liver may cause progressive increase of the SPBF which may be the early clue in the producing portal hypertension. "P P 29 0701"P 29 0701**The Laparoscopic Cholecystectomy Associated with Operation for Hernia or Incisional Hernia**

*J. Avram, M. Murariu, H. Abed, Al. Andea, R. Avram

First Surgical Clinic, University of Medicine and Pharmacy Timisoara, RomaniaThe association of cholelithiasis with hernia or incisional hernia poses a problem for the surgeon in evaluating whether laparoscopic cholecystectomy, a classic cholecystectomy followed by hernia or incisional hernia operation or a simultaneous operation is the preferred approach for this particular condition. The best choice is especially difficult, by the paucity of data on laparoscopic techniques in this situation.In the First Surgical Clinic Timisoara in the period 1.01.94–15.01.96 we performed 296 laparoscopic cholecystectomies (L.C.) and we found at 7 cases the association of cholelithiasis with hernia: { -}2 cases with infraumbilical incisional hernia (one of these was a giant one); { -}4 umbilical hernias, { -}1 epigastric supraumbilical hernias. The 7 patients were females, age between 31–68. We choosed the solution of simultaneous operation: L.C. and operation for hernia.Under general anesthesia we performed an incision at the niveau of the hernia, we isolated the peritoneal sack. Through a direct cutdown onto the peritoneum we controlled the presence of adherence and we prevented a visceral injury and as in a open laparoscopy we inserted laparoscopic port. A purse string suture is placed around the fascia and peritoneum in order to prevent excessive CO_2 leak. We inserted the laparoscope and the other 3 additional ports. In the case of under-umbilical hernia we reduced the peritoneal sack with separate suture In the cases of umbilical hernia we introduced the first port through the umbilical sack. At the epigastric hernia we introduced the first port through the epigastric hernia and the 2-nd port infraumbilical. We performed normally the laparoscopic cholecystectomy and we finished by repairing the abdominal wall, closing the fascial defect. In 1 incisional hernia we performed a parietal aloplastia with net.The postoperative evolution was good in all the cases. Liver and bile ducts, 2: Gallstones, formation, treatmentLaparoscopic surgery: TherapyClinical practice: Management strategy }" "The Laparoscopic Cholecystectomy Associated with Operation for Hernia or Incisional Hernia"

"P P 29 0702"P 29 0702**Comparison between Ultrasonographic Diagnosis and Intraoperative and Histological Findings in Patients with Laparoscopic Cholecystectomy**

*P. Georgiev, E. Belokonski, K. Vassilev, S. Handjiev, K. Daiev

Military Medical Academy, Sofia, BulgariaSince 1992 laparoscopic cholecystectomy is a method of choice for treatment of the symptomatic cholelithiasis. Ultrasonography is a basic method for exact diagnosis and indications for operative treatment. The aim of this study was the comparison between the preoperative ultrasonographic diagnosis and intraoperative and histological findings. We used Braghetto's classification to divide our patients according to the ultrasonographic diagnosis to 4 groups:I. Usual chronic calculous cholecystitis: 368 patients.II. Acute calculous cholecystitistype II A with thickness of gallbladder wall < 5 mm: 21 patients.type II B with thickness of gallbladder wall > 5 mm: 15 patients.III. Scleroatrophic chronic cholecystitis: 46 patients.There is the high level of coincidence of the preoperative ultrasonographic diagnosis with videoendoscopical and histological findings. Our experience demonstrated that patients with cholecystitis type II B and type III had need from the prolongation of the operative time, between them the frequency of complications is higher, more frequent is the conversion to open cholecystectomy. Braghetto's classification proposes the possibility for determination of course of surgical intervention and estimation of probability for conversion and intraoperative and postoperative complications. "P P 29 0706"P 29 0706**A Comparison of N_2O and CO_2 Pneumoperitoneums during Laparoscopic Cholecystectomy, with Special Reference to Postoperative Pain**

*P. Aitola, I. Airo, S. Kaukinen, P. Ylitalo

Departments of Surgery and Anaesthesiology, Tampere University Hospital and Medical school, University of Tampere, Finland

Department of Pharmacology, Clinical Pharmacology and Toxicology, University of Tampere, Tampere and Diaconess Institute, Helsinki, FinlandNitrous oxide (N_2O) pneumoperitoneum has been shown to be less pain provoking than carbon dioxide (CO_2) pneumoperitoneum during diagnostic laparoscopy under local anaesthesia. There are no reports of whether N_2O has that benefit also on major surgical laparoscopic procedures under general anaesthesia. In the present study we compared the effects of N_2O and CO_2 pneumoperitoneums on postoperative pain and on cardiorespiratory variables during laparoscopic cholecystectomy.Forty patients scheduled for laparoscopic cholecystectomy due to symptomatic cholelithiasis were randomised to either N_2O or CO_2 pneumoperitoneum groups. Heart rate, blood pressure, pulse oximetry and end tidal CO_2 were continuously monitored during the operations. Arterial blood gases were analysed three times during the procedures. Serum cortisol, epinephrine and norepinephrine concentrations were measured before insufflation, at the end of and 8 hours after the operations. The intensity of postoperative pain was measured using visual analogue pain scale.No differences between the two groups in baseline or perioperative blood pressures, heart rates or pulse oximetry values were found. The patients in the CO_2 group had significantly lower pH values than the patients in the N_2O group at the end of the operation. In the CO_2 group a respiratory acidosis developed as seen in significantly increased arterial and end tidal CO_2 values and decreased pH. No differences between the groups in serum cortisol or epinephrine levels were found. At the end of and after the operations norepinephrine levels were higher in the N_2O group than in the CO_2 group. The patients in the N_2O group required less anaesthetic agent (enflurane) during the operations and had significantly lower pain scores one hour, six hours and the next morning 23 and 24 hours postoperatively.Patients operated with N_2O pneumoperitoneum had no side-effects of CO_2 and were less painful postoperatively than those operated with CO_2. Nitrous oxide is a good alternative for CO_2, especially when prolonged laparoscopic operations are performed on patients with chronic cardiopulmonary diseases. Laparoscopic surgery: Therapy }" "A Comparison of N2O and CO2 Pneumoperitoneums during Laparoscopic Cholecystectomy, with Special Reference to Postoperative Pain"

"P P 29 0707"P 29 0707**6 Years of Laparoscopic Cholecystectomy: *Results* on 1778 Patients****D. Lomanto, A. Paganini[1], F. Carlei[2], M. Nardovino[3], M. Guerrieri, F. Giacovazzo, M. Sottili, P. Lepiane, A. Cicalese, Meli E. Zarba, E. Lezoche[1]**

II Clinica Chirurgica, Universit\'e0 degli Studi ""La Sapienza"", Roma

[3] I.N.I. Canistro (AQ)

[1] Patologia Chirurgica, Universit\'e0 di Ancona

[2] Dipartimento Medicina Sperimentale, L'Aquila*Aim of the Study:* Laparoscopic cholecystectomy is today the standard therapy for gallstones disease. Improved experience with this technique allows to achieve better results. Aim of this study was to analyse our large series to evaluate the results achieved.*Methods:* Between 1991 and 1996 1778 patients were submitted to laparoscopic cholecystectomy for gallbladder lithiasis. Preoperative imaging study consisted of US in all cases, i.v. cholangiography in 134 cases and ERCP in 81 cases. The lithiasis was complicated by acute cholecystitis (39 cases), empiema (16 cases), hydrops (24 cases) and adenomioma (5 cases). 565 patients had been submitted to previous laparotomies (25 upper abdomen, 540 lower abdomen). 1724 (97%) of pts underwent IOC A bile duct lithiasis was associated in 165 cases (9.3%) whose 4.2% unsuspected.*Results:* Intraoperative complications occurred in 65 cases (3.6%): most common were bleeding (18 cases) and loss of small stones (43 cases) but we also observed a small bowel lesion, a diaphragm lesion and two lesions of biliary tract (1 choledocus and 1 common hepatic duct). Our conversion rate was 1.4% (25 cases) and it was due to bleeding (10 pts), visceral lesions (4 pts), cholecystitis (2 pts), multiple visceral adhesions (5 pts) and bile duct lithiasis (4 cases). Postoperative complications were 71 (3.9%): 15 parietal abscesses, 22 parietal hematomas, 6 incisional hernias through umbelical port, 15 subhepatic bile collections, 8 intraperitoneal bleeding and 5 residual VBP lithiasis. We also report a case of mortality due to cardiogenic shock.*Conclusions:* Laparoscopic cholecystectomy performed in experienced centers can achieve optimal results in terms of morbidity, in-hospital stay and recovery to normal activities of the patients shorter than open cholecystectomy.

"P P 29 0709"P 29 0709**Bile Duct Injury during Cholecystectomy in the Era of Laparoscopy**

*J. Nicolet, A. Sa Cunha, A. Sauvanet, J. Belghiti

Department of Digestive Surgery, Hospital Beaujon, University Paris VII, Clichy, FranceThe development of laparoscopic cholecystectomy (LC) has been associated with a rise in the incidence of bile duct injury (BDI). The aim of this study was to assess the changes in the presenting features and management of BDI in the era of LC.*Methods:* All BDI cases (primary or secondary referal) treated at our center since january 1979 have been included for analysis.*Results:* Between 1979 and 1989, 31 patients (average: 2.8 per year) were treated for BDI after cholecystectomy vs 39 patients from 1990 to 1995 (average: 6.5 per year). Of these most recent 39 patients, 16 (41%) have had an open cholecystectomy (OC) and 23 (59%) have had a LC. In 12 (31%) patients, the BDI was discovered during the operation: 6 (38%) during OC and 6 (26%) during LC. The presenting features in the 27 patients in whom BDI was not discovered at the time of surgery were as follows: n Septic Biliary Biliary Emergency syndrom fistula ascites reoperationOC 10 1 (10%) 3 (30%) 1 (10%) 3 (30%)LC 17 8 (47%) 4 (24%) 8 (47%) 12 (71%)Of the 18 (46%) patients undergoing an angiography, 9 (50%) had a lesion of the hepatic artery or of the portal vein; 4 (45%) after OC vs 5 (66%) after LC. The type of biliary lesion according to Bismuth's classification was identical in the both groups. Endoscopic treatment was not attempted in any case after OC but was attempted in 9 (39%) cases after LC. Seven (78%) of these patients were finaly operated. Roux-en-Y hepaticojejunostomies was performed in 11 patients (69%) after OC and 16 (70%) after LC.*Conclusion:* this study confirms an increase in the incidence of BDI in patients undergoing laparoscopic cholecystectomy although 40% are still related to open cholecystectomy. Bile duct injury after laparoscopic cholecystectomy are diagnosed later, notably through septic and peritoneal complications, and are more frequently accompanied by vascular lesions. But these findings and the attempt of per-cutaneous or endoscopic treatments do not seem to have changed the type of reparation. Laparoscopic surgery: Therapy }" "Bile Duct Injury during Cholecystectomy in the Era of Laparoscopy"

"P P 29 0710"P 29 0710**Incidence of Bile Duct Stone Disease Occurring after Prophylactic Cholecystectomy Incorporated in Curative Gastrectomy for Cancer****H. KOBORI, R. HADA, Y. SUGIYAMA, N. WAJIMA, M. SUGAI, D. SEITO, Y. MIKAMI, H. SUZUKI, M. KONN**

Department of Surgery, Hirosaki University School of Medicine, Hirosaki, Japan*Background and Aim:* We reported a 6 to 10 times higher incidence of gallstone disease in curatively gastrectomized patients for cancer (Dig Surg 6: 39–45, 1989, Gastroenterology 104: A362, 1993). One possible factor for this lithogenesis is impaired gallbladder (GB) motility brought about by vagal denervation (Dig Surg 6: 39–45, 1989), and another possible factor to be altered GB bile composition related to bile infection (Gastroenterology 104: A371, 1993, 106: A340, 1994). Since 1989, we have employed concomitant cholecystectomy for its prophylaxis, especially when total gastrectomy or a duodenum-bypassing subtotal gastrectomy plus hepatoduodenal lymph node dissection were performed. A follow-up study has indicated that the prophylactic cholecystectomy is effective. However, the possibility of increasing incidence of bile duct stone disease after prophylactic cholecystectomy remained to be settled.*Methods:* We performed a follow-up study employing periodic ultrasound (per 6 months) on the incidence of bile duct stone in a series of 150 patients having undergone a curative gastrectomy for cancer and cholecystectomy. The patients consisted of 106 males and 44 females aged 60.0 – 10.3 y. Cholecystectomy in these patients had already been performed before gastrectomy in 9 patients (Group A), was concomitantly performed for biliary disease in 59 patients (Group B) or for prophylaxis in 77 patients (Group C) or for other reasons (Group D). The follow-up period (duration) was 44.4 – 36.0 for Group A, 53.4 – 33.7 for Group B, 33.2 – 23.0 for Group C and 16.3 – 10.4 mo for Group D, respectively.*Results:* Bile duct stone was diagnosed in only one of the 150 patients (1/150, 0.7%) and that in Group C (prophylactic cholecystectomized patients). The patient (62 y aged male) had undergone total gastrectomy, distal pancreatectomy, splenectomy and prophylactic cholecystectomy. A bile duct stone developed 39 mo latter.*Discussion and Conclusion:* The low incidence of bile duct stone (0.7%) demonstrated in the present study may verify the concomitant cholecystectomy as a sufficient means for the total prevention of gallstone disease occurring after curative gastrectomy for cancer. Liver and bile ducts, 2: Gallstones, formation, treatment }" "Incidence of Bile Duct Stone Disease Occurring after Prophylactic Cholecystectomy Incorporated in Curative Gastrectomy for Cancer"

"P P 29 0711"P 29 0711**Can Preoperative Variables Predict Symptomatic Outcome after Cholecystectomy?I.B. Andersen, L. Bardram, L. Borly, E. Christensen, H. Kehlet, L. Paloheimo,**

*L. H\'f8jgaard

Department of Surgical Gastroenterology, Hvidovre Hospital, Denmark

Clinical Physiology and Nuclear Medicine, Hvidovre Hospital, Denmark

Medical Department B, Bispebjerg Hospital, University of Copenhagen, Denmark

Department of Clinical Biochemistry, Rigshospitalet, University of Copenhagen, DenmarkCholecystectomy for symptomatic gallstone disease results in pain relief in most of the patients, but for 20–30% abdominal pain is present also after the operation, as the so-called postcholecystectomy syndrome.*The aim* of this study was to investigate whether preoperative variables could predict the symptomatic outcome after cholecystectomy.*Methods:* 102 patients were referred to elective cholecystectomy in a two year prospective study. Median age was 45 years, range 20–81. A preoperative questionnaire on pain, symptoms, history etc. was completed, and the questions on pain and symptoms were repeated postoperatively after 6 weeks and one year. Preoperative cholescintigraphy and sonography evaluated gallbladder motility, gallstones and gallbladder volume. CCK-profile was measured after meal stimulation. Bile, gallbladder and stones were analysed after the operation. Preoperative variables in patients with or without pain were compared statistically and significant variables were combined in a logistic regression model to predict the postoperative outcome*Results:* 80 patients completed all questionnaires. Of the 80 patients 21 had abdominal pain after the operation, whereas 59 had no pain postoperatively. Patients with pain one year after cholecystectomy were characterized by preoperative presence of a high dyspepsia score, ""irritating"" abdominal pain and an introvert personality. Further by absence of ""agonizing"" pain and absence of symptoms coinciding with pain. $\{ ?\}^2 = 47$, d.f. 5, $p < 0.000001$. Of 18 patients predicted as having postoperative pain, 15 had this (PVpos = 0.83). Of 62 patients predicted as having no pain postoperatively, 56 had this (PVneg = 0.90). Overall 88.7% of the patients were classified correctly according to this reclassification.*Conclusion:* In this prospective study on postoperative outcome after cholecystectomy preoperative symptoms were able to predict abdominal pain after cholecystectomy. Since reclassification gives too optimistic results, the model should be validated in independent patients. Liver and bile ducts, 2: Gallstones, formation, treatment }"

"P P 29 0712"P 29 0712**Hepatectomy for Metastatic Liver Tumors from Colorectal and Gastric Cancers**

*S. Miyagawa, S. Kawasaki

First Department of Surgery, Shinshu University, School of Medicine, Matsumoto, Japan*Purpose:* Long-term survival after hepatectomy was examined between patients with metastatic liver tumors from colorectal and gastric cancers.*Methods:* Between January 1990 and February 1996, 50 patients underwent hepatectomy for metastatic liver tumors from colorectal cancer (colon group) and 16 from gastric cancer (gastric group).*Results:* The mortality rate within 30 postoperative days was zero, although one patient died from cerebral bleeding in the hospital (1.5%). In the colon group, hepatectomy was performed synchronously with removal of the primary lesion in 8 patients (16%) and metachronously in 42. The mean number of resected liver tumors was 3 ranging from 1 to 17. Repeated hepatectomy for recurrent liver tumors was performed in 10 patients (20%) (two times in 8 patients and three times in 2). On the other hand, in the gastric group, hepatectomy was carried out synchronously in 8 patients (50%) and only one patients (6.3%) underwent repeated hepatectomy for recurrent liver tumor. The colon group had a higher percentage of repeated hepatectomy than the gastric group, but not significantly ($p = 0.199$). In the colon group, the cumulative 1-yr survival rate after initial hepatectomy was 86.8%; 2-yr rate 75.9%; 3-yr rate 65.7%; and 5-yr rate 65.7%, respectively, although in the gastric group, 1-yr, 2-yr and 3-yr survival rates were 65.0%, 27.9% and 0%, respectively. Significantly longer survival after initial hepatectomy was observed in the colon group ($p = 0.0012$).*Conclusion:* Hepatectomy can provide long term-survival for patients with metastatic liver tumors from colorectal cancer. Oncology, general: TherapyOncology, specific: Liver, biliary }" "Hepatectomy for Metastatic Liver Tumors from Colorectal and Gastric Cancers"

"P P 29 0713"P 29 0713**Surgical Treatment of Liver Echinococcosis: Our Experience**

*B. Bakula, I. Zoricic, N. Makek, T. Anic, Z. Perko

University Dept of Surgery, Sveti Duh General Hospital, Zagreb, CroatiaBetween January 1991 and March 1996 we operated 94 patients with liver echinococcosis. There were 79 (84%) females and 15 (16%) males. Average age was 39.2 years (SD – 16.5 years). Diagnosis was made by ultrasound, computerized tomography and serological testing. More common the right liver lobe has been affected (70.7% vs. 29.3%). Partial pericystectomy with drainage was the most common operation, performed in 44 (46.7%) cases. Partial pericystectomy with choledochotomy, ""T-tube"" drainage and suturing of open biliar ducts were performed in 10 (10.6%) patients, where cysts were centrally situated or biliary leakage was seen. Liver resections were done in patients with liver parenchyma destruction, multiple cysts or inadequate drainage openings: right hepatectomy, left hepatectomy and atypical resections in 9 (9.6%), 7 (7.4%) and 17 (18.1%) cases respectively. In one patient marsupialization was performed because of his bad condition and cyst infection. Six (6.4%) patients had secondary peritoneal echinococcosis, so besides liver procedures, total pericystectomies of these cysts were done, too. Nine patients were reoperated because of recidive of the disease, and one patient was reoperated four times. During postoperative course we did not have heavily complications. In eight (8.5%) patients abdominal collections have occurred, and ultrasound punction and drainage were performed. In one case relaparotomy, drainage, suturing of the biliar duct and ""T-tube"" drainage were necessary due to subhepatic abscess. It could be concluded that liver echinococcosis can be managed with partial pericystectomy in the majority of cases, with good curative effects and low postoperative complications course. Choledochotomy with ""T-tube"" drainage is additional method for centrally situated cysts or evident biliar leakage, and liver resections for a large degree parenchyma destruction or inadequate drainage openings.

"P P 29 0714"P 29 0714**Immunohistochemical Investigation in Occurrence of Endocrine Cells and Lysozyme in Chronic Cholecystitis**

*M. Onda, Y. Ozawa, T. Honjo, T. Okuda, Y. Sumiyama

Third Department of Surgery, Toho University, School of Medicine, Tokyo, Japan*Aim:* We investigated the functional significance of the occurrence of endocrine cells and lysozyme in cholelithiasis tissue by using the histochemical and immunohistochemical methods to clarify the etiology of chronic cholecystitis.*Materials and Methods:* The subjects consisted of 120 cases chronic cholecystitis surgically removed in our department and we selected 100 cases to show histologic evidence of metaplasia for study. Of the 120 patients, 53 were men and 67 were women, they ranged in age from 34 to 88 years, mean, 56.2 years. All specimens were fixed in 10 per cent neutral buffered formaldehyde immediately after cholecystectomy, embedded in paraffin and sectioned at 5 \'b5m. Grimelius reactions were used to bring out the argyrophil cells. Special mucin stainings were applied to identify the periodic acid-Schiff (PAS) followed by alcian blue. For the immunohistochemical demonstration, we used an streptoavidin-biotin immunoperoxidase procedure (SAB) by monoclonal antibody.*Results:* In normal gallbladder mucosa, endocrine cells and lysozyme were not demonstrated. In chronic cholecystitis, non-metaplastic group in 20 cases also were not observed these cells. The expression rate of the occurrence of endocrine cells and lysozyme of metaplastic group were found in 48 (48%) and 63 (63%) of 100 cholecystitis, respectively. These cells were apparently formed by the metaplastic differentiation. The endocrine cells were found more abundantly in the body and fundus region than in the neck region. Among the hormones determined immunohistochemically, serotonin was detected most frequently followed by cholecystokinin, somatostatin, gastrin and pancreatic polypeptide. Various hormone-containing cells showed a high correlativity between the development of metaplasia and degree of cholecystitis. These cells were apparently formed by the metaplastic differentiation. And lysozyme also showed a close relationship to the metaplasia.*Conclusions:* It was recognized a strong correlation between endocrine cells and degree of metaplasia and cholecystitis. And it is suggested that endocrine cells has strongly influence on the occurrence and development of chronic cholecystitis. Therefor, there is much hope to the clinical application of hormone therapy in the treatment of cholecystitis. [2] Clinical Physiol./Nuclear Med., Hvidovre Hospital, University of Copenhagen, DK-2650 Denmark

[3] Dept. Surg. Gastroent, Aarhus

[4] Dept. Surg. Gastroent, Aalborg

[5] Odense University HospitalsAbdominal pain occurs in 20–30% of patients after cholecystectomy. The main cause of this pain remains unclear. Patients with acute cholecystitis (AC) could perhaps be expected to benefit more from surgical treatment than patients operated due to uncomplicated gallbladder stone disease (UGSD), as the necessity to operate is more unquestionable in patients with AC.*Purpose:* To compare pain and dyspepsia after cholecystectomy for AC with pain and dyspepsia after cholecystectomy for UGSD.*Methods:* All patients (223 women, 122 men) cholecystectomized for AC at 4 Danish University hospitals during the period from 1986 to 1990, and a control group of age and sex-matched patients (213 women, 83 men) cholecystectomized for UGSD, were invited to participate in a questionnaire concerning the occurrence of abdominal pain and dyspepsia before and after cholecystectomy.*Results:* 534 patients (83%) completed the questionnaire. Complains of abdominal pain were found in 37% with equal frequency in the AC and UGSD group (37% vs 38%). Women suffered more often from abdominal pain after cholecystectomy than men (42% vs 29%, OR = 1.75). Although more than one third complained of abdominal pain after cholecystectomy, 93% were improved or cured by the operation and this occurred more often in UGSD than AC (95% vs 89%) ($P = 0.02$). In general cholecystectomy reduced nausea ($P < 0.0001$) and vomiting ($P < 0.0001$) but aggravated flatulence ($P < 0.0001$). Abdominal pain was significantly correlated to dyspepsia after cholecystectomy in both groups.*Conclusion:* Pain occurs with equal frequency in AC and UGSD after cholecystectomy. "P P 29 0716"P 29 0716**Therapeutical Approach to Acute CholecystitisD. Lomanto, A. Paganini[2], F. Carlei[1], M. Guerrieri[2], M. Nardovino[1], G. Dalsasso, F. Giacovazzo, Meli E. Zarba, E. Lezoche[2]**

[1] II Clinica Chirurgica, University of Rome ""La Sapienza"", INI Canistro (AQ)

[2] Patologia Chirurgica Universit\'e0 di Ancona, Italia*Purpose of the Study:* Laparoscopic cholecystectomy (LC) is the gold standard for uncomplicated cholelithiasis: more debated are indications and timing in acute cholecystitis (AC). Aim of our study was to evaluate results of LC in patients with present or previous acute cholecystitis.*Methods:* Between 1991 and 1995 1778 pts. were submitted to LC for symptomatic cholelithiasis. Of these 158 pts. (8.9%) were admitted with the diagnosis of AC identified by clinical, lab and ultrasonographic signs. 5 of these presented with signs of cholangitis and in four of them common bile duct stones were demonstrated. Among the AC group, 39 pts. underwent LC within 48 hours from the clinical onset of symptoms (Group A). 119 patients, including elderly or high risk pts as well as pts. referred to us more than 48 hours after the onset of symptoms and pts. treated in the first two years of this study, underwent medical treatment and surgery was delayed of 5–7 weeks (Group B).*Results:* Conversion rate was 7.7% in Group A and 0 in Group B. Mean operative time was significantly shorter in Group B (49.2 minutes vs. 78.5 of Group A). In both groups no common bile duct injuries were observed. Morbidity was 8.3% in group A (2 port site infections and 1 hemoperitoneum, treated conservatively) and 4.2% in Group B (3 port site infections, 1 parietal hematoma and 1 biloma, treated conservatively). No mortality was observed. Mean postoperative hospital stay was 4.2 and 2.5 days respectively in Group A and B.*Conclusion:* Our results suggest that LC can be safely performed by skilled surgeons within 48 hours from the clinical onset of symptoms in no high risk patients. In high risk patients a delayed operation seems justified, as far as cholangitis is not present. "P P 30 0717"P 30 0717**Prognostic Factors of Liver Excretory Function in Patients Undergoing Biliary Decompression for Obstructive Jaundice**

*C.Y. Chen, S.C. Shiesh, X.Z. Lin

National Cheng Kung University Hospital, Tainan, Taiwan*Aim:* We conducted this study to identify the predictors of recovery of liver excretory function in patients with obstructive jaundice.*Materials and Methods:* Twelve consecutive patients were recruited, with mean age 60.6 – 9.9 y-o, male 9, female 3. The underlying diseases were common bile duct stone: 4, and biliary malignancy: 8. They received nasobiliary drainage (NBD, 4) or percutaneous transhepatic choledochal drainage (PTCD, 8) according to clinical indications. Serum and bile were collected for biochemistry tests. The recovery of liver function was evaluated by indocyanine green retention test (ICG R_{15}). Patients with a ICG R_{15} reduction ratio less than 50% were considered as poor recovery (group 1, n = 6) while a good recovery was thought if the reduction ratio higher than 50% (group 2, n = 6). The clinical parameters were compared between two groups.*Results:* Sequential change of serum & biliary content are as follows: Day 0 Day 3 Day 6 Gr. 1 Gr. 2 Gr. 1 Gr. 2 Gr. 1 Gr. 2*(Biliary)*Bile acid 5.8 – 5.7 24.4 – 23.9* 1.0 – 0.9 5.2 – 2.2\'86 2.1 – 2.5 7.2 – 3.1*Bil – T 49 – 76 53 – 77 16 – 8 78 – 30\'86 33 – 39 55 – 33Volume/day – – 1158 – 349 701 – 286 1108 – 251 595 – 249**(Serum)*Ap 585 – 276 348 – 289* 437 – 257 262 – 195 343 – 205 201 – 96*Bil – T 19.0 – 6.7 11.7 – 5.9 11.4 – 3.6 4.4 – 1.5* 9.5 – 2.5 3.2 – 0.9\'86*p < 0.05; \'86 p < 0.01 by Mann-Whitney U testThe ICG reduction ratio was significantly correlated with the bile volume and the concentration of bile acids ({ g} = { -}0.8 & { g} = 0.74 respectively, p < 0.01).*Conclusion:* Post-obstructive choleresis and thin bile (low concentration of biliary bile acid) are bad prognostic factors for recovery of liver function. Both conditions are sequel of prolonged obstruction and a longer time for recovery is expected. "P P 30 0718"P 30 0718**Role of Atrial Natriuretic Peptide on the Pathogenesis of Renal Dysfunction in Patients with Obstructive Jaundice**

*F.J. Padillo, J.M. Gallardo, M. Rodriguez, A. Naranjo, P. Montilla, F. Infante, G. Mi\'f1o, C. Pera, A. Sitges-Serra[1]

Hospital Reina Sof\'eda; C\'f3rdoba, Spain

[1] Hospital del Mar; Barcelona, Spain*Purpose of the Study:* To investigate the sodium regulating hormones status and the role of the atrial natriuretic peptide (ANP) on the pathogenes\'eds of the extracellular water (ECW) depletion and renal dysfunction in patients with obstructive jaundice (OJ). *Methods:* Forty two patients with OJ were evaluated. There were 21 women and 21 men with a mean age of 69 yrs (range 38–90). Fourteen patients had benign conditions and 28 periampullary tumors. Plasma ANP, Aldosterone (Ald) and Renin (Ren) concentrations were measured by radioimmunoassay. Extracellular water (ECW) was determined using tetrapolar bioimpedance. Fractional sodium excretion (FNaEx) and creatinine clearance (CrCl) were also measured. A control group (CG) of 14 healthy subjects matched for age (mean age 64 yrs; range 37–84) and sex (6 women and 8 men) were used as controls for hormonal measurements. *Results:* Ninety one percent of OJ patients had elevated ANP (> 60 pg/ml) vs 7% in CG (p < 0.001). Mean values were 119 – 46 pg/ml in OJ group vs 40 – 16 in CG (p < 0.001). Plasma Ald concentrations compared with CG was 156 – 72 vs 43 – 21 pg/ml (p < 0.001). Forty seven percent of OJ patients had elevated Ald concentrations (> 160 pg/ml) (p < 0.001). CrCl was 95 – 65. Twenty eight percent of patients had low CrCl (< 50 ml/min). FNaEx was 0.63 – 0.49. Patients with CrCl < 50 ml/min had higher Fractional sodium excretion (0.84 vs 0.55; p = 0.15). Sixty five percent of patients had ECW lower than 22% body weight. Plasma Renin concentrations was also higher in OJ patients than CG (41 – 54 vs 16 – 9 uU/ml; p < 0.01). *Conclusion:* The present study reports that plasma ANP is increased in patients with obstructive jaundice. Endocrine and extracelullar water alterations could related to renal dysfunction. These findings are relevant to the perioperative management of patients with obstructive jaundice.

"P P 30 0719"P 30 0719**Polypeptides from Red Cell Membranes: Electrophoresis Reveals Effects of Biliary Obstruction with High Bilirubin Levels in Rats**

*B.R. Vargas-del-Carpio[1], K. Madi[2], M. Palatnik[3]

[1] Dept. of Gastroenterology, Hospital C. Fraga F°, Fac. Medicina, Univ. Fed. do Rio de Janeiro, RJ, Brazil

[2] Dept. of Pathology, Hospital C. Fraga F°, Fac. Medicina, Univ. Fed. do Rio de Janeiro, RJ, Brazil

[3] Dept. of Hemotherapy, Hospital C. Fraga F°, Fac. Medicina, Univ. Fed. do Rio de Janeiro, RJ, BrazilExperimental biliary obstruction in Wistar rats leads to differences in the polypeptides of the red cell membranes that can be detected by polyacrylamide gel electrophoresis in the presence of sodium dodecyl sulfate. Here we compare the pattern obtained in ghosts from normal rats and rats with high bilirubin levels in plasma, 5–11 days after experimental biliary duct obstruction. Ghost membranes from normal human subjects were also examined.After surgery, rats with coluria were sacrificed and biochemical tests for bilirubin, transaminase and amylase in plasma and an analysis of biliary/digestive tract histopathology were performed. Ghost membranes were solubilized and the polypeptides were separated on 7.5% polyacrylamide gels (stacking gel 4.9%) according to Laemmli (Nature 227: 680, 1970), and stained with Coomassie blue.The operated rats exhibited coluria, colangitis, ductal dilatation with cystus, and pancreatitis; and in liver, portal fibrosis with ductal proliferation. The biochemical results were consistent with the obstruction: high levels of bilirubin and of all the enzymes tested. Electrophoresis of ghosts revealed differences from normal rats between 75 and 25 kDa. At 53 kDa, a prominent band (designated 4.6) was found in normal rats between the bands 4.9 and 4.2, but disappeared with prolonged biliary obstruction. This band is not found in humans. Band 6 (35 kDa), present in humans, is absent from normal rats but appears after prolonged biliary obstruction. The intensity of bands 7 and 8 (29 and 25 kDa) increases in operated rats. Partial reversal of this profile was observed when the obstruction reversed spontaneously. We conclude that biliary obstruction with high bilirubin levels can affect red cell membrane polypeptides, depending on the severity and duration of the obstruction. *Support: CAPES, FUJB, UFRJ.* Liver and bile ducts, 2: Bile formation, cholestasisLiver and bile ducts, 2: Biliary cysts, atresia }" "Polypeptides from Red Cell Membranes: Electrophoresis Reveals Effects of Biliary Obstruction with High Bilirubin Levels in Rats"

"P P 30 0720"P 30 0720**Factors Associated with Incleased Biliary Pressure in Bile Duct Obstruction**

*J.K. Lee, P.L. Rhee, J. Kim, K.C. Koh, S.W. Paik, J.C. Rhee, S.W. Choo[1], I.W. Choo[1]

Division of Gastroenterology, Samsung Medical Center, Seoul, Korea

[1] Department of Radiology, Samsung Medical Center, Seoul, Korea*Purpose:* Increased bile duct pressure is the major factor responsible for acute cholangitis and bacteremia. Therefore, prompt medical or surgical decompression of bile under high pressure should be accomplished as fast as possible. But, measurement of bile duct pressure is invasive. So, the present study was undertaken to find out the clinical factors to predict the increased biliary pressure in patients with bile duct obstruction.*Methods:* Thirty-three patients with bile duct obstruction underwent percutaneous transhepatic biliary drainage (PTBD). Intraductal pressure was measured as soon as bile duct pucture was performed. Bile cultures were performed in 24 patients and blood cultures were performed in 21 patients. Correlation of bile duct pressure and severity of pain, duration of symptom, fever, leukocytosis, serum bilirubin, serum alkaline phosphatase, or bile duct diameter were statistically analyzed.*Results:* Bacteremias were noticed in 5 of the 17 patients with positive bile culture. Bacteremia was associated with the increased biliary pressure. Bacteremia was demonstrated when the biliary pressure was 22 cmH_2O or more. Biliary pressure was associated with the severity of pain and body temperature. Significant correlation was not found between the duration of symptom, leukocytosis, serum bilirubin, serum alkaline phosphatase, or bile duct diameter and biliary pressure.*Conclusion:* Increased biliary pressure in patients with bile duct obstruction is more likely to be associated with severity of pain and fever than leukocytosis, bilirubin level, alkaline phosphatase level, or bile duct diameter. Liver and bile ducts, 2: Bile formation, cholestasis }" "Factors Associated with Incleased Biliary Pressure in Bile Duct Obstruction"

"P P 30 0721"P 30 0721**Bilirubinate Conjugates in Common Duct Bile of Patients with Choledocholithiasis**

*O. Sandstad, T. Osnes, P. Urdal[1], V. Skar, M. Osnes

Department of Internal Medicine, Ulleval hospital, Oslo, Norway

[1] Department of Clinical Chemistry, Ulleval hospital, Oslo, NorwayCommon bile duct stones are mainly brown with Ca-bilirubinate as a major component. Deconjugation of bilirubinate glucuronides by bacterial betaglucuronidase seem to be of importance. Our aim was to analyse the composition of common bile duct stones and relate this to bilirubinate conjugates in common duct bile.*Material and methods:* Common bile duct stones and common bile duct bile were collected endoscopically from 56 patients (29 women) with mean age 75 years (range 50–95). The stones were dried and 5 mg of each stone was crushed and dissolved in N,N-dimethylformamide/dimethyl sulfoxide and cholesterol concentration was measured enzymatically on a Cobas Bio centrifugal analyser. Stones with $< 50\%$ cholesterol were considered pigment stones. Biliary pH was measured. Bilirubinate conjugates were analysed immediately by high performance liquid chromatography. A 25 minutes gradient on a C18 column and detection at 440 nm was used. Concentrations were calculated as area under the curve on a computer.*Results:* Forty-four stones (78%) were pigment stones. All 25 patients with duodenal diverticula had pigment stones ($p < 0.01$). Total bilirubin % Bilirubin Biliary \'b5mol/l diglucuronide* pHPigment stonesn = 44 613 – 472 59 – 12 7.95 – 0.45Cholesterol stones n = 12 504 – 311 67 – 8 7.96 – 0.46*t-test, $p < 0.025$No significant differences were found for the other conjugates.*Conclusion:* The percentage of the main bilirubinate conjugate, bilirubin diglucuronide, is decreased in common duct bile of patients with pigmented compared to cholesterol stones. Liver and bile ducts, 2: Gallstones, formation, treatment }" "Bilirubinate Conjugates in Common Duct Bile of Patients with Choledocholithiasis"

"P P 30 0722"P 30 0722**Symptomatic Gallstone Disease: Which Patients Should Have ERCP?**

*E. Trondsen, B. Edwin, O. Reiertsen, A. F\'e6rden, H. Fagertun, A.R. Rosseland

Surgical Dept., Central Hospital of Akershus, Nordbyhagen, NorwayFor selection of patients with symptomatic gallstone disease to ERCP, clinical indicators of common bile duct stones (CBDS) (history, biochemical tests, ultrasonography (USG)) are too sensitive and may result in a large frequency of negative ERCP. In the present study a discriminant function (DF) for the probability of CBDS (confining age, bilirubin, ALAT, GT) was tested prospectively, and also compared to ultrasonographic CBDS indicators.192 patients were included, 32 proved to have CBDS, and 160 not. Blood sampling was done mean 1.7 days prior to cholecystectomy or ERCP. Ultrasonography (USG) was performed in 171 patients (25 with and 146 without CBDS), ERCP in 71 patients, and both procedures in 57 patients.Clinical criteria for CBDS was positive in 152 patients (79.2%), 21.1% of them actually had stones, and there were no false negatives (sensitivity 100%, specificity 25%). DF was positive in 50 patients (26.0%), 60% of them had CBDS, and there were two false negatives (sensitivity 93.8%, specificity 87.5%).At USG mean bile duct diameter was 4.8 mm in patients without CBDS and 8.4 mm in patients with CBDS. In patients with diameter 6 mm or less (normal range), nine had stones and 116 not, with diameter > 6 mm, 16 had CBDS, 30 had not. Sensitivity of USG was 68.0% and specificity was 79.5%. There was a correlation between diameter at USG and ERCP ($p < 0.001$), but r was only 0.543.Clinical characterisation is most sensitive for CBDS detection, but has low specificity. DF is more specific and sensitive than USG, is easy to use, and seems efficient in selecting symptomatic gallstone patients to ERCP. Clinical practice: Management strategyLiver and bile ducts, 2: Gallstones, formation, treatment }" "Symptomatic Gallstone Disease: Which Patients Should Have ERCP?"

"P P 30 0724"P 30 0724**Bacterial Biofilm Formation: Clinical Bacteriology and Sem Analysis****A. Basoli[1], F. Fiocca[1], M. Cristaldi[1], E. Grasso[1], G. Scopelliti[1], M. Crovaro[1], A. Domenicucci[1], D. Apa[1], L. Baldassarri[2], R. Di Rosa[3]**

[1] Istituto II Clinica Chirurgica, Universit\'e0 ""La sapienza"", Roma

[3] Dip. Clinica Medica, Universit\'e0 ""La sapienza"", Roma

[2] Dipartimento Ultrstrutture, Istituto Superiore Sanit\'e0We studied basic mechanism of biliary stent clogging to investigate on factors involved in it. *Material and Methods:* In one year period 22 biliary stents (10 for transhepatic access) of different plastic materials (polyethylene, polyurethane and teflon) and different diameters (10–12 F) were explanted. They were cut, before transversally from the duodenal and the biliary extremities (5 mm), then lengthwise; two parts, dipped into PBS solution to be sonicated, therefore they were analyzed by quantitative microbiology. The others were immersed into gluteraldeide diluited 1:10, to be analyzed by scanning electron microscopy. 12 stents were substituted for dislocation or for charge therapy, while 7 were explanted due to occlusion (mean implantation time was 95.8 days, range 18–210) *Results:* microbiological analysis didn't reveal a bacterial colonization in 7 out of 22 stents (mean implantation time 12.8 days, range 2–24, median 8). Only one of these was removed because of blockage, and SEM revealed heavy deposit of organic material. During the whole period of implantation an antibiotic therapy was administrated. Cholangitis episodes occurred in four patients, while the other patients presented symptoms of jandice or cholestatis. 15 stents (mean implantation time 73.3 days, range 4–210, median 21) revealed: *14 Enterococcus spp., 3 E. clocae, 2 E. coli, 2 candida and 1 C. freundii, Bacillus, Veillonella, Corynebacterium. spp.*. SEM analysis provided indications in three cases that microrganism were present though culture had resulted negative. *Conclusion:* bacterial cells were attached to both the inner and outer stent surface enclosed into a fibbrillar matrix, suggesting that the first event of stent clogging is the development of an adherent bacterial biofilm. Microrganism of duodenal origin, *Enterococcus* spp. 64% mainly rapresened as component of the biofilm deposited on stent. Nevertheless in the case of stent with transhepatic access, biliary side risulted more early colonized then the duodenal side. We can speculate biliary stasis plays a foundamental role in the drainage failure.

"P P 30 0725"P 30 0725**The Presence of $CaCO_3$ in the Gallbladder Stones Is a Marker for the Bile pH at which Cholelithogenesis Occurs****I.O. Rada, D. Silasi, M. Mracec, Domnita Rada, Liliana Ivanov, Doina S\'e2ntimbreanu, F.C. Rada**

University of Medicine and Pharmacy, Timisoara, Rom\'e2nia, str. Siret no. 6Cholesterol cholelithiasis etiopathogeny remains an uncertain and controversial matter. We determined during surgical procedures the pH in the gallbladder, the common bile duct and the common hepatic duct using the pH meter Digital 100. The presence of cholesterol crystals was studied with a polarized light microscope and we analyzed the composition of gallbladder stone layers.*Results:* in all cases when the bile pH was above 8, we discovered cholesterol crystals or conglomerates. In all cholesterol stones we found precipitates or crystals of calcium carbonate. In layers of lighter colors of the stones the $CaCO_3$ concentration is increased up to 18% and the radioopacity more evident.*Conclusions:* bile alkalization disturbs colloid micelles by reducing the volume and making thinner the double electric layer that keeps the particles in suspension, favoring the sedimentation and conglomeration of cholesterol. Constant identification of $CaCO_3$ in all cholesterol stones resulting from HCO_3 ion and calcium under a pH level above 8 in bile – represents a marker of the moment of the cholesterol sedimentation. The phenomenon of bile alkalization (pH above 8) disturbs the stability of the colloid micelles and represents the initial moment of the lithogenesis. The conglomeration of the precipitate (cholesterol and $CaCO_3$) can also involve billiary pigments resulting in layering of various colors and radioopacity of the gallbladder stones sections. Such gallstones implanted steril in a dog's gallbladder are dissoluted and eliminated in several weeks. In humans bile acidification determines the same process that can be followed by ultrasonography. "P P 30 0726"P 30 0726**Changes in the Excretion of Bile Acids into the Greater Circulation System with the Continous Infusion of Bile Acids into the Portal Vein of the Rat: A Biochemical and Microautoradiographic Study**

*T. Matsumoto[1], H. Igimi[2], H. Tada, T. Nomura, K. Katsu

[1] Second Department of Internal Medicine, Osaka Medical College, Osaka, Japan

[2] Shionogi Corporation, Osaka, Japan*Purpose:* We continously infused taurocholic acid (TCA) and ^{3}H-TCA into the portal vein of rat. We biochemically and microautoradiographyically analyzed the process of its excretion into the greater circulation and the distribution of ^{3}H-TCA in hepatic lobe. We examined this basic research might become one test method in the evaluation of hepatic function.*Material and methods:* Male Sprague-Dawley rats weighing 250-300 g were used. We continously infused 2 mM-TCA into the portal vein of rat over 30 minutes under the following conditon.(the infusion speed of TCA was 10 ml/h, 15 ml/h, 20 ml/h)We sampled the venous blood of the rat at 5 minutes interval from the cannula inserted into the cervical vein to study the excretion of bile acids into the greater circulation system.We infused 2 mM-^{3}H-TCA into the portal vein of rat under the 15 ml/h. The liver of rats were removed at 3, 6, 12 minutes after infusion, and we made frozen tissue samples. We microautoradiographyically observed the continual changes in the distribution of the ^{3}H-TCA in hepatic lobe.*Results and discussion:* The following results were obtained.(1) When 2 mM-TCA was continously infused through the portal vein, that the upper limit of infusion speed to which the hepatic cells were able to treat the TCA, and prevent its excretion into the greater circulation system, was 15 ml/h.(2) As ^{3}H-TCA was continously infused through the portal vein, microautoradiographic study of TCA incorporation showed, the so-called gradient, in which the grain moves from the hepatic cells surrounding the portal vein, into the area near the central venous system.Further studies will be conducted involving an experimental model of hepatic injury. Liver and bile ducts, 2: Bile acids synthesis }" "Changes in the Excretion of Bile Acids into the Greater Circulation System with the Continous Infusion of Bile Acids into the Portal Vein of the Rat: A Biochemical and Microautoradiographic Study"

"P P 30 0727"P 30 0727**Treatment of Gallstones in the Elderly by Oral Bile AcidsG.I.S.Co. (Interdisciplinary Group for the Study of Cholelithiasis)**

ItalyAn oral bile acids treatment of symptomatic uncomplicated gallstone disease in the elderly can be proposed as alternative approach to surgery, which presents in these patients a greater risk of mortality and morbidity as compared to young adult subjects.*Aim* of this study was to evaluate the clinical efficacy of two different treatment of gallstones in elderly subjects by means of bile acids (Tauroursodeoxycholicacid-TUDCA- and Chenodeoxycholic+Ursodeoxycholic acids - CDCA+UDCA).124 elderly patients with symptomatic uncomplicated gallbladder stones were studied: 66 (11 male, 55 female, age range 65–90) were treated by, CDCA-UDCA (5 + 5 mg/Kg/day) and 58 (25 male, 33 female, 65–92) by TUDCA (500 mg/day) for 1 year. The diagnosis was made by Biliary US, Plain Abdomen X-ray and Oral Cholecystography. All subjects presented one or more episode(-s) of biliary pain in the six months prior the study; 44 were also affected by dyspepsia (27 in TUDCA, 17 in CDCA-UDCA group). Patients were followed-up clinically every 3 and by US every 6 months.42/66 subjects in CDCA-UDCA (24 drops: 9 operations for pain or complications, 9 deaths unrelated to gallstones, 1 side effects, 5 follow-up unattended) and 38/58 in TUDCA (20 drops: 1 operation for pain or complications, 9 deaths unrelated to gallstones, 3 side effects, 7 follow-up unattended) group completed the study. 4 total and 2 partial dissolution in CDCA-UDCA and 8 total dissolution in TUDCA group were observed. In 51 patients of CDCA-UDCA and in 39 of TUDCA group symptoms could be followed-up: CDCA-UDCA: 38 had become asymptomatic, 4 had dyspepsia and all 9 still symptomatic were operated; TUDCA: 25 had become asymptomatic, 11 suffered from dyspepsia and 3 were still symptomatic (1 of whom operated).*Conclusions:* 1) Gallstones dissolution in the elderly by oral bile acids seems to be scarcely effective; 2) no difference between the two bile acids was observed; 3) during oral bile acid therapy the majority of elderly subjects with gallstones show an improvement of their symptoms Liver and bile ducts, 2: Gallstones, formation, treatment }" "Treatment of Gallstones in the Elderly by Oral Bile Acids"

"P P 30 0728"P 30 0728**Effect of the Combination of Chenodeoxycholic and Ursodeoxycholic Acid in Gallstone DissolutionG.I.S.CO. (Interdisciplinary Group for the Study of Cholelithiasis)**

ItalyCombination of two bile acids (CDCA+UDCA) has been described as capable of dissolving cholesterol gallstone in more than 60% of cases. Recently a lower percentage of complete dissolution (21%) has been reported.*The aim* of this study was to evaluate the efficacy of the combination of CDCA+UDCA in dissolving cholesterol gallstone in a large number of symptomatic unselected patients and to compare the efficacy of two different types of drug administration (single dose at bedtime or two doses at meals).A total of 212 pts (71 male, 141 female, mean age 46.4 yrs, range 18–65) with radiolucent gallstone in a functioning gallbladder was enrolled in 9 centres in North East Italy. All received CDCA+UDCA (5 mg/kg/day each) for 12 months or until dissolution. The drug was randomly administered in a single dose at bedtime or in two doses at main meals. Follow-up was performed by clinical evaluation every 3 months and biliary ultrasound every 6 months.151 pts completed the study; 1 died from causes not related to gallstones; 18 were operated because of severe biliary pain and/or complications; 11 stopped the treatment for adverse reactions; 31 dropped-out. Complete and partial dissolution were observed in 18.4% and 8.9% patients (intention to treat) or 25.8% and 12.6% (per protocol) respectively. The success of therapy was inversely related to the diameter of stone. No difference in dissolution was observed according to the different administration schedules (chi square = 0.015, p: ns)*In conclusion:* 1. the combination of CDCA+UDCA is effective in dissolving radiolucent gallstones in less than one fifth of unselected patients. 2. The drug administration schedule does not affect the results of the therapy. Liver and bile ducts, 2: Gallstones, formation, treatment }" "Effect of the Combination of Chenodeoxycholic and Ursodeoxycholic Acid in Gallstone Dissolution"

"P P 31 0729"P 31 0729**Effect of Age, Cholecystokinin and Erythromycin on Gallstone and/or Biliary Sludge Formation in the Guinea PigM.R. Mas, \'dc. Ateskan, S. Nalbant, H. \'d6zotuk, H. Erdem, F. Kocabalkan**

GATA Int. Med. Dept. Ankara/TurkeyIn this study we aimed to evaluate the effect of age, cholecystokinin and erythromycin treatment on gallstone and/or biliary sludge formation. Guinea pigs (30 1-mo-old and 30 3-year-old) were placed on a cholelithogenic diet for 4 weeks while 10 guinea pigs of each group remained on normal diet. Ten guinea pigs of each group received respectively: cholelithogenic diet and daily intraperitoneal injection of 0.9% saline (control group), cholelithogenic diet and daily intraperitoneal injection of CCK (0.5 nmol/kg), cholelithogenic diet and daily erythromycin stearat (2 mg/kg) by nasogastric tube.After 4 weeks guinea pigs were killed and gallbladders were examined for gallstones and/or biliary sludge. The concentrations of bile constituents were determined. We observed no gallstone and/or sludge in the 1-mo-old-group. In the 3-years-old group; control 9 out of 10, cholecystokinin 5 out of 10, erythromycin 4 out of 10. In two age groups cholelithogenic diet significantly reduced the concentrations of bile salts and increased the cholesterol concentration and increased bile protein in 3-yr-old group. Treatment with cholecystokinin and erythromycin didn't alter the bile salt concentrations in both and reduced cholesterol in 1-mo-old. The ratio of bile salts/bile cholesterol reduced in both. However, treatment didn't alter this ratio in 3-years-old group but increased in 1-mo-old group. We conclude that major factors in the increased incidence of gallstones and/or biliary sludge formation in aged guinea pigs are increased; concentrations of bile protein, bile cholesterol and reduced concentration of bile salts and ratio of bile salts/bile cholesterol. Treatment with CCK and erythromycin decreased the incidence by decreasing bile protein and increasing bile lesitin and probably by increasing gallbladder motility. Clinical practice: Management strategyLiver and bile ducts, 1: Hepatotoxicity, ethanol }" "Effect of Age, Cholecystokinin and Erythromycin on Gallstone and/or Biliary Sludge Formation in the Guinea Pig"

"P P 31 0730"P 31 0730**Effects of Nitric Oxide Donors on Gallbladder Motility in Humans**

*T. Pawlik, S. Bednarz, P. Thor, J.W. Konturek

I Department of Internal Medicine and Institute of Physiology Jagiellonian University, Krak\'f3w, PolandGallbladder emptying is controlled by complex nervous and humoral mechanisms. It has been previously reported that endogenous nitric oxide (NO) is a neurotransmitter in the gallbladder (GB). The inhibition of NO synthase results in the increase of the intraluminal pressure of GB and this effect can be reversed by the pretreatment with L-arginine (L-Arg). The aim of this study was to evaluate the effects of Glyceryl Trinitrate (GTN), Molsidomine (MO) and L-Arg as potential sources of NO on fasting GB volume and on GB emptying rate, which was induced by modified sham feeding (MSF) and standard meal. The healhty subjects (9 men and 8 women), age range 25–37 years participated in this study. GB volume was examined by means of an ultrasonographic method. Volumens were calculated as described by Everson and co. GB volumes were measured every 10 min for the first 45 min. there after at 15-min intervals up to a total observation period of 2 h. After recording of control values (26.3 + 4 cm3), 0.5 mg GTN was administered sublingually, or 4 mg MO orally or L-Arg (12.63 g of L-Arg in 300 ml of 0.9% NaCl) was infused i.v. over 90 min. It was found that the fasted GB volume was significantly increased after GTN by 22 + 2 and after MO by 25 + 6%. MSF-induced GB emptying was completely inhibited by GTN and MO. Whereas, postprandial GB emptying was reduced maximally by 35.6 + 3% ($p < 0.1$) after pretreatment with GTN and by 40.3 + 5% ($p < 0.1$) after MO. L-Arg was without any effect on resting or stimulated GB volume. The results of the study support the hypothesis that NO, released from GTN and MO (but not synthesized from L-Arg) is the biologically active messenger which relaxes GB at rest and inhibits its emptying during active contraction. These effects also indicate that long-term therapy with NO donors might reduce GB. motility and increase lithogenicity due to retention of bile in the GB. Motility, general: Receptors and signals }" "Effects of Nitric Oxide Donors on Gallbladder Motility in Humans"

"P P 31 0731"P 31 0731**Contractile Function of Gallbladder Sludge and its Natural History**

*M. Nakajima, A. Itabashi, T. Nakajima[1]

Department of Clinical Laboratory, Saitama Medical School, Moroyama, Japan

[1] The Third Department of Internal Medicine, Saitama Medical School, Moroyama, JapanThe purpose of this study is to assess gallbladder function in patients with sludge and its natural history.The subjects were 42 patients with gallbladder sludge [SL], 47 patients with gallstone [GS] and in 15 normal [NL]. None of them had diabetes mellitus with neuropathy, liver cirrhosis gastrectomy and total parental nutrition. Gallbladder volume was calculated using ellipsoid formula by ultrasonography. After obtaining the gallbladder fasting volume, they had standard fatty meal and were measured every 5 minutes for 90 min. All of subjects with no treatment were examined at 12-month intervals for 3 years. Informed consent was obtained all of subjects.Fasting gallbladder volume was no significant difference among the three groups. Maximum gallbladder contractility (MGC) was SL 47.2 – 10.1%, GS 45.7 – 9.9 and NL 61.7 – 11.4. Differences among the three groups (by Student's t test) was significant by seen for SL vs. NL ($p < 0.01$) and GS vs. NL ($p < 0.01$). An evolvement of gallbladder sludge into stone was observed in 8 patients (19%) and disappearance of gallbladder sludge was observed 14 patients (33%) for 3 years. MGC between these two groups (46.0 – 8.1%, 53.8 – 7.5) was significantly different ($p < 0.05$).These results suggested that natural history of the gallbladder sludge was affected by contractile function of the gallbladder. Liver and bile ducts, 2: Gallstones, formation, treatmentRadiology and ultrasound: Diagnosis }" "Contractile Function of Gallbladder Sludge and its Natural History"

"P P 31 0732"P 31 0732**Biliary Motility Disorders and Biochemical Patterns in the Patients with Diabetes MellitusE.V. Beloborodova, V.G. Borodulin, L.V. Kireeva, T.V. Galuza, T.A. Milovanova, L.M. Pustovoytova**

Siberian State Medical University, Tomsk, RussiaThe aim of the work was to study motor activities of the biliary system and the biochemical composition of the bile in the diabetes mellitus. 83 patients were investigated with moderate degree of diabetes mellitus in clinically compensated stage, 63 patient had the 1 type (1st group) and 20 – 2 type (2nd group) of the disease. Average age was 28 + 0.2 and 48 + 0.5 correspondingly. 50% of all were males in both groups. Endoscopy, ultrasound scan, duodenal probe and dynamic hepatobiliscintiscanning were performed in the clinic. Clinical picture showed the following symptoms of biliary tract disorders; aches under the right ribs, bitter taste and dispepsia. 80% of the first and 98% of the second groups had the reduction of gallbladder tone which was revealed by the raising of bladder bile portion and the 4th phase time bile excretion prolongation. Sphincter of Oddi hypertone was observed in the isolated cases in both groups (1 and 2). The most significant clinical signs were: reduction the bile acids and phospholipids reduced concentration in the bladder bile as well as cholatocholesterol coefficient which was more strongly marked (4.2 + 0.21) in the 2nd group than (6.3 + 0.32) in the first one. Hepatobiliscintiscanning data showed sharp reduction of contractile ability of gallbladder in all the patients in the 2nd group. During a 1.5 hour period of observation the gallbladder contraction has not been shown. 2/3 of the 1st group had hypomotor disorders moderate in character in both groups. Taking into account the significant bile production and secretion disorders in the patients with diseases mellitus it seems to be necessary to include to the therapeutical complex the remedies regulating biliary system activities. Liver and bile ducts, 2: Bile formation, cholestasis }" "Biliary Motility Disorders and Biochemical Patterns in the Patients with Diabetes Mellitus"

"P P 31 0733"P 31 0733**The Prokinetic Drug Cisapride Improves the Caerulein-Induced Contraction and the Refilling of the Human GallbladderA. Szepes, L. Mad\'e1csy, B. Velo˝sy, J. Lonovics**

First Department of Medicine, Albert Szent-Gy\'f6rgyi Medical University, Szeged, Hungary*Introduction:* Prokinetic effects of cisapride on the gastrointestinal tract have been studied extensively. Studies of its action on the well-functioning gallbladder (GB), however, are limited and the results are not unanimous. The aim of this study was to determine whether oral administration of cisapride could improve the caerulein-induced contraction of the human GB.*Patients and methods:* GB diameters (GBD) were measured and GB volumes (GBV) were calculated by Dodd's formula by means of real-time ultrasonography in 7 gallstone-free patients with a normal caerulein-induced GB ejection fraction (GBEF > 35%). After an overnight fast, 1 ng/kg/min caerulein (Takus) was administered i.v. for 10 min. The GBD was measured after 0, 5, 10, 15, 20, 25, 30 and 60 min, and the GBEF and the refilling of the GB (GBR) were calculated. Within one week a single dose of 10 mg cisapride (Coordinax, Janssen Pharmaceutica) was administered orally in 10 ml of water to all patients, the GBD was measured after 0, 30, 60, 90 and 120 min and the cisapride-induced changes in the GBV were calculated. After 120 min, caerulein was administered i.v. and the determinations of GBEF and GBR were repeated.*Results:* The mean caerulein-induced GBEF in the basic study was in the normal range (50.99 – 18.6%). Cisapride administration significantly increased the fasting GBV (45.0 – 21.7 vs. 33.6 – 15.9 ml, p = 0.02). The caerulein-induced GBEF improved slightly, but significantly after cisapride administration as compared with the basic study: 60.42 – 18.3% and 50.99 – 18.6%, respectively (p = 0.003). The cisapride administration enhanced GBR (229.8 – 55 vs. 163.3 – 24.5%, p = 0.015).*Conclusions:* The prokinetic drug cisapride increases the fasting GBV by approximately 36%, and causes a significant improvement in the caerulein-induced GBEF and GBR. (Supported by a grant from the Ministry of Social Welfare: ETT 609/1993/02). Motility, general: Functional GI disorders }" "The Prokinetic Drug Cisapride Improves the Caerulein-Induced Contraction and the Refilling of the Human Gallbladder"

"P P 31 0734"P 31 0734**Effects of Cisapride on Biliary Drainage in Patients with Sphincter of Oddi Dysfunction and with Normal Sphincter of Oddi Motility Measured by Quantitative Hepatobiliary Scintigraphy**

*L. Mad\'e1csy, B. Velo˝sy, A. Szepes, J. Lonovics, L. Csernay[1]

First Department of Medicine, Albert Szent-Gy\'f6rgyi Medical University, Szeged, Hungary

[1] Department of Nuclear Medicine, Albert Szent-Gy\'f6rgyi Medical University, Szeged, HungaryCisapride is a gastrointestinal prokinetic drug which enhances motility by directly stimulating the release of acetylcholine of the myenteric plexus. It has been shown that cisapride increases bile flow in animals by an inhibitory effect on the sphincter of Oddi (SO) motility, possibly mediated via non-adrenergic, non-cholinergic neurons. Recent human investigations by endoscopic SO manometry revealed that cisapride decreased the SO basal pressure in patients with biliary stones, but did not have a similar effect in healthy volunteers. The aim of the present study was to evaluate the effect of cisapride on the biliary drainage by quantitative hepatobiliary scintigraphy (QHBS).*Methods:* QHBS was performed in 11 cholecystectomized patients with dyspeptic symptoms. QHBS and SO manometry indicated that 5 patients had an SO dysfunction (SOD) of biliary type II and III, but the remaining 6 had a completely normal SO motility (control group). 140 MBq EHIDA was given intravenously, and digital images were obtained at one frame/min. for 90 min. Time-activity curves were generated from regions of liver parenchyma (LP), hepatic hilum (HH) and common bile duct (CBD). The time to peak activity (Tmax), and the half time of excretion (T1/2) were calculated. Next, cisapride (Coordinax, Janssen Pharmaceutica) was given at 3 {\'b4} 10 mg/day to all patients an ambulatory basis. 2 weeks later, QHBS was repeated in the presence of 10 mg cisapride given orally in 10 ml of water 60 min before EHIDA administration.*Results:* In the control group, all patients had normal biliary transit and the quantitative parameters were within the normal limits during the first QHBS study (LP: Tmax: 10.8 – 1.9, T1/2: 23.8 – 2.9; HH: Tmax: 15.2 – 3.2, T1/2: 25.0 – 4.5; CBD: Tmax: 23.2 – 6.6, T1/2: 28.6 – 8.1 min.). In the remaining 5 SOD patients biliary transit and quantitative parameters were increased (LP: Tmax: 14 – 2.3, T1/2: 31.5 – 11.6; HH: Tmax: 23.8 – 4.5, T1/2: 37.5 – 5.0; CBD: Tmax: 41.5 – 13.1, T1/2: 71.3 – 16.0 min.). Cisapride administration caused significant decreases in T1/2 over the HH and CBD both in the controls (22.6 – 4.1 and 23.2 – 6.8 min) and in the SOD patients (29.0 – 2.2 and 41.5 – 10.8 min).*Conclusion:* The QHBS results proved that the administration of cispride significantly accelerates biliary drainage by improving the transpapillary flow both in patients with an SO dysfunction and in patients with normal SO motility. (Supported by ETT 609/1993/02). Motility, general: Functional GI disorders }" "Effects of Cisapride on Biliary Drainage in Patients with Sphincter of Oddi Dysfunction and with Normal Sphincter of Oddi Motility Measured by Quantitative Hepatobiliary Scintigraphy"

"P P 31 0735"P 31 0735**Abnormal Postprandial Gallbladder Emptying in Type 2 Diabetics (NIDDM) is Related to Increased B-Glucose but not to Gastric Emptying Rate**

*E. \'d8ster-J\'f8rgensen, N. Qvist, P. Thye-R\'f8nn, L. Rasmussen, S.A. Pedersen

Medical dept., Assens Hospital, Depts. of Surgical Gastroenterology, Medical Endocrinology & Clinical Physiology, Odense University Hospital, Denmark*Purpose:* To describe the relation of gallbladder emptying (GBE) to gastric emptying (GE), antroduodenal postprandial motor index (PMI), B-glucose and P-insulin in 8 healthy males and 8 patients with IDDM.*Methods:* Continuous antroduodenal pressure recordings. GBE and GE were measured scintigraphically. For GBE a continuous infusion of ^{99m}Tc-Mebrofenine 40 MBq/h was used, and for the GE a standard meal (100 g omelet tagged with 40 MBq ^{99m}Tc-sulphur colloid and 150 ml water mixed with 8 MBq ^{111}In-DTPA) was ingested in phase I of MMC. P-insulin was measured by RIA.*Results:* In normals as well as in patients meal ingestion elicited gallbladder emptying after a short lag-phase, however in 3 out of 7 patients with NIDDM a reduced emptying rate and augmented residue at nadir was found. In this subgroup of patients the characteristics of GE and PMI were similar to those patients with normal GBE and the control group. B-glucose in the subgroup of patients with abnormal GBE was median 15.7 mmol/l (9.6–16.0) compared to a median value of 7.4 mmol/l (5.7–17.3) in the patients with normal GBE. The values for P-insulin were 10.1 p mol/l (7.7–14.8) and 14.1 (4.7–20.4), respectively.*Conclusions:* The abnormal gallbladder emptying in patients with NIDDM was related to elevated B-glucose but not to changes in GE. These findings indicate that hyperglucosemia may impaire GBE. Motility, general: Receptors and signalsMotility, specific: StomachNutrition: Nutrients and gut function }"

*E. \'d8ster-J\'f8rgensen, N. Qvist, P. Thye-R\'f8nn, L. Rasmussen, S.A. Pedersen

Medical dept., Assens Hospital, Depts. of Surgical Gastroenterology, Medical Endocrinology & Clinical Physiology, Odense University Hospital, Denmark*Purpose:* To compare the characteristics of gallbladder emptying (GBE) in normal persons (NP) (4 young and 4 elderly males) with the characteristics of GBE in otherwise healthy male diabetics (8 young IDDM and 8 elderly NIDDM) with a short disease duration and without late complications.*Methods:* GBE was measured by scintigraphy during 5 h using a continuous infusion of ^{99m}Tc-Mebrofenine 40 MBq/h. The standard meal, which consisted of an omelet (100 g, 1400 kJ, 60E% fat) and 150 ml water, was ingested in a MMC phase I.*Results:* The *pattern* and characteristics of GBE in *NP* was *an unabrupted emptying* after *a lag-phase* (= time until 10% GBE) of *median* 11 min (*octiles* 6–19) with *a rate* of 0.80%/min (0.73–0.81) until *the nadir* was reached after 150 min (120–190) with *a residue* of 1% (0–12). There were no difference in GBE characteristics between the young and the elderly. In *IDDMs* the lag-phase exceeded 19 min in 6 (*range* 23–68), the GBE-rate exceeded 0.81%/min in 5 (*range* 0.82–1.60), the nadir was below 120 min in 3 (*range* 60–70) and the residue at nadir was above 12% in 5 (*range* 21–115). In *NIDDMs* the lag-phase exceeded 19 min in 7 (*range* 31–68), the GBE was below 0.73%/min in 4 (*range* 0.33–0.70) and was above 0.81%/min in 2 (*range* 0.82–0.91). The nadir did not differ from NP but the residue at nadir exceeded 12% in 7 (*range* 14–64). In 1 subject the gallbladder was non-functioning.*Conclusions:* In IDDMs and in NIDDMs the lag-phase was prolonged. In IDDMs an interruption of gallbladder emptying after 60–70 min took place in 3/8 individuals. In NIDDMs the emptying rate was reduced and the residue augmented at nadir in 3/7 individuals. Motility, general: Receptors and signalsMotility, general: InnervationNutrition: Nutrients and gut function }" "Postprandial Gallbladder Kinetic in Normals, Type 1 (IDDM) and Type 2 (NIDDM) Diabetics"

"P P 31 0737"P 31 0737**Real Time Ultrasonography for Measurements of Galldbladder Motility in Children with Upper Dyspeptic Syndrom**

*I.M. Russeva, M.D. Georgieva-Shakola

Dept. of Pediatrics, Medical University, Varna, BulgariaMotility disorders of galldbladder are a problem in pediatric gastroenterology. Early diagnosis by real-time ultrasonography is applied in measurements of gastrointestinal motility particulary of this of galldbladder. Study's aim was: to establish the disorders of galldbladder motility & their structure according to modern noninvasive diagnostic method; to reveal the role of prokinetic in hypokinesia and spasmolytic in hyperkinesia of galldbladder. In 1996, 25 children (14 girls and 11 boys) aged 9–14 years with upper dyspeptic syndrome were investigated. They were examined clinically and by real-time ultrasonography. The ellipsoid method was applied in measurement of galldbladder motility. After 30 min. & 50 g. chocolate control investigation was performed. The patients with hypokinesia were treated with Motilium (0.5 mg/kg 2 m), these with hyperkinesia with Spasmalgon (synthetic cholinolytic { -}20 mg/kg 1 m). After 2 m. the same method of measurement of galldbladder motility was applied. Dyskinesia of galldbladder was established in 16/25 cases (64%): hypokinesia-in 14/25 cases (56%) and hyperkinesia-in 2/25 cases (8%). After 2 m. in 12/14 hypokinetic patients clinical symptoms were not observed. In 10 of them-ultrasonographic measurement of galldbladder was normal. Complete healing (clinical & ultrasonographic) was established in hyperkinetic patients. It was concluded that real-time ultrasonography should be the diagnostic method of choice in childhood galldbladder motility disorders. These disorders are very common in children. Prokinetic or spasmolytic reduce the symptoms & motility changes. Radiology and ultrasound: DiagnosisMotility, general: Functional GI disorders }" "Real Time Ultrasonography for Measurements of Galldbladder Motility in Children with Upper Dyspeptic Syndrom"

"P P 31 0738"P 31 0738**Spontaneous Bacterial Peritonitis in Brazil: Prevalence, Predictive Factors and Prognosis**

*F.A.F. Figueiredo, H.S.M. Coelho, J.A. Segadas, A. Queiroga, C.R. Silva

Universidade Federal do Rio de Janeiro (UFRJ/Universidade Estadual do Rio de Janeiro (UERJ), Rio de Janeiro, Brasil*Background/Aims:* Spontaneous Bacterial Peritonitis (SBP) is a common and potentially fatal complication of cirrhosis. Multiple variants of this infection have been described during the past decade. Few studies have investigated SBP in Brazil. In order to investigate prospectively prevalence, predictive factors and prognosis of the episode of SBP, we studied 143 in and outpatients with cirrhosis admitted to UFRJ and UERJ between January, 1995 and January, 1996.*Methods:* All patients were submitted to a questionarie, phisical examination, blood analysis and abdominal paracentesis with ascitic fluid analysis. Seventy-four variables were analysed. The patients were followed for a mean follow-up period of 4 months and survival was determined.*Results:* The prevalence of SBP was 20%. Culture-positive SBP, Culture-negative Neutrocytic Ascites and Bacterascites were identified in 24%, 66% and 10%, respectively. After uni- and multivariate analysis, only anterior gastrointestinal hemorrhage, serum albumin and ascitic fluid C4 reached statistical significance ($p = 0.05$) as predictive factors for the development of the SBP. The in-hospital and follow-up mortality rates were 33.3% and 53.8% for the SBP patients and 8.5% and 31.9% for the non-SBP patients, respectively ($p = 0.01$ and $p = 0.04$). The cumulative probability of survival in the SBP group was significantly lower than the probability of the non-SBP group ($p = 0.05$).*Conclusions:* We conclude that SBP is a frequent complication, depends of the severity of liver failure and is a marker for poor prognosis in patients with liver cirrhosis. Liver and bile ducts, 1: Cirrhosis: ascites, encephalopathyClinical practice: Epidemiology (non cancer) }" "Spontaneous Bacterial Peritonitis in Brazil: Prevalence, Predictive Factors and Prognosis"

"P P 31 0739"P 31 0739**The Effect of Erythromycin and Cisapride on Postprandial Gallbladder Emptying in Healthy HumansJ. Tsiaoussis, G. Tzovaras, E. Chrysos, E. Epanomeritakis, N. Kariotakis, A. Mantides, O. Zoras,**

*E. Xynos, J.S. Vassilakis

Dept of General Surgery, University Hospital of Heraklion*Backgraound:* Cisapride and erythromyicin exhibit prokinetic properties and increase the rate of postprandial gastric emptying. The *aim* of the study was to evaluate the potential effects of erythromycin and cisapride on gallbladder postprandial emptying in healthy volunteers.*Subjects-Method:* Ten healthy male subjects (age: 25–33, mean age: 29 years) had their gallbladder emptying assessed by real-time ultrasonography on three different occasions, two days apart each, and in a random order as follows: a) after ingestion of 300 ml of fresh milk (lipids 4%) (postpradial emptying) b) after giving 200 mg erythromycin intravenously followed immediately by the ingestion of 300 ml of milk and c) after giving 10 mg of cisapride per os followed 30 min later by the injection of 300 ml of milk. Gallbladder volume was calculated every 5 min for 60–90 min. From the emptying curves (plotting of volume against time) the pattern of emptying was assessed, and the lag phase duration, the ejection fraction and time by which maximal emptying was achieved were calculated.*Results:* Erythromycin significantly reduced the lag phase duration from 3.6 – 4.2 SDmin (milk alone) to 1.3 – 3.5 SDmin (milk plus erythromycin) ($p < 0.04$) and increased the lag phase of postprandial gallbladder emptying from 60.6 – 8.5 SD% (milk alone) to 78 – 8.5 SD% (milk plus erythromycin) ($p < 0.0006$). Cisapride increased the ejection fraction of postpradial gallbladder emptying from 60.6 – 8.55 SD% (milk only) to 67.1 – 8.8 SD% (cisapride plus milk) ($p < 0.005$). The effect of erythromycin on postrandial gallbladder emptying was significantly more pronounced than that of cisapride (ejection fraction: 78 – 8.5 SD% after erythromycin and milk vs 67.1 – 8.8 SD% after cisapride and milk; $p < 0.005$).*Conclusions:* Erythromycin and cisapride significantly enhance the postprandial gallbladder motor response, by increasing the extent of emptying. Motility, general: Functional GI disorders }" "The Effect of Erythromycin and Cisapride on Postprandial Gallbladder Emptying in Healthy Humans"

"P P 31 0740"P 31 0740**Interdigestive Gallbladder Contractions in a Real-Time Ultrasonographic Study: Differences between Patients with Gallstones and Controls**

*B. Brand, S. K\'fchne, E.F. Stange

Department of Internal Medicine I, University of L\'fcbeck, Germany*Aim:* Spontaneous gallbladder contractions occur in phase II of the migrating motor complex. This study compares these contractions in gallstone patients and controls. *Method:* We evaluated a new technique using a fixed fingertip array (Picker, Hofheim). Gallbladder dimensions of asymptomatic (n = 7) and symptomatic (n = 8) gallstone patients, as well as healthy controls (n = 10) were registered continuously. After a fasting period of at least 6 hours we measured all individuals every 5 minutes over a 6–8 hour period. Gallbladder volumes were estimated by the ellipsoid method. Minor oscilations less than 30% were excluded. To calculate the total amount of bile released per hour (gallbladder-index) we added all contractions and divided them by the total measurement time in hours. Exclusion criteria: cholecystitis, cholestasis, liver cirrhosis, thoracical or abdominal surgery, diabetes mellitus, age > 65 years, relevant medication. *Results:* Spontaneous gallbladder contractions of up to 86% and 35 ml were observed in all individuals except in 4 asymptomatic patients. Compared to the controls we found a significant reduction in frequency and magnitude of the contractions in asymptomatic but not in symptomatic gallstone patients. Controls Asymptomatic Symptomatic x SD x SD x SDSpont. contractions % 47.7 – 8.0[2] 16.7 – 19.5 46.3 – 5.6[2]Spont. contractions ml 16.8 – 6.2[1] 6.1 – 7.6 11.9 – 3.2Gallbladder-index %/h 26.3 – 12.9[2] 4.1 – 5.0 20.5 – 7.0[2]Gallbladder-index ml/h 8.9 – 4.8[2] 1.4 – 1.6 4.8 – 1.3[2]Number of contract./h 0.5 – 0.2[2] 0.1 – 0.1 0.4 – 0.1[2]1 p < 0.05, 2 p < 0.01 vs asymptomatics (Mann-Whitney-U-Test)*Conclusion:* Asymptomatic but not symptomatic gallstone disease appears to be associated with a reduced gallbladder motility in the interdigestive state. Gallstone patients with normal spontaneous contractions are likely to be symptomatic. Liver and bile ducts, 2: Gallstones, formation, treatment }" "Interdigestive Gallbladder Contractions in a Real-Time Ultrasonographic Study: Differences between Patients with Gallstones and Controls"

"P P 31 0741"P 31 0741**Poor Postprandial Gallbladder Contractility Does Not Predict Impaired Interdigestive Motility**

*B. Brand, S. K\'fchne, E.F. Stange

Department of Internal Medicine I, University of L\'fcbeck, Germany*Aim:* Impaired postprandial gallbladder motility is established as an exclusion criterion for nonsurgical treatment of gallstone disease (oral bile salts, shock wave lithotrypsy). Little is known about the spontaneous gallbladder motility during phase II of the migrating motor complex, though fragment clearance may also be influenced by this mechanism. We compared the postprandial and the spontaneous gallbladder contractility of gallstone patients and healthy controls.*Method:* By using a fixed fingertip array (Picker, Hofheim), gallbladder diameters of 7 asymptomatic and 8 symptomatic gallstone patients, 2 diabetics as well as 10 healthy controls were registered. After a fasting period of at least 6 hours we measured every 5 minutes over 6–8 hours. The individual volumes were calculated from the corresponding diameters using the ellipsoid method and regression analysis. The postprandial gallbladder contraction was registered with a 3.5 Mhz curved array 45 minutes after a standardized fatty meal (250 ml Nutrodrip). Exclusion criteria: cholecystitis, cholestasis, liver cirrhosis, thoracical or abdominal operations, age > 65 years, relevant medication.*Results:* The means of postprandial versus spontaneous contractions were comparable in the healthy (52.3 vs 47.7%) and the symptomatic (57.6 vs 46.3%) but not in the asymptomatic (51.1 vs 16.7%) and the diabetic group. However, the individual values were correlated poorly in the healthy (r: 0.26, p = 0.47) and the symptomatic (r: 0.05, p = 0.91) group. Four individuals (one out of each group) showed impaired postprandial contraction (< 30%) but three of them had a normal interdigestive motility. *Conclusion:* Postprandial contractility alone may be an inadequate measure of gallbladder function. Postprandial and interdigestive contractions correlate poorly suggesting different mechanisms of stimulation. Gallstone patients with poor postprandial but sufficient interdigestive contractility should probably not be excluded from non-surgical treatment. Liver and bile ducts, 2: Gallstones, formation, treatment }" "Poor Postprandial Gallbladder Contractility Does Not Predict Impaired Interdigestive Motility"

"P P 31 0742"P 31 0742**Can Cisapride Overcome the Effects of Octreotide (OT) on Gallbladder Emptying?**

*M.J. Veysey, P. Malcolm[1], P. Jenkins[2], G.M. Murphy, J.A.H. Wass, R.H. Dowling

Gastroenterology Unit, Guy's Hospital and Campus, UMDS, London

[1] Dept of Radiology, Guy's Hospital and Campus, UMDS, London

[2] Depts of Endocrinology St Bartholomew's Hospital, London

[3] The Radcliffe Infirmary, Oxford, UK*Background:* We and others have shown that OT inhibits meal-stimulated gallbladder (GB) emptying and induces the formation of cholesterol-rich GB stones. The effects of the prokinetic drug, cisapride, on the GB are controversial and it is not known whether cisapride can overcome the inhibition of GB emptying caused by OT and thereby prevent the formation of OT-induced GBS.*Methods:* We, therefore, used a randomised, double-blind, placebo-controlled, cross-over design to study the effects of cisapride (10 mg qds for 2 weeks) on GB emptying, assessed by real-time ultrasound after a fat-rich liquid meal, in 8 acromegalic patients (age range 21–69 yrs; 4 women) receiving long-term (> 3 months) octreotide (100–200 \'b5g tds) and in 8 non-acromegalic patients (age range 28–74 yrs; 5 women) from the Gastroenterology Outpatient Clinic. Fasting (FV) and residual (RV) GB volumes, the extent of GB emptying — as assessed by the ejection fraction (EF) — and the rate of GB emptying (RGBE) were calculated.*Results:* Mean values – SEM Acromegalic patients Non-acromegalic patients Cisapride Placebo Cisapride PlaceboFV (ml) 56 – 8.5** 37 – 5.6 25 – 4.6* 15 – 1.3RV (ml) 38 – 7.2* 24 – 4.4 8 – 1.3 6 – 0.3EF (%) 31 – 6.8 36 – 6.9 65 – 2.6 60 – 2.1RGBE (ml/min) 0.48 – 0.19* 0.28 – 0.13 0.38 – 0.08* 0.24 – 0.05*p < 0.05, **p < 0.005 compared to placebo*Summary/Conclusions:* These results show that cisapride increases the FV and, in the acromegalics, the RV, but leaves the EF unchanged, whilst significantly increasing the RGBE. Since stasis (large RV) and EF are probably more important than RGBE in GBS pathogenesis and if GB dysmotility is rate-limiting, cisapride is unlikely to prevent the formation of OT-induced GBS. Liver and bile ducts, 2: Gallstones, formation, treatment }" "Can Cisapride Overcome the Effects of Octreotide (OT) on Gallbladder Emptying?"

Istituto di Fisiopatologia Medica, Universita' ""G. D'Annunzio"", Chieti, Italia

[1] Dipartimento di Medicina Interna e Gastroenterologia, Universita' di Bologna, Italia

[2] Istituto Scientifico Ospedale S. Giuseppe, Centro Auxologico Italiano, Piancavallo, Verbania, ItaliaObesity is considered a risk factor for gallstone formation. Very low calorie diets (VLCD) represent a common treatment for morbid obesity; however an increased risk of gallstone formation has been reported during rapid weight loss induced by VLCD. Impaired gallbladder motility is considered among the pathogenetic factors for gallstone development. Since diet composition, and mainly its fat content, modulates gallbladder contraction and most of the commonly used VLCD are characterized by a low fat content, this study was aimed at evaluating in obese subjects during weight loss the effect of different VLCD on gallbladder motility, biliary lipid composition and gallstone formation. Sixteen gallstone-free obese subjects (4 males, 12 females, age: 35.5 – 2.8 yrs, BMI: 41.3 – 1.4 kg/m^2, mean – SE) were studied. Gallbladder motility was evaluated by an ultrasonographic (US) technique in response to a standard liquid meal. Subjects were randomly allocated to two weight reduction programs, each lasting 90 days; each program (A and B) was characterized by a different VLCD: -A: 520 kcal, 3.1 g of fats, 39.1 g of proteins, 123.2 g of carbohydrates; -B: 570 kcal, 12.5 g of fats, 51.1 g of proteins, 60.4 g of carbohydrates. At days 45 and 90 of the program the appearance of gallstones was investigated by US and gallbladder motility study repeated as at baseline; in 4 subjects for each group biliary lipid composition was also evaluated. Statistical analyses were performed using Mann-Withney test (independent samples) and Wilcoxon test (paired samples); results were expressed as mean – SE. BMI significantly (p {\'a3} 0.05) decreased in each group during the program: A, from 40.3 – 1.5 to 33.8 – 1.2 kg/m^2; B, from 42.3 – 2.0 to 35.4 – 1.6 kg/m^2. Gallbladder motility, expressed as percent emptying, remained unchanged during the program A (58.8 – 4.2 before, 71.1 – 3.5 at day 45, 68.4 – 4.0 at day 90), while a significant (p {\'a3} 0.04) increase at day 45 but not at day 90, was observed during program B (56.4 – 4.5 before, 72.4 – 3.2 at day 45, 66.4 – 5.2 at day 90). Fasting gallbladder volume decreased during weight reduction but this decrease was significant (p {\'a3} 0.04) in group B (35.7 – 4.6 ml before, 23.4 – 5.3 at day 45, 25.2 – 3.8 at day 90) but not in group A (34.6 – 4.5 ml before, 25.8 – 3.7 at day 45, 26.9 – 4.2 at day 90) Tree out of the 8 subjects (37.5%) who followed the program A, but none in the program B, developed asymptomatic gallstones. Biliary cholesterol, expressed as percent molar, significantly (p {\'a3} 0.05) increased at day 45, and then decreased, while no differences were found in biliary bile acids and phospholipids. These results suggest that VLCD with high fat content could prevent gallstone formation in obese subjects during weight reduction. Liver and bile ducts, 2: Gallstones, formation, treatment }" "Obesity and Rapid Weight Loss: Effect of Differen Very Low Calorie Diets on Gallbladder Motility and Gallstone Formation"

"P P 31 0744"P 31 0744**Role of 5-Hydroxytryptamine in Gall Bladder Motility**

*M.C. Fendt, J.N. Plevris, P.W.F. Hadoke, P.C. Hayes, I.A.D. Bouchier

Liver Research Laboratories, University Department of Medicine, The Royal Infirmary, Edinburgh EH3 9YW, Scotland UK*Introduction:* The bovine gall bladder is a useful model to study motility due to its similar morphological structure and bile composition to human gall bladder. Control of contraction by CCK and cholinergic neurones is well documented, but the role of 5-Hydroxytryptamine (5-HT) is not adequately investigated. This study aimed to investigate the role of 5-HT in mediating contraction and the effect of the selective 5-HT_3 antagonist Ondansetron. *Methodology:* Bovine gall bladder muscle strips (0.5 {\'b4} 1.0 cm) were placed into 10 ml organ baths and attached to an isometric force transducer (Grass FT03), linked to a computer to record the contraction traces. The organ baths contained Krebs Henseleit solution, continuously perfused with 95% O_2 and 5% CO_2, at 37\'b0C. Cumulative concentration response curves were produced to KCl (2.5–320 mM) and 5-HT (10{ -8} – 3 {\'b4} 10{ -4} M). The role of 5-HT_3 receptors was studied by performing concentration-response curves to 5-HT in the presence of Ondansetron (45 minutes, 10{ -8} M, 10{ -7} M, 10{ -6} M) followed by a concentration response curve to 5-HT.*Results:* The optimum resting force was found to be 3 g. A concentration-dependent contraction was elicited to both KCl and 5-HT. The maximum contraction to KCl occured at 80 mM and to 5-HT at 10{ -4} M. Frequent phasic contractions occurred especially at submaximal stimulation and were abolished by addition of 10{ -5} M indomethacin in the bathing medium. Ondansetron had no effect in the concentrations used in the maximum response of 5-HT curve.*Conclusion:* 5-HT, an important gut neurotransmitter, has a role as a mediator in gallbladder motility. Ondansetron, a widely used powerful anti-emetic, did not affect contractility, suggesting no role of 5-HT_3 receptors in gallbladder motility in our experimental model. Motility, general: Receptors and signals }" "Role of 5-Hydroxytryptamine in Gall Bladder Motility"

"P P 31 0745"P 31 0745**Cholescintigraphic Assessment of Bile Flow Delay in Symptomatic Cholecystectomized Individuals**

*E. Tankurt, E. Ellidokuz, H. Durak, B. Degirmenci, H. Akbaylar, I. Simsek, \'d6. G\'f6nen

Depts. of Gastroenterology and Nuclear Medicine, Dokuz Eyl\'fcl University, Izmir, TurkeyCholescintigraphy is one the proposed methods in the evaluation of sphincter of oddi functions in cholecystectomized individuals.*Aim:* We evaluated the scintigraphic hepatic hilum-duodenum transit time (HHDTT) in symptomatic and asymptomatic cholecystectomized outpatients in this study.*Methods:* Ten cholecystectomized patients with typical biliary type pain were included in the study. These were 2 males and 8 females with a mean age of 51.1 – 10.4. Seven asymptomatic cholecystectomized individuals (all female with a mean age of 45.0 – 14.5) were included, as the control group. All of the patients and control subjects were evaluated by ERCP and/or ultrasonography (USG) and had no evidence of choledocholithiasis. Biliary emptying was measured by hepatobiliary scintigraphy using 5 mCi Tc-mebrofenine.*Results:* HHDTT was longer than 8 minutes in 6 patients (60%) while it was 7 minutes or shorter in all of the control subjects. The mean value of HHDTT was 12.7 – 3.3 (3–19) and 6.0 – 0.4 (4–7) minutes in patients and controls respectively ($p < 0.05$). On the other hand, dilatation of common bile duct (more than 8 mm) was present in 6 patients but none of the controls. No correlation was found between the common bile duct diameter and HHDTT.*Conclusion:* Cholescintigraphic HHDTT is delayed in some cholecystectomized patients with typical biliary type pain. This group may require further investigations or therapy (e.g. sphincterotomy). Endoscopy, specific: BiliaryRadiology and ultrasound: Diagnosis }" "Cholescintigraphic Assessment of Bile Flow Delay in Symptomatic Cholecystectomized Individuals"

"P P 32 0747"P 32 0747**Incidence of Colorectal Adenomas (CRA) in a Cohort without Prior Personal or Family History of CRA or Colorectal Cancer (CRC)**

*B. Paillot, P. Czernichow, P. Michel, A.M. Queuniet, C. Daubert

Centre H. Becquerel and Hop. Ch. Nicolle F 76031 Rouen, FranceAlthough people without history of CRA or CRC constitutes the vast majority of the population, it is difficult to recommend a definite attitude towards prevention for this group which is considered at low risk, according to prevalence studies. The aim of this study was to evaluate the incidence rate which has not been determined until now. The study includes 450 persons enrolled in a colonoscopic cancer prevention program since 1979 to 1992 who had at least 2 flexible sigmo\'efdoscopies. Participants who had at the 1st exam present or past personal or first degree relatives history of CRA or CRC were excluded. The material consist of 298 women (66%); 170 persons were less than 50 yrs old (38%) while 28 were 70 or older (16%). The mean annual incidence rate has been calculated with a 95% confident interval (CI) from the actuarial method. Age and sex influence has been evaluated by mean of the Log-rank test. The median time of follow-up was 46 mths (9–160) and 163 persons (36.2%) underwent more than 2 exams (max. = 6). 32 subjects with CRA have been detected i.e. a mean annual incidence rate of 1.7% (CI: 1.0%–2.3%). It was higher for men than for women (p < 03), and it increased with age (p < 0.01). These rates are much lower than those known for people with prior CRA or CRC which are about 10%/yr, and could be taken into consideration when screening the general population by sigmo\'efdoscopy. Oncology, general: Screening, preventionOncology, general: EpidemiologyOncology, specific: Colon, rectum }" "Incidence of Colorectal Adenomas (CRA) in a Cohort without Prior Personal or Family History of CRA or Colorectal Cancer (CRC)"

"P P 32 0748"P 32 0748**Negative Influence of Homologus Blood-Transfusions on the Evolution of Patients with Coloorectal Carcinoma. {A Meta-analysis}R. Meier[1],**

*Ch. Beglinger[2], M. M\'fcller

[1] Cantonal Hospital Liestal, Switzerland

[2] University Hospital Basle, Switzerland

Janssen-Cilag AG, Baar, SwitzerlandSeveral publications mainly based on retrospective data, had shown a Negative influence of homologous blood-transfusions (HBT) on the evolution of patients with colorectal carcinoma. Several prospective studies have tried to clarify the issue and this analysis is an attempt to quantitatively assess the current knowledge.*Material and Methods:* This analysis concerns only prospective studies in colorectal Ca. listed in Medline between 1984 and 1996. Patients were classified as receiving homologous blood (HBT), autologous (ABD) or no blood transfusion (No BT). The time of transfusion considered was from the immediate pre- until the post-operative period. The parameters analyzed were 1\'b0) the incidence of post-operative infections and 2\'b0) Recurrence rates (both local & distant) at study end-point (usually 5 years). Data were analyzed using the Mantel-Haentzel-Peto method; significance was accepted if $p < 0.05$.*Results:* Rate of infections: 5 Studies compared HBT to No BT (N = 1594) and 3 studies compared HBT to ABD (N = 694) Rate of infections were 32% vs. 12% ($p < 0.001$) and 27% vs. 22% (n.s.). Recurrence rates: 3 Studies compared HBT to No BT (N = 1556) and 2 studies compared HBT to ABD (N = 338) Rate of recurrence were 41% vs. 24% ($p < 0.001$) and 41% vs. 31% (n.s.). The combined risk of an infection and/or recurrence is almost significantly higher after HBT than after ABD (Odds Ratio = 1.32; p = 0.054).*Conclusions:* Patients requiring a BT appear to be at higher risk of infection or recurrence than No BT, but the comparability of these pts. is questionable. Patients receiving HBT appear to be at a somewhat greater risk of infection or recurrence than those receiving ABD. Larger studies are needed in order to give a final answer to this question. }" "Negative Influence of Homologus Blood-Transfusions on the Evolution of Patients with Coloorectal Carcinoma. {A Meta-analysis}"

"P P 32 0749"P 32 0749**Human Papillomavirus (HPV) and Colon Cancer: No Viral DNA Sequence Found neither in Tumors nor in Normal Adjacent MucosaeE. Jullian, R. Benamouzig, A. Mordrelle, A. Martin, A. Pompidou, J. Rautureau**

Hospital Saint Vincent de Paul, 75014 Paris, France

Hospital Avicenne, 93009 Bobigny Cedex, FranceThe presence of human papillomavirus 6, 16, 18 and 33 was previously reported in up to 50% of colorectal carcinomas (Cheng et al, Gut 1995). The E6 protein of these high risk types was shown to bind to the tumor suppressor p53 protein and to promote its degradation. The aim of our study was to further investigate the putative role of these HPV types in colorectal carcinogenesis.Tumoral samples stored in liquid nitrogen from 55 patients were used. Normal adjacent mucosae was also available in all these cases. All clinicopathological data including age, sex, histological differentiation, immunohistochemical p53 status, tumour stage, tumour location, metastatic status and survival years were recorded. Samples were growded in liquid nitrogen. DNA was extracted with phenol-chloroform after lysis in buffer with detergent and proteinase K. Two PCR experiments were performed: (i) multiplex PCR using 3 sets of primers (E6 gene of HPV 16, 18 and internal control target located into the embryonic myosin heavy chain gene (ii) another one using consensus L1 primers. The PCR products were analysed after restriction mapping on 5% polyacrylamide gel stained with ethidium bromide. This multiplex HPV 16/18 PCR shows a sensitivity of 15 viral copies per sample. HPV DNA sequences could not be detected in any of the tumoral sample nor in the normal adjacent mucosa by any of the PCR techniques used.These results suggest that HPV are not involved in colorectal carcinogenesis at least in French patients.

"P P 32 0750"P 32 0750**The Role of Cholecystectomy in the Oncogenesis of the Digestive Tract****Daniel Ţuculanu[1], Ioan Romosan[1], Iosif A. Szucsik[2], Constantin Tudor[1], Lelia Susan[1], Calin Dascau[1]**

[1] 4-th Medical Clinic, University of Medicine and Pharmacy Timisoara, Romania

[2] 3-rd Surgical Clinic, University of Medicine and Pharmacy Timisoara, RomaniaThe preset study estimates the oncogenic risk after cholecystectomy, starting from the fact that the duodeno-gastric reflux (commonly noticed in cholecystectomized patients) is one of the major factors involved in the occurence of gastric epithelium metaplasia.The authors have carried out a retrospective analysis of 462 cases that were consecutively diagnosed in our medical department with cancers of the digestive tract: 67 cases with oesophageal cancer, 223 cases with gastric cancer and 172 cases with colo-rectal cancer.Seventy-nine patients had cholecystectomy in their history (9% of those with oesophageal cancer, 17% of those with gastric cancer, and 20% of those with colo-rectal cancer). In all three localisations the subgroups of cholecystectomized patients presented certain features thar differentiated them from the rest of the patients: in the case of the oesophagus we noticed the predominence of the feminine gender, of the localisation in the lower third, and of the adenocarcinoma histological type; in the case of the stomach we noted the prevalence of the fungating endoscopic type and of intestinal histological type; in the case of colo-rectal cancer the localisation in the right half of the large bowel were predominant. A common characteristic for all localisations was the earlier age when the cancer set in and a long period since the surgical intervention.All these data suggest that cholecystectomy plays a role in the oncogenesis of the digestive tract, either through the direct action of the biliary constituents (lysolecithin, biliary acids), or through the sensitivisation of the mucosa to the action of other aggresive factors. "P P 32 0751"P 32 0751**Family Study on Colorectal Cancer from the Digestive Cancers Registry of ""Calvados"": An Intermediate Report**

*N. Andrieu[1], G. Launoy[2], R. Guillois[1], C. Ory-Paoletti[1], M. Gignoux[2]

[1] Unit\'e9 INSERM 351, Villejuif, France

[2] Registre des tumeurs digestives du Calvados, Caen- FranceIn France, colorectal cancer (CCR) is the most frequent cancer for both females and males (26000 new cases each year). Although an increased risk has been associated with a family history of CCR in nearly all epidemiological studies, few population-based family studies have been performed. A population-based family study has been carried out in Calvados, France, from September, 1st, 1993.The main aim of this study is to define the role of genetic factors in the disease transmission accounting for environmental factors from a sample of systematically recorded family data. Results of a feasibility study connected with the above study showed a high proportion of contacted people who agreed to participate and a good representativity of the recruited cases compared with the registered cases.A report of the definitive study progress is presented in this paper. During 30 months, 837 new cases of colorectal cancer have been diagnosed in Calvados. Four hundred three families have been included today. A high proportion of included persons (index cases and relatives) accepted being taken a blood sample (about 80%). The mean age for the index cases is 68.1 years for men (age range: 39 to 91 yrs) and 69.8 years for women (age range: 34 to 94 yrs). Twenty two per-cent of the families have at least one colorectal cancer in addition to the index case. For 14 per-cent of them, at least one colorectal cancer occurred in the first degree relatives (i.e: sibship, children or parents). Fifteen per-cent of the families have at least one breast cancer, 13% a stomach cancer. For 7 per-cent of the families, one breast or one stomach cancer occurred in the first degree relatives.The recruitment of new cases will stop in September 1997. About 670 families are expected to be included. "P P 32 0752"P 32 0752**Selenium Status in the Patients with Colorectal Adenoma and Colorectal Carcinoma**

*R. Krstic, M. Ugljesic, T. Milosavljevic, M. Bulajic, I. \'d0ujic

Institute for Digestive Diseases, University Clinical Center, Belgrade, YugoslaviaSelenium is increasingly recognized as a versatile antucarcinogenic agent. Selenium appears to operate by several mechanisms depending on dosage and chemical form of Selenium (Se) and the nature of the carcinogenic stress. Se prevents the malignant transformation of cells by acting as a ""redox switch"" in the activation/inactivation of cellular growth factors and other functional proteins through the catalysis of oxidation/reduction reactions.We investigated Se status in the colorectal adenoma (CA) group of patients (pts.) who underwent endoscopic polypectomy, and operated group of pts. with colorectal carcinoma (CC). The control group were healthy volunteers from Public Health Medicine. Concentrations of Se were examined in polyp tissue, carcinoma tissue, plasma, erythrocyte, lymphocytes, hair and 24-h urine samples. Malonedyaldechyde (MDA) was also investigated as an indicator of oxidation stress. The results showed that CA group and CC group of pts. had significantly lower concentrations of Se in Er and in plasma, Se concentrations were increased in urine, and it was lower in hair and Ly, but not significantly. Se concentrations in CA tissues was higher, in CC tissue was lower, comparing with healthy volunteers. Concentrations with Se were lower in the examined operative edge of the colonic tissue in the CC group, comparing with healthy volunteers. Values of MDA were 200–1000 times higher in the CC tissue and 6–40 times in the CA tissue, comparing with healthy volunteers. *N.E. Samalavicius, R.K. Drasutis, V. Kucinskas, M. Stukonis, V. Grazienė, A. Buineviciu¯tė, E. Avizienytė, A. Kirtiklis

Vilnius University Red Cross Hospital Dep. of Abdominal Surgery, Z¯ygimantu 3 2001, Vilnius, Lithuania*Purpose of the study:* While establishing the polyposis register, to present data on familial adenomatous polyposis patients (FAP) in local population.*Methods used:* From March 1995 to March 1996, possible data on polyposis patients in our republic was collected and information disseminated via professional and public sources about the register and disease itself. Screening of the 1\'b0 relatives was centralized and attempts to coordinate prophylactic treatment were made. Criteria of registration followed international guidelines.*Results:* 23 polyposis families were registered with known 54 affected persons. 9 of these families have been isolated cases. A detailed information on 17 patients with colorectal cancer revealed 4 (23.5%) to have synchroneous cancers. Earliest onset of colorectal cancer was in a 21 year old male. From 16 patients 12 (83%) had duodenal adenomas, from 16 patients 4 (32%) had mandibular osteomas and 13 (93%) of 14 patients had CHRPE (congenital hypertrophy of retinal pigment epithelium. First DNA tests have been performed for our polyposis patients.*Conclusion:* Increasing collaboration with medical professionals and knowledge about FAP should be an important factors influencing further successful registration and treatment of FAP patients.

"P P 32 0754"P 32 0754**Screening for Hereditary Non-Polyposis Colorectal Cancer within a County Register in Romania**

*L. Gheorghe, G. Aposteanu, C. Gheorghe, Al. Oproiu

Center of Gastroenterology, Fundeni, Bucharest, RomaniaOne of the most important roles of the hereditary non-polyposis colorectal cancer (HNPCC) Registry is to coordinate the screening programs. It provides the opportunity for colorectal cancer (CRC) prevention in family members who are at 50% lifetime risk. The aim of this prospective controlled longitudinal study was to evaluate the efficacy of the screening within a county HNPCC Registry (established in early 1989) in Bucharest area in Romania.; 21 families fulfilling ""the Amsterdam criteria"" were extracted from a cohort of 808 CRC between March 1990–March 1996. For the ascertainment of probands, information were collected about all types of malignancies, age at onset, location and histology. The genealogical studies and pedigrees construction were made as accurate as possible. The family members at risk were identified and call-up into the study. The screening group consisted in 54 subjects undergoing periodic examinations (full colonoscopy/sigmoidoscopy and barium enema) at 2–3 yr. interval whereas 87 subjects of the control group had no screening examinations. The adenoma/CRC detection and survival curves were compared by the Kaplan-Meier product limit method between the two groups of asymptomatic at-risk subjects. Adenoma/CRC occurred in 10/6 screened subjects (16.5% positive examinations) vs 2/20 control subjects. The tumor Dukes stage (A + B vs C + D) was more favorable in screened group with one case of death caused by CRC vs 10 in control group at the end of the study. Although the adenoma/CRC occurrence did not differ significantly (p = 0.81), survival curves showed a significantly better survival in screened vs non-screened subjects (p = 0.04).*Conclusion:* the 2–3 yr. interval screening programs on HNPCC, although detecting a similar rate of neoplastic colorectal changes, demonstrate a significant survival benefit in screened vs non-screened subjects with HNPCC, contributing to a more favorable prognosis.

"P P 32 0755"P 32 0755**Hereditary Non Polyposis Colon Cancer (HNPCC) Prevalence: A Prospective Multicentric Study**

*G. Riegler, A. Savastano, F. Selvaggi, R. Ciociano, G. Riccio, E. Manzo, R. Iorio, R. Carratu', Gruppo di Studio SIED-Campania, P. Borgheresi, G.B. Rossi, G.D. DePalma, P. Russo, A. Piscitelli, F. Baldi, F. Guardascione, P. DiGiorgio, E. D'Avenia, F. Montanaro, E. Parente, O. Saffiotti, M. Bozzi

Seconda Universita'di Napoli, Cattedra di Gastroenterologia -ItalyPrevalence of HNPCC was reported to be 1–5% depending on the adopted criteria.The aim of this study was to define the prevalence in a South Italy region (Campania), lacking in a Cancer Register.We have studied 501 patients with endoscopic first diagnosis of colorectal cancer, observed in 13 Campania clinics. The Family Pedigrees have been collected and all cases of cancer reported, checking the diagnosis from death certification, case sheet and evidence of the family doctor. The 501 patients included 275 men and 226 women: 61 (12.2%) = < 50 years of age. Twenty-four (4.8%) showed vertical trasmission -and 38 (7.6%) trasversal aggregation- of colorectal cancer. Rigth colon localization (upper splenic flexure) was shown by 125 (25%) pts with 7 cases (1.4%) of synchronic tumours.We have identified 5 (1.0%) HNPCC families that corresponded to Amsterdam criteria (a = at least three colorectal cancer, b = two first-degree relatives with cancer in different generation, c = one of them less of 50 years old).Amsterdam criteria seemed to be too restrictive, so we have weighted the prevalence with the ""three less one criteria method"": a + b conditions were shown by 6 pts (1.2%), a + c by none, b + c by 3 pts. (0.6%).In conclusion, with expanded criteria, fourteen HNPCC patients were recorded with a prevalence of 2.79%.

"P P 32 0756"P 32 0756**Increased Prevalence of Adenomas in Colorectal Cancer Patients from HNPCC Kindreds**

*A. Suspiro, P. Fidalgo, M. Cravo, P. Lage, P. Chaves, C. Nobre Leit\'e3o, F. Costa Mira

Servi\'e7o de Gastrenterologia, Instituto Portugu\'eas de Oncologia, Lisbon, Portugal*Background:* Hereditary non-polyposis colorectal cancer (HNPCC) is an autosomal dominantly inherited syndrome characterized by propensity to develop colorectal cancer (CRC) at a young age. There is increasing evidence that aggressive adenomas are the precursor lesions in HNPCC. Whether there is an increased prevalence of adenomas is still unclear. The assessment of the nature of precancerous lesions in HNPCC will have a major impact on the design of preventive strategies. *Aims:* To compare the prevalence and histopathology of adenomas in CRC-bearing members of HNPCC kindreds with sporadic CRC patients. *Patients and Methods:* We included 11 patients with CRC retrospectively classified as belonging to HNPCC kindreds (Group A) and 59 consecutive patients with sporadic CRC (Group B). HNPCC was diagnosed according to Amsterdam criteria. Absence of information regarding the entire colon was an exclusion criteria for both groups. We registered all adenomas found in the perioperative colonoscopy, operative specimen and endoscopic examinations of the remaining large bowel during routine surveillance. Adenomas and cancers were classified according to WHO criteria. Staging was by the Dukes classification. Differences between groups were calculated using the chi-square test. *Results:* Group A – 11 patients, 1 male and 10 females, mean age 54.2 (\'b1 13.9); Group B – 59 patients, 31 males and 28 females, mean age 59 (\'b1 10.3). CRC location: Group A – rectum 18% (2/11), left colon 18% (2/11), right colon 64% (7/11); Group B – rectum 45% (26/59), left colon 25% (15/59), right colon 30% (18/59). CRC histopathology and Dukes stage were similar in both groups (except for the greater frequency of mucinous tumors in Group A – 54% vs 17%). We found synchronous adenomas in 54% of patients in Group A (6/11) and in 25% of patients (15/59) in Group B – $p < 0.05$. There was a trend towards greater adenoma size in Group A (19.8 mm vs 13.9 mm) compared to Group B. We found no differences in the frequency of villous features or high grade dysplasia. Mean time of follow up was similar in both groups (58.2 months, 4–495). Metachronous adenomas were detected in 66.6% of Group A patients and 15.7% of Group B patients – $p < 0.01$. *Conclusions:* CRC in HNPCC patients in associated with an increased prevalence of adenomas, both synchronous and metachronous. This strongly supports the idea that adenomas are the precursor of cancer in HNPCC, further supporting the profilactic value of colonoscopic surveillance.

"P P 32 0757"P 32 0757**Mutational Analysis of the hMLH1 Gene Using an Automated Two-Dimensional DNA Typing System**

*S. Sasaki, T. Muto[1], Y. Nakamura[2]

[1] First Dept. of Surgery, The University of Tokyo, Tokyo, Japan

[2] Laboratory of Molecular Medicine, Institute of Medical Science, Tokyo, Japan*Purpose:* At present, single-strand conformation polymorphism (SSCP) is the most widely used method of mutational analysis because of its simplicity and relatively high sensitivity. However, SSCP is not economical when the number of samples is small. Moreover, regarding sensitivity, the method called denaturant gradient gel electrophoresis (DGGE) is more excellent. Hence, we tried to set up optimal conditions of an automated two-dimensional DNA typing system based on the principle of DGGE for mutational analysis of hMLH1 and to examine its usefulness as a mutational analysis method.*Methods:* To determine optimal conditions, we used five different kinds of germline mutation among six HNPCC pedigrees and two somatic mutations in a single RER+ sporadic endometrial cancer, which had been already revealed by other means. Furthermore, by this method we screened the entire coding regions of hMLH1 in DNAs isolated from affected individuals belonging to two HNPCC kindreds and four HNPCC-like kindreds, and from four patients with multiple primary cancers as well as eight RER+ sporadic colorectal cancers.*Results:* All mutations used as positive controls were detectable by the 2-D DNA methods. Twenty-one spots covering all 19 coding exons were visualized on a single gel, and we could envisage whether and where any mutations existed. We also detected novel germline mutations in one HNPCC proband and one RER+ sporadic colorectal cancer, and one polymorphism in two HNPCC-like kindreds.*Conclusion:* This new diagnostic method is very useful and offers a major improvement over current approaches. "P P 33 0758"P 33 0758**The Influence of Intestinal Transit Rate on Colonic Luminal pH and Stool Short Chain Fatty Acid Concentration**

*S.J. Lewis, K.W. Heaton

Department of Medicine, Bristol Royal Infirmary, Bristol BS2 8HWPopulations at low risk of colonic cancer consume large amounts of fibre and starch (fermented by bacteria to short chain fatty acids (SCFA)) and pass acid bulky stools. Traversing the colon SCFA are absorbed and luminal pH increases to neutral. One SCFA, butyrate, is the colon's main energy source and inhibits malignant transformation *in vitro*. Low colonic pH should be associated with high levels of butyrate and thus decreased predisposition to cancer. We set out to test two hypotheses: 1. Altering colonic transit rate alters colonic pH. 2. Distal colonic luminal pH is correlated with the SCFA (especially butyrate) content of the stools.13 healthy volunteers took in turn supplements of wheat bran (mean 28.3 g/day), senna laxative and loperamide, each for nine days with a 2 week washout period. Before and in the last 4 days of each intervention period dietary intake, whole gut transit time (WGTT), stool pH, stool SCFA concentrations (by GLC) and intracolonic pH (using a radiotelemetry capsule for continuous monitoring) were assessed.There was no difference between dietary intakes specifically total fibre, NSP or fat at the start and end of each interventional period. pH measurements were similar in the distal colon and stool. WGTT decreased and stool output increased with wheat bran and senna, *vice versa* with loperamide. Changes in WGTT were least impressive for wheat bran. Baseline stool SCFA concentration correlated with distal colonic pH (r = { -}0.417, p = 0.01) and WGTT (r = { -}0.623, p < 0.001), similar correlations were seen for baseline stool butyrate (distal pH r = 0.434, p = 0.007 & WGTT r = 0.610, p < 0.001).Colonic pH and stool SCFA concentration: effect of transit-altering agents Mean Colonic pH Stool SCFA (\'b5mol/g)*p < 0.05 Middle Distal Butyrate Total start end start end start end start endWheat bran 6.8 6.6 7.1 6.9* 69 79 443 451Senna 6.9 6.4* 7.1 6.7* 63 193* 376 836*Loperamide 6.9 7.0 7.1 7.2 69 23* 531 345*There is a relationship between bowel transit rate (diet being constant) and stool pH, stool SCFA concentration and distal colonic pH. This may explain the associations between colonic cancer and dietary fibre, stool output and stool pH, in that stool pH is a marker for SCFA levels including butyrate.

"P P 33 0759"P 33 0759**Non-Invasive Recording of Colonic Electrical Activity Based on Experimental InvestigationsA. Noeva,**

*P. Penchev, H. Kadiyan, P. Gurkov, A. Atanassova

Inst. of Physiology, Bulgarian Academy of Sciences, ""Acad. G. Bonchev"" Str., bl. 23, Sofia 1113, BulgariaThe study was aimed at non-invasive recording of the electrical activity of the human colon, i.e. electrocolography (EcolG).Experiments were made on dogs with silver, bipolar, ball-shaped electrodes chronically implanted on the muscle wall of the colon. Skin electrodes were placed on the abdominal wall in the beginning of each experiment. Slow waves were led off in the electrocolomyogram (EColMG), corresponding to low-amplitude waves in the non-invasive electrocologram (EColG). The bursts of spike potentials with the colonic slow waves in the EColMG corresponded to an increase of the amplitude of the EColG waves, manifesting an increased colonic motility. There was a good correlation between the number and frequency of spike potentials in a group and the wave amplitude in the EColG. Thus the functional state of the colon could be judged by the differences in the amplitude of the EColG waves.The electrical activity of the descendent colon of fifteen healthy volunteers was recorded by skin electrodes sticked on the abdominal wall along the descendent colon projection. The electrogastrogram (EGG) was led off too. The electrical activity of the colon and stomach were recorded on an original 2-channel electrogastrograph. A method for complete elimination of the cardiac artifacts was elaborated and successfully implemented. The means – S.E.M. of the frequency of colonic and gastric waves were calculated. Two kinds of EColG waves according to the frequency were identified: i) waves with a frequency in the range of 5.85 – 0.50 cpm and ii) waves with a frequency in the range of 2.37 – 0.31 cpm. The frequency of the EColG waves was compared with that of the EGG waves. There was a significant difference between the frequencies of the EColG waves and the frequency of the EGG waves – 3.26 – 0.26 cpm (n = 7).Thus the proposed electrogastrographic method proved to be suitable for non-invasive registration of the electrical activity of the human colon. It could also provide reliable information on the EColG wave frequencies at visual inspection.Supported by Grant L-539 from the National Fund ""Scientific Research"", Bulgaria. }" "Non-Invasive Recording of Colonic Electrical Activity Based on Experimental Investigations"

*H. Akiho[1], Y. Chijiiwa[2], H. Okabe[2], N. Harada[2], Y. Motomura[2], Y. Iwakiri[2], H. Nawata[2]

[1] Harasanshin Hospital, Taihakucho 1–8, Hakata-ku, Fukuoka, Japan

[2] Third Department of Internal Medicine, Faculty of Medicine, Kyushu University, Fukuoka, JapanStudies on the functional changes in colonic muscle from patients with ulcerative colitis (UC) have yielded conflicting results. This study was designed to evaluate the inflammation-associated changes in colonic muscle motility using isolated cecal circular smooth muscle cells from guinea pigs with carrageenan-induced colitis (UC-like colitis).The smooth muscle cell length in the basal state of animals with colitis was compared with that in normal animals. In addition, the effect of contractile agents (cholecystokinin-8 [CCK-8], carbachol), and relaxing agents (N6, 2{\'a2}-O-dibutyryl adenosine 3{\'a2}, 5{\'a2}-cyclic monophosphate [dBcAMP] and N2, 2{\'a2}-O-dibutyryl guanosine 3{\'a2}, 5{\'a2}-cyclic monophosphate [dBcGMP]) on isolated muscle cells with or without colitis were assessed.In the basal state, the mean cell length in animals with colitis was significantly ($p < 0.001$) shorter than that in normal animals. CCK-8 and carbachol-induced contraction with colitis was significantly decreased by 72.2% ($p < 0.05$) and 60.3% ($p < 0.001$), respectively, compared with that in normal animals. dBcAMP and dBcGMP had no significant effect on smooth muscles from animals with colitis.The data showed that the weak contractile response in animals with colitis was due to the basal cell length which was significantly shorter than that in normal animals, and suggested that the relaxing mechanism of smooth muscles in animals with colitis was disturbed. *J. Schill, H.-J. Krammer, J.C. Lee, W. Meier-Ruge[1], M.V. Singer

Department of Medicine IV, Univ. Hosp. of Heidelberg at Mannheim, Germany

[1] Dept of Pathology, Univ. of Basel, SwitzerlandTraditional histopathological methods like the acetylcholin-esterase reaction on sections of the colon bowel are normaly used to diagnose and to investigate the histopathology of abnormalities of the enteric nervous system including the hypoganglionosis. The hypoganglionosis is only defined as a reduction of nerve cells of about 50%.In contrast to these methods we have investigated the histopathology of the enteric nervous system in whole mount preparations of resected segments of the colon of 10 patients suffering from severe constipation caused by aganglionosis and hypoganglionosis by NADPH-diaphorase reaction.We could recognize that the meshwork of the enteric plexus is very irregular. The density of the ganglia and nervestrands is reduced. The ganglia are very small and contain a small number of nerve cells. The morphology of the nerve cells is very uniform in contrast to normal enteric nerve cells. Functionally the nerve cells are characterised by week NADPH-staining as expression of low NOS-content, which can cause constipation.We may conclude that NADPH-diaphorase-reaction on whole mount preparations of the human colon is a simple and reproducible method for the histopathological investigation of congenital defects of the ENS. Using this methods we could provide a completion to the previous histopathological image of the hypoganglionosis.sponsored by DFG: Kr 1257/2-1 Motility, general: InnervationMotility, specific: Colon, anorectum }" "Histopathology of Hypoganglionosis in Whole Mount Preparations of the Human Colon"

"P P 33 0762"P 33 0762**Direct Contractile Effect of CCK on Caecal Circular Smooth Muscle Cells Via Both CCK_A and CCK_B Receptors**

*Y. Motomura, Y. Chijiiwa, Y. Iwakiri, H. Akiho, T. Kabemura, H. Nawata

Third Department of Internal Medicine, Faculty of Medicine, Kyushu University, Fukuoka, JapanCholecystokinin (CCK) contracts gastrointestinal smooth muscle cells. However there has not been sufficient investigation about receptors for CCK on smooth muscle cells. Receptors for CCK are divided into two subtypes: CCK_A and CCK_B. This study was designed to investigate the CCK receptor subtype responsible for caecal circular smooth muscle contraction by CCK.*Methods:* Smooth muscle cells were isolated from caecal circular smooth muscle layer of the guinea pig. Cells were stimulated by test agent. At the end of incubation, acrolein was added. The length of 50 cells in microscopic fields was measured by image splitting micrometry, and the percent decrease in mean cell length was determined by comparison with the control. Kinetic studies were performed. Cells were incubated with a fixed concentration of CCK-8 for various length of time. For subsequent experiments, the optimal incubation time was used. A dose-response curve for CCK-8 (10^{-13}–10^{-8} M) was determined. We assessed the inhibitory effect of various concentrations of CCK_A receptor-selective antagonist, FK480 on 10^{-9} M CCK-8-induced contraction; the inhibitory effect of various concentrations of CCK_B receptor-selective antagonist, YM022 on 10^{-9} M CCK-8-induced contraction; the inhibitory effect of 10^{-10} M FK480 on each concentrations of CCK-8-induced contraction; the inhibitory effect of 10^{-10} M YM022 on each concentrations of CCK-8-induced contraction; and the inhibitory effect of a combination of 10^{-10} M FK480 and 10^{-10} M YM022 on each concentrations of CCK-8-induced contraction.*Results:* Both FK480 and YM022 inhibited 10^{-9} M CCK-8-induced contraction in a concentration-dependent manner. A significant inhibition was obtained at a concentration as low as 10^{-10} M FK480 and 10^{-10} M YM022. At a concentration of 10^{-10} M, both FK480 and YM022 shifted the concentration-response curve for CCK-8 to the right. In addition, a combination of 10^{-10} M FK480 and 10^{-10} M YM022 shifted the concentration-response curve for 10^{-10} M FK480 alone or 10^{-10} M YM022 alone to the right.*Conclusion:* Our results strongly suggest that the guinea-pig caecal circular smooth muscle cell contains both CCK_A and CCK_B receptors and the contractile effect of CCK-8 is mediated via both of these receptors. Motility, general: Receptors and signalsMotility, specific: Colon, anorectum }" "Direct Contractile Effect of CCK on Caecal Circular Smooth Muscle Cells Via Both CCKA and CCKB Receptors"

"P P 33 0763"P 33 0763**Long-Term Octreotide Treatment Increases Large Bowel Transit Time (LBTT), the Proportion of Deoxycholic Acid (% DCA) in Serum and the Risk of Gallstone Formation**

*M.J. Veysey, S.R.D. Arraton, A. Mallet[1], P. Jenkins[2], G.M. Murphy, J.A.H. Wass, R.H. Dowling

Gastroenterology Unit, UMDS of Guy's and St Thomas' Hospitals, London

[1] Mass Spectrometry Laboratory, UMDS of Guy's and St Thomas' Hospitals, London

[2] Depts of Endocrinology St Bartholomew's Hospital, London

[3] The Radcliffe Infirmary, Oxford, UK*Background:* OT increases the % DCA and the cholesterol saturation of gallbladder bile and together with impaired meal-stimulated gallbladder emptying, this induces the formation of cholesterol-rich gallbladder stones (GBS). Prolongation of intestinal transit has been proposed as the mechanism for the increase in the % DCA, but our earlier unpaired studies failed to show a significant effect of OT on large bowel transit — important since the colon is the site of DCA formation and absorption.*Methods:* We, therefore, used a radio-opaque marker shape technique to measure LBTT in 8 acromegalic patients (age range 22–69; 4 women) before and during long-term (> 3 months) octreotide treatment (100–200 \'b5g tds by sc injection). Moreover since there is an exchange, and ultimately an equilibrium, between bile acids in serum and bile, we also measured the % DCA in fasting serum from 6 of these patients, using gas chromatography-mass spectrometry.*Results:* The mean LBTT increased from 42 – SEM 4.3 h before to 55 – 5.1 h during OT treatment ($p < 0.0001$) and the mean % DCA increased from 15 – 2.5% to 28 – 4.7% ($p < 0.05$). Furthermore, there was a significant linear relationship between LBTT and % DCA ($r = 0.87$, $p < 0.0005$).*Conclusions:* The results of these paired studies show that OT prolongs LBTT and leads to an associated increase in the % DCA in serum, and by implication the % DCA in bile — thereby increasing the risk of gallstone formation. Liver and bile ducts, 2: Gallstones, formation, treatmentLiver and bile ducts, 2: Bile acids synthesisMotility, specific: Colon, anorectum }" "Long-Term Octreotide Treatment Increases Large Bowel Transit Time (LBTT), the Proportion of Deoxycholic Acid (% DCA) in Serum and the Risk of Gallstone Formation"

"P P 33 0764"P 33 0764**Presence of Functional Receptors for Corticotropin Releasing Hormone in Caecal Circular Smooth Muscle Cells of Guinea Pig**

*Y. Iwakiri, Y. Chijiiwa, Y. Motomura, H. Akiho, H. Nawata

Third Department of Internal Medicine, Faculty of Medicine, Kyushu University, Fukuoka, JapanSmooth muscle cells isolated separately from the caecal circular smooth muscle layer of the guinea pig were used to investigate whether corticotropin releasing hormone (CRH) can inhibit directly the contraction produced by cholecystokinin octapeptide (CCK-8). And the role of adenylate cyclase and guanylate cyclase in the direct inhibitory effect of CRH was examined. In addition, ^{125}I-CRH binding was examined to demonstrate the presence of specific binding site for CRH on isolated smooth muscle cells.*Methods:* The inhibitory effect of various concentrations of CRH on 10{ ¯9} M CCK-8-induced contraction was examined. And the effect of 2{\'a2}, 5{\'a2}-dideoxyadenosine (an inhibitor of adenylate cyclase), adenosine-3{\'a2}, 5{\'a2}-(cyclic) monophosphorothionate (an inhibitor of cAMP-dependent protein kinase), phorbol 12-myristate 13-acetate (an inhibitor of particulate guanylate cyclase), 6-amilino-5, 8-quinolinedione (an inhibitor of soluble guanylate cyclase) on the CRH-induced relaxation of caecal circular smooth muscle cells were examined. In addition, the time course changes in ^{125}I-CRH binding and the ability of unlabeled peptides to displace ^{125}I-CRH were examined.*Results:* CRH inhibited the contractile response produced by 10{ ¯9} M CCK-8 in a concentration-dependent manner. An inhibitor of particulate guanylate cyclase and an inhibitor of soluble guanylate cyclase had no significant effect of the relaxation produced by CRH. In contrast, an inhibitor of adenylate cyclase and an inhibitor of cAMP-dependent protein kinase significantly inhibited the relaxation produced by CRH in a concentration-dependent manner. The specific binding of ^{125}I-CRH to isolated smooth muscle cells reached maximal binding at 120 min. The specific binding of ^{125}I-CRH was inhibited by unlabeled CRH in a concentration-dependent manner.*Conclusion:* Our findings show the direct inhibitory effect of CRH on caecal circular smooth muscle cells, and strongly suggest the presence of CRH receptor coupled to adenylate cyclase leading to generation of cAMP and activation of cAMP-dependent protein kinase on these cells. "P P 33 0765"P 33 0765**Faster Intestinal Transit is Associated with Lower Serum Oestrogens**

*S.J. Lewis[1], R.E. Oakey[2], H.H.G. McGariggle[3], K.W. Heaton[1]

[1] Dept of Medicine, Bristol Royal Infirmary, BS2 8HW

[2] SAS Centre for Steroid Hormones, Leeds General Infirmary, LS2 9LN

[3] Dept of Obs & Gynae, University College London, WC1E 6HXAny factor limiting reabsorption of oestrogens from the colon should lead to increased faecal excretion of oestrogen and reduced serum oestrogens. High fibre diets and wheat bran suppliments reduce serum oestrogens, perhaps explaining associations between a high fibre intake and reduced risk of breast cancer. We hypothesised that fibre reduces serum oestrogen concentrations by speeding colonic transit, reducing the time for bacterial deconjugation (by { b}-glucuronidase a pH dependent enzyme) and/or reabsorption of oestrogens. To test this we altered whole gut transit times (WGTT) in 3 ways and looked for changes in serum oestrogen and in stool pH and { b}-glucuronidase activity.40 healthy premenopausal volunteers were randomised to one of 3 groups. Ten subjects took senna then after a washout period wheat bran, both for 2 menstrual cycles. Another 10 did the reverse. A third group of 20 subjects took loperamide to slow down transit for two cycles. All supplements were taken in the maximum tolerated dose. At the beginning and end of each study period blood was taken for oestrogens (day 6 of the menstrual cycle), a 4 day dietary record was kept, WGTT was measured and stools were analysed for pH and { b}-glucuronidase activity.Serum oestrone sulphate, the major storage form of oestrogen, fell with wheat bran (average dose 20 g/day) and with senna; both unconjugated and non-protein bound oestrone fell only with senna. No significant changes in serum oestrogens occurred with loperamide. Senna and loperamide caused significant alterations in WGTT; changes in those taking wheat bran supplements tended towards a reduction ($p = 0.06$). No significant changes were seen in faecal { b}-glucuronidase activity. Stool pH changed only with senna, where it fell. There was no significant change in dietary intakes.Changes in geometric means of serum oestrogens (pmol/l) *$p < 0.05$ Oestradiol Oestrone Oestrone sulphate Start End Start End Start EndWheat bran 281 262 240 246 1745 1523*Senna 261 226 252 206* 1833 1647*Loperamide 233 249 219 240 1641 1820Speeding up intestinal transit can lower serum oestrogens. Faster intestinal transit may explain the epidemiological association of low risk of breast cancer with a high fibre intake. "P P 33 0766"P 33 0766**Differential Sensitivity of Isolated Smooth Muscle Cells from Normal and Inflamed Human Colons to Contractile Agents. Effects of Calcium Channel BlockersJ.C. Boyer, C. Guitton, P. Pouderoux, M.O. Christen[1], J.L. Balmes, J.P. Bali**

Unit\'e9 Fonctionnelle d'Exploration de la Fibre Lisse, Service d'H\'e9patogastroent\'e9rologie et Alcoologie, CHU Car\'e9meau, Nimes, France

Laboratoire de Biochimie des Membranes, INSERM CJF 92-07, Facult\'e9 de Pharmacie, Montpellier, France

[1] Solvay Pharma, 42, rue Rouget de Lisle 92151 Suresnes Cedex, FranceContractile activity of colonic smooth muscles from patients with IBD yielded conflicting results: some of them showed a decreased activity as compared to normal muscles, others reported no significant changes. We compare contractile response to different agonists of smooth muscle cells (SMC) enzymatically isolated from normal (n = 32) and inflamed (n = 33) human colons. The effects of calcium channel blockers (diltiazem and pinaverium bromide) were also evaluated. Contractile responses to CCK (1 nM), CCh (1 nM) and KCl (20 nM) were evaluated by video-microscopic measurements of the mean length of 100 isolated SMC. The efficacies of agonists were significantly lower to induce contraction of inflamed (CCK: 11.86 – 1.40%, CCh: 10.76 – 1.27%, KCl: 11.12 – 1.40%) than normal (CCK: 16.81 – 1.15%, CCh: 15.72 – 1.14%, KCl: 16.14 – 1.20%) colonic SMC; a significant increase in the level of contractions with age was observed ($p < 0.05$, Spearman test's). In contrast, no significant correlation with sex, smoking, or with the presence of other diseases was found. Pinaverium induced a significant decrease in cell contraction (about 70%) as well in cells from normal as from inflamed tissues. Diltiazem also induced a decrease in cell contraction, but this effect was lower (55%).In conclusion, this study reveals that contraction of SMC from human colons due to the three main agonists CCK, CCh and KCl (i) increased with age in agreement with a higher sensitivity of the colon with age, (ii) was reduced in patients with inflamed tissues, (iii) calcium channel blockers significantly reduced cell contraction in cells from human colon. }" "Differential Sensitivity of Isolated Smooth Muscle Cells from Normal and Inflamed Human Colons to Contractile Agents. Effects of Calcium Channel Blockers"

"P P 33 0767"P 33 0767**Relations between Methanogenesis and Sulfate Reduction in the Human Colon**

*H. Kroczynski, P. Pochart, P. Marteau, J. Dor\'e9, J.C. Rambaud

INSERM U290 Paris, France

CNAM Paris, France

INRA Jouy en Josas, FranceSulfate-reducing bacteria (SRB), which could be important in the pathogenesis of ulcerative colitis and inflammatory bowel diseases, are normal inhabitants of the human colon where they represent the major source of sulfide ($S^{2\{-}$}) from the reduction of dietary and mucinous sulfate. Since they can use H_2 as electron donor, authors hypothesized that SRB outcompete the obligate H_2-utilizing methanogens for H_2, leading to a mutual exclusion between methanogenesis and sulfate reduction (*Sred*).*Aim:* To test this hypothesis, we compared fecal SRB, $S^{2\{-}$} and *Sred* between methane-excretors (CH4+) and non methane-excretors (CH4{ -})*Methods:* SRB populations able to use H_2 as electron donor (*Desulfovibrio* and *Desulfobulbus*) were enumerated by the agar shake dilution method, $S^{2\{-}$} measured using the methylene blue method and *Sred* by incubation at 37\'b0C under anaerobic conditions in the presence of an excess of sulfate (35 mM). All SRB counts were expressed as $\log_{10}$ CFU/g wet weight, results are mean – SEM.*Results:* 1) All CH4+ harboured SRB ranging from 4.9 to 8.0 $\log_{10}$ CFU/g. 2) None of the differences between the two groups were statistically significant Group SRB $S^{2\{-}$} *Sred* $\log_{10}$/g \'b5mol/g \'b5mol/g/hCH4+ (n = 17) 6.6 – 0.3 0.9 – 0.1 3.2 – 0.5CH4{ -} (n = 16) 6.5 – 0.3 1.1 – 0.4 2.2 – 0.4*Discussion:* These results do not support the hypothesis of a mutual exclusion between methanogens and SRB in the human colon. Like in other intestinal methanogenic environments such as the sheep rumen, methanogens and SRB co-exist. The latter may actually behave as H2-producer using lactate as electron donor and transferring reducing equivalents to methanogens, as it has been shown in vitro using low sulfate concentrations, conditions usually prevailing in the human colon. Intestinal disorders: IBD, etiology and geneticsNutrition: MetabolismNutrition: Nutrients and gut function }" "Relations between Methanogenesis and Sulfate Reduction in the Human Colon"

"P P 33 0769"P 33 0769**Ursodeoxycholic Acid Treatment in Patients with Primary Constipation and Hypercholesterolemia**

*L. Zamboni, M. Malavolti, R. Talarico, C. Cicognani, A.M. Morselli Labate, C. Sama, L. Barbara

Dipartimento di Medicina Interna e Gastroenterologia, University of Bologna, Bologna, ItalyUrsodeoxycholic acid (UDCA), the 7 beta epimer of Chenodeoxycholic acid (CDCA), is a dihydroxy bile acid widely used in the treatment of chronic liver disease, cholesterol gallstones, hypercholesterolemia and dyspepsia. UDCA is able to stimulate the receptor dependent uptake of LDL and it has a strong choleretic effect but, in contrast to CDCA, it does not cause any increase of LDL cholesterol, nor diarrhea, nor abnormal results in liver function tests.*Aim* of our study was to investigate the effect of UDCA treatment in patients with primary constipation and hypercholesterolemia. *Methods.* Eleven subjects (4 males, 7 females; age: 59.7 – 7.4 mean – SD) with primary constipation (basal number of bowel movements BM = 2.55 – 0.52 and report of hard stools in all cases: HS = 100%) and hypercholesterolemia (> 200 mg/dl; mean – SD = 240 – 21 mg/dl) were treated for 4 weeks with 9 mg/Kg/day of UDCA in a cross-over study vs. Placebo (4 wks). Differences between the two treatments and basal values were evaluated by means of the Wilcoxon matched pairs (BM and cholesterol) and the McNemar (HS) tests.*Results.* During the study no patient complained about diarrhea, nor presented hypertransaminasemia. BM was significantly ($P < 0.01$) higher after UDCA (4.57 – 1.79) than Placebo (2.45 – 0.32), while the presence of HS was lower (18.2% vs. 100%; $P < 0.01$). During UDCA treatment a significant ($P < 0.05$) decrease in serum cholesterol (227 – 0.05 mg/dl) was also observed. The relationship between the increase in the number of bowel movement and the decrease in serum cholesterol level showed an r value of 0.571 ($P = 0.067$). *Conclusions.* These data support the findings that a slight malabsorption of bile acids could be involved in the serum cholesterol lowering during UDCA treatment. In summary, since UDCA has been widely used without any side effect, it could be proposed in the management of patients with primary constipation and hypercholesterolemia. Intestinal disorders: ConstipationLiver and bile ducts, 2: Bile formation, cholestasis }" "Ursodeoxycholic Acid Treatment in Patients with Primary Constipation and Hypercholesterolemia"

"P P 33 0771"P 33 0771**Diurnal Motor Change in Canine Colostomized SegmentR. Hada[1], N. Wajima, H. Kobori, K. Mikami, M. Sugai, Y. Sugiyama, M. Konn**

[1] Department of Clinical Physiology, Hirosaki University School of Allied Medical Sciences, Hirosaki, Japan

Department of Clinical Surgery, Hirosaki University School of Allied Medical Sciences, Hirosaki, Japan*Background:* The colonic motor activity in dogs is characterized by recurring groups of contraction burst which are separated by motor quiescence. We reported in UEGW' 94 that increased length of the motor quiescence may be the \lquoteinterdigestive motor pattern\rquote of the canine colon (Gut 33: A 183, 1994). *Aim:* To assess the diurnal motor profile in colostomized segment and to correlate it to that in the upper GI tract. *Methods:* Four force transducers (FT_1 through FT_4) were implanted on the colon of 9 dogs at an equidistance with FT_1 on the ascending colon and FT_4 on the level of the caudal mesenteric artery. Another FT was implanted on the terminal ileum to distinguish the digestive from the interdigestive motor phase. The dogs were fed either 20 or 10 g/kg meal to modify the duration of the digestive motor phase and a 24 recording of the colonic motor activity was performed. The duration of each group of contraction burst (contractile state, CS) and the length of each motor quiescent state (QS) were sequentially plotted against postprandial time lapse and their temporal profiles were correlated with the first ileal MMC. Later the colon was transected between FT_2 and FT_3 to establish a double-barrelled colostomy and a 24 h recording was resumed. *Results:* In the intact dogs with either 20 or 10 g meal, CS at each FT except FT_4 did not significantly change throughout the recording session. At FT_1 through FT_3, shortening of QS occurred at 2–4 h and significant increase of QS occurred at 15.3 – 0.3 h with 20 g meal and at 11.5 – 0.8 h with 10 g meal. The onset of this QS prolongation was closely correlated with the appearance of the first ileal MMC (r = 0.95 { -} 0.92, p < 0.001). In the colostomized dogs, the motor profile in the oral colon (FT_1 and FT_2) was identical to that before colostomy, while no shortening of QS in the early postprandial period nor prolongation of QS in the interdigestive phase was observed in the distal colon (FT_3 and FT_4). Instead, CS and QS recurred periodically with a fixed value of 4.7 – 0.1 min for CS and 32.6 – 1.8 min for QS, respectively. *Conclusion:* Prolongation of QS in the colon is temporally locked with the interdigestive motor phase of the upper GI tract. Bowel continuity is essential for this QS prolongation to occur over the length of the colon. Each small segment of the colon has its own contractile rhythm which is, however, entrained by the rhythm in a more proximal adjacent segment so far as the bowel wall is continuous. Motility, specific: Colon, anorectum }" "Diurnal Motor Change in Canine Colostomized Segment"

"P P 33 0772"P 33 0772**Pseudo-Obstruction of the ColonG. Kouraklis, St. Rossonis,**

*E. Misiakos, J. Kakisis, A. Papachristodoulou, G. Karatzas, J. Gogas

2nd Department of Propedeutic Surgery, Athens University Medical School, Laiko General Hospital, Athens, GreecePseudo-obstruction of the colon is an acute derangement of the intestinal motility with no evidence of any other obstruction or pathology. Since many controversies still exist in pathogenesis, diagnosis and therapy, the authors report their experience on the subject.During the period January 1969–January 1996, 29 such cases were treated in our Department. Mean age was 71.5 years and there were 17 female and 12 male patients. Clinical picture was that of ileus, while in 15 patients palpation of the abdomen revealed diffuse tenderness. Radiology showed dilatation of the large bowel and on rectal examination air or feces were found. Diagnosis of pseudo-obstruction was established on these findings. First therapeutic attempt was conservative and consisted in administration of fluids and electrolytes, nasogastric suction and rectal tube insertion. Symptoms resolved in 8 cases, while urgent colonoscopy decompression was successfully performed in 7 out of 29 cases. Fourteen patients required operative treatment. Eight of them were submitted to caecostomy and 6 patients to loop colostomy of the transverse colon. Postoperative morbidity occurred in 4 patients, which included cardiac, pulmonary and renal insufficiency. One patient died from bronchopneumonia and heart failure.In conclusion, pseudo-obstruction of the colon demands prompt diagnosis and correct treatment because of the high incidence of colon rupture and the elevated mortality rate this complication presents. Motility, general: Functional GI disordersMotility, specific: Colon, anorectum }" "Pseudo-Obstruction of the Colon"

"P P 33 0773"P 33 0773**Cisapride in the Treatment of Functional Constipation Refractory to Previous TherapyX. Busquets, V. Toledo-Pimentel, N. Gom\'e0, Ll. Cus\'ed, C. Martinez[1]**

Unitat D'Aparell Digestiu, Gabinet de Diagnosi i Troctament Girona, Spain

[1] Clinical R&D Department, Janssen Research FoundationChronic functional constipation is a very common reason for consultation.*Objective:* The purpose of this study is to assess the efficacy of cisapride in patients with functional constipation refractory to therapy (diet with fiber and laxatives).*Patients and Methods:* A total of 32 patients aged 18–65 years were included. All of them suffered constipation, defined as less than 3 bowel motions per week and not improving on standard therapy (fiber-rich diet and laxatives). They also had low or no urge to defecate and hard stools. The patients underwent an anorectal manometric study and all of them showed an alteration in the rectal-anal inhibitory reflex (RIR) before starting therapy with cisapride 10 mg t.i.d. for two months. Clinical visits were made at 30 and 60 days to assess symptom response. After 30 days without treatment, efficacy was assessed both clinically and manometrically. The efficacy parameters were the number of weekly motions, the improvement in the urge to defecate, and the consistency of stools.*Results:* 98% of the 32 patients participating in the study were women. The analysis of weight, age and height variables showed no statistically significant differences. Cisapride increased the weekly frequency of spontaneous bowel motions in 84% of the cases. The mean baseline value of weekly motions was 2.1/w at the start of the study. After a 12-week follow-up, the average of weekly motions was 5.0/w ($p = 0.0001$). The urge to defecate and the consistency of stools improved similarly to the frequency of motions. The clinical response was consistent with normalization or improvement in RIR in subsequent manometric controls.*Conclusion:* The results show that cisapride is a useful drug for treating constipation related to an RIR impairment, since it significantly increases the frequency of spontaneous bowel motions, improves the urge to defecate and the consistency of stools, and its therapeutic effect persists 4 weeks after discontinuing therapy. *A.F. Celik, A. Dobrucali, H. Ilkova, M. Ozyazar, U. Gorpe, E. Oktay, N. Bagriacik

University of Istanbul, Cerrahpasa Medical Faculty, Dept of Int Med, TurkeyFaecal incontinence is a troublesome problem in diabetic patients. To unveil the extensiveness of faecal and gas incontinence, 250 diabetic outpatients (159 females, 91 males, mean age 53 – 13 and mean diabetes age 10.6 – 7.6) with good glycemic control (HbAlc < 8) and 250 age and sex matched non-diabetic (NDM) outpatients (161 females, 89 males, mean age 50 – 13) were compared in terms of the below parameters using a visual scale analogue questionnaire. The people who had had abdominal operations and those with organic gastrointestinal, metabolic and hormonal diseases were excluded. All patients also filled in the neuropathy symptom score questionnaire. DM NDM % Scores % Scores pFeeling of defecation: 9.7 + 1.2 9.9 + 0.7 p > 0.05Gas and stool discrimination: 9.0 + 2.5 9.8 + 1.1 p < 0.05Interference with social life: 0.2 + 1.3 0.1 + 0.7 p > 0.05Stool incontinence: 8.6% 0.34 + 1.4 1% 0.01 + 0.16 p < 0.05*Interference with social life: 0.14 + 0.9 0.06 + 0.75 p > 0.05Gas incontinence: 79% 3.2 + 2.8 54% 2.3 + 2.7 p < 0.05*Interference with social life: 1.09 + 2.2 0.33 + 1.11 p < 0.05Stool consistency: 2.67 + 0.8 2.79 + 0.8 p > 0.05Laxative use: 15% 8% p < 0.05*Straining 3.33 + 3.55 2.62 + 3.05 p < 0.05(Stool consistency: 1: Pellety, 2: Hard, 3: Normal, 4: Soft, 5: Watery) All comparisons made using independent samples t test, those marked * with chi-square as well.Only straining and laxative usage correlated with neuropathy symptom score (p < 0.05).We found out that although the rate of stool incontinence is increased in diabetic patients than in non-diabetics, this does not interfere with social life considerably. Despite the presence of stool incontinence, the preserved consistency of stool hinders incontinence be perceived as a major social problem in diabetics. Gas incontinence and its interference with social life seem to be much prominent problems in diabetic patients. "P P 34 0775"P 34 0775**Effect of a Selective Calcium Antagonist Pinaverium Bromide on Rectal Distension-Induced Sensitivity during Experimental Inflammation in Rat**

*J. Fioramonti, M.O. Christen, L. Bueno

Departement of Pharmacology, INRA Toulouse and Solvay Pharma, Suresnes FranceThe major features of functional bowel disorders, such as IBS (Irritable Bowel Syndrome) are hypermotility and hypersensitivity of the gut characterized by a lower threshold perception. Pinaverium bromide (PB) a gastrointestinal selective calcium antagonist is indicated in the treatment of IBS. Recently it has been shown to inhibit intestinal contractions induced by GI hormones and mediators [1] suggesting an effect on visceral sensitivity. The aim of this work was to determine the effect of PB on rectocolonic inhibitor reflex and on visceral pain induced by rectal distension in rat in basal state and in hypersensitive state associated with rectal wall inflammation.A series of 6 Wistar rats (250–300 g) was chronically equipped with 2 groups of 3 nichrome electrodes implanted in the wall of the proximal colon and 3 electrodes on the abdominal striated musculature. Rectal distensions with increasing volumes (0.4; 0.8; 1.2 and 1.6 ml) were performed, using an arterial embolectomy catheter, before and 3 days after TNB/ethanol administration (80 mg/kg in 1 ml/kg volume). Pinaverium bromide (10 mg/kg p.o.) was administered one hour before distension.Rectal distension induced an inhibition of colonic motility and an increase in abdominal contractions in a volume-related manner. Pinaverium did not significantly modify the frequency of colonic nor abdominal contractions in normal conditions whatever the volume of rectal distension. Rectal inflammation reinforced the inhibitory rectocolonic reflex and enhanced the abdominal response. Pinaverium bromide significantly ($p < 0.05$) reduced abdominal contraction frequency induced by distension at 1.2 and 1.6 ml volume in inflammatory conditions; for a distension of 1.6 ml the number of abdominal contractions per 5 min was 16.5 – 4.9 for PB *vs* 23.9 – 8.0 for control.In conclusion, pinaverium bromide (Dicetel') has a marked effect on rectal distension-induced visceral pain in inflammatory conditions in rats. These findings further support the therapeutic value of pinaverium bromide, a GI selective calcium antagonist, in IBS given its effect on both hypermotility and hypersensitivity of the gut.

"P P 34 0776"P 34 0776**Influences of Dietary Fiber, Guar Gum, and 1,2-Dimethylhydrazine (MNH) on Prostaglandin (PG) Contents in Rat Colonic Mucosa**

*H. Goto, S. Hase, Y. Niwa, T. Arisawa, S. Kanamori, K. Tachi, T. Watanabe, Y. Hisanaga, T. Hayakawa, S. Sugiyama[1], Y. Shimomura[2]

2nd Dept of Internal Medicine, Nagoya University School of Medicine, Nagoya

[1] Dept. of Clinical Biochemistry, Institute of Applied Biochemistry, Gifu

[2] Dept. of Bioscience, Nagoya Institute of Technology, Nagoya, Japan*Purpose.* It has been reported that populations, who consume foods with much fibrous materials and reduce levels of animal fats, have a decreased risk of colonic cancer. However, its precise mechanism remains unknown. This study was designed to clarify effects of dietary fiber, guar gum and DMH, a well known carcinogen, on rat colonic mucosal PG contents.*Materials and Methods.* Five weeks old male Sprague–Dawley rats were divided into 4 groups; a) the non-fiber group: rats were fed a non-fiber diet, b) the guar gum group: rats were fed a fiber diet containing 15% guar gum, c) the non-fiber + DMH group; rats, which were fed a non-fiber diet, were infected with 60 mg/kg of DMH subcutaneously every 6 days 4 times for one month, d) the guar gum + DMH group; rats, which were fed a fiber diet containing 15% guar gum, were infected with 60 mg/kg of DMH as well as group c). All animals were fed each diet for 30 days and sacrificed. After colon was immediately removed, its length and weight were measured and mucosal PGs were assayed by high performance liquid chromatography.*Results.* In the guar gum group and guar gum + DMH group, the length and weight of colon significantly increased compared with those in the non-fiber group and the non-fiber + DMH group, but DMG did not affect on them. Five kind of PGs, *i.e.*, 6-keto-$PGF_{1\{ a}$}, TXB_2, $PGF_{2\{ a}$}, PGE_2 and PGD_2 were detected in rat colonic mucosa. The intake of guar gum resulted in the increase in PGE_2 contents and the decrease in 6-keto-$PGF_{1\{ a}$} and PGD_2 contents. Administration of DMH increased significantly 6-keto-$PGF_{1\{ a}$}, TXB_2 and PGE_2 contents. Guar gum cancelled DMH-induced increase in 6-keto-$PGF_{1\{ a}$}, TXB_2 contents.*Conclusion.* These results suggest that 6-keto-$PGF_{1\{ a}$} and TXB_2 is likely to be related to DMH-induced changes in rat colon, and that the cancellation of these changes in PG contents by fiber diet might contribute to the prevention of occurrence of colonic cancer. Oncology, general: Proliferation, carcinogenesis }" "Influences of Dietary Fiber, Guar Gum, and 1,2-Dimethylhydrazine (MNH) on Prostaglandin (PG) Contents in Rat Colonic Mucosa"

"P P 34 0777"P 34 0777**The Pattern of Distribution of the Interstitial Cells of Cajal (ICC) in the Human Colon**

*R. Hagger, C. Finlayson[1], I. Jeffrey[1], D. Kumar

Dept. of Surgery, St. George's Hospital, London, United Kingdom

[1] Dept. of Histopathology, St. George's Hospital, London, United Kingdom*Aim:* The interstitial cells of Cajal are a population of cells in the gastrointestinal tract which are attracting increasing attention as their putative role in the control of gut motility is evaluated. The aim of this study was to establish the pattern of distribution of ICC in the wall of the normal human colon.*Methods:* ICC express the proto-oncogene c-kit, a cell surface tyrosine receptor. ICC were identified in the colon by immunohistochemical staining, using a rabbit polyclonal anti-c-kit antibody (Oncogene Science). Normal colonic tissue was defined as non-involved tissue obtained at surgical resection for a non-obstructing carcinoma of the colon. The regions of interest were right, transverse and left colon. Thirty nine cases were studied.*Results:* The pattern of distribution of ICC in the colon was the same for the right, transverse and left colon. In the longitudinal muscle layer ICC were identified in the muscle bulk in parallel orientation with the muscle fibres, and also in association with penetrating blood vessels. In the intermuscular plane, many ICC formed a network surrounding the myenteric nerve plexus. In the circular muscle layer ICC were again found in the bulk of the muscle in parallel orientation with the muscle fibres and in association with blood vessels, ICC were also seen lining the intramuscular septa. ICC were identified lining the inner layer of smooth muscle fibres at the submucosal border of the circular muscle. ICC were not identified in the submucosa, muscularis mucosa or mucosa.*Conclusion:* The pattern of distribution of ICC is constant throughout the colon, showing no regional variation, and is consistent with a role in the control of colonic motility. Motility, specific: Colon, anorectum }" "The Pattern of Distribution of the Interstitial Cells of Cajal (ICC) in the Human Colon"

"P P 34 0779"P 34 0779**NK1- and NK2-Receptor Gene Expression during TNB-Induced Colitis in Rats**

*D. Renzi, A. Calabro', C. Panerai, M. Tramontana[1], S. Evangelista[1], C. Surrenti

GI Unit, Dept. of Clin. Pathophysiology, University of Florence, Italy

[1] Malesci Pharmaceuticals, Florence, ItalyIncreasing evidence indicates that Substance P (SP) and neurokinin A (NKA) are involved in the regulation of several intestinal functions, including absorption/secretion, motility, and immune function. Due to the multiplicity of effects, they have been implicated in the pathogenesis of inflammatory bowel diseases. SP and NKA effects on target cells are mediated by specific receptors, NK_1 and NK_2: while SP appears to preferentially activate NK_1 receptors, NKA activates NK_2 receptors. In this study we examined the spatiotemporal pattern of NK_1 and NK_2 receptor gene expression during TNB-induced colitis in rats. *Methods:* colitis was induced by intracolonic administration of 0.25 ml of TNB (120 mg/ml) in 50% ethanol. Groups of 5 rats were sacrificed at each of the following time points: 0, 3, 6, 15, 24, 72 h, 1, 2 and 4 weeks after TNB administration. NK_1 and NK_2 gene expression was analyzed on frozen sections by in situ hybridization with ^{35}S-labeled anti-sense and sense RNA probes and the autoradiographic signal was quantified by an image analysis system. *Results:* moderate NK_1 and NK_2 receptor gene expression was found in the normal rat colon; however, while NK_2 receptor gene expression was localized to smooth muscle cells of the muscularis mucosae and circular muscle, NK_1 receptors were found to be expressed in the circular muscle and cells of myenteric plexus ganglia. De novo expression of both NK_1 and NK_2 receptor mRNA was observed during the acute phase of TNB colitis in mesenchymal cells around dilated submucosal vessels; in contrast, expression in smooth muscle cells of the muscularis mucosae and propria was clearly down-regulated, starting as early as 3 h after TNB and reaching a nadir at 24–72 h. Tachykinin receptor gene expression gradually returned to normal thereafter. We were not able to identify any specific signal on epithelial cells, probably due to the very low, if any, basal expression and to the extensive necrosis of the mucosa following TNB administration. *Conclusions:* our findings suggest that reduced N_{K1} and NK_2 receptor gene expression may play some role in the progressive colonic dilatation commonly observed during the acute phase of TNB-induced colitis. "P P 34 0780"P 34 0780**Rectal Mucosal EGF Receptor Tyrosine Kinase (EGF-R tyr-k) Activity and Tyrosine Protein Phosphorylation are Increased in Patients with Adenomatous Polyps (a.p.), Ulcerative Colitis (u.c.) and Colon Cancer (c.c.)**

*E. Malecka-Panas, J. Tureaud, P.P. Liberski, A.P.N. Majumdar

Dept. Digest. Tract Dis. & Metab Disord., Med School, Lodz, Poland, Wayne St Univ, USATyrosine kinase (tyr-k) and a number of growth factors, like EGF and TGF-alpha are known to stimulate G.I. tract proliferation. In humans increased colonic mucosal proliferative activity has been observed in a.p., u.c. and c.c. The aim of the presented study was to determine the differencies of proliferative patterns and their correlation in patients with a.p., u.c., and c.c., as reflected by colonic mucosal EGF-R tyr-k, tyrosine protein phosphorylation and PCNA immunoreactivity.The study population comprised 40 patients, aged 36–76 years (mean 58), in which 10 had a.p., 10 – u.c. in remission phase, 10 c.c. and 10 were healthy controls. 6–8 rectal mucosal biopsy specimen were obtained at 10 cm from anal verge and at least 10 cm from any macroscopical mucosal changes during sigmoidoscopy. EGF-R tyr-k was increased in colonic mucosa by 35.2% – in patients with a.p., by 40.6% – in patients with u.c. and by 123% in patients with c.c. Tyrosine phosphorylation of several mucosal proteins (e.g. Mr of 55, 100, 155 and 170) in patients with a.p. and u.c. was 2–3 fold increased and in patients with c.c 5–6 fold increased, when compared to corresponding control levels. Expansion of proliferative zone towards crypt surface and significant increase ($p < 0.01$) of PCNA mean labeling indices were observed in patients with a.p., u.c. and c.c. as regards to the control group. Significant correlation between EGF-R tyr-k activity and PCNA LI values ($p < 0.001$) was observed within examined group of patients.Increased values of EGF-R tyr-k activity in overmentioned groups of patients may suggest, that tyrosine phosphorylation is involved in colon carcinogenesis. "P P 34 0781"P 34 0781**Human Gallbladder Mucin is also Biosynthesized in the Human Colon, But Not in the Small Intestine**

*B.J.W. Van Klinken, H.A. B\'fcller, J. Dekker, A.W.C. Einerhand

Pediatric Gastroenterology & Nutrition, Academic Medical Center, Amsterdam, The Netherlands*Purpose:* Inflammatory bowel disease is thought to be associated with alterations in colonic mucins, which form the most important structural components of mucus. Nine human mucin genes, named *MUC1–4, 5A/C, 5B* and *MUC6–8,* have been identified. Besides the mucins of which the genes have been cloned at least one other mucin has been reported: Human Gallbladder Mucin (HGBM), that was originally identified in the human gallbladder [1]. HGBM is also expressed in LS174T cells, a human colon adenocarcinoma cell line [2], suggesting that it may also be expressed in the human colon. Therefore, we studied the biosynthesis of HGBM along the longitudinal axis of the human intestine.*Methods:* To analyze mucin biosynthesis, biopsies of the human gallbladder, duodenum, jejunum, colon ascendens, transverse colon and sigmoid were pulse-labeled with [^{35}S]methionine/cysteine or [^{35}S]sulfate and chase-incubated with complete medium. The biopsies were obtained from healthy tissues. Biopsies and culture media were homogenized and mucins were immunoprecipitated from the homogenates using antibodies raised HGBM (anti-HGBM), which were shown to recognize the unique termini of HGBM [1]. This was followed by analysis on reducing SDS-PAGE and fluorography.*Results:* HGBM precursors were immunoprecipitated from homogenates of human gallbladder, colon ascendens, transverse colon and sigmoid, but not from the duodenum or jejunum. HGBM precursors were detectable at about 470 kDa on SDS-PAGE similar to the molecular mass of HGBM precursors reported by Klomp and co-workers [1]. In pulse-chase analyses of human colon ascendens and sigmoid, mature HGBM was secreted into the medium and was detected at about 600 kDa on SDS-PAGE. Very similar biosynthesis of mature HGBM in the human gallbladder was previously reported [1].*Conclusions:* Apart from expression in the human gallbladder, HGBM precursors are detectable specifically in the human colon suggesting that this mucin may have a specific function in the large intestine. In addition, mature HGBM was also detected in the colon and secreted. Based on the respective molecular masses of their precursors, HGBM is not identical to MUC1–4, MUC5A/C, MUC6 or MUC7 [2]. Therefore, HGBM may be identical to MUC5B or MUC8, or may constitute a novel mucin.

"P P 34 0782"P 34 0782**Sodium Channels are Present in the Upper Crypt but Not the Crypt Base in the Distal Colon of the Glucocorticoid-Treated Rat**

*G.M. Fraser, Y. Niv, M. Sterlin, D. Ecke, M. Bleich, R. Greger, B. Schwartz

Dept. Gastroenterology, Beilinson Medical Center, Clinical Biochemistry Unit, Soroka Medical Center, Israel

Dept. Physiology, Freiburg University, GermanySodium channels are induced in the rat distal colon by short-term corticosteroid treatment. It has been proposed that these channels are confined to luminal cells whereas chloride secretion is a property of crypt base cells. We used three methods to map the distribution of Na channels along the crypt-lumen axis.*Methods.* Five colonocyte populations (C1–C5) from lumen to crypt base were prepared by Ca^{2+} chelation (EDTA). Whole crypts were prepared using a modification of this method. Amiloride-sensitive $^{22}Na^{+}$ uptake (ie Na^{+} channel activity) was determined in vesicles from each cell population using a K^{+} diffusion gradient. Similarly $^{22}Na^{+}$ uptake by whole cells was performed on pooled luminal and crypt colonocytes. A whole-cell patch clamp technique was used to measure membrane conductance (Gm) and voltage (Vm) in luminal, mid-crypt and crypt-base colonocytes during changes in Na^{+} concentration or with 10 micromolar amiloride.*Results.* Glucocorticoid-naive rats showed no evidence of electrogenic Na^{+} transport. Amiloride inhibited $^{22}Na^{+}$ uptake in vesicles by 60%, 40%, 17%, 11% and 0% in colonocyte populations C1–C5 respectively. In whole cells, amiloride-sensitive $^{22}Na^{+}$ uptake was 20 pmoles Na^{+}/mg protein in the luminal cell population and absent in crypt-base colonocytes. Whole cell recordings of Vm showed hyperpolarization and decrease in Gm when bath Na^{+} was removed or amiloride was added indicating that Na^{+} channel activity was inhibited. The effect was maximal in luminal cells, absent in crypt-base cells and intermediate in the mid-crypt. *Conclusion.* Using 3 different methods we have shown that glucocorticoid-induced Na^{+} channel activity in rat distal colon exhibits a gradient with absent activity in the crypt and maximal activity at the luminal surface. This distribution may have implications for theories of cellular maturation along the crypt-lumen axis. }" "Sodium Channels are Present in the Upper Crypt but Not the Crypt Base in the Distal Colon of the Glucocorticoid-Treated Rat"

"P P 34 0783"P 34 0783**Human Colonocytes from Endoscopical Biopsies: Isolation, Biochemical Characterization, and Expression of Human Stress Proteins**

*G. Pedersen, J. Hendel, B. Giese, T. Saermark, J. Brynskov

Dept. Medical Gastroenterology C, Herlev University Hospital, DK-2730, Denmark*Purpose:* Biochemical and biological characterization of normal human colonic epithelial cells has been difficult due to lack of suitable methods for culture of epithelial cells from biopsy material. Therefore, colonic crypts isolated from surgically removed bowel or cancer cell lines have been widely used to study colonocyte functions in vitro. We present here a simple method for the isolation of human colonic epithelial cells isolated from routine biopsies, and demonstrate that these cells metabolize butyrate and express human stress proteins, HSP 60 and 70.*Methods:* Human biopsies obtained by routine diagnostic colonoscopy were treated with EGTA/EDTA and/or enzymes to separate the epithelial cells from the connective tissue. The cells isolated were grown for 1–3 days and the number of cells surviving was monitored by methyl tetrazoleum (MTT) test and DNA quantitation. Colonocyte metabolism of butyrate and glucose was quantitated by $^{14}CO_2$ liberation. The expression of HSP 60 and 70 was measured by PCR and immunoelectrophoresis.*Results:* Electron microscopy showed that cells with the typical features of colonic epithelial cells could be isolated from a small number of biopsies (n = 2–4, 5–20 mg of tissue). Enzymes and thiols were not necessary and appear harmful to the cells. The cells were viable for at least 3 days as judged from MTT and DNA measurements and were able to incorporate radiolabelled aminoacids and sugars into proteins. The butyrate metabolism had a K_m-value of 0.6 mM. The cells also metabolized glucose. The cells expressed heat chock proteins, HSP 60 and 70 as judged by PCR as well as electrophoretic immunoblotting.*Conclusion:* The experiments show that these primary cultures allow the study of human colonic epithelial functions in vitro. The possibility to establish primary cultures of colonocytes from patients undergoing routine endoscopy may be most valuable in the study of inflammatory bowel diseases. "P P 34 0784"P 34 0784**Butyrate Transport in Rat Colonic Apical Membrane VesiclesO. Schr\'f6der, J. Stein, W.F. Caspary**

Division of Gastroenterology, II. Department of Internal Medicine, Johann Wolfgang Goethe-University, Frankfurt, Germany*Background:* In order to study the specifity of the luminal butyrate-HCO_3-antiporter, the inhibitory potency of several SCFA, their mercapto- and bromoanalogues and anion-channel blockers on the ^{14}C-butyrate influx from rat colonic apical membrane vesicles has been determined.*Methods:* Apical membrane vesicles (AMV) of the rat colonocytes were prepared by a discontinous sucrose gradient after isolation of membrane caps. Quality of the membrane preparations was proven by several functional and structural parameters. ^{14}C-butyrate uptake was measured by rapid filtration technique.*Results:* Preloading of AMV with HCO_3 or butyrate stimulated ^{14}C-butyrate uptake and resulted in transient accumulation. HCO_3-stimulated butyrate uptake showed an apparent K_m of 44.7 – 5.9 mmol/l and a v_{max} of 33.2 – 2.7 nmol {\'b4} mg protein{ ¯1} {\'b4} 3 sec{ ¯1}. Intravesicular butyrate uptake was substantially inhibited by addition of 20 mmol/l of acetate (41.4%), propionate (52.4%), butyrate (39.3%) and 3-mercaptopropionate (43.0%), whereas addition of 20 mmol/l of formate, hexanoate, heptanoate, valerate, isovalerate, 2-bromopropionate, 4-bromobutyrate or 1 mmol/l of DIDS and SITS did not alter uptake. 3-mercaptopropionate had a competitive inhibitory effect on butyrate uptake with a binding constant following inhibition of 6.25 – 0.87 mmol/l and a $v_{max\ (i)}$ of 5.82 – 1.01 nmol {\'b4} mg protein{ ¯1} {\'b4} 3 sec{ ¯1}.*Conclusion:* Rat colonic luminal butyrate-HCO_3-antiport is mediated by a low affinity transport system, which is specific for unbranched SCFA with a chain length from 2 to 4 carbon atoms and 3-mercaptopropionate. }" "Butyrate Transport in Rat Colonic Apical Membrane Vesicles"

"P P 34 0785"P 34 0785**Sulphydryl Blocker Induced Rat Colitis is Ameliorated by Intravenous (IV) Injection of Antibody to Colonic Surfactant-Like Particle (C-SLP)**

*R. Eliakim, D. Rachmilewitz, F. Karmeli, P. Cohen[1], D.H. Alpers

Department of Medicine, Jerusalem, Israel

[1] Department of Pathology, Jerusalem, Israel

St. Louis, MO, U.S.A.We recently characterized a model of experimental colitis induced by iodoacetamide (IA), a sulphydryl blocker, and accompanied by increased leukotriene (LT), prostaglandin E (PGE) and nitric oxide (NO) generation. We also isolated and characterized rat C-SLP and produced its specific antibody (C-SLPAb). The aim of this study was to evaluate the role of C-SLP in IA colitis.Colitis was induced in male Sprague-Dawley rats by intracolonic administration of 0.1 ml 3% IA. C-SLPAb, SP-A-Ab or control serum (0.3 ml) was injected IV 48 hours prior to, at, or 24 hours after damage induction, colons isolated, rinsed with saline, damage assessed, 10 cm segment weighed and tissue processed for microscopy and colonic mucosal NO synthase (NOS) activity measured.Intracolonic IA resulted in extensive macroscopic and microscopic damage, increased colonic weight and NOS activity. C-SLPAb significantly decreased macroscopic damage by {\'b3} 70% when given prior to, or concomitantly with IA, as well as macroscopic damage and colonic weight, without affecting NOS activity. Antibody to SP-A, a specific SLP protein, had no protective effect on damage, nor did injection of C-SLPAb 24 hours after damage induction. Treatment No. Lesion Weight NOS (mm^2) (g/10 cm) (nmol/g/min)None 20 None 0.60 – 0.02 2.00 – 0.13IA 21 460 – 83* 1.4 – 0.1* 6.6 – 1.1*IA + control serum 6 664 – 141* 1.7 – 0.2* 5.7 – 0.4*IA + C-SLPAb (48 h pre) 13 136 – 56** 1.17 – 0.08** N.D.IA + C-SLPAb 11 104 – 37** 1.10 – 0.05** 6.8 – 0.4IA + SP-A-Ab 6 576 – 196* 1.57 – 1.87* N.D.* < 0.05 vs. control; **< 0.05 vs. IA.IA-induced colitis is ameliorated by IV injection of C-SLPAb by a mechanism yet unknown but probably not via NOS activity. [1] Center for Research in Human Nutrition, Nantes, Paris, France

[2] Institut de Recherche Jouveinal, Fresnes, Paris, France

[3] INSERM U410, Paris, FranceEndogenous peptides like PYY and NPY exhibit an antisecretory effect in experimental models probably through neuronal sigma sites. Igmesine is a new sigma ligand that was shown to be active in animal models of diarrhea without affecting intestinal motility.*Aim of the study:* To assess the effect of two doses (25 and 200 mg) of igmesine, a sigma ligand, on intestinal hypersecretion induced by prostaglandin E2 (PGE2) in man.*Methods:* 2 groups of 8 healthy volunteers participated in this placebo-controlled randomized double-blind crossover study: 8 received igmesine 25 mg and placebo, 8 received igmesine 200 mg and placebo during 2 different sessions. At each session, the experimental procedure was as follows: on the first day, a triple lumen tube was placed into the jejunum. On the following two days, 2 intestinal perfusion sessions were performed, 24 hours apart, each according to the following sequence: oral intake of igmesine (8 subjects: 25 mg, 8 subjects: 200 mg) or placebo at t0, intraluminal perfusion (10 ml/min) of an isotonic solution from t0 to t90 min and then perfusion of a solution containing PGE2 (Prostine E_2^R, 5 \'b5mol/l) from t90 to t270 min. The intestinal fluid was continuously collected at the proximal and distal tips of the catheter to assess the movements of water and electrolytes in the intestinal segment being studied (30 cm), PEG being used as marker.*Results:* Although inactive at 25 mg dose (data not shown), igmesine 200 mg strongly reduced the secretory flow of water and electrolytes during the PGE2 perfusion (Table, m – s.e.m., * $p < 0.05$, ANOVA). H_2O Na^+ K^+ $Cl^{\{-}$} $HCO_3^{\{-}$} (ml/h) (mmol/h) (mmol/h) (mmol/h) (mmol/h)Placebo 285 – 63 39 – 8 2.0 – 0.3 32 – 7 7 – 1Igmesine 200 *35 – 27 *5 – 8 *1.0 – 0.3 *3 – 7 *2 – 1ANOVA for repeated measures over time showed that the effect of igmesine 200 mg was maintained during the PGE2 perfusion. No side effect related to igmesine was reported.*Conclusion:* This study shows for the first time in man the intestinal antisecretory effect of a sigma ligand, suggesting the potential interest of this new pharmacological class as a therapeutic tool. "P P 34 0787"P 34 0787**Distribution of CEA/FAS/FAS-Ligand/Tunel in Normal and Ulcerative Colitis Colon**

*M. Iwamoto[1], K. Makiyama[1], S. Izumi[2], T. Koji[2], S. Kohno[1], P.K. Nakane[2]

[1] Dept. of Int. Med. (II), Nagasaki Univ. Sch. of Med., Nagasaki, Japan

[2] Depts. of Histology and Cell Biology, Nagasaki Univ. Sch. of Med., Nagasaki, JapanThe luminal epithelial cells of colon are positive for Fas antigen (Fas) and Fas-ligand (Fas-L) on their baso-lateral surfaces, contain TUNEL positive nucleus and undergo apoptosis. The apical surface of these cells are also positive for carcinoembryonic antigen (CEA), a maker of terminally differentiated colonic epithelial cells. Our finding that the Fas/Fas-L/TUNEL associated epithelial cells were found in the crypt of active ulcerative colitis (UC) prompted us to investigate whether CEA is also associated with these cells.Portions of biopsies of normal colon and that of colon of active UC were fixed in 10% formalin and processed using a routine histology procedure. The breaks in nuclear DNA were detected by TUNEL method. Fas and Fas-L were localized using rabbit antisera against an extra-cellular domain of Fas and an intra-cellular domain of Fas-L as the first antibody, respectively. For the localization of CEA using CEA, mouse monoclonal anti-human CEA as the first antibody.The CEA was limited to the apical surface of the luminal surface epithelial cells of normal colon. Whereas, in the UC colon, CEA was at the apical surface of the luminal and crypt epithelial cells. The distribution of the CEA positive cells coincided with that of cells with apoptotic markers, namely Fas/Fas-L/TUNEL.The coincidental expression of CEA on cells with various apoptosis markers suggest that the cells undergoing apoptosis in the crypts of UC colon are fully differentiated and the hastened differentiation of epithelial cells in UC colon maybe a cause of apoptosis. Intestinal disorders: IBD, basicImmunology and microbiology: InflammationMotility, specific: Colon, anorectum }" "Distribution of CEA/FAS/FAS-Ligand/Tunel in Normal and Ulcerative Colitis Colon"

"P P 35 0788"P 35 0788**Corrections of Postoperative Incontinence in Children by Penna's OperationV.N. Grona,**

*A.A. Muzalev

Donetsk State Medical University, Illicha avenue 16, Donetsk, 340003, Ukraine*Introduction.* Unsatisfactory functional results following operative treatment of anorectal defects constitute 30%–50%.*Materials and methods.* Correction of postoperative incontinence was made in 20 patients (8 boys and 12 girls). All the children had been operated on previously by various techniques for anorectal defects and ensueing complications. Out of 20 patients 8 children were operated twice, 4 – trice. A scarry deformity of the anorectal area was revealed in all the children, out of them 5 patients showed anterior ectopy of the rectum with empairment of the entrance to the vagina, the posterior wall of the distal third of the vagina was destroyed. Rectal tenesmus in all the patients decreased sharply or was apsend.When choosing a technique of surgical correction of postoperative incontinence we prefered Penna's operation wich allowed to form a locking apparatus from the remaining elements of the pubo-perineal loop and the external sphincter of the rectum. 1 to 1.5 month prior to the operation all the children had been applied suspended two-trunc colostoma. If the patients had previously undergone abdomino-perineal proctoplastics, they were applied transversostoma (8 patients); and sigmostoma after perineal proctoplasty (12 patients).Soft profilactic bougerage of the rectum was begun at 15 days, transrectal electrostimulation of the sphincter apparatus muscles was carried out 3 to 4 weeks later. Temporary colostoma was closed 1.5 to months following Penna's operation.*Results.* 18 patients were followed up from 6 months to 5 years. Good results were received in 10 patients, satisfactory – 7 patients. unsatisfactory – one patient. Underdevelopment of the sacrococcygeal portion of the spine was the major reason of the unsatisfactory result in the study.*Conclusion.* We consider Penna's operation in this category of patients to be the operation of choice. Intestinal disorders: ConstipationIntestinal disorders: Anorectal disordersIntestinal disorders: Anorectal disorders: children }" "Corrections of Postoperative Incontinence in Children by Penna's Operation"

"P P 35 0789"P 35 0789**Overlapping Sphincteroplasty for Anal Incontinence**

*G. Rotondano, P. Esposito, L. Pellecchia, A. Novi, G. Romano

Department of General Surgery and Organ Transplantation, University of Naples ""Federico II"", School of Medicine, Naples, ItalySurgical correction of anal incontinence is best suited to those patients with traumatic disruption of the sphincter ring. Such damage may result from obstetric as well as iatrogenic injuries or, less frequently, road accidents or sexual abuse. Surgical repair by wrap-over technique has been shown to restore satisfactory function in most cases. The present study intended to assess clinical and functional results of overlapping sphincteroplasty.From 1991 to 1995, a total of 40 repairs were performed in 39 severely incontinent patients (17 M, 22 F; mean age 34 – 11 years, range 23–52). Preoperative and postoperative assessment included anal manometry, endosonography and electromyography. Mean follow-up was 23 months (range 5–54). Statistical analysis was performed using the Wilcoxon signed rank test. Aetiology of anal incontinence is shown in the table. Etiology N. patients PercentObstetric injury* 16 41%Previous anorectal surgery 21 53.8%Road accident 2 5.2%Total 39 100%*2 patients with associated recto-vaginal fistulaEndosonography was able to preoperatively reveal 36/39 external anal sphincter defects with a 92% correlation with surgery. Overall, 36 patients were clinically improved by surgery with 30 (78%) regaining normal continence and 6 (14.4%) showing fair function. Only one patient received a temporary colostomy. Septic complications occurred in 7 cases (18%). The procedure failed in three patients (7.6%) who were then submitted either to a re-do sphincteroplasty or to an electrically stimulated graciloplasty. All of them are totally continent after their salvage procedure. Endosonography is useful in mapping the anal sphincters and plan the best type of operation. Overlapping sphincteroplasty is the procedure of choice in case of traumatic anal incontinence. Dynamic graciloplasty can be offered to highly selected patients in whom previously attempted conventional repairs had failed. Intestinal disorders: Anorectal disorders }" "Overlapping Sphincteroplasty for Anal Incontinence"

"P P 35 0793"P 35 0793**Balloon Expulsion Test and Perineometry as a Screening Test in Diagnosing Anismus**

*C.I. Sohn, P.L. Rhee, J. Kim, K.C. Koh, S.W. Paik, J.C. Rhee

Division of Gastroenterology, Samsung Medical Center, Seoul, Korea*Purpose:* The aim of this study is to investigate the role of balloon expulsion test and perineometry as a screening test in diagnosing defication disorder.*Method:* The inclusion criteria was defication disorder patients on Rome criteria, that is excessive straining on more than 25% of occasions and sensation of incomplete evacuation on more than 25% of occasions. All the patients were diagnosed the cause of defication disorder through balloon expulsion test in left lateral decubitus position and sitting position, perineometry, colon transit time, deficogram including ejection fraction of defication, anorectal manometry and sigmoidoscopy to rule out organic disease. 10 asymptomatic persons were also examined as a normal control.*Result:* Among 60 defication disorder patients, anismus was (56%), descending perineum syndrome (7%), rectocele (3%), rectal intussuception (1%), conbined disorder (7%) and normal pelvic function (25%). The weight that was needed to expel balloon in left lateral decubitus position in anismus patients was significantly higher than normal control (average 767 gm:330 gm, $p < 0.05$). The time that was needed to expel balloon in sitting position was significantly longer than normal control (average 5.6 min:2 min, $p < 0.05$). Perineal movement in anismus patients was significantly shorter than normal control (average 0.7 cm:1.3 cm, $p < 0.05$). The weight that was needed to expel balloon in left lateral decubitus position in anismus patients was inversely related to ejection fraction on deficogram.*Conclusion:* Balloon expulsion test and perineometry are good screening test in the diagnosis of defication disorder.

"P P 35 0794"P 35 0794**Visceral Sensitivity and Systemic Autonomous Responses to Rectal Distension in Healthy Volunteers**

*M.B. Jacobsen, S. Spetalen, S. Blomhoff, M. Vatn

Rikshospitalet, University of Oslo, NorwayVisceral sensitivity is claimed to be changed in IBS patients. In 18 healthy, female volunteers (19–57 years) we assessed retest reliability and normal values for rectal visceral perception by a computerised barostat (Synectics, Sweden) and sympathetic, and parasympathetic responses to rectal distension. Unchanged position of the barostat balloon was secured by concomitant anal pressure registrations and the pressure values for feeling of gas, urge to defecate and discomfort were registered by a randomised, double staircase inflation procedure in phasic distension mode with 1 mmHg steps lasting 20 seconds with 30 seconds intervals. The intrarectal pressure reported to cause discomfort was repeated as a singular inflation at the end of the study. Heart rate variability (HRV) and skin conductance (SC) were recorded throughout the study. Influence of posture changes were measured by positioning the subjects towards an adjustable plate which could be tilted in 5 degrees intervals. The whole protocol was repeated after two days. First feeling of gas was at (mean – SD) 11.8 – 5.4 mmHg, urge to defecate at 13.5 – 6.0 and discomfort at 29.3 – 10.1 mmHg. 95% confidence interval for discomfort in healthy females is 20.2–38.8 mm Hg and for compliance 7.5–11.9 ml/mmHg.Correlation coefficients (c.c.) (Pearson) for these parameters were 0.89, 0.91 and 0.79 respectively. Student T-test showed no differences and coefficients of variation were 0.24, 0.20, and 0.24 respectively. Following exposure to the discomfort threshold skin conductance increased 0.4 – 0.5 \'b5S compared to baseline at a latency of 4.6 – 2.0 sec. The c.c. (test-retest) was 0.78. Basal HRV was 70 – 92 ms and remained unchanged following induction of rectal discomfort with a c.c of 0.92. Changes in posture within 30 degree did not influenced volumes in the balloon at high pressure levels, while large differences were noted at lower pressures. In conclusion, measurements of visceral sensitivity and peripheral autonomous responses to rectal discomfort were performed with high reproducibility. "P P 35 0795"P 35 0795**Dynamic Graciloplasty for Faecal Incontinence: The One Stage Procedure**

*J.-L. Faucheron, E. Tarla, P. Leyman, J.-P. Lefaucheur, R. Parc

Centre de Chirurgie Digestive, Hospital Saint-Antoine, Paris, FranceDynamic graciloplasty is a new surgical option in the treatment of severe faecal incontinence. If most authors prefer a two-stage procedure (transposition of the gracilis muscle around the anus and implantation of the electrical stimulator and intra-muscular electrodes few weeks later), the construction of the neo-sphincter can be performed by a one stage graciloplasty and implant procedure. To assess this new technique we report the results of a prospective study conducted from June 1994 to May 1996.Eighteen patients (8 women) of mean age 33 years (range 15–62) were operated on for severe faecal incontinence. The aetiology of incontinence was anal atresia (n = 8), surgical or obstetrical trauma (n = 6), non-surgical trauma (n = 3) and spina bifida (n = 1). Four patients had a previous unsuccessfull Pickrell operation and were operated on in a two-stage procedure. Three further patients also had a delayed stimulator implantation because of a perineal operative complication. In all other patients a one-stage dynamic graciloplasty was performed.There were no difference between the one-stage procedure (n = 11) and the two stage procedure (n = 7) with regard to:\bullet clinical functional result\bullet manometric results\bullet surgical complications (sepsis, pain, explant).The advantages of the one-stage procedure over the two-stage procedure are: better electrode positioning, less risk to the nerve because it is more readily identifiable and one surgical act instead of two. Clinical practice: Management strategyIntestinal disorders: Anorectal disordersMotility, specific: Colon, anorectum }" "Dynamic Graciloplasty for Faecal Incontinence: The One Stage Procedure"

"P P 35 0796"P 35 0796**Perianal Bleeding, Pruritus Ani, and the Baboon Syndrome**

*H. Rohde, H. Heegewaldt, E. Lohmar, J. Brings, R. Eisebitt

Gastroenterologic Unit and Institute for Numeric Statistics, Cologne, Germany*Background:* Pathogenesis and aetiology of perianal bleeding, itching, pain and burning are often obscure. Inadequate cleansing (Smith 1982, Alexander-Williams 1983, Jones 1992) is accused as well as wet wipes (Harrington 1992) and moist toilet paper (Bruynzel 1992).*Methods:* We asked two groups of patients by a 41-item-questionnaire about their daily cleaning habits (shower, bath, moist toilet paper or water after motions etc.). Those who came for gastroscopy (n = 130) without anal complaints (G) and patients with a Baboon syndrome (Bs) defined as perianal lesions caused by overvigorous anal cleansing (n = 182) with bleeding, itching and burning. The latter had proctological investigation and endoscopy of the colon. Patients with a Bs were urged to refrain from use of water to clean their anus. Follow up after four weeks by telephone interview (anal symptoms) and by haemocult test was performed in those 67 patients with a Bs only and no lesions at total colonoscopy.*Findings:* Remarkable differences were found between the Bs- and the G-group: many doctors seen because of anal complaints (53% vs 15%), using a wet face-cloth after motions (40% vs 23%), using water and fingers after motions (22% vs 8%), washing their anus before sleeping (45% vs 25%), being treated because of piles (40% vs 20%). At 4-weeks follow up pruritus ani of Bs-patients had dropped from 45% to 5%, pain from 36% to 3%, haemocult testing became negative in all patients who changed their cleaning habits but symptoms and haemocult test remained nearly unchanged when this regimen was refused ($p < 0.001$, McNemar).*Conclusion:* To find out the cause of perianal bleeding, itching, pain and burning it is of utmost importance to ask patients about their daily cleaning habits. In contrast to most gastroenterologist we recommend only dry anal cleaning to prevent a Baboon syndrome.

*A. G\'f3mez, J.A. Correa, T. Le\'f3n, M. P\'e9rez, J.M. Pajares

Gastroenterology Department, Hospital de la Princesa, Madrid, Spain*Aim:* To assess prospectively the effect of fiber additions on internal bleeding haemorrhoids and haemorrhoidal prolapse.*Patients and Methods:* 50 patients (mean age = 48.3 – 13 yrs., 29 M/21 F) were referred to our Department for endoscopic study of recurrent rectal bleeding. All the patients underwent anoscopy before and after treatment to evaluate a) haemorrhoids bleeding on contact, b) the number of congested haemorrhoidal cushions and c) the degree of haemorrhoidal prolapse. Exclusion criteria were the presence of coagulation disorders or potentially bleeding colorectal lesion and the concomitant intake of laxative, anticholinergic or prokynetic drugs. Patients were randomiced in two groups, 23 in the study group were treated with 35 g/d of Plantago Ovata and 27 in the control group with placebo for a 40 day course. Differences in the number of bleeding episodes, congested haemorrhoidal cushions and degree of prolapse were analyzed with the Student's test and the Welch Correction. A significance level of $p < 0.05$ was accepted.*Results:* 1 patient from the study group and 3 from the control group were excluded. During the first 15 days of treatment, the number of daily bleeding episodes decreased from 5.2 – 2.9 to 4.8 – 3.8 in the study group versus 6.7 – 3 to 6.4 – 3 in the control group (n.s.). The next 15 days it decreased to 3.1 – 2.7 and 5.5 – 3.2 respectively ($p < 0.05$). A further reduction to 1.1 – 1.4 was found after the last 10 days in the study group versus 5.5 – 2.9 in the control group ($p < 0.001$). The number of congested haemorrhoidal cushions decreased from 2.5 – 1 to 1.6 – 1.2 ($p < 0.01$) in the study group, without differences in the control group. No change in the degree of haemorrhoidal prolapse was observed after treatment in the study group nor in the control group.*Conclusions:* 1) Fiber supplements significantly improved bleeding from internal haemorrhoids; 2) Therapeutic fiber effects are not immediate, appearing at least after a month of treatment; 3) Fiber does not reduce haemorrhoidal prolapse but significantly improves congested haemorrhoidal cushions. "P P 36 0799"P 36 0799**Metronidazole Resistance Influences the Efficacy of the Short-Term Triple Therapies, Involving Metronidazole, in the Eradication of Helicobacter Pylori (Hp)**

*S. Georgopoulos[1], S. Karatapanis[1], V. Vretou[2], S. Katranis[1], A. Mentis[3], V. Artikis[1]

[1] Dept. of Gastroenterology of Athens General Hospital ""ELPIS"", Athens, Greece

[2] Dept. of Pathology of Athens General Hospital ""ELPIS"", Athens Greece

[3] Dept. of Bacteriology of Hellenique Pasteur Intitute, Athens, GreeceRecent studies have shown that newer, one week, triple therapies, involving Metronidazole (Met), are highly effective and safe in treating Hp infection.*The aim* of our study was to estimate the efficacy of two, one week, triple therapies, involving Met, on Met sensitive ($Met^{(S)}$) and Met resistant ($Met^{(R)}$) Hp strains.*Patients–Methods:* Sixty-one patients (aged 19–83 yrs, mean 44.9) with a positive Hp culture, were randomized in two treatment groups. Group A (n = 32, 22 men, 62.1% smokers) received Omeprazole 20 m bid + Amoxicilline 1 gr bid + Met 500 mg bid for one week. All patients underwent a new endoscopy 4 weeks after the end of treatment to assess eradication of Hp (by CLO-test, histology and culture). Antibiotic test was performed in all isolated Hp strains.*Results:* Eradication of Hp was achieved in 27/32 (84.4%) patients of group A vs 21/29 (72.4%) of group B (p = NS). The incidence of $Met^{(R)}$ Hp strains was 12/32 (37.5%) in group A vs 11/29 (27.9%) in group B (p = NS). According to Met resistance of Hp strains the success rate of both therapies was: Group A: 20/20 (100%) in $Met^{(S)}$ strains vs 7/12 (58.3%) in $Met^{(R)}$ strains ($p < 0.01$) and Group B: 17/18 (94.4%) in $Met^{(S)}$ strains vs 4/11 (36.4%) in $Met^{(R)}$ strains ($p < 0.05$).*Conclusion:* The response to treatment of patients harbouring $Met^{(R)}$ Hp strains was significantly lower compared to those with Met(S) strains, in the Met containing newer, one week, triple therapies. Consequently, their efficacy, in the treatment of Hp infection, might be negatively influenced in areas with high (> 35%) incidence of Met Hp resistance. [3] Dept. of Bacteriology of Hellenique Pasteur Intitute, Athens, GreeceRecent studies have shown that newer, one week, triple therapies based on Clarithromycin (CL) are highly effective and safe in treating Hp infection.*The aim* of our study was to estimate the influence of metronidazole (Met) resistance in the Hp eradiation rates achieved by two, one week, triple regimens that involve either one (CL) or two (CL plus Met) antibiotic agents.*Patients-Methods:* 78 patients (aged 19–83 yrs, mean 45.6) with a documented Hp infection (by CLO-test, histology and culture) were randomized in two treatment groups: Group A (n = 40, men 27, 62.5% smokers) received Omeprazole (Ome) 20 mg bid +CL500 mg bid +Metronidazole (Met) 500 mg bid, for one week. Group B (n = 38, men 24, 61.3% smokers) received Ome 20 mg bid +CL500 mg bid +TBD (De Nol) 120 mg qid, for one week. All patients underwent a new endoscopy 4 weeks after the end of treatment to assess eradication of Hp. Antibiotic sensitivity test was performed in cultured Hp isolates.*Results:* Eradication of Hp was achieved in 34/40 (85%) patients of group A vs 34/38 (89.5%) of group B (p = NS). Culture and antibiotic sensitivity test revealed 12/32 (37.5%) Met resistant (Met^R) Hp strains in group A and 13/32 (40.6%) in group B (p = NS). The response to treatment of patients harbouring $Met^{(R)}$ strains was significantly lower compared to those with $Met^{(S)}$ strains, in group A, [7/12 (58.3%) vs 20/20 (100%), $p < 0.01$]. In contrast, the efficacy of group B regimen was comparable in $Met^{(R)}$ and $Met^{(S)}$ strains [12/13 (92.3%) vs 17/19 (89.5%), p = NS].*Conclusion:* The efficacy of the newer, short-term, triple therapy involving two antibiotics (CL + Met) is probably depended on the incidence of Met^R Hp strains. In areas with low CL resistance of Hp, an alternative mono-antibiotic triple regimen may be equally effective and well tolerated. "P P 36 0802"P 36 0802**Intravenous Omeprazole Plus Antibiotics in Helicobacter-Related Peptic Ulcer Patients with Major Stigmata of Recent Hemorrhage — A Preliminary Report of a Randomized Controlled Trial**

*C.Y. Chen[1], C.Y. Chen, T.T. Chang, X.Z. Lin

[1] Department of Internal Medicine, Chia-Yi Christian Hospital, Taiwan

National Cheng Kung University Hospital, Taiwan*Aims:* Eradication of H pylori significantly reduces the rate of ulcer rebleeding. Dual therapy with omeprazole and amoxicillin should be considered in all H pylori-positive patients with ulcer bleeding. The aim of the present study was to examine the effect of intravenous route of dual therapy in active ulcer bleeding.*Methods:* In a prospective study, one hundred and thirty two patients with endoscopy documented ulcer bleeding with major stigmata of recent hemorrhage (active bleeding or non-bleeding visible vessel) were entered. Endoscopic injection therapy was performed in all patients with a mean volume of 7.5 mL of 1:10000 epinephrine. One hundred patients (75.5%) with documented H pylori infection (by rapid urease test and histologic findings) were randomly assigned to receive 40 mg omeprazole intravenously every day and ampicillin-sulbactam 750 mg three times daily intravenously for 3 days and 20 mg omeprazole twice daily and 500 mg amoxicillin three times daily for 11 days (Group A) or 20 mg omeprazole twice daily and 500 mg amoxicillin three times daily for 2 weeks (Group B). Subsequently, both group received 20 mg omeprazole daily orally for 4 weeks. Patients underwent a second endoscopy 3 days later and again at the end of 6 weeks.*Results:* Early rebleeding occurred less in Group A. (1/50 or 2% vs 5/50 or 10%, $P > 0.05$). All these 6 patients were excluded. Disappearance of major SRH was significantly higher in Group A (45/49 or 91.8%) than in Group B (32/45 or 71.1%; $P > 0.05$) at the second endoscopy. H pylori eradication rates were 89.7% (44/49) in Group A and 77.7% (35/45) in group B. ($P > 0.05$) Ulcer healing rates were 93.8% (46/49) in Group A and 95.5% (43/45) in Group B. ($P > 0.05$)*Conclusions:* Intravenous form of dual therapy can be started immediately in HP-positive ulcer hemorrhage with major SRH. Rapid disappearance of major SRH and lower early rebleeding rate could be achieved. It can be an alternative choice for H pylori treatment in acute peptic ulcer bleeding. "P P 36 0803"P 36 0803**Relevance of Metronidazole Resistance in Predicting Failure of Omeprazole, Clarithromycin and Tinidazole to Eradicate *Helicobacter Pylori***

*P. Moayyedi, D.S. Tompkins[1], P.L. Ragunathan[1], D.M. Chalmers, A.T.R. Axon

Centre for Digestive Diseases, Leeds General Infirmary, Leeds, UK

[1] Dept. Public Health Medicine, Leeds, UK*Introduction:* Omeprazole 250 mg od/bd, clarithromycin 250 mg bd and tinidazole 500 mg bd for 7 days (OCT) is an effective regimen against *H pylori* but the effect of metronidazole resistance on this regimen is unclear. *Methods:* *H pylori* positive patients were prescribed OCT and cure of the infection was assessed by ^{13}C-UBT 5 weeks after therapy. Metronidazole resistance was determined by the disc diffusion method. Samples were stored at { -}70\'b0C for re-culture and MIC assessment by E test. *Results:* 141 *H pylori* infected patients were enrolled. The organism was successfully cultured in 119/141 (84%) cases and the overall eradication rate was 125/141 (89%). The incidence of metronidazole resistant strains was 121/141 (38%). OCT was successful in 62/69 (90%) patients harbouring fully sensitive strains of *H pylori* compared with 42/45 (93%) of patients with strains that were resistant to metronidazole alone (p = 1.0). MIC was assessed in 23 samples. A cut-off point of > 4 mg/L to define metronidazole resistance gave eradication rates of 57% in sensitive and 56% in resistant strains. If the cut-off was re-defined as > 32 mg/L then eradication rates were 70% in sensitive but only 30% in resistant strains. *Conclusion:* The disc diffusion method is not helpful in predicting OCT failure but the E test may be of value. [1] Gastroenterology and Pathology, Istanbul, Turkey

Departments of Cerrahpasa Medical Faculty of Istanbul University, Istanbul, TurkeyHelicobacter pylori (Hp.) is the principal cause of chronic active gastritis and duodenal ulcer, and has been linked epidemiologically with the development of gastric carcinoma. The aim of this study was to evaluate the efficacy and tolerability of low and high dose short-term triple therapies for cure of Hp infection. 60 patients with Hp infection (16 with duodenal ulcer disease and 44 with antral gastritis) were divided two groups (30/30) for different cures. First group was treated with omeprazole 20 mg o.i.d, klarithromycin 250 mg, b.i.d. and metronidazole 500 mg, b.i.d and second group was treated with omeprazole 20 mg b.i.d, klarithromycin 500 mg b.i.d. and metronidazole 500 mg b.i.d. for a week. Four weeks after the treatment withdrawal, cure of Hp infection was evaluated by urease test and histopathologic examination. The eradication rate of Hp infection was 50% in the first group (18 patients were reported side effects; methallic taste in 17 and pruritus in one) and 80% in the second group (24 patients were reported side effects; methallic taste in 24, epigastric diccomfort and mild nausea in 12 and diarrhea in 3) ($p < 0.05$). In conclusion; eradication rate of one week triple theraphy with omeprazole, klarithromycin and metronidazole combination was increased with high doses but also side effects were increased with augmented doses. Therapy Omeprazole 20 mg o.i.d Omeprazole 20 mg b.i.d Klarithromycin 250 mg b.i.d Klarithromycin 500 mg b.i.d Metronidazole 500 mg b.i.d Metronidazole 500 mg b.i.dMean age 43 (18–70) 47 (18–73) > 0.05Male/Female (n) 10/20 12/18 > 0.05Antral gastritis (n) 30 30 > 0.05Duodenal ulcer (n) 9 7 > 0.05Hp. eradication rate (%) 50 80 < 0.05Side effects (%) 56 80 < 0.05 Oesophageal gastric duodenal disorders: Helicobacter Pylori }" "Comparison of the Effect of Omeprazole, Klarithromycin and Metronidazole Combinations in Different Two Doses for One Week Therapy of Helicobacter Pylori Infection"

"P P 36 0805"P 36 0805**Comparison of Two One-Week Triple Therapy Regimens in the Eradication Rates of *Helicobacter Pylori* Infection with Associated Duodenal Ulcer. A Randomized Study (Preliminary Results)**

*M. Forne, J.M. Viver, J.C. Espinos, S. Quintana, A. Salas, J. Garau

Hospital M. de Terrassa, Barcelona, Spain*Aim:* To evaluate the efficacy and tolerability of two one-week triple regimens in *H. pylori* eradication and duodenal ulcer healing. *Methods:* 171 consecutive patients with duodenal ulcer and proved *H. pylori* infection diagnosed by rapid urease test, histology (2 biopsies from antrum and 2 from the corpus) and/or culture (2 biopsies from the antrum), were randomized in two short treatment groups. Group (OCC): patients (84) were given omeprazole 40 mg bd, clarithromycin 500 mg bd and colloidal bismuth subcitrate (CBS) 120 mg qd for 7 days. Group (OCA): patients (87) were treated with the same dosage of omeprazole and clarithromycin plus amoxicillin 1 gr bd for 7 days. No patient received follow-up treatment. Ulcer healing and *H. pylori* eradication were assessed 4 weeks after cessation of therapy. *Results:* Three patients 2/OCA and 1/OCC group were lost to follow-up. *H. pylori* was eradicated in 68/83 patients of the OCC group, (81.9%); 95%-CI: 71%–89% and in 77/85 patients of the OCA group (90.6%); 95%-CI: 81%–96%. (OCC vs OCA: $p = 0.1$). Duodenal ulcer healing was documented in 77/83 (92.8%) patients in the OCC group and in 80/85 (94%) patients in the OCA group ($p = 0.7$). Ulcer healing was more frequently observed in patients cured of *H. pylori* infection than in the group of the patients with persisting infection (96.5% *vs* 73.9%; $p < 0.001$). Side effects were infrequent and minor, one patient (OCA) suffered from slight dizzineses during the last two days of treatment that persisted for another 7 days, and one patient (OCC) had skin rash (clarithromycin was stopped on day 5 of therapy). *Conclusions:* 1. Both one-week regimens were effective in the eradication of *H. pylori* and duodenal ulcer healing; 2. They were well tolerated and their cost is similar. "P P 36 0807"P 36 0807**Cost Savings Using the International Gastro Primary Care Group (IGPCG) Management PlanJ. Brun, S.A. Brunton, F. Carelli, H. Haslbauer, P. Heyse, H. Maurer, P. O'Connor, W. Peterz, K. R\'fcdy,**

*M.J. Whitaker

International Gastro Primary Care GroupUpper gastrointestinal (GI) disorders are common in many countries world-wide and the costs of treatment represent a significant proportion of primary health care budgets. In the UK, for every 20 patients visiting their GP, one will have upper GI symptoms and therefore, optimal management is important. The IGPCG has devised an upper GI management plan in the form of a treatment algorithm which leads GPs logically through the paths of diagnosis and treatment options. This management plan allocates patients, based on predominant symptoms to one of the following subcategories: motility disorder likely, ulcer disease likely or gastro-oesophageal reflux disease (GORD) likely.A computer model was designed to evaluate whether using the IGPCG management plan can lead to cost savings in practice. Current upper GI treatment costs were obtained from International Marketing Statistics (IMS) Mediplus search of 47,303 patients taken from 728 GPs. Figures for overall cost per patient and for the different disease subcategories were established for current practice and the IGPCG management plan.The overall cost per patient is \'a398.48 currently, compared to \'a366 for the IGPCG algorithm which represents a saving of 30%. For the two upper GI disease subcategories, motility and ulcer, the IGPCG cost per patient is considerably lower than currently. The estimated current cost per motility patient is \'a3130 compared to an IGPCG cost of \'a354. IGPCG analysis of total costs including GP time and use of hospital services, revealed that of the three disease subcategories motility patients had the lowest cost per patient.In conclusion, using the IGPCG algorithm significantly reduces treatment costs, particularly for those patients with an underlying motility disorder who are treated with prokinetic drugs such as cisapride. Clinical practice: Management strategy }" "Cost Savings Using the International Gastro Primary Care Group (IGPCG) Management Plan"

"P P 36 0808"P 36 0808**Does Initial Choice of *Helicobacter Pylori* (Hp) Treatment Regimen Influence the Recurrence Rate of Duodenal Ulcer (DU)? A Meta AnalysisJ.Q. Huang, Y. Chen, J. Wilkinson,**

*R.H. Hunt

McMaster University Medical Centre, Hamilton, Ontario, CanadaDU has a one year recurrence rate over 60% in untreated patients and – 30% in patients on maintenance therapy (APT 1990;4:283). Studies suggest that cure of Hp infection reduces DU recurrence. However, data sets are small and results vary considerably between studies and regimens. We undertook a meta analysis to evaluate any differences in DU recurrence with respect to Hp status and the different drug regimens used for DU healing and eradication. *Methods:* A fully recursive, Medline search identified 126 articles from 1984 to 1995. 41 met inclusion criteria: i) DU healed by antisecretory drug and antimicrobial(s) and documented endoscopically; ii) ulcer recurrence diagnosed by endoscopy; iii) Hp status ascertained by {\'b3} two methods; iv) adult patients and articles in English language. Studies were grouped by different regimens, Hp status and time points following DU healing. *Results:* Groups 6 m (%) arms 12 m (%) arms 18 m (%) arms 24 m (%) armsOne 293/476 (68) 9 221/529 (42) 19 19/64 (30) 5 27/100 (27) 5Two* 335/435 (77) 8 479/552 (87) 14 33/43 (77) 2 64/90 (71) 3Three$^{*\#}$ 186/199 (94) 9 767/866 (89) 23 33/38 (87) 2 96/119 (81) 2Hp^{+**} 345/598 (58) 15 244/606 (40) 21 24/81 (30) 3 37/150 (25) 4Hp$^{\{-}$} 470/495 (95) 15 957/993 (96) 28 61/64 (95) 3 82/89 (92) 3No. expressed as No. in remission/No. assessed. m = months; One = CBS/H_2RA/PPI; Two = two-drug regimen; Three = three-drug regimen. *vs one $p < 0.001$; $^{\#}$vs two $p < 0.001$; **vs Hp$^{\{-}$} $p < 0.001$ by log rank test, Kaplan-Meier.*Conclusions:* Results confirmed DU recurrence in up to 73% untreated patients after 24 months irrespective of Hp status. Hp eradication significantly changed DU natural history and reduced recurrence rate to 4% at 12 months and 8% at 24 months. Three-drug regimens achieved the highest remission rate over time compared to one and two-drug regimens. DU recurrence depends on initial drug regimen and Hp status. "P P 36 0809"P 36 0809**Effect of Omeprazole, Clarithromycin and Tinidazole on the Eradication of Helicobacter Pylori and Healing of Gastric Ulcer**

*F. Bazzoli, R.M. Zagari, S. Fossi, P. Pozzato, C. Mwangemi, L. Ricciardiello, P. Simoni, A. Roda, E. Roda

Cattedra di Gastroenterologia, Universit\'e0 di Bologna*Background.* Eradication of Helicobacter (H.) pylori is a key factor for the cure of peptic ulcers. Eradication of H. pylori seems to be more difficult to achieve in gastric ulcer (GU) patients than in patients with duodenal ulcer (DU) or gastritis. On the other hand healing rates after conventional treatment with antisecretory drugs were also reported to be lower in GU than in DU patients. Recently, we reported the high efficacy of 1 week low-dose triple therapy with Clarithromycin, Omeprazole and Tinidazole on long-term eradication of H. pylori infection in patients with non-ulcer dyspepsia and DU. *Purpose.* The aim of the present study was to investigate the efficacy of 1 week low-dose treatment with Clarithromycin, Omeprazole and Tinidazole followed by 3 weeks of Omeprazole in eradicating H. pylori infection and ulcer healing in patients with GU. *Methods.* 49 patients (28 males, 21 females; age (yrs) range 32–71, mean 49) with non-NSAID GU and H. pylori infection received Omeprazole 20 mg u.i.d. for 4 weeks and, during the first week, a combination antimicrobial treatment with Clarithromycin 250 mg b.i.d. and Tinidazole 500 mg b.i.d.. H. pylori infection as well as eradication was assessed by histology (Haematoxylin-Eosin, Giemsa), quick urease test and 13C-Urea Breath Test (13C-UBT). Upper GI endoscopy with 3 antral and 2 corpus-fundus biopsies and 13C-UBT were performed prior to treatment and at 1, 3 and 6 months after the end of treatment. The healing rate in patients treated with antimicrobials was compared to a H. pylori positive, nonNSAID GU historical control group (no. 53; 31 males; age (yrs) range 30–75, mean 50) previously treated with Omeprazole 20 mg u.i.d. for 4 weeks, matched by age, sex, history of smoking and site and size of GU. *Results:* Only 2 patients complained of moderate glossitis and transient taste disturbance which cleared up after completing therapy. At 1 month after the end of treatment, eradication of H. pylori was obtained in 47/49 patients (95.9%, 95% CI: 90.3%–100%). Ulcers healed in 46/49 (93.9%, 95% CI: 87.2%–100%) of the patients treated with antimicrobials and in 38/53 (71.7%, 95% CI: 59.6–83.8; $p < 0.003$) of the omeprazole patients control group. Follow-up evaluations performed at 3 and 6 months confirmed H. pylori eradication and persistent healing of GU in the patients treated with antibiotics. *Conclusions:* One week low-dose triple therapy with Omeprazole 20 mg u.i.d., Clarithromycin 250 mg b.i.d. and Tinidazole 500 mg b.i.d. is also highly effective in H. pylori eradication in patients with GU. The GU healing rates in patients treated with antibiotics and antisecretory drugs are significantly higher than those reported in patients treated with only antisecretory agents. Oesophageal gastric duodenal disorders: GD disorders, acid pepticOesophageal gastric duodenal disorders: Helicobacter Pylori }" "Effect of Omeprazole, Clarithromycin and Tinidazole on the Eradication of Helicobacter Pylori and Healing of Gastric Ulcer"

"P P 36 0810"P 36 0810**Clarithromycin-Based Therapy Failure: What Comes Next?**

*J.P. Gisbert, D. Boixeda, C. Mart\'edn de Argila, F. Bermejo, A. Al-Mostafa, C. De la Serna, A. Garc\'eda Plaza

""Ram\'f3n y Cajal"" Hospital, Madrid, Spain*Purpose:* Recently, eradication therapies containing clarithromycin have been extensively used and are associated with a high *H. pylori* eradication rate. However, it is still to be elucidated how to proceed when these therapies fail. This topic is of an utmost concern because of the ever increasing use of claritromycin-based therapies. Therefore, we studied the efficiency of omeprazol + amoxycillin + metronidazole (OAM) in this situation, to avoid retreatment with clarithromycin.*Methods:* Eleven patients treated unsuccesfully with one-week twice-daily therapy with omeprazol (20 mg) + clarithromycin (500 mg) + amoxycillin (1 g) (OCA) received a therapy consisting of omeprazole (20 mg b.i.d.), amoxycillin (1 g b.i.d.) and metronidazole (500 mg b.i.d.) (OAM) for one week. This same combination was administered to six patients in whom omeprazol (20 mg b.i.d.) plus clarithromycin (500 mg t.i.d.) (OC) had also failed in eradicating *H. pylori.* Our previous protocols defined eradication failure as the presence of *H. pylori* in biopsies (H & E) or a positive C^{13}-urea breath test. A breath test was repeated one month after completing therapy in all patients, but endoscopy (with biopsies) was performed in only ten patients. Compliance was evaluated by tablet count. Eradication was defined as the absence of *H. pylori* by breath test and histology (when available).*Results: H. pylori* eradication rates were 36% (4/11) and 83% (5/6) in groups OCA and OC, respectively (Fisher test, p = 0.088). The distribution of demographic variables in both groups was: age (44 – 17/54 – 16 yrs), sex (82/100% males), and smoking (36/17%), respectively. Compliance of therapy was complete in all patients. No relevant adverse effects were reported.*Conclusion:* These preliminary results suggest that a one-week twice-daily OAM therapy has a low efficiency in eradicating *H. pylori* when a previous triple therapy with clarithromycin and amoxycillin (OCA) has failed. However, if the results of this study are confirmed, OAM combination could be an alternative when dual therapy with clarithromycin (OC) has failed. Oesophageal gastric duodenal disorders: Helicobacter PyloriOesophageal gastric duodenal disorders: GD disorders, acid peptic }" "Clarithromycin-Based Therapy Failure: What Comes Next?"

"P P 36 0812"P 36 0812**Comparison of Lansoprazole and Omeprazole Against Gastric H/K-ATPase, H^+ Secretion and Growth of H. Pylori**

*A. Garner, C.S. Goodwin, S.M.A. Bastaki, I. Chandranath, N. Mustafa, A. Thibodeau[1], J.G. Forte[1]

Faculty of Medicine & Health Sciences, United Arab Emirates University, Al Ain, U.A.E.

[1] Department of Molecular & Cell Biology, University of California at Berkeley, U.S.A.*Purpose:* Lansoprazole (L) is a fluorinated derivative of omeprazole (O) and rival PPI for treatment of ulcer disease. This study seeks to identify pharmacological properties which differentiate these two drugs. *Methods:* Inhibition of aminopyrine (AP) accumulation and enzyme recovery were measured in rabbit gastric glands. Acid output was measured in vivo in rat and guinea pig. MIC values against H. pylori were determined for ten fresh isolates. Drugs were incorporated in agar plates, inoculated then incubated in a microaerophylic atmosphere for 5 days.*Results:* There was no significant difference between the IC-50 values for inhibition of AP accumulation by L (0.53 – 0.08 \'b5M) and O (0.47 – 0.08 \'b5M). Recovery of glands, assessed by AP reaccumulation after treating with 20 mM 2-mercaptoethanol, was also identical. Both L and O were more effective inhibitors of stimulated acid output than basal secretion and both drugs displayed a similarly sustained duration of action in the rat with inhibition of acid secretion detectable 24 hr after dosing at 2 mg/kg s.c.However L (IC-50 1.2 \'b5mol/kg) was 2.5-times more potent than O (IC-50 3.0 \'b5mol/kg) measured 2 hr after i.v. injection. This may reflect differences in pharmacokinetic handling in the rat since the two drugs were of similar potency in anaesthetized guinea pigs. MICs for L against H. pylori varied between 32 \'b5g/ml (6 strains) and 64 \'b5g/ml (3 strains) up to 128 \'b5g/ml (one strain). L was marginally more effective than O against H. pylori but there was considerable overlap in activity.*Conclusions:* L is essentially indistinguishable from O as an inhibitor of H^+ transport and acid output. Claimed differences in binding to isolated enzyme would appear to be irrelevant for antisecretory activity and hence clinical efficacy. Potency differences in rat may reflect species specific pharmacokinetic properties resulting from polyfluorination. While both L and O inhibit H. pylori, relevance of this bactericidal action of PPIs is debatable, particularly since they are given as enteric-coated formulations. "P P 36 0813"P 36 0813**Short-Term Therapy of Helicobacter Pylori Gastritis**

*M.M. Dollinger, M. Kroesen, H.C. Dollinger

Department of Internal Medicine, University of Ulm, Germany*Aim:* The study was designed to compare the efficacy and tolerability of the Al-Mg-antacid hydrotalcite (HT) and the proton pump inhibitor (PPI) pantoprazole given in combination with different antibiotics for the eradication of H. pylori in patients with chronic gastritis and non-ulcer dyspepsia (NUD). The study also examined the gastritis variables and the correlation between the H. pylori status and the dyspeptic symptoms.*Methods:* Fifty-six patients with positive histology and positive ^{13}C-urea breath test who were found to have dyspepsia were divided into three groups. Group A: 11 pts were given two tablets of HT q.d.s. (total neutralization capacity 111.2 mval/d) and ampicillin 1000 mg b.d. for 10 days. Group B: 20 pts were treated with pantoprazole 40 mg b.d. and ampicillin 1000 mg b.d. for 10 days. In both groups, metronidazole 500 mg b.d. was given for the last three days (days 8–10). Group C: 25 pts received pantoprazole 40 mg b.d. plus clarithromycin 500 mg b.d. and metronidazole 500 mg b.d. for 7 days. Eradication was determined using ^{13}C-UBT one month after the end of treatment. Differences in the degree and activity of gastritis between initial and final endoscopies were calculated by Wilcoxon matched pairs test. Symptom severity was scored by patients visual analogue scales (VAS) and by doctors' assessment.*Results:* H. pylori eradication was achieved in 45% of group A, 70% of group B, and 96% of group C. Independently of the eradication regimen, cure of the infection brought a marked reduction in the degree of antral gastritis and an even greater improvement in the activity, with a resolution of symptoms in 88% of pts.*Conclusion:* The results support the causal relation between H. pylori infection and gastritis. Furthermore, in chronic gastritis, H. pylori seems to play an important role in the symptoms of NUD. The success of antimicrobial therapy can be improved by effective control of gastric acid secretion, and the one-week triple therapy with PPI and two antibiotics not only is well tolerated, but also has high and similar efficacy in comparison with the eradication regimens in gastric and duodenal ulcer. Oesophageal gastric duodenal disorders: Helicobacter PyloriOesophageal gastric duodenal disorders: GD disorders, acid peptic }" "Short-Term Therapy of Helicobacter Pylori Gastritis"

"P P 36 0814"P 36 0814**Evaluation of the Combination of Omeprazole and Azithromycin with or without Metronidazole in Eradicating Helicobacter Pylori**

*A. Vcev, A. Vceva, D. Pezerovic, D. Stimac, M. Rubinic, A. Ivandic, B. Dmitrovic, D. Vukovic, N. Micunovic

Clinical Hospital Osijek Clinical Hospital Centre Rijeka, Croatia*Purpose:* We evaluated the benefit of 7 therapeutic schedules with omeprazole (OME) and azithromycin (AZ) with or without metronidazole (ME) for eradication of Helicobacter pylori.*Methods:* Helicobacter pylori status was determined by rapid urease test and hystology before and 4 weeks or more after therapy. 7 groups of H. pylori infected patients with peptic ulcer disease were studied. Group 1 (n = 25) and 2 (n = 25) received OME 20 mg/day for 14 days and AZ 500 mg/day for 5 days. Group 2 received and ME 3 {\'b4} 500 mg/day for 5 days. Group 3, 4, 5, 6 and 7 received OME 40 mg/day for 14 days. Group 3 (n = 16) received AZ 500 mg/day for 5 days. Group 4 (n = 20) received AZ 500 mg/day for 9 days. Group 5 (n = 20) received AZ 500 mg/day for 9 days and ME 3 {\'b4} 500 mg/day for 7 days. Group 6 (n = 19) received AZ 2 {\'b4} 500 mg for 9 days. Group 7 (n = 15) received AZ 2 {\'b4} 500 mg/day for 9 days and ME 3 {\'b4} 500 mg/day for 7 days. Side effects were recorded in all patients.*Results:* The eradication rate in group 1, 2, 3, 4, 5, 6 and 7 was 64%, 72%, 62.5%, 70%, 75%, 73.7% and 86.6%. 21.4% (30/140) patients experienced minor or mild side effects, none discontinued therapy because of side effects.*Conclusion:* We conclude that omeprazole 40 mg/day for 14 days, azithromycin 2 {\'b4} 500 mg/day for 9 days and metronidazole 3 {\'b4} 500 mg/day for 7 days is effective treatment for eradication H. pylori infection. "P P 36 0815"P 36 0815**Eradication of Helicobacter Pylori Decreases the Rate of Duodenal Ulcer Recurrence and RebleedingG. Macr\'ec, S. Milani, E. Surrenti, M.T. Passaleva, G. Ciancio, S. Faenzi, O. Morelli, M. Romano, A. Calabr\'f2, G. Salvadori, C. Surrenti**

Gastroenterology Unit, Department of Clinical Pathophysiology, and University of Florence, Italy*Background:* gastrointestinal hemorrhage is the most frequent complication of peptic ulcer disease. It has recently been suggested that HP infection may be a risk factors for the relapse of peptic ulcer and rebleeding. *Aim:* we evaluated the effects of HP eradication on the recurrence of bleeding from duodenal ulcer (DU) in young patients with 46 to 70 months of follow-up. *Methods:* from June 90 to June 92, we analyzed 32 pts (all males, mean age 30.2 yrs, range 22–46) with endoscopically proved HP positive bleeding DU. All pts received Omeprazole (40 mg/day) for 4 wk followed by Colloidal Bismuth (480 mg/day) for 2 wk associated with Amoxicillin (2 g/day) during the first wk, substituted by Metronidazole (750 mg/day) during second wk. After 6 wk all pts underwent upper digestive endoscopy with antral biopsies in order to assess ulcer healing and HP eradication (Giemsa stainign and rapid urease test). Upper digestive endoscopy with antral biopsies was performed once a year for 46–70 months. *Results:* Ulcer healing was found in 32/32 pts (100%). HP eradication was obtained in 23/32 pts (71.9%). After 12 months, 2 previously eradicated pts had been reinfected (8.7%). In the following 24 month, ulcer recurred in 10/11 HP-positive pts (reinfected and eradicated). Rebleeding was noted in 5/11 (45%) HP-positive pts. These pts were treated with omeprazole 40 mg/day for 4 wk with complete healing. In the following 24–48 month ulcer recurred in 10/11 pts HP-positive pts. Rebleeding was noted in 7/10 (70%) of them. Patients who were not reinfected by HP (21/32) did not show any evidence of DU relapse during follow-up. Thus, the rate of rebleeding episodes along the period of the follow-up was significantly lower in pts with long term eradication of HP, in comparison with those who did not. *Conclusion:* long term eradication of HP can decrease the rate of DU recurrence and rebleeding. }" "Eradication of Helicobacter Pylori Decreases the Rate of Duodenal Ulcer Recurrence and Rebleeding"

"P P 36 0816"P 36 0816**Triple Therapy (Omeprazol + Amoxicillin + Clarithromycin) for Helicobacter Pylori Eradication in Patients with Peptic Ulcer. No Difference between Six or Twelve Days**

*C. Hermida, J.A. Moreno, P. Carpintero, J.M. Mateos, R. GaGr\'e1valos, J.M. Pajares

Servicio de Medicina Digestiva, Hospital Universitario de La Princesa, Universidad Aut\'f3noma de Madrid, Spain*Intro:* Modern therapies for eradication of Helicobacter pylori try to be more effective and to achieve better compliance being shorter and cheaper. Some seven-days regimens with omeprazole, amoxicillin and clarithromycin have proved high eradication rates. In Spain available packaging of both antibiotics used carries 12 capsules in. If we use 7 days regimens we need double number of packages and lots of pills are wasted.*Aim:* To ascertain the efficacy of a triple therapy with omeprazole, amoxicillin and clarithromycin for Helicobacter pylori eradication in regimens of 6 and 12 days.*Patients and Methods:* We conducted a clinical trial to eradicate Helicobacter pylori infection in patients with peptic ulcer. 132 consecutive patients (80 M/52 F, mean age: 49.7, range: 19–84) submitted to upper digestive tract endoscopy because symptoms of dyspepsia, were included in the study. Diagnosis of Helicobacter pylori infection was achieved when, at least, two of the following tests were positive: histologic examination of antral biopsy specimens in frozen tissue sections on H-E and Giemsa, rapid urease test (Jatrox-test) and C^{13} urea breath test. Triple therapy consisting in omeprazole 20 mg/bid, amoxicillin 1 g/bid and clarithromycin 500 mg/bid was given to patients at the time of diagnosis. Duration of treatment was non-randomly assigned for 6 and 12 days. Control of eradication was assessed by C^{13} urea breath test after 6 weeks of finishing treatment. Statistical analysis was performed using $\{ ?\}^2$ test with Yates correction.*Results:* Eradication rates in the different groups are: 6 days 81.7% (67/82)12 days 86% (43/50)No statistical difference of eradication was found between both regimens (6 vs 12 days). Costs of the 2 regimens were 85 and 170 $, respectively for 6 and 12 days.*Conclusions:* 1. Triple therapy (omeprazol + amoxicillin + clarithromycin) in a short course of 6 days is so effective for eradicating Helicobacter pylori in peptic ulcer than a 12 days therapy. 2. Cost-effectiveness for a 6 days regimen is excellent. "P P 36 0819"P 36 0819***Helicobacter Pylori* Eradication with Dual and Triple Therapy: A Cost-Effectiveness Analysis**

*S. Viergutz[1], P. Malfertheiner[2], G. Gatz[3], M. Schlander[3]

[1] gmi, Munich, Germany

[2] University of Magdeburg, Germany

[3] Byk Gulden Pharmaceuticals, Konstanz, Germany*Purpose: Helicobacter pylori (H. pylori)* is broadly accepted as a major prerequisite for the development of peptic ulcer disease and its elimination prevents ulcer relapse in the vast majority of patients. This health economic study compares the cost-effectiveness of two extensively tested treatment schemata: a 14 days dual therapy with a proton pump inhibitor (PPI) and amoxycillin, which produced variable cure rates and a 7 days short term triple therapy (i.e. a PPI and two antibiotics), which resulted in very high cure rates.*Methods:* Possible therapy courses for *H. pylori*-cure were implemented by a decision tree model. The probabilities for the use of a particular course of treatment were determined by a survey of 100 office-based specialists in Germany. The underlying eradication and ulcer relapse rates were analysed by literature research and subsequent meta-analysis. For the analysis, direct costs (medication, diagnostics and consultations with the physicians) were considered.*Results:* Taking only the medication costs into account, the *daily* costs of triple therapy were higher than those of dual therapy. However, the *total* medication costs of triple therapy were 34% lower than those of dual therapy. Carrying out a cost-effectiveness analysis, from the point of the German healthcare system, the total costs per year for a patient with successful *H. pylori* eradication therapy were DEM 1082 with dual and only DEM 657 with triple therapy. The robustness of this result was validated by several sensitivity analyses concerning the medication costs (price range) and the eradication rates (confidence intervals).*Conclusion:* This health economic analysis showed that triple therapy is not only *more effective* but also *more efficient* than dual therapy.

"P P 36 0820"P 36 0820**What Is the Best Rescue Therapy for Omeprazole Plus Amoxicillin?**

*C.Y. Chen[1], C.Y. Chen, T.T. Chang, X.Z. Lin

[1] Department of Internal Medicine, Chia-Yi Christian Hospital, Taiwan

National Cheng Kung University Hospital, Taiwan*Introduction:* Helicobacter pylori infection has change the natural course of peptic ulcer disease. Dual therapy with omeprazole and amoxicillin was the most popular therapy in the treatment of Helicobacter infection. Better compliance, few side effect and rapid disappearance of ulcer symptoms made it become the first line anti-HP therapy. However, variable success rate was results.*Patients and Methods:* 425 patients with endoscopically documented peptic ulcer and positive H pylori infection were included. The definition of positive H pylori infection consisted of both positive CLO test and histological examination. Everyone received Omeprazole 20 mg bid and amoxicillin 500 mg tid for 14 days. Ranitidine 150 mg bid was given for 4 weeks. Repeat endoscopy was done to look for ulcer healing and H pylori eradication. The eradication rate of dual therapy was 76%. There were 102 patients who failed in initial H pylori eradication. We made randomization into three group: group A (36 patients): omeprazole 20 mg bid and amooxicillin 500 tid for 14 days, group B (33 patients): De-Nol 300 mg qid, amoxicillin 500 mg qid, metronidazole 500 mg qid for 14 days; group C (33 patients): omeprazole 20 mg bid, clarithromycin 250 mg bid, metronidazole 500 mg bid for 7 days. Repeat endoscopic examination with 4 biopsy (2 antrum and 2 body) for H pylori eradication was done 4 weeks after anti-Hp therapy.*Results:* Total eradication rate of H pylori in the second line therapy was 81.3% (83/102), including group A: 63.8% (23/36), group B: 90.9% (30/33), and group C: 90.9% (30/33). We further classified the eradication rate into the subgroup according to CLO < 1 hour (I), and CLO > 1 hour (II): CLO < 1 hour CLO > 1 hour TotalGroup A 12/22 (52.1%) 11/14 (78.5%) 23/36 (63.8%)Group B 16/18 (88.8%) 14/15 (93.3%) 30/33 (90.9%)Group C 15/17 (88.2%) 15/16 (93.7%) 30/33 (90.9%) 43/57 (75.4%) 40/45 (88.0%) 83/102 (81.3%)We found that triple therapy and PPI, carithromycin, metronidazole got better HP eradication than high dose dual therapy. (P < 0.05) There was no significant difference in the H pylori eradication in subclassification into CLO < 1 hour or CLO > hour in rescue therapy.*Conclusion:* New and traditional triple therapy both were good regimens for rescue of initial failure of dual therapy. Bacterial urease activity seemed not influence the H pylori eradication in the second line rescue therapy. "P P 36 0821"P 36 0821**Three-Day Octreotide-Assisted *Helicobacter Pylori* Triple Eradication Therapy. Six Month Follow-Up**

*S.D. Ladas[1], H. Malamou-Lada[2], G. Economou[1], P. Tassios[1], S.A. Raptis[1]

[1] Gastroenterology Unit, Second Department of Internal Medicine, Evangelismos Hospital, Athens University, Greece

[2] Microbiology Department, Penteli Children's Hospital, Athens, Greece*Purpose.* Orally administered antibiotics for *H. pylori* eradication therapy exert their effect by local diffusion into the gastric mucosa. However, gastric emptying reduces antibiotic-mucosa contact time. We tested the hypothesis that a three-day *H. Pylori* triple eradication therapy with concurrent octreotide administration may potentiate antibiotic effect by delaying gastric emptying.*Methods.* 26 symptomatic H. pylori-positive patients with active duodenal (n = 20) or gastric (n = 6) ulcer participated in this pilot study. All patients received a three-day course of octreotide (0.1 \'b5g subcutaneously t.d.s.), amoxycillin and metronidazole (500 mg orally q.d.s.) and colloid bismuth subsitrate (CBS) (240 mg b.d). CBS treatment was continued for another four days. Endoscopy with antral biopsies for CLO-test, culture and crush tissue smears were performed on admission to the study, at 4, 8 weeks and six months post-treatment.*Results.* 24/26 (92.3%) ulcers were completely healed at 4 weeks and remained healed at 8 weeks. All 24 patients with a healed ulcer became *H. pylori* negative at 4 weeks. The eradication rate at 8 weeks was 88.5% (23/26). All 24 patients remain asymptomatic at 6 months. In 19/24 patients who accepted to have endoscopy at six months, ulcers remained healed, but the *H. Pylori* eradication rate dropped to 68.4% (13/19).*Conclusion.* Our results show that a three-day octreotide-assisted *H. pylori* eradication triple therapy is highly effective, to maintain a peptic ulcer in remission at six-month follow-up.

"P P 36 0822"P 36 0822**What Is the Optimal Method of H. Pylori Eradication in Patients Chronically Treated with Non-steroid Antyinflammatory Drugs?H. Kordecki, R. Kosik, P. Milkiewicz**

Dept. of Gastroenterology M. Curie Hospital, Szczecin, PolandWide use of non-steroid antyinflammatory drugs (NSAID) markedly increased the frequency of gastric and duodenal mucosal lesions. It is suggested that eradication of H. pylori (H.p.) in persons with some mucosal changes being protractedly treated with NSAID is more optimal and cheaper method in comparison with those continually taking prostaglandins (e.g. misoprostol).*The aim of our study* was to estimate the relapse rate of mucosal lesions 10 months after the end of therapy in persons chronically taking NSAID. Eradication of H.p. was carried out in the majority of patients. The remaining patients were treated wit H-2 blockers only.*Material and methods:* Endoscopic examinations were performed (EVIS 100 – Olympus equipment) in 150 patients receiving chronically NSAID. In 107 persons (71%) taking NSAID leasions were found: 87 patients stomach erosions, 61 stomach ulcers, 75 duodenal erosions and 53 duodenal ulcers. Thirty-two were diagnosed to have multiple ulceration and erosions. In 75 (70%) out of this group H.p. infection was disclosed (rapid urease test and microscopical examination). However negative results were detected in 32 patients (34%). Patients who had mucosal lesions in stomach or/and duodenum were treated by one of these four methods:1. ranitidine only (R)2. colloidal bismuth with amoxicillin and metronidazole (CB + A + M)3. omeprazole with amoxicillin and metronidazole (O + A + M)4. omeprazole with clarithromycin and tinidazole (O + C + T)*Results:* Treatment No of One month after therapy Ten months after therapy pat. healings eradication healings eradication rate rate rate rateR 12 6 (50%) 2 (17%) 2 (17%) 0 (0%)CB + A + M 25 19 (76%) 16 (64%) 9 (36%) 7 (28%)O + A + M 26 24 (92%) 24 (92%) 24 (92%) 3 (88%)O + C + T 12 11 (92%) 12 (100%) 12 (100%) 12 (100%)*Conclusions:*1. The best method resulting in long-term-healing and eradication of H.p. was the treatment with O + C + T.2. The therapy with H-2 blockers is ineffectiv in H.p. positive patients protractedly taking NSAID. "P P 36 0823"P 36 0823**Triple Therapy with Omeprazole, Clarithromycin and Amoxicillin for Cure of Helicobacter Pylori Infection**

*S.P. Chen, B. Lian, S.H. Wen

Dept. of Gastroenterology, Peking Union Medical College Hospital, Beijing, ChinaThe aim of this clinical study is to determine the eradication rate of Helicobacter pylori (Hp) infection using omeprazole 20 mg twice daily, clarithromycin 500 mg twice daily and amoxicillin 1000 mg twice daily for one or two weeks, in comparison with colloidal bismuth subcitrate 240 mg twice daily, amoxicillin 1000 mg twice daily and metronidazole 400 mg twice daily for two weeks. 168 patients with Hp associated chronic gastritis or duodenal ulcer were allocated to three therapeutic groups: Group I (N = 55) and Group II (N = 57) were treated with triple therapy of omeprazole, clarithromycin and amoxicillin for one week and two weeks respectively, and Group III (N = 56) was treated with bismuth triple therapy for two weeks. The Hp status was determined by rapid urease test and histology of Warthin-Starry stain.The eradication rates in group I, Group II and Group III were 89.2%, 94.8% and 71.4% respectively. The eradication rates of both Group I and Group II were significantly higher than that of Group III ($P < 0.05$). There were no statistical significant difference in the eradication rate between Group I and Group II. The incidence of side effects in Group III (49.6%) was signicantly higher than that in Group I (19.3%) and Group II (25.8%). There were two patients withdrawn due to side effects during bismuth triple therapy.Our results showed that triple therapy with omeprazole, clarithromycin and amoxicillin is more effective and better tolerated than the bismuth triple therapy in the treatment of H. pylori infection. "P P 36 0824"P 36 0824**Comparison of Different Drug Regimens for Helicobacter Pylori Eradication**

*S.M. Kamal, M.A. Sakr, A. Hafez, M. Salah, H. Kosha

Departments of Tropical Medicine, Microbiology and Pathology, Ain Shams University, Cairo, Egypt*Background:* Helicobacter pylori (HP) has a world wide distribution, however in Egypt the incidence of infection rises to over 80% in young adults. Eradication of HP from the forgut has been sought using multiple agents in the form of dual or triple therapy regimens. No treatment schedule is yet considered ideal either due to limited access of antimicrobial agents or the organisms resistance especially to imidazoles.*Aim:* To compare the efficacy and side effects of four alternative triple therapy regimens.*Patients and Methods:* One hundred patients with endoscopically proven upper gastrointestinal lesions 35% duodenal ulcer and 28% gastric ulcer, 22% antral gastritis, 15% duodenitis, who are also positive to H.P. by histological biopsies stained by Gienisa, CLO test and serology. Histopathological assessment was done to all patients prior initiation of therapy. Patients were randomized into groups according to the following drug combinations: Group (1): (n = 25) Ranitidine 300 mg + Amoxicillin (AMO) 500 mg t.d.s. + Metronidazole 4 {\'b4} 250 mg. Group (2): (n = 25) Ranitidine 300 mg + AMO 500 mg t.d.s. + Tinidazole 500 mg B.d. Group (3): (n = 25) Omeprazole (Omp) 40 mg + AMO 500 mg t.d.s. + Met 4 {\'b4} 250 mg. Group (4): (n = 25) Omp 40 mg + AMO 500 mg t.d.s. + Tinidazole 500 mg B.d. Antimicrobials were given for 2 weeks and anti secretory drugs were given for 4 weeks. Reassessment was done 4 weeks after the end of antimicrobial therapy and after 6 months by endoscopic examination and biopsy. In patients showing failure of adequate eradication inspite of compliance to treatment, culture of H.P was done using metronidazole and tinidazole amoxicylline impregnated strips or discs.*Results:* Endoscopic evidence of healing was detected in 80% (20/25) of group 1, 92% (23/25) of group 2, 84% (21/25) of group 3 and 96 (24/25) in group 4. duodenal ulcer responded in 33 (94.3%) of cases, gastric ulcer in 25 (98.3%), antral gastritis in 19 (86.4%) and duodenitis in 13 (86.7%). The percentage of H.P eradication was 80%, 92%, 88% and 96% in groups 1, 2, 3, 4 respectively with an overall H.P eradication in 89% of the patients. The side effects were uncommon (nausea in 5%, diarrhoea in 2% and bitter taste in 2%). Out of the 11 patients who failed to erradicate H.P., 8 (72.7%) were resistant to metronidazole, one to amoxycillin and one to tinidazole and no resistance was detected in the last patients. Relapse rate was 3%.*Conclusion:* (1) Omeprazole + Amoxycillin + Tinidazole was the most effective regimen for eradication of H.P (96%). (2) Triple therapy with H, antagonist (Rantidine) + Amoxycilline and Tinidazole proved good effectiveness (92%) and was more economic than Omeprazole triple therapy. (3) Tinidazole was more effective than metronidazole and was not accompanied with resistance. Padova, Italy

[1] Venezia, Italy

[2] Trento, Italy

[3] Dolo, Italy

[4] Montebelluna, ItalyHp infection plays a different role in the pathofisiology of gastric (GU) and duodenal ulcer (DU). Since now, few studies are available on GU follow-up after Hp eradication. Therefore, the aim of this study was to evaluate ulcer relapse rate after Hp eradication in GU patients. *Material and Methods:* we enrolled in a prospective multicenter study 72 consecutive outpatients (mean age 49; range 26–79, M/F 38/34) referred for Hp positive GU. Hp status was evaluated by three different tests (histology, CLO test and serology). Study design: four endoscopies were performed during the follow-up: at baseline, two months after the end of a triple therapy treatment, at six and twelve months. Hp eradication was considered successful when both histology and CLO test resulted negative. *Results:* Over 72 patients 14 subjects remained Hp positive after the treatment. One out of the 58 eradicated pts become positive at six months. Seven GU relapses were observed (5 in Hp{ -} and 2 in Hp+ pts); in 2/5 Hp{ -} pts relapsed, a NSAIDs intake was documented. *Conclusions:* 1) Hp eradication in GU is related with a low relapse rate (5/57); 2) Contrary to the outcome observed in DU pts, only 2/14 Hp+ GU relapsed during a twelve months follow-up; 3) Almost 50% of GU relapses in Hp{ -} pts are related with NSAIDs assumption. }" "Helicobacter Pylori Eradication in Gastric Ulcer Disease: One Year Prospective Multicenter Study"

"P P 36 0826"P 36 0826**One Year Follow-Up after Eradication of H. Pylori Infection in Preventing Duodenal Ulcer Bleeding****S. Salandin, N. Dal B\'f2, S.A. Grassi[1], M. Ferrana, S. Kusstatscher, F. Vianello, A. Pilotto, M. Bortolon, F. Farinati, G. Battaglia[2], F. Di Mario**

Padua University, Italy

[1] Marostica, Italy

[2] Venice Hospital, Italy*Aim:* The study was designed to evaluate the role of Hp infection associated with NSAIDs intake in duodenal ulcer bleeding. *Methods:* In an open five years prospective study (12–24 months) 50 consecutive patients Hp positive (37 M, 13 F; mean age 56, range 27–68) showing in the last 12 months at least one episode of bleeding duodenal ulcer, endoscopically documented, were enrolled. Eighteen subjects showed an intake of ulcerogenic drugs (NSAIDs+ve) causally related with bleeding episode. From each patient smoking habit, alcohol intake, blood group and family history of peptic ulcer were also recordered. The Hp status was assessed by means of urease test, hystology and serology. After an informed consent all patients received an eradication therapy (dual or triple regimen for 14 days); eradication rate was assessed 2 months after the end of the treatment as mentioned above. All subjects were followed-up by endoscopy (every 12 month and at any symptomatic recurrence) and clinical evaluation every six months. *Results:* Overall, in 35 out of the 50 patients (70%) Hp infection was eradicated (12 NSAIDs+ve and 23 NSAIDs{ -}ve). Only one patient (Hp+ve/Nsaids{ -}ve group) showed a bleeding episode at the fifth month of follow-up. Seven patients showed ulcer relapse (3 in Hp+ve/NSAIDs+ve and 4 in Hp+ve/NSAIDs{ -}ve group); no Hp{ -}ve patient relapsed. No statistical differences were detected in Hp+ve vs Hp{ -}ve subjects as regards clinical and epidemiological parameters. *Conclusions:* These preliminary data seem to confirm the importance of Hp infection eradication in preventing bleeding duodenal ulcer, both in NSAIDs positive and negative groups. }" "One Year Follow-Up after Eradication of H. Pylori Infection in Preventing Duodenal Ulcer Bleeding"

"P P 36 0827"P 36 0827**In vitro Evaluation of Helicobacter Pylori Resistance to Five Antimicrobial Agents in Italy**

*A. Savio, R. Negrini, S. Di Nocera, A. Paterlini, P. Cesari, G. Franzin, S. Orsola

FBF Hospital, Brescia, ItalyWe evaluated the ""in vitro"" sensitivity to metronidazole, amoxycillin, tetracyclin, eritromicin and azytromicin of 66 strains of Helicobacter pylori (H. pylori) isolated from the gastric mucosa of dyspeptic patients.Susceptibility was determined by disc diffusion on agar plates. 29 patients (group A) had never been treated for H. pylori infection while 37 patients had previously received an unsuccessful treatment for the infection: 9 patients (group B) had been treated whith omeprazole + amoxycillin and 28 patients (group C) with tinidazole + amoxycillin + colloidal bismuth subcitrate and/or omeprazole.All the isolates from group C were found to be resistant to metronidazole. The natural metronidazole resistance, evaluated in patient without previous anti-H. pylori treatments containing nitroimidazoles, was around 21% (17% and 33% in group A and B respectively) and wasn't related to age or sex. No strains resistant to azytromicin were found. Tetracyclin resistant strains accounted for 4.5% (0%, 11% and 7% in group A, B and C respectively). The overall resistance to azytromicin was 15% (9%, 0% and 25% in group A, B and C). Susceptibility to eritromicin, tested in 15 cases only, always matched with azytromicin susceptibility.The occurrence of strains of H. pylori resistant to nitroimidazoles as well as to macrolides is rather frequent in our geographic area. In our study a resistance to metronidazole was always found in case of failure of the therapeutic schedule containing a nitroimidazole: this suggests to avoid further alternative therapeutic combinations including nitroimidazoles in these cases.In vitro testing of H. pylori sensitivity seems to be important before embarking on treatments aimed at eradicating this bacterium. This holds true particularly in course of therapeutical trials, in case the eradication of this microrganism is of crucial importance as in low-grade gastric MALT lymphoma, and after a previous unsuccessful antibacterial treatment. "P P 36 0828"P 36 0828**A Second Regimen of Omeprazole (O) Plus Amoxicillin (A) Increases the Rate of H. Pylori (HP) Eradication in Patients with Duodenal Ulcer**

*S. Michopoulos, H. Bouzakis, M. Sotiropoulou[1], I. Vougadiotis, E. Pardalos, I. Papaspyrou[1], N. Kralios

[1] Gastroenterology Unit, ""Alexandra"" Univ. Hospital, Athens, Greece

[1] Pathology Unit, ""Alexandra"" Univ. Hospital, Athens, GreeceThe combination of O + A has been proposed as an HP eradication treatment with controversial efficacy. It has been suggested that pre-treatment with O reduces the eradication rate. On the other hand, resistant to A, HP strains have not yet been identified. The *aim of our study* was to examine if a second administration of O + A increases significantly the overall success rate of HP eradication and whether the pre-treatment with O or duration of antibiotic treatment influence these results. *Patients and Methods:* 149 patients with duodenal ulcer were enrolled in our study. They have been randomly allocated in 2 groups and received respectively: *Group I:* (80 patients) Pre-treatment with O 20 mg for 10 days, followed by O 40 mg + A 2 gr for 10 days and O 10 mg for 20 days and *Group II* [controls]: (69 patients) who received both O 40 mg + A 2 gr from the beginning, subdivided in *IIa:* (29 patients): O + A for 10 days plus O 20 mg for 30 days and *IIb:* (40 patients): O + A for 15 days plus O 20 mg for 25 days. The patients of group I who failed to eradicate HP were randomly subdivided into *Ia:* 22 patients who received the same regimen and *Ib:* 28 patients who received both O + A from the beginning (O 40 mg + A 2 gr for 10 days plus O 20 mg for 30 days). The HP eradication has been estimated by histology (2 antral + 2 fundic biopsies) 4–6 weeks after the end of each treatment. *Stat:* Chi-square *Results:* 20% (CI: 11–29) of group I (75 patients) and 37% (CI: 24–49%) of group II (63 patients) eradicated HP after the first treatment $p < 0.05$ (11 drop out). Additionally 12/22 patients of group Ia and 12/28 of group Ib eradicated HP after the second attempt of O + A (NS) [10 drop out]. There was no difference between IIa and IIb. The subgroup IIb was significantly different from group I ($p < 0.05$). *Conclusions:* 1) The simultaneous administration of OM + A for 15 days has the best eradication rate, but remains low (37%). 2) The readministration of O + A has a substantial additional success rate, irrespectively of pre-treatment with O. Clinical practice: Management strategyOesophageal gastric duodenal disorders: Helicobacter Pylori }" "A Second Regimen of Omeprazole (O) Plus Amoxicillin (A) Increases the Rate of H. Pylori (HP) Eradication in Patients with Duodenal Ulcer"

"P P 36 0829"P 36 0829**Cimetidine and Amoxicillin — Clavulanic Acid for Ulcer Disease with Helicobacter and Herpes Simplex Virus**

*N.A. Vinogradov, M.A. Vinogradova, R.R. Gazizova

Hospital No 3, Moscow, Bashkir Medical University, Ufa, Russia*Purpose:* To evaluate the cimetidine and amoxicillinclavulanic acid made by Smith Kline Beecham (Tagamet and Augmentin respectively) for cases of peptic ulcer. To assess the influence of infection with Herpes Simplex virus (HSV) on ulcer disease.*Patients and methods:* 55 patients aged 18–80, illness duration 1–20 years: 26 stomach ulcer (SU), 26 duodenal ulcer (DU), 3 with SU and DU at once. Concomitant reflux-esophagitis — 22, cronic pancreatitis — 18. Bleeding (Forrest I–II) — 8 cases, when cimetidine was used i.v. 200 mg every 6 hours till hemostasis and then orally 800 mg per day alike the peptic ulcer exacerbation dose. Three comparable randomized groups: the 1st (n = 20) received cimetidine as monotherapy, the 2nd (n = 20) — cimetidine with Augmentin 375 mg 3 times a day for 10 days, the 3rd (n = 15) cimetidine with the triple therapy (bismut subcitrate, metronidazole, ampicillin). Helicobacter pylori (HP) was isolated by histological or cytological methods. The presence of HSV in the mucosa biopsy specimens was verified by fluorescein-iso-thio-cyanate-linked HSV-antibodies.*Results:* Ulcer healing was sooner in the 2nd versus the 3rd group, and was the letest in the 1st. HP elimination occurred in 18 of the 2nd and in 12 patients of the 3rd group Cimetidine caused esophagitis and pancreatitis remission. The most resistant to therapy ulcers were characterized by laboratory evidence of HP and HSV simultaneous presence in the mucosa.*Conclusion:* Cimetidine and amoxicillin-clavulanic acid combined therapy is an advisable regimen for peptic ulcer with HP. HSV must cause immunosuppression with subseguent mucosa restitution depression and HP-infection aggravation. "P P 37 0830"P 37 0830**Local Immune Response on Helicobacter Pylori Associated Gastric Ulcer before and after Eradication TreatmentR. G. Gr\'e1valos, A. Terr\'e9s,**

*M. F. Bermejo, J.A. Moreno, J.M. Mateos, J.M. Pajares

Gastroenterology Department, Hospital de la Princesa, Madrid, SpainThe development of peptic ulcer is associated with the presence of Helicobacter pylori (HP). The *Aim* of this study was to determinate the phenotype, distribution, and expression of immunological phenotype markers and antigenic recognition molecules (HLA class I and II) in the gastric mucosa of gastric ulcer patients before and after the eradication treatment.*Methods:* Immunoperoxidase staining was performed in frozen cryostate sections from antrum gastric biopsies of 15 patients with HP associated gastric ulcer before and after eradication of the bacteria. Controls included mucosa from no infected healthy donors. Gastric biopsies were obtained through upper endoscopy, and status HP was determined by rapid ureasa test, ^{13}C-urea breath test and histological examination. Sections were stained with the following monoclonal antibodies: anti-CD2, anti-CD4, anti-CD8, anti-CD11b, anti HLA-DR and W6/32.*Results:* Before treatment intraepythelial lymphocytes (IEL) and lamina propia T cells were CD8+ while CD4+ cells were predominant in follicles. Most of them, CD8+ and CD4+ cells expressed the activation marker CD2+. CD11b expresion was high and numerous cells expressing this marker infiltrate the lamina propia. HLA-DR expression by epithelial cells was noticeable. After treatment the infiltration of mononuclear cells remain very similar to pretreatment status but expression by the epithelium was also noticed.*Conclusion:* Helicobacter pylori eradication in patients affected of gastric ulcer does not affect the mononuclear infiltration in the mucosal lamina propia. However, a noticeable decrease of neutrophilic-macrofagic infiltration can be observed in that location after eradication.
Oesophageal gastric duodenal disorders: Helicobacter Pylori }" "Local Immune Response on Helicobacter Pylori Associated Gastric Ulcer before and after Eradication Treatment"

"P P 37 0831"P 37 0831**Decrease of Mucosal Interleukin 8 Contents in Patients with *Helicobacter Pylori*-Gastritis after Successful Eradication**

*T. Fujino, H. Kuwayama, M. Tachibana, M. Fukuyo, Y. Shijo, K. Chishima, N. Shimoyama, Y. Katayama, K. Kitazawa, K. Kawauchi, T. Saito, H. Mori

Department of Medicine, Dai-Ni University Hospital, Tokyo Women's Medical College, TokyoAlthough the precise pathogenesis is not known, infection of Helicobacter pylori (*H. pylori*) causes mucosal inflammation of the stomach, leading to persistent chronic active gastritis. Gastric mucosal inflammation is characterized by neutrophil accumulation with abundant release of a number of cytokines including interleukin 8. In the present study we assessed mucosal interleukin 8 content before and after *H. pylori* eradication with special reference to histologic gastritis. Sixty gastritis patients with *H. pylori* infection was enrolled in this study. Four biopsies were taken each from antrum and gastric body. Three biopsies were processed for histology, culture, and rapid urease test respectively. Remaining one was homogenized and stored at { -}80\'b0C for later measurement of mucosal interleukin 8 (IL-8) content. IL-8 and protein were measured by EIA and Bio-Rad respectively. Endoscopy with biopsy sampling was made at least 4 weeks after dual *H. pylori* eradication therapy, consisting metronidazole 250 mg and amoxicillin 250 mg t.i.d. for 14 days. When any of the above 3 tests positive it was considered *H. pylori*-positive. Only when all 3 tests were negative, it was considered as being *H. pylori*-negative. Results of IL-8 were summarized in the following table (pg/mg). Eradication outcome IL8 Before Tx IL8 After TxSuccess 397.190 – 51.804 49.547 – 12.094*Failure 470.643 – 60.483 395.618 – 80.239*Significant difference from Tx failure group.*Conclusion:* Gastric mucosal content of IL8 was significantly decreased after successful eradication of *H. pylori* which was well correlated with improvement of histologic gastritis.

"P P 37 0832"P 37 0832**Usefulness of Symptomatological Pattern in Predicting the Outcome of Dyspeptic Patients after Hp Eradication: A Prospective Six Months Study****A. Buda, M. Bortolon, S. Salandin, N. Dal Bo`, S. Kusstatscher, G. Laino, G. Leandro[1], G. Battaglia[2], F. Vianello, M. Cassaro, M. Rugge, F. Di Mario**

Padua, (BA) Italy

[2] Venice, (BA) Italy

[1] Castellana Grotte (BA) ItalyThe usefulness of H.p. eradication in NUD is still controversial. For a better evaluation of dyspeptic patients which could have an improvement of their symptoms after eradication, they were subdivided in three groups: A: ulcer-like; B: dismotility-like; C: reflux-like. *Methods:* 119 H.p. positive subjects (61 M; mean age 51.5; range 25–76) entered an open, prospective controlled study. All underwent different treatment schedules with either Amoxicillin or Clarithromycin plus Metronidazole and Omeprazole for one week. Endoscopy: at baseline and two months after the end of therapy (T2); 7 gastric biopsies were taken from gastric antrum and body to assess Hp status by histology (Giemsa, Warthin Starry, immunohistochemistry) and rapid urease test (CLO test). All pts remained untreated for a six months follow-up period (T6). *Results:* Overall, 86/119 (74.5%) pts were cured and 96% showed a disappearance of gastritis activity at T2. Eradication rate in the 3 groups was 79.3% group A; 68.3% group B; 75.8% group C). Overall, 45% of eradicated subjects and 22% of not-eradicated were asymptomatic at T2, 31% and 6.2% at T6, respectively. Subdividing the pts according with their symptomatological pattern, the percentages were as follows: Group A: T2 = 60.9%; T6 = 65.2% Group B: T2 = 36.5%; T6 = 7.4% Group C T2 = 43.5%; T6 = 39.2% ($p = 0.001$). *Conclusions:* 1) Overall, 44.8% and 31% of dyspeptic pts were symptom-free 2 and 6 months after a successful H.p eradication therapy, respectively. 2) Higher asymptomatic rate was obtained in the ulcer-like group (60.9% at T2, unchanged at T6); 3) The disappearance of gastritis activity was confirmed in 96% of cured patients. }" "Usefulness of Symptomatological Pattern in Predicting the Outcome of Dyspeptic Patients after Hp Eradication: A Prospective Six Months Study"

"P P 37 0833"P 37 0833**Effect of Eradication of Helicobacter Pylori on Gastric Histology and Gastric Function Parameters in Gastric Ulcer**

*G. Maconi, P. Parente, M. Lazzaroni, O. Sangaletti, M. Minguzzi, S. Bargiggia, L. Vago[1], G. Bianchi Porro

Department of Gastroenterology, L. Sacco Hospital, Milan, Italy

[1] Department of Pathology, L. Sacco Hospital, Milan, Italy*Aim.* The evolution of gastritis and the behaviour of serum gastrin and pepsinogen (PgI) levels and gastric emptying of solids were studied in 16 consecutive patients (11 males; mean age: 54.5 – 9.1 yrs) with H. pylori (Hp) positive, uncomplicated, non-NSAIDS related gastric ulcer (GU) over a follow-up of three months after eradicating therapy.*Patients and methods.* Gastritis score was assessed according to the Sydney System on antral and corpal biopsies before the treatment consisting of omeprazole 40 mg a day for 1 month and amoxicillin 1 g three times daily for 14 days, and 3 months after ulcer healing. In addition a series of functional tests including basal and meal-stimulated serum gastrin concentration, serum PgI levels and an evaluation of gastric emptying of solids by means of serial ultrasonographic measurement of gastric antrum area were performed at the same intervals.*Results.* Double therapy for Hp resulted in successful eradication in 8 of 16 patients. In Hp-eradicated pts mean activity and inflammatory scores of gastritis in antrum and corpus significantly fell after 3 months. No significant changes of mean gastritis scores were observed in the case and control group concerning intestinal metaplasia and atrophy both in the antrum and corpus. In contrast, pts with persistent Hp infection showed a significant worsening of gastritis activity in the corpus after treatment. In Hp eradicated patients the means of integrated gastrin response to meal [(AUC pg/ml/h): 23428 – 5727 vs 17623 – 3993], but not fasting gastrin concentration [(pg/ml) 67.7 – 14.4 vs 59.6 – 11.9)], fell significantly during the follow-up and also serum Pg I levels significantly decreased as compared to baseline [(ng/l) 95.0 – 27.8 vs 79.7 – 32.3]. In contrast fasting and maximal antral area and gastric emptying remained unchanged over time. In the control group, no significant modifications of any of the above mentioned parameters were observed during the follow-up.*Conclusion.* Our findings suggest that, as already shown in duodenal ulcer pts, Hp eradication significantly reduces gastric activity, but not atrophy and intestinal metaplasia, in GU pts as well. In addition, gastrin and Pg I relase, but not gastric emptying are significantly modified in the short-run by Hp eradication Oesophageal gastric duodenal disorders: Helicobacter PyloriOesophageal gastric duodenal disorders: GD disorders, acid peptic }" "Effect of Eradication of Helicobacter Pylori on Gastric Histology and Gastric Function Parameters in Gastric Ulcer"

"P P 37 0834"P 37 0834**Gastric Mucosa Nucleolar Organiser Regions (AgNORs) and Helicobacter Pylori Infection: Impact of Eradication**

*T. Rokkas, C. Liatsos, A. Lazaris, D. Tabakopoulos, E. Panagou, A. Karameris

Gastroenterology Unit and Histopathology Laboratory 401 Army General Hospital, Athens, GreeceDespite the fact that the association of Helicobacter pylori (H. pylori) with an increased risk of gastric cancer has been well-documented, the exact mechanisms of this association, have not been elucidated.*Aim:* The aim of the present prospective study was to contribute to the exploration of these mechanisms by studing the relationship between H. pylori infection and the silverstaining nucleolar organiser regions (AgNORs) in endoscopic biopsies in gastric antrum as it is known that the number of AgNORs per nucleus has been positively correlated with proliferative rate and ploidy. To do that we studied a total of 28 H. pylori (+) patients and the results were compared with 22 endoscopically and histologically normal H. pylori ({ -}) patients (control group), who were comparable to the H. pylori (+) group for age and sex. In addition a group of 10 H. pylori (+) patients were examined before and after successful eradication of H. pylori and normalisation of gastric histology.*Results:* In the H. pylori (+) patients the mean number of AgNORs per nucleus was 5.43 – 0.18 (SEM) and was significantly higher than the respective number in the control group (3.27 – 0.13, p = 0.001). In patients studied before and after H. pylori successful eradication the corresponding numbers were 5.50 – 0.31 and 3.20 – 0.20 (p = 0.003) and the latter did not differ significantly from the control group of H. pylori ({ -}) patients.*Conclusions:* H. pylori infection alters the replication cycle of gastric mucosa inducing hyperproliferation and possible ploidy abnormalities. However, it remains unclear whether these alterations are induced directly by the bacterium or by the gastric inflammation.
Oesophageal gastric duodenal disorders: Helicobacter PyloriOncology, general: Proliferation, carcinogenesis }" "Gastric Mucosa Nucleolar Organiser Regions (AgNORs) and Helicobacter Pylori Infection: Impact of Eradication"

"P P 37 0835"P 37 0835**Evolution of Histologic Lesions of Gastric Mucosa after Eradication of *H. pylori* in Duodenal Ulcer Patients. A Six-Month Follow-Up Study**

*J.P. Gisbert, D. Boixeda, C. Redondo, Ranz F. Hern\'e1ndez, Mart\'edn C. de Argila, C. De la Serna, L. De Rafael

""Ram\'f3n y Cajal"" Hospital, Madrid, Spain*Purpose:* To study changes in histologic gastritis at gastric antrum and body after *H. pylori* eradication in duodenal ulcer patients, at an early stage and after six months.*Methods:* Seventy-six patients with duodenal ulcer disease were prospectively studied. At endoscopy biopsy specimens were taken from duodenal bulb, gastric antrum, body and fundus (H&E, Gram stain and culture). A patient was considered to be *H. pylori+* when microbiology or histology demonstrated colonization in any location. An endoscopy with biopsy samples taken from antrum and body was performed one month after therapy completion and four months later. Different therapy regimens were used: amoxycillin/clavulanate plus omeprazole or ranitidin; classic triple therapy; and omeprazole or ranitidin alone.*Results:* All patients were *H. pylori+*. Eradication was achieved in 47% (n = 36) of patients. In *H. pylori* eradicated patients, rates of chronic gastritis/chronic active gastritis prior to treatment and two and six months later were, respectively: 100/96%; 38/23%; 16/5.6% in gastric antrum. The corresponding values for gastric body were: 54/38%; 12/12%; 12/5.6%. An histologic improvement, overall and in the acute inflammatory component, was observed one month after therapy completion ($p < 0.001$). Four months later, although histologic improvement was more marked, differences were not significant compared with results in the first month. No changes in histologic pattern was observed when eradication failed.*Conclusion:* An improvement in gastric antral and body gastritis was associated with *H. pylori* eradication in duodenal ulcer patients. This successful evolution was observed immediately after eradication and confirmed six months after diagnosis. "P P 37 0837"P 37 0837**Erosive Duodenitis and *Helicobacter Pylori* Infection: Response to Eradication Therapy with Omeprazole, Amoxycillin and Clarithromycin**

*J.P. Gisbert, D. Boixeda, Mart\'edn C. de argila, F. Bermejo, C. Redondo, A. San Rom\'e1n, Plaza A. Garc\'eda

""Ram\'f3n y Cajal"" Hospital, Madrid, Spain*Purpose:* To study the prevalence of *H. pylori* infection in patients with erosive duodenitis, the associated gastric histologic lesions, and the response to an eradication therapy with omeprazole and two antibiotics.*Methods:* Fifty-five patients with erosive duodenitis were prospectively studied (mean age 48 – 16 yrs, 70% males). At endoscopy, biopsies from both gastric antrum and body were obtained for histologic study (H&E). A C^{13}-urea breath test was also performed. Omeprazole (O) 20 mg b.i.d. plus two of the following antibiotics were administered for one week: amoxycillin (A) 1 g b.i.d., clarithromycin (C) 500 mg b.i.d., metronidazole (M) 500 mg b.i.d. Endoscopy (with biopsies) and breath test were repeated 1 month after completing therapy.*Results:* All patients were *H. pylori*-positive (n = 55). Overall, eradication was obtained in 85% (95% CI = 74–92%). Eradication rates for different therapies were: OAC: 94% (29/31); OCM: 85% (11/13); OAM: 64% (7/11) ($p < 0.05$ when comparing OAC and OAM). Overall, duodenal erosion healing was obtained in 80% (74–88%). Healing rates for different therapies were: OAC: 87% (27/31); OCM: 92% (12/13); OAM: 45% (5/11). Both OAC and OCM achieved better healing rates than OAM ($p < 0.05$). Duodenal erosion healing was achieved in 87% (75–94%) of cases with eradication therapy success, while only in 38% (n = 3) when eradication was not achieved ($p < 0.01$). An histologic improvement, both in the gastric antrum and body, was demonstrated in *H. pylori*-negative patients ($p < 0.01$). Compliance of therapy was complete in all patients and no relevant adverse effects were reported.*Conclusion:* A high prevalence (100%) of *H. pylori* infection in patients with erosive duodenitis was observed. A one-week twice-daily therapy with omeprazole plus two antibiotics (OAC or ACM) was very effective in *H. pylori* eradication, duodenal erosion healing, and resolving associated histologic gastritis. These observations suggest that erosive duodenitis should be considered a variant form of duodenal ulcer disease and be treated accordingly, that is, with *H. pylori* eradication therapy. Oesophageal gastric duodenal disorders: Helicobacter PyloriOesophageal gastric duodenal disorders: GD disorders, acid peptic }" "Erosive Duodenitis and Helicobacter Pylori Infection: Response to Eradication Therapy with Omeprazole, Amoxycillin and Clarithromycin"

"P P 37 0838"P 37 0838**Eradication of H. Pylori Infection in Patients with Corporal Atrophic Gastritis (CAG): A Consecutive Open Study****B. Annibale, M. Marignani, M. Paoletti, S. Angeletti, M.R. Aprile[1], G. D'Ambra, C. Bordi[1], G. Delle Fave**

Dept Gastroenterology, University ""La Sapienza"" Roma, Italy

[1] Dept Pathology, University ""La Sapienza"" Parma, ItalyCAG is a condition characterized by atrophy of oxyntic mucosa hypo/achlorydria and fasting hypergastrinemia. It has recently been observed that a significant proportion of CAG patients are Hp infected and that Hp infection is significantly associated with the development of corporal atrophy in patients treated long-term with proton pump inhibitors. No studies until now have been specifically addressed to prospectively investigate in CAG patients, if it is possible to treat the infection since the lack of acid secretion could determine less favourable condition to its eradication. *Materials and Methods* 19 consecutive patients (15 F, 4 M aged 34–72) with Hp positive CAG (histology, colture, Ig G; at least two of these tests positive) were treated for 4 wks with bismuth subsalicilate 240 b.i.d.; amoxicilline 1 g. tid post-prandially and metronidazole 250 mg tid post-prandially were given during the first 2 wks of therapy. Endoscopy was again performed after 6 mos, to evaluate Hp status by histology and colture in antral (n = 5) and body biopsies (n = 8). The gastritis status was graded according to the Sydney system. Fasting gastrin levels (pg/ml; specific RIA) and title of IgG Hp (U/l; Elisa GAP test, Biorad) were also determined. Results are expressed as median (range), non-parametric test for paired data was used for statistical evaluation. *Results:* Overall eradication rate was 78.9% (15/19 pts). Minor side effects were recorded in about half of patients, but none determined therapy withdrawn. Gastrin levels decreased dramatically in eradicated patients [220 (49–1400) vs 42 (10–285); $p < 0.001$] as IgG Hp [80 (10–100) vs 31 (0–65); $p < 0.005$] Corporal chronic inflammation and atrophy were significantly reduced after eradication [respectively: 2 (1–3) vs 1 (0–2); $p = 0.001$ and 2 (1–3) vs 1 (0–3); $p = 0.031$]. Inflammation activity completely regressed [1 (0–3) vs 0 (0–0)]. *Conclusions:* These data show that is possible to efficaciously treat Hp infection in corporal atrophic gastritis, obtaining a pronunced reduction of fasting gastrin levels and a significative reduction in the score of chronic gastritis. Oesophageal gastric duodenal disorders: Helicobacter PyloriOesophageal gastric duodenal disorders: Secretion: mechanism, regulation }" "Eradication of H. "P P 37 0839"P 37 0839**Cure of *Helicobacter Pylori* Infection Does Not Affect Acidity in the Spontaneously Secreting Stomach of Duodenal Ulcer Patients**

*B. Tillenburg, U. Peitz, G. B\'f6rsch, M. Stolte, J. Labenz

Elisabeth Hospital Essen and Klinikum Bayreuth, Germany*Purpose:* The present study was designed to evaluate the long-term effect of curing *H. pylori* infection on the intragastric acidity in duodenal ulcer patients.*Methods:* Eleven duodenal ulcer patients infected by *H. pylori* were studied. 24-hour pH recordings were performed before treatment of the infection as well as 4 weeks and 1 year after the cure. Glass electrodes were placed 5 cm below the cardia.*Results:* Cure of *H. pylori* infection was associated with a marked improvement of antrum and corpus gastritis and a decrease of the fasting gastrin levels. The acidity in the spontaneously secreting stomach, however, remained unchanged: median gastric pH during 24 hours (before cure *vs* 4 weeks after cure *vs* 1 year after cure): 1.1 *vs* 1.2 vs 1.2, $p > 0.3$, daytime: 1.0 *vs* 1.1 vs 1.1, $p > 0.4$, postprandial: 1.4 *vs* 1.3 *vs* 1.3, $p = 0.5$, night-time: 1.6 *vs* 1.0 vs 1.1, $p > 0.1$; mean $[H^+]$ activity (24 hours): 88.4 *vs* 70.4 *vs* 79.0 h {\'b4} mmol/l, $p > 0.45$).*Conclusions:* Despite a decrease of the gastrin release and a decrease of the acid output (El Omar et al, Gastroenterology 1995; 109: 681–91), the intragastric acidity remains unchanged after the cure of a *H. pylori* infection in duodenal ulcer patients, suggesting that the net effect of the decreased acid output on the gastric pH is compensated by other mechanisms, e.g. the loss of neutralizing substances like ammonia generated by *H. pylori.* Oesophageal gastric duodenal disorders: Helicobacter PyloriOesophageal gastric duodenal disorders: GD disorders, acid pepticOesophageal gastric duodenal disorders: Secretion: mechanism, regulation }" "Cure of Helicobacter Pylori Infection Does Not Affect Acidity in the Spontaneously Secreting Stomach of Duodenal Ulcer Patients"

"P P 37 0840"P 37 0840**Role of *H. Pylori* Eradication in the Prophylaxis of Ulcer Bleeding Recurrence**

*J.P. Gisbert, D. Boixeda, C. Mart\'edn de Argila, R. Aller, V. Defarges, J. Urmann, A. Garc\'eda Plaza

""Ram\'f3n y Cajal"" Hospital, Madrid, Spain*Purpose:* Several studies have demonstrated that eradication of *H. pylori* (HP) is associated with a low rate of ulcer recurrence. Our purpose was to verify the effect of HP eradication on ulcer bleeding recurrence.*Methods:* Patients with acute hemorrhage secondary to duodenal ulcer were included in this prospective study. Exclusion criteria were the administration of antibiotics, bismuth, or non-steroidal anti-inflammatory drugs within 30 days prior to endoscopy. During hospitalization a therapy with H_2 antagonist at standard doses was administered. Biopsies were obtained (H&E) at diagnostic endoscopy, and a C^{13}-urea breath test was also performed in the following days. At discharge, HP+ patients were randomised to receive different eradication therapies (proton pump inhibitor (PPI) plus 1 or 2 antibiotics, for 2 and 1 week, respectively), followed by the PPI up to 1 month. Endoscopy with biopsies was repeated 1 month after completing therapy, and a breath test was performed again. Eradication was defined as the absence of HP by both diagnostic methods. Patients with therapy failure received a second course of therapy. Patients with therapy success did not receive maintenance anti-ulcer therapy and were controlled at 6 and 12 months with a C^{13}-urea breath test.*Results:* At present, thirty-three patients (mean age: 49 – 12 years, 89% males) have achieved eradication (two of them required a second course of therapy). Ulcer healing was achieved in 88% (CI 95%: 73–95%) of patients. In the four cases with ulcer persistence, healing was reported in an ultimately endoscopy performed 1 month later. Follow-up of patients was: 2 mths (n = 4), 6 mths (n = 23), and 1 yr (n = 6). Reinfection was not demonstrated in any patient at 6 or 12 mths. No bleeding episodies were observed in the follow-up period (mean: 6 mths, range: 2–12 mths).*Conclusion:* This preliminary study suggests that rebleeding does not occur in patients with complicated ulcers with HP infection eradicated. Therefore, this data recommend HP eradication as the treatment of choice after hemorrhage from a duodenal ulcer, and suggest that maintenance anti-ulcer therapy is not necessary if eradication is achieved. "P P 38 0841"P 38 0841**Effects of Nonsteroidal Anti-Inflammatory Drugs on Glutathione S-Transferases of the Rat Digestive Tract**

*E.M.M. Van Lieshout, D.M. Tiemessen, W.H.M. Peters, J.B.M.J. Jansen

Dept. of Gastroenterology St. Radboud University Hospital, Nijmegen, the NetherlandsNonsteroidal anti-inflammatory drugs (NSAIDs) have been demonstrated to reduce cancer rates in oesophagus, stomach and colon of both humans and animals. Earlier, we showed that high human gastrointestinal tissue levels of glutathione S-transferase (GST), a family of detoxification enzymes consisting of class Alpha, Mu, Pi and Theta isoforms, were inversely correlated with cancer risk. We investigated whether the NSAIDs indomethacin, ibuprofen, piroxicam, acetyl salicylic acid (ASA) and sulindac, incorporated in the diet at 25, 400, 400, 400, and 320 ppm, respectively, influenced rat gastrointestinal GSTs. Male Wistar rats were fed normal or supplemented lab chow for two weeks. Oesophagus, stomach, intestines and liver were isolated and cytosolic fractions were prepared. Herein, GST activity towards 1-chloro-2,4-dinitrobenzene was measured and levels of GST isozymes were determined by densitometrical analyses of Western blots after immunodetection with monoclonal antibodies. Wilcoxon rank sum test was used to assess statistical significance of differences between treated and control groups. Indomethacin, ibuprofen, piroxicam and sulindac induced GST enzyme activity and class Mu levels in oesophagus and small intestine, and GST Alpha levels in small intestine. Piroxicam enhanced gastric and hepatic GST Alpha levels as well. GST Pi levels were raised in stomach by ibuprofen, ASA and sulindac, in small intestine by indomethacin, piroxicam, ASA and sulindac. In conclusion, enhancement of glutathione S-transferases, resulting in a more efficient detoxification of carcinogens, may explain in part the anticarcinogenic properties of nonsteroidal anti-inflammatory drugs. [3] Dept of Medicine, Western Hospital, Melbourne, Australia

[4] Astra Hassle AB, Molndal, Sweden*Background* Gastric and duodenal ulcers and erosions are commonly associated with NSAIDs, but there are few comparative QoL data that can be used to assist in identifying optimal treatment of such lesions.*Aim* To compare the effect on QoL of omeprazole (ome) 20 or 40 mg om or misoprostol (miso) 200 \'b5g qid during healing. In the maintenance study ome 20 mg om was compared with miso 200 \'b5g bid or placebo.*Methods* QoL was assessed in an international double-blind parallel-group study. In the healing phase 618 male (40%) and female (60%) arthritic patients, mean age 59 years, with ulcers or erosions, completed the Nottingham Health Profile (NHP) and the Gastrointestinal Symptom Rating Scale (GSRS) at baseline and after 4/8 weeks. In the maintenance phase, 513 patients were re-randomised and treated for 6 months. The NHP is a general health profile and measures the burden of illness, while GSRS, which uses a seven-graded Likert scale, evaluates 15 gastrointestinal symptoms which combine into clusters describing Diarrhoea, Indigestion, Constipation, Abdominal pain, and Reflux.*Results* Patients with arthritis generally have a poor health-related QoL, in particular regarding fatigue, sleep disturbances, mobility and pain. During healing, ome 20 mg om showed a significant advantage in relieving reflux symptoms ($p < 0.0005$), abdominal pain ($p < 0.0005$), indigestion ($p = 0.04$) and total GSRS score ($p < 0.0005$) compared with miso, while miso induced diarrhoea ($p < 0.0005$). During maintenance, ome was similarly more effective in relieving reflux symptoms ($p = 0.0005$), abdominal pain ($p = 0.003$), indigestion ($p = 0.008$), and overall symptoms ($p = 0.0003$) than miso. Also the lower dose of miso induced diarrhoea compared to placebo ($p = 0.04$).*Conclusion* In arthritic patients, who are severely incapacitated in terms of Qol, omeprazole 20 mg om provided more effective control of dyspeptic symptoms and was better tolerated than misoprostol. Oesophageal gastric duodenal disorders: GD disorders, acid peptic }" "Quality of Life (QoL) in Patients with Non-Steroidal Anti-Inflammatory Drug (NSAID) Associated Gastroduodenal Lesions During Healing and Maintenance. "P P 38 0845"P 38 0845**Short-Term Corticosterone Treatment: Different Effects in the Gastrointestinal Tract**

*P. Gama, E.P. Alvares

Institute of Biomedical Sciences, S\'e3o Paulo, BrasilThe feeding pattern and hormones are associated with tissue maturation in different systems, and the GI tract has been widely studied. Although glucocorticoids are thought to have a major importance in growth, a clear response is not yet established for the cell proliferation of the developing gastric and intestinal epithelia. The aim of this study was to evidence the effect of short-term corticosterone administration on the proliferative process of the gastric and intestinal epithelia of 18-d-old suckling rats.For that purpose, we divided the animals into 3 groups: fasted and fed controls (i.p. injection of NaCl); fed hormone-treated (i.p. injection of corticosterone 50 \'b5g/g b.wt.). We examined: a) cell kinetics parameters as metaphasic index (MI) (in both organs) and cell production rate (CPR) (in the stomach), which were achieved by vincristine blockade; b) gastric mucosal and gland thickness; c) possible morphological alterations. All these parameters were analysed in histological slides. Cell proliferation and thickness were subject of Mann-Whitney statistical test.The MI was greatly inhibited in the gastric mucosa ($P < 0.01$), in opposition to the lack of effect observed in the jejunum. The CPR was also inhibited by corticosterone ($P < 0.05$), but no significant effect was detected in thickness. We did not observe any ulcer formation in either organs.These results suggest that the short-term corticosterone administration leads to a potent inhibition of the cell proliferation only in the gastric mucosa. These experiments light up the different responsiveness of the GI tract to corticosterone during suckling period.Supported by FAPESP 92/5086-2 and 92/3970-2 Oncology, general: Proliferation, carcinogenesisNutrition: Nutrients and gut function }" "Short-Term Corticosterone Treatment: Different Effects in the Gastrointestinal Tract"

"P P 38 0846"P 38 0846**Gastric Parietal Cell Canallicular Index after NSAID Treatment in Osteoarthritic Patients**

*M. Valenzuela, J.L. Martin-Ruiz, A. Caballero-Plasencia, I. Alvarez-Cienfuegos, F.F. Nogales

Department of Medicine, University of Granada, SpainParietal cell canallicular index is related with the acid secretory activity of parietal cells. The *aim* of this study was to assess canallicular index before and after a 7 days treatment with indomethacin or droxicam. *Patients:* 32 osteoarthritic patients, randomly allocated to one of the two treatment groups, underwent endoscopy and biopsies of the gastric corpus mucosa. *Methods:* Biopsies were processed for transmission electronic microscopy. Images at 2500x of 20 parietal cells per patient were analyzed by computerized densitometric morphometry. The size of the secretory canallicular system was automatically measured. The rate of the size of the canalliculum to the size of the cytoplasm was considered as the canallicular index (CI). *Results:* CI was (mean – SEM) 17% – 1.3 before treatment and reached 26% – 1.6 after treatment ($p < 0.001$). CI in superficial parietal cells reached 27 – 2 ($p < 0.005$), and 23% – 2 in the profound parietal cells (p = n.s). There were no differences between both therapeutics groups. *Conclusions:* Parietal cell canallicular index, an estimation of the secretory canallicular size, increased after 7 days treatment with NSAID mainly in the most superficial parietal cells. This finding express a hyperestimulation state of the parietal cells which might be an important pathogenic factor in NSAID-induced gastropathy, supporting the indication for preventive co-treatments with proton pump inhibitors. "P P 38 0847"P 38 0847**Alteration of the Gastric Mucus and the Gastric Resistance Induced by Aspirin**

*M. Kagoshima, H. Kodaira, H. Shimada

Department of Clinical Pharmacology, School of Pharmaceutical Sciences, Kitasato University, Tokyo, JapanIt is well known that the gastric mucus plays an important role in protecting the stomach from noxious agents such as ethanol. However, we reported that oral administration of aspirin reduced the gastric mucosal lesions induced by absolute ethanol or 0.6 N HCl, although aspirin removed the gastric surface mucus (Gastroenterology 104 (4): A 121, 1993). In this study, we attempted to examine the effects of aspirin on the mucus in gastric juice, mucous gel later, surface layer and deep layer, and examined causality between the mucus movement and the gastric resistance.*Method.* Male Wistar rats (180–200 g) were used. The gastric mucus was examined histochemically and biochemically till 24 hr. after oral administration of aspirin (100–300 mg/kg, p.o.). Histochemical studies: Removed stomachs were opened along the greater curvature and fixed in absolute ethanol ({ -}80\'b0C). The paraffin tissue sections of both corpus and antrum were stained with AB-PAS, HID-AB, UEA-I (Ulex europaeus Agglutinin I) and PNA (Peanut Agglutinin) stainings, and then observed histochemically. Each positive area was measured by our computer image processing system. Biochemical studies: Gastric mucin were prepared from gastric juice, mucous gel, surface and deep mucosa. Each sample was used for analysis of hexose and sialic acid.*Results.* Surface mucus (PAS or UEA-I positive mucus) in both corpus and antrum significantly decreased at 0.25 to 12 h. after oral administration of aspirin. Hexose contents also decreased in corpus mucosa. However, the deep corpus mucus (PNA positive mucus) significantly increased at 0.25 to 1 h. after administration of aspirin. Sialomucin was scarcely detected in normal mucosa but increased in the mucosa at 1 to 12 h. after oral administration of aspirin. Sialic acid increased in gastric juice, mucous gel, and surface mucosa at 1 h. after administration of aspirin. Moreover, acidic mucin (HID-AB positive mucus) increased in surface mucosa at 6 to 12 hr. and recovered to normal range at 24 hr. after administration of aspirin.*Conclusion.* We concluded that the aspirin-treated stomach enhanced the resistance to injury caused by strong irritants and this function is probably mediated by gastric mucus such as PNA positive mucus in deep mucosa and sialomucin in juice, gel layer and surface layer. Oesophageal gastric duodenal disorders: GD disorders, acid peptic }" "Alteration of the Gastric Mucus and the Gastric Resistance Induced by Aspirin"

"P P 38 0848"P 38 0848**Low Dose Misoprostol as Prophylaxis Against Low Dose Aspirin-Induced Gastroduodenal Mucosal Injury**

*M.T. Donnelly[1], A.F. Goddard[1], B. Filipowicz[1], S.V. Morant[2], M.J. Shield[2], C.J. Hawkey[1]

[1] Division of Gastroenterology, University Hospital, Nottingham NG7 2UH, UK

[2] Searle Medical & Clinical Research Department, P.O. Box 53, Lane End Road, High Wycombe, Bucks, HP12 4HL, UK*Introduction:* Misoprostol, a prostaglandin analogue, given in conventional doses (200 \'b5g bd – qds) prevents aspirin-induced gastroduodenal mucosal damage, but is associated with side-effects. In view of the increasing use of low dose aspirin for secondary prevention of vascular disease, we wished to study whether low dose misoprostol (100 \'b5g) could prevent gastroduodenal damage due to low dose aspirin (300 mg) whilst avoiding side-effects.*Methods:* 32 age and sex-matched healthy volunteers aged 18–45 were enrolled in this double blind, placebo controlled, parallel group study. Endoscopy was performed on days 0, 5, 14 and 28. Paired antral and corpus biopsies were taken for prostaglandin estimation and plasma samples for thromboxane estimation. Mucosal abnormalities and adverse events were noted. Volunteers were randomised to one of two drug regimens: 100 \'b5g placebo misoprostol and aspirin 300 mg daily or 100 \'b5g misoprostol and aspirin 300 mg daily for 28 days. Compliance was assessed by tablet counting, prostaglandin and thromboxane measurements. The primary endpoint was the total number of gastroduodenal erosions assessed endoscopically. Anatomical site and nature of erosions were secondary endpoints.*Results:* Data were analysed using a generalised linear model. 28 day results Misoprostol Placebo *p* value% Subjects with haemorrhagic erosions 12.5 50 < 0.05No. of haemorrhagic erosions/subject 0.38 3.25 < 0.001% Subjects with non-haemorrhagic erosions 18.8 18.8 NSNo. of non-haemorrhagic erosions/subject 0.38 1.19 < 0.05% Subjects with petechiae 6.3 43.8 < 0.001No. of petechiae/subject 1.25 6.44 < 0.05There was no significant difference in the side-effect profile between the placebo and misoprostol treated groups.*Conclusions:* We conclude that low dose misoprostol provides effective prophylaxis against endoscopically assessed gastroduodenal mucosal damage caused by low dose aspirin and is free of significant side-effects. Clinical practice: Management strategy }" "Low Dose Misoprostol as Prophylaxis Against Low Dose Aspirin-Induced Gastroduodenal Mucosal Injury"

"P P 38 0849"P 38 0849**Prostaglandin Enhances the Recovery of Mucin Content in the Surface Layer of Rat Gastric Mucosa at the Restitutional State after NSAID (HCl-Aspirin) Induced Mucosal Damage**

*T. Sakai, K. Ishihara, K. Saigenji, K. Hotta

Departments of Internal Medicine and Biochemistry, School of Medicine, Kitasato University, Sagamihara, JapanApplying the newly developed mucus-scraping method, the mucin content was measured in the different layers of rat gastric mucosa which had been injured by topical application of HCl-Aspirin, and the effect of a prostaglandin (PG) E_2 derivative was estimated after its administration at 3 hrs following the injury.*Material and Methods:* Male Wistar rats weighing 160–170 g were orally administered 0.15 N HCl-Aspirin (20–200 mg/kg) and killed at 1, 3, 5, and 7 hrs following the drug administration. Gastric lesions were macroscopically observed, and then the surface mucosa, deep corpus and antrum mucosa were separately collected. The mucin in each layer was extracted, and the content was determined as previously described (Gastroenterol Jpn 1992; 27: 466–472). 16, 16-Dimethyl PGE_2 (30 \'b5g/kg) was administered 3 hrs after the HCl-Aspirin administration, and the effect of this agent on the gastric mucosal restitution was estimated by determining the mucin content in each layer of the mucosa at 7 hrs.*Results:* 1) Gastric macroscopic injury was observed in all cases of HCl-Aspirin treated rats at 3 hrs. 2) At 7 hrs after the administration, the macroscopic and light microscopically observable injury induced by the 50 mg/kg HCl-Aspirin was significantly recovered. 3) A considerable decrease and a notable recovery in the surface mucin was noted at 3 and 7 hrs, respectively, after the administration, but the mucin content of the deep corpus was not significantly changed during the experimental period by this HCl-Aspirin dose. 4) The PG treatment after 100 mg/kg HCl-Aspirin administration significantly recovered the surface mucin content. (126% vs. control, 200% vs. single HCl-Aspirin dosing) However, no significant change in the deep corpus mucin content could be achieved.*Conclusion:* Changes in gastric mucin content induced by low dose (50 mg/kg) HCl-Aspirin were mainly limited to the surface mucosal layer. PG might participate in the restitution of the gastric mucosa by the accumulation of mucin mainly in the surface mucous cells. The estimation of mucin content in the different layers of the gastric mucosa could be a useful tool to study the restitution from gastric mucosal injury. "P P 38 0850"P 38 0850**Alendronate Causes Gastric Mucosal Damage Similar to AspirinD.Y. Graham, H.M. Malaty,**

*R.W. Goodgame

VAMC, and Baylor College of Medicine, Houston, TX USAAlendronate and pamidronate are primary amino-bisphosphonates used in the treatment of metabolic bone disease. Both drugs have been associated with erosive esophagitis and pamidronate is approved in the US only for parenteral use. In rats, alendronate causes gastric mucosal damage similar to aspirin or NSAIDs. *Methods:* We performed a blinded, crossover, randomized, single-center, placebo controlled comparison of alendronate (40 mg/day), aspirin (1,300 mg/day), and placebo using endoscopy to evaluate the presence and degree of mucosal damage to the esophagus, stomach, and duodenal bulb. *Results:* 12 normal volunteers were studied both before and after 4 days of drug therapy. Placebo caused no visible endoscopic damage. In contrast, both aspirin and alendronate were associated with visible gastric mucosal injury in the majority of those studied (75% and 58%, respectively) and both were significantly greater than placebo ($p < 0.001$). The gastric mucosal injury was deemed severe in 50% of those receiving either alendronate or aspirin. One alendronate-associated gastric ulcer was also seen. Esophageal and duodenal bulb injury was seen once each and both were associated with alendronate. *Conclusion:* The primary amino-bisphosphonate alendronate causes mucosal injury to the upper gastrointestinal tract similar to aspirin. Even when used according to manufacturer's dosing instructions alendronate should be used with caution. Oesophageal gastric duodenal disorders: GD disorders, acid peptic }"

"P P 38 0851"P 38 0851**Production of Inflammatory Mediators in Patients with NSAID-Induced Gastropathy**

*V.D. Pasechnikov, D.V. Bobryshev, S.G. Mnatsakanian, I.G. Khripunova

Stavropol Medical Academy, Stavropol, RussiaArthritis patients (AP) have an increased risk of the upper gastrointestinal tract mucosal damage because of their need of long-term non-steroidal anti-inflammatory drugs (NSAID) therapy.The aim of this study was to investigate whether cytokines and arachidonic acid metabolites are involved in the inflammatory reaction of NSAID-induced injury of gastric mucosa (GM) and to determine the effect of cytoprotective therapy on GM in AP.In 10 AP receiving Diclofenac (100 mg, daily, orally; 3 weeks) and 10 AP patients receiving Arthrotec (0.2 \'b5g Misoprostol-PGE_1 + 50 mg Diclofenac, orally, bid; 3 weeks), the GM production of IL-1, TNF, 6-keto-$PGF_{1\{ a}$}, TxB_2 and LTB_4 was measured in biopsy specimens after incubation in special conditions.The levels of IL-1, TNF, TxB_2 and LTB_4 was markedly increased ($p_{1-5} < 0.05$), whereas 6-keto-$PGF_{1\{ a}$}, production was significantly ($p_{1-2} <$ 0.05) decreased in the GM in AP, before and 3 wks after start of Diclofenac therapy. No significant differences were found between the production of IL-1, TNF, 6-keto-$PGF_{1\{ a}$}, TxB_2 and LTB_4 in the GM in AP before and after Arthrotec therapy.The results of this study show that the GM injury mediators production in AP treated by Diclofenac differed from those receiving Arthrotec. NSAID may cause adherence of neutrophils to the vascular endothrelium, probably through the release of cytokines and arachidonic acid metabolites. It may play a role in ischemic cell injury, and impaired repair of mucosa. Misoprostol, as a part of Arthrotec, effectively prevented Diclofenac-induced GM injury mediators production. "P P 38 0852"P 38 0852**Selective COX-2 Inhibition: Its Relevance for NSAID-Gastrointestinal Toxicity**

*H.G. Dammann, F. Burkhardt, Th.A. Walter

Institute for Clinical Research, Hamburg, Germany*Purpose:* The main limitation in the use of NSAIDs is their gastrointestinal (GI) toxicity. The recent discovery of cyclooxygenase isoforms has resulted in further elucidation of the mechanisms of action of NSAIDs. An inducible cyclooxygenase COX-2 produces mediators of inflammation, and a constitutive cyclooxygenase COX-1 has a cytoprotective effect on the gastric mucosa. Consequently NSAIDs that have a higher activity against COX-2 than COX-1 may produce fewer GI-side effects. Meloxicam is a new NSAID derived from enolic acid with a preferential COX-2 inhibitory capacity.*Methods:* Meloxicam has been tested in controlled short- and long-term clinical trials in over 5000 patients, mainly in osteoarthritis (OA) and rheumatic arthritis (RA) to determine its clinical efficacy and GI-safety profile.*Results:* In the treatment of OA and RA meloxicam 7.5 and 15 mg daily was as effective as standard doses of naproxen, piroxicam and diclofenac. Meloxicam, however, produced fewer GI-side effects. Compared to the other drugs significantly less upper GI perforation, ulceration and bleeding occured with meloxicam ($p < 0.05$). Overall, there were significantly ($p < 0.05$) fewer discontinuations due to GI-side effects with meloxicam (meloxicam 7.5 mg and 15 mg: 3.5 and 4.8% respectively, piroxicam: 6.7%, diclofenac: 10.5%, naproxen: 10.7%) as well as less dyspepsia and abdominal pain.*Conclusions:* Meloxicam shows a favourable GI-tolerability profile. This seems to be directly related to its preferential inhibitory effect on COX-2 over COX-1. Thus, the main advantage of selective COX-2 inhibition will be in producing an improved risk/benefit profile for the NSAIDs by maintaining efficacy, but improving GI-safety. "P P 38 0853"P 38 0853**Combination Therapy of Rebamipide, a Novel Antiulcer Agent, with Low Dose Metronidazole and Amoxicillin Decreases Gastric Mucosal IL-8 and Heals Gastritis**

*M. Tachibana, T. Fujino, H. Kuwayama, M. Fukuyo, Y. Shijo, K. Chishima, N. Shimoyama, K. Kitazawa, Y. Katayama, M.K. Kawauchi, T. Saito, H. Mori

Department of Medicine, Daini University Hospital, Women's Medical College, Tokyo, Japan*Objective* Rebamipide is a novel antiulcer agent used in Japan. The exact mode of rebamipide action is not known, but proposed mechanisms of this compound include anti-radical formation. Because gastric *Helicobacter pylori* infection is characterized by active persistent mucosal inflammation, we assessed the effect of rebamipide on H pylori-gastritis. *Methods H. pylori* status was confirmed by culture, histology, and rapid urease test at the time of endoscopy. A total of 56 *H. pylori* positive gastritis patients were enrolled in this clinical trial. Patients were randomly assigned into 2 groups and received either rebamipide 100 mg + amoxicillin 250 mg + metronidazole 250 mg t.i.d. or rebamipide 100 mg alone. Rebamipide was continued for 6 weeks whereas 2 antibiotics were for the first 2 weeks only. Four biopsies were taken each from antrum and gastric body. Three biopsies were processed for histology, culture, and rapid urease test respectively. Remaining one was homogenized and stored at { -}80\'b0C for later measurement of mucosal interleukin 8 (IL-8) content. IL-8 and protein were measured by EIA and Bio-Rad respectively. Reendoscopy was performed at least 4 weeks after completion of all medication.*Results H. pylori* eradication was achieved in 21 among 26 patients treated with rebamipide + amoxicillin + metronidazole. None of the patient treated with rebamipide alone showed eradication of *H. pylori.* Gastric mucosal IL-8 contents were significantly decreased after successful eradication, which was well correlated to the improvement of histologic gastritis, in rebamipide + amoxicillin + metronidazole group.*Conclusion* Rebamipide with low dose metronidazole and amoxicillin normalizes gastric mucosal IL-8 and heals gastritis. "P P 38 0854"P 38 0854**Decreased Levels of cGMP in Gastric Mucosa after Acute NSAID Administration. Relationship with Gastric Injury and Its Prevention by Phosphodiesterase Inhibition**

*J. Esteban[1], M.A. Rodriguez[1], J.A. Martin[1], M.M. Espinosa[1], V. Motilva[2], M.J. Martin[2], C. Alarcon[2], D. Delgado[2], J.M. Herrerias[2]

[1] Servicio Central de Investigaci\'f3n en Ciencias de la Salud, Universidad de C\'e1diz, Espa\'f1a

[2] Servicio Aparato Digestivo, Hospital Universitario ""Virgen Macarena"", Universidad de Sevilla, Espa\'f1a*Purpose:* NSAID-induced gastric injury is related with the decrease of mucosal protective mechanisms. As opposed to this, cGMP increases mucus production and endothelial cells proliferation. Therefore, the decrease of synthesis of prostaglandins produces a fall in gastric mucosal levels of cGMP. Then, it is possible that NSAID-induced gastric damage can be related with decreased levels of cGMP in gastric mucosa. In this sense, we have investigated the levels of cGMP in gastric mucosa after NSAID administration, their relationship with NSAID-induced gastric damage and its prevention by phosphodiesterase inhibition by 3-isobutyl-1-methyl-xantine (IBMX). *Methods:* We have used Wistar male rats (200–250 g). The NSAID tested have been: piroxicam (PIR) (5, 10 and 20 mg/Kg), sodium diclofenac (DIC) (10, 25, 50 and 100 mg/Kg) and acetylsalicylic acid (ASA) (100, 300 and 500 mg/Kg), in all cases the way of administration was p.o. Three hours after NSAID administration the animals were anesthesized with pentobarbital, the stomach removed, the gastric injury (UI) measured in mm^2 and the mucosa scraped and frozen until cGMP determination by immunoassay. IBMX (10 mg/Kg) was administered s.c., when neccessary, 10 minutes before NSAID. *Results:* NSAID-induced gastric injury has been related with the fall of cGMP levels in gastric mucosa ($p < 0.01$). Similarly, both gastric injury and decreased levels of cGMP were dose related. On the contrary, IBMX administration prevents both, NSAID-induced gastric damage and cGMP fall in gastric mucosa. Levels of cGMP after ASA 100, 300 and 500 mg/Kg and after IBMX (50 and 100 mg/Kg of AAS) (153.8 – 77.5; 58.9 – 12.7; 51.8 – 15.2; 149.3 – 81.9; 144.8 – 61.6), PIR 5, 10, 20 mg/Kg and after IBMX (10 and 20 mg/Kg) (112.8 – 34.8; 68.3 – 11.1; 51.7 – 16.9; 154.8 – 55.8; 148.3 – 49.4) and DIC 10, 25, 50 and 100 mg/Kg and after IBMX (25, 50 and 100) (171.3 – 73.8; 68.9 – 20.5; 59.4 – 9.8; 48.3 – 8.1; 146.3 – 31.6; 151.6 – 44.1; 87.3 – 21.6). UI after ASA 100, 300 and 500 mg/Kg and after IBMX (0.45, 2.31; 5.15; 0.35; 0.48), PIR 5, 10 and 20 mg/Kg and after IBMX (0.93; 1.87; 3.21; 0.33; 0.39) and DIC 10, 25, 50 and 100 mg/Kg and after IBMX (0.67; 2.45; 4.59; 7.66; 0.41; 0.50; 0.62; 2.21). *Conclusions.* cGMP plays an important role in NSAID-induced gastric injury and the maintenace of its levels at normal concentrations prevents the production of gastric mucosal damage. "P P 38 0855"P 38 0855**Effects of Ammonia Solution and Teprenone on Growth Factors, Gastric Mucus and Serum Gastrin in Acetic Acid-Induced Gastric Ulcers in Rats**

*Y. Tahashi, S. Asada, E. Umegaki, H. Takiuchi, K. Katsu

2nd Dept, of Internal Medicine, Osaka Medical College, Osaka, Japan*Objective:* Ammonia produced by *H. Pylori* is considered to be responsible, in part, for the prolongation and recurrence of gastric ulcer in man. We induced prolonged acetic acid-induced gastric ulcer in rats by administering ammonia solution to the animals, and its effect was evaluated by assaying growth factors, gastric mucus quantity and serum gastrin level. In addition, anti-ulcer activity of teprenone, a mucosal protective agent, was evaluated after the coadministration with ammonia solution.*Materials and Methods:* An acetic acid gastric ulcer was induced in male Wistar strain rats by the method of Okabe et al. and a prolonged gastric ulcer model was obtained by administering 0.1% ammonia solution to the animals. Rats given tap water instead of ammonia solution served as controls. Teprenone was administered orally in a dose of 200 mg/kg/day admixed with ration. Animals were sacrificed at various time intervals after ulcer induction and the ulcer size was measured. The ulcer lesion was punched out as a tissue specimen for determination of b-FGF, TGF-{ b} 1, PDGF by ELISA. The quantity of surface cell mucus was calculated in computerized image of microscopic section after PAS staining. The serum gastrin level was determined by RIA system. These results were compared among the control, ammonia and ammonia + teprenone group.*Results:* The healing of ulcer was delayed in the ammonia group, compared to the control group, while coadministration with teprenone tended to inhibit the delay of ulcer healing. The tissue level of b-FGF was increased with time, but was lower at all times in the ammonia group than in the control group. In the ammonia + teprenone group, on the other hand, there was an improvement in the tissue level of b-FGF. The tissue level of TGF-{ b} 1 was lower in the ammonia group than in the control group at one time during the experiment, but was again improved with the administration of teprenone. There was no difference in tissue level of PDGF between the ammonia and the control groups, while its level was increased in the ammonia + teprenone group. The quantity of surface cell mucus and the serum gastrin level were lower in the ammonia group than in the control group, and were higher in the ammonia + teprenone group than in the ammonia group.*Conclusion:* The results of this study suggest that the presence of ammonia in the stomach causes the delay of gastric ulcer healing and effects the tissue levels of growth factors, gastric mucus quantity, serum gastrin level and even the quality of ulcer healing. "P P 38 0856"P 38 0856**Changes of Gastric Endocrine Cell Numbers in Rats by Long-Term Treatment with Ammonia**

*Moriya Yusuke[1], Kashiwagi Hideyuki, Chen Gang, Omura Nobuo, Aoki Teruaki

Department of Surgery (II), The Jikei University School of Medicine, Tokyo, Japan

[1] Department of Surgery, The Kohno Clinical Medicine Researc Institute*Aim.* This study investigated the changes of gastrin-immunoreactive cell (G-cell), somatostatin-immunoreactive cell (D-cell), and enterochromaffine-like cell (ECL-cell) numbers in stomachs of rats by 4 or 8 week treatment with ammonia.*Method.* Wistar male rats (8 week old) were treated with distilled water (control), 0.001%, 0.01% or 0.1% ammonia solution (p.o.) for 4 weeks ($A4_{0.001\%}$, $A4_{0.01}$, $A4_{0.1\%}$) or 8 weeks ($A8_{0.001}$, $A8_{0.01}$, $A8_{0.1\%}$). G-cells, D-cells and ECL-cells were immuno-stained with labeled streptavidin–biotin–peroxidase complex method using antibodies to synthetic human gastrin-17, a commercially available somatostatin or histamine antibody. And the cell with visible nuclei was only counted.*Results.* The G-cell numbers in $A4_{0.001\%}$ and $A8_{0.001\%}$ group were not significantly different from those of the control group. The G-cell numbers were significantly increased in $A4_{0.01\%}$, $A8_{0.01\%}$ and $A4_{0.1\%}$ group. However, the G-cell numbers in $A8_{0.1\%}$ group was significantly decreased compared with those of the control group. The D-cell numbers in $A4_{0.001\%}$, $A4_{0.01\%}$, $A8_{0.001\%}$ and $A8_{0.01\%}$ group were not significantly different from those of the control group. The D-cell numbers in $A4_{0.1\%}$ showed a tendency to decrease, and it was significantly decreased in $A8_{0.1\%}$ group. The ECL-cell numbers in $A4_{0.001\%}$ group was not significantly changed compared with the control group, but they were significantly increased in $A8_{0.001\%}$, $A4_{0.01\%}$, $A8_{0.01\%}$ and $A4_{0.1\%}$ group. However, the ECL-cell numbers in $A8_{0.1\%}$ group was significantly decreased compared with those of the control group.*Conclusion.* In this study, the G-cell and ECL-cell numbers were changed depending on ammonia concentration and its administrated period. The low dose of ammonia increased the G-cell and ECL-cell numbers, but the high dose decreased. It may be explanation for changes in gastric endocrine induced by H. pylori infection. Oesophageal gastric duodenal disorders: GD disorders, acid pepticOesophageal gastric duodenal disorders: Helicobacter PyloriOesophageal gastric duodenal disorders: Secretion: mechanism, regulation }" "Changes of Gastric Endocrine Cell Numbers in Rats by Long-Term Treatment with Ammonia"

"P P 38 0857"P 38 0857**Role of Free Radicals in Rat Experimental Model of Chronic Gastritis with Ammonia**

*E. Umegaki, S. Asada, Y. Tahashi, H. Takiuchi, T. Matsumoto, Y. Takao, C. Shimamoto, I. Hirata, K. Katsu

2nd Department of Internal Medicine, Osaka Medical College, Takatsuki, Osaka, JapanHelicobacter pylori (Hp) is known to be closely related to gastroduodenal mucosal lesions. The etiologic mechanisms in Hp induced gastric mucosal injury are presumed to be associated with ammonia produced by urease activity of Hp, monochloramine, and immunological cross reactions. In this study, we assessed the effects of ammonia water on the gastric mucosa and whether free radicals and glutathione (GSH) are involved in the induction of gastric mucosal lesions. In addition, we evaluated the effect of novel anti-ulcer agent tetraprenylacetone (teprenone) in the experimental model with ammonia.*Materials and methods:* Male SD rats were used and sacrificed 6 weeks after the beginning of the study. Gastric mucosal injury was induced by giving 0.1% ammonia water ad libitum for 6 weeks. *Group A;* Water was offered ad libitum. *Group B;* 0.1% ammonia water was offered ad libitum for 6 weeks. *Group C;* 0.1% ammonia water was offered ad libitum and 200 mg/kg/day of teprenone was administrated orally for 6 weeks. The tissue sections of removed stomach were prepared to measure the thickness of gastric mucosa in the body and antrum. Serum gastrin levels and tissue levels of myeloperoxidase (MPO), GSH and LPO (which is the index of lipid peroxidation) in the frozen gastric mucosa were determined.*Results:* (mean – SD, *** $p < 0.005$ vs. Group A.) Gastrin (pg/ml) mucosal thickness (\'b5m) body antrumGroup A. 106 – 13.9 766 – 19.1 55l – 21.0Group B. 122 – 11.4 744 – 22.2 457 – 12.7*** Group C. 99.6 – 6.3 768 – 24.0 536 – 16.8 MPO LPO GSHGroup A. 0.52 – 0.27 6.6 – 1.2 1012 – 208Group B. 1.09 – 0.09*** 10.5 – 1.2*** 1164 – 198Group C. 0.67 – 0.09 6.4 – 1.3 1217 – 226*Conclusion:* It was suggested that a significant elevation in MPO and LPO activity is associated with gastric mocosal atrophy induced by long-term administration of ammonia water, and that the anti-ulcer agent teprenone inhibits the gastric mucosal atrophy without the elevation in MPO and LPO activity. Oesophageal gastric duodenal disorders: Helicobacter Pylori }" "Role of Free Radicals in Rat Experimental Model of Chronic Gastritis with Ammonia"

"P P 38 0858"P 38 0858**Importance of Sensory Nerves and Nitric Oxide (NO) in Gastric Cytoprotection Induced by Epidermal Growth Factor (EGF)**

*S.J. Konturek, T. Brzozowski, Z. Sliwowski

Inst. Physiol. Univ. Sch. Med., Krakow, Poland*Purpose:* Capsaicin and NO have been shown to protect the gastric mucosa against various irritants but their relative importance in the cytoprotection afforded by EGF has not been determined.*Methods:* In this study we examined the effects of intragastric (ig) capsaicin in small dose (0.5 mg/kg), to excite the sensory nerves or in a large systemic (sc) dose (125 mg/kg), to deactivate these nerves, as well as EGF or capsaicin plus EGF on ethanol-induced gastric damage. In addition, the influence of total salivectomy to remove endogenous source of EGF or suppression of endogenous NO synthase with N^G-nitro-L-arginine (L-NNA 40 mg/kg iv) on ethanol-induced gastric lesions was tested. Gastric lesions were measured planimetrically and gastric blood flow (GBF) was examined by laser Doppler technique.*Summary of results:* Topical application of 100% ethanol produced widespread hemorrhagic mucosal lesions (area – 80 mm^2) accompanied by about 60% reduction in GBF. Pretreatment with capsaicin (0.5 mg/kg ig), EGF (50 \'b5g/kg sc) or their combination significantly reduced the area of ethanol lesions while restoring the GBF. These protective and hyperemic effects of capsaicin, EGF and their combination were almost completely eliminated by earlier deactivation of sensory nerves by pretreatment with large dose of capsaicin. Salivectomy, which by itself aggravated ethanol-induced lesions, failed to affect the protection and hyperemia afforded by EGF and capsaicin. The suppression of NO synthase with L-NNA reduced significantly the protection and hyperemia caused by EGF and capsaicin. The addition to L-NNA of L-arginine (300 mg/kg iv), the substrate of NO synthase, restored almost completely the protective and hyperemic effects of EGF and capsaicin. Application of $CGRP_{8–37}$, an antagonist of calcitonin gene-related peptide (CGRP), decreased the hyperemia induced by topical capsaicin, EGF or both.*Conclusion:* Cytoprotective and hyperemic effects of EGF involve the excitation of capsaicin-sensitive nerves and endogenous formation of NO and CGRP.

"P P 38 0859"P 38 0859**Interaction of Capsaicin-Sensitive Nerves with Epidermal Growth Factor (EGF) on Healing of Acute and Chronic Gastric Ulcerations in Rats**

*T. Brzozowski, P.Ch. Konturek, E.G. Hahn, S.J. Konturek

Inst. Physiol., Univ. Sch. Med., Krakow, Poland

Dept. Med. I, Univ. Erlangen, Germany*Purpose:* Capsaicin (CAP) applied in a small dose protects gastric mucosa by stimulation of sensory nerves but administered in large neurotoxic dose aggravates the mucosal injury due to deactivation of these nerves. EGF accelerates healing of gastric ulcers but its interaction with sensory nerves on this healing has not been assessed.*Methods:* We examined the effects of small (0.5 mg/kg po) and large dose (125 mg/kg sc) of CAP on healing of acute stress-induced lesions and chronic acetic acid-induced gastric ulcers. The rats were sacrificed at 0, 6, 12 and 24 h after restraint stress and 7 days after induction of chronic ulcers. The area of gastric ulcers was measured by planimetry, the gastric blood flow (GBF) by laser Doppler flowmetry, the DNA synthesis by incorporation of ^{3}H-thymidine to DNA and the EGF in the oxyntic mucosa by RIA and RT-PCR.*Summary of results:* Stress produced acute lesions with a marked fall of GBF (by – 35%) and DNA synthesis (by – 50%). After 24 h these lesions were reduced by 75%, the GBF and DNA synthesis were restored and mucosal EGF was markedly increased. Salivectomy delayed significantly the healing of stress lesions and reduced further the synthesis of DNA and GBF. Stimulation of sensory nerves with CAP (0.5 mg/kg) significantly enhanced the healing of these lesions and raised GBF and DNA synthesis. In contrast, CAP-induced sensory denervation significantly delayed healing and caused a fall in GBF and DNA synthesis at all time intervals after stress. These effects were further aggravated by salivectomy, which resulted in about 80% reduction in mucosal EGF content. CAP at a small dose also accelerated the healing of chronic gastric ulcers and raised markedly GBF and expression of EGF in ulcer area, whereas CAP-denervation and salivectomy delayed healing and reduced the GBF and EGF expression in the ulcer area.*Conclusion:* Sensory neurons interact with endogenous EGF in healing of both acute and chronic gastric ulcers.

"P P 38 0860"P 38 0860**Synchronized Induction in Cyclin-Dependent Kinase Cdk2 and FGF Receptor during Gastric Ulcer Healing**

*B.L. Slomiany, J. Piotrowski, A. Slomiany

Res, Ctr., UMDNJ, Newark, NJ USAThe processes of gastric mucosal repair, characterized by massive cell migration, proliferation, differentiation and remodeling, are regulated by growth factors and the extent of cellular expression of their receptors. Cellular responses to growth factors and the cell passage through G1 phase of cell cycle are mediated by D-type cyclins and their specific cyclin-dependent kinases. In the study presented herein, we assessed the gastric mucosal expression of basic fibroblast growth factor receptor (bFGF-R) and cyclin-dependent kinase (Cdk2 p34) with ulcer healing. The chronic gastric ulcers were induced in rats with acetic acid. Following recovery, the animals were treated twice daily for 14 consecutive days either with a 100 mg/kg of ebrotidine or vehicle, sacrificed at different healing intervals, their stomachs dissected and subjected to bFGF-R and Cdk2p32 quantitization. The ulcer area was measured by planimetry. In the FGF-R assays mucosal membrane bound ^{125}IbFGF was quantitated in a gamma counter, while ELISA was employed for Cdk2 p34, measurements. In the absence of ebrotidine the ulcer healing time was 14 days, while treatment with ebrotidine produced a 71% decrease in ulcer area by the 5th day and a complete healing by the 7th day. The results of parallel assays of bFGF-R and Cdk2 p34 revealed that the expression of FGF-R reached a maximum of 2.2-fold increase by the 4th day of healing and remained elevated (1.4-fold) for up to 10 days. Accelerated ulcer healing with ebrotidine was also reflected in Cdk2, the expression of which showed the highest (2.1-fold) increase by the 4th day of healing. The results suggest that the cell cycle regulatory kinase Cdk2 p34 during cellular proliferation associated with ulcer healing is controlled differentially by FGF-R, the induction of which determines the cell cycle progression through G1 and into S phase. "P P 38 0861"P 38 0861**Cell Cycle Progression with Ulcer Healing by Sulglycotide**

*A. Slomiany, J. Piotrowski, D. Skrodzka, B.L. Slomiany

Res. Ctr., UMDNJ, Newark, NJ USAThe progression of the events associated with gastric mucosal repair following injury is controlled in an orderly manner by a plethora of extracellular bioactive factors exerting their effect on the cell cycle. The transitions between different cycle states are regulated by a family of of nuclear proteins, cyclins and cyclin-dependent kinases, the expression of which vary through the cycle stages. The purpose of this investigation was to evaluate the expression of cyclin dependent kinase (CDK) and proliferating cell nuclear antigen (PCNA) with chronic ulcer healing by sulglycotide. The study was carried out on rats with acetic acid induced chronic gastric ulceration. Following postoperative recovery, the animals were given twice daily for 14 consecutive days either a 200 mg/kg dose of sulglycotide or vehicle. At different time interval of healing the animals were sacrificed, their stomachs dissected and the mucosa subjected to PCNA and CDK quantitization. The results of assays established that ulcer healing was accompanied by an increase in mucosal expression of PCNA and CDK, In the absence of sulglycotide treatment, the maximum expression of PCNA (4.7 fmol/ml) occurred by the second day of healing and remained elevated for up to six days, while CDK showed the highest activity (17.4–19.7 fmol/ml) at 4–6 days. Sulglycotide caused acceleration in the rate of ulcer healing and this process was reflected in in a 2.2-fold enhancement in PCNA expression over that of controls on the second day of treatment and a 2.5-fold enhancement on the sixth day, whereas the CDK expression reached a maximum 2-fold enhancement (33.7 fmol/ml) by the sixth day of treatment and remained elevated (32 fmol/ml) for up to 10 days. The findings indicate that cytoprotective agent, sulglycotide, has the ability to modulate the processes associated with cell cycle progression. [3] National Cancer Institut, Frederick, USA

[4] Univ. School of Medicine Osaka, Japan*Introduction:* HGF and trefoil peptides are potent growth factors which are locally secreted during gastric ulcer healing. We assessed the role of HGF, its receptor c-met and trefoil peptides in an experimental gastric ulcer model.*Methods:* Wistar rats with a fundic cryoulcer were treated subcutaneously for 3 and 15 days with either placebo, 1 {\'b4} 40 \'b5mol omeprazole or 2 {\'b4} 100 \'b5g/kg HGF. Ulcer healing was assessed by repeated videoendoscopy, immunohistochemistry and in situ hybridization.*Results:* HGF treated rats showed identical healing curves as placebo in contrast to omeprazole which accelerated ulcer healing. HGF treated rats showed a 80% increase of epithelial cell proliferation compared with placebo on day 15, but not in the early healing phase. HGF-receptor protein was decreased on days 3 and 8, but overexpressed in the regenerative glands on day 15. HGF mRNA was detected in mesenchymal cells of the ulcer bed on day 15. Both trefoil peptides rSP (rat spasmolytic polypeptide) and pS2 (mouse one p-domain) mRNAs were significant increased in the regenerative epithelium on days 3 and 15. HGF did not influence the expression of trefoil peptides.*Conclusion:* The expression of HGF in mesenchymal cells of the ulcer base and of HGF-receptor in regenerative glands on day 15, suggest a significant role of HGF in the glandular reconstruction in the late phase of ulcer healing. The strong expression of trefoil peptides in the early and late ulcer healing phases supports their relevant role in gastric ulcer healing. "P P 38 0863"P 38 0863**Chronological Changes of G-Cell and ECL-Cell Numbers After Long-Term Acid Suppression in Rats**

*Chen Gang, Kashiwagi Hideyuki, Omura Nobuo, Moriya Usuke, Hagiwara Eiitirou, Aoki Teruaki

Department of Surgery (II), The Jikei University School of Medicine, Tokyo, Japan*Aim.* This study investigated the chronological changes of gastrin-immunoreactive cell (G-cell) and enterochromaffine-like cell (ECL-cell) numbers in stomachs of rats after 4-week treatment with histamine H_2 receptor antagonist.*Method.* Wistar male rats were treated with famotidine (15 mg/kg/day p.o.) for 4 weeks. After withdrawal of the drug, rats were divided into 8 groups: F_0 (on the day of cessation of famotidine administration), F_3 (3 days after cessation of famotidine). F_5 (5 days), F_7 (7 days), F_{10} (10 days, F_{14} (14 days), F_{28} (28 days) and F_{56} (56 days) group and control group (n = 6). G-cells and ECL-cells were immuno-stained with labeled streptavidin–biotin–peroxidase complex method using antibodies to synthetic human gastrin-17, and a commercially available histamine antibody. And the cell with visible nuclei was only counted.*Results.* The G-cell number significantly increased in F_0, F_3, F_5, F_7 and F_{10} group compared with control group, but the numbers in F_{14}, F_{28} and F_{56} returned to the control level. The ECL-cell number significantly increased in all famotidine-treated groups and they had not returned to the control level by 56 days after cessation of famotidine.*Conclusion.* The long-term high-dose famotidine administration produced the increase of the G-cell number and ECL-cell number in the rats. The G-cell number seemed to return to the control level in 14 days after cessation of the drug. However, the ECL-number did not return to the control level in this study.

"P P 38 0864"P 38 0864**Nitric Oxide in the Regulation of Gastrin Release and Gastric Emptying in Humans**

*J.W. Konturek, H. Fischer, P.M. Gromotka, R. Stoll, S.J. Konturek, W. Domschke

Department of Medicine B, University of M\'fcnster, M\'fcnster, Germany

Institute of Physiology, Jagiellonian University, Krak\'f3w, PolandNitric oxide (NO) has been shown to be formed from L-arginine (L-Arg) by constitutive NO synthase in epithelial cells, endothelial cells and nitrinergic nerves of the digestive tract. NO has been implicated in gastric hyperemia associated with gastric secretory stimulation by pentagastrin in anesthetized rats as noncholinergic and nonadrenergic mediator. Recently, it has been shown that NO is involved in the control of gastric acid secretion and gastrin release under physiological conditions in dogs and that those effects are partially mediated by the release of somatostatin. The aim of this study in 10 healthy volunteers was to evaluate the role of NO in the control of gastrin and somatostatin release in response to ordinary feeding. Gastric acid secretion was determined by means of continuous intragastric pH-metry (Digitrapper, Synectics, Stockholm, Sweden) after feeding with 500 ml of caloric, semiliquid meal (Fresubin, Fresenius, Bad Homburg, Germany). Plasma levels of gastrin, somatostatin and insulin were measured using specific radioimmunoassays. The gastric emptying rate after feeding was determined using ^{13}C-acetate breath test. In this double blind study gastric secretory activity and gastric emptying rate were determined in random order on three different days after pretreatment with 0.9% NaCl (control), N^G-monomethyl-L-arginine (L-NMMA 60 nmol/kg-min i.v.) or combination of L-NMMA and L-Arg (30 \'b5mol/kg-min i.v.). Pretreatment with L-NMMA suppressed the postprandial increase in gastrin release and caused a small but significantly higher rise of plasma somatostatin when compared to control values. The gastric emptying half-time was reduced by about two fold and during the median two hours, postprandial intragastric pH showed tendency to increase above control values (L-NMMA: 3.6 – 0.4 vs. control: 3.3 – 0.5) but this rise was not statistically significant. Plasma insulin level reached significantly higher postprandial values in tests with L-NMMA compared to control tests probably due to enhanced gastric emptying of meal. Those effects of L-NMMA on the gastric secretory and motor activity as well as plasma hormone release were not observed in tests after pretreatment with the combination of L-NMMA and L-Arg. We conclude that: 1) endogenous NO is involved in the regulation of postprandial gastrin release and these effects appear to be mediated, at least in part, by the release of somatostatin; 2) endogenous NO appears also to be involved in the regulation of gastric emptying presumably mainly through its excitatory action on the proximal stomach, and 3) inhibition of NO synthase enhances plasma insulin release probably due to increased gastric emptying of carbohydrate containing caloric meal. [1] James Paget Hospital, Norfolk, UKWe and others have shown that capsaicin and epidermal growth factor (EGF) protect against gastric mucosal injury in several experimental models. Both chilli, which contains capsaicin, and saliva, which contains EGF, have been proposed as possible protective factors in the pathogenesis of human peptic ulcer disease.The present study aims to understand the mechanisms of gastroprotection afforded by capsaicin and EGF. We investigated the effect of capsaicin, EGF, and a combination of capsaicin plus EGF on ethanol-induced gastric mucosal injury in intact rats, and in rats subjected to sensory ablation, sialoadenectomy, or both operations (n = 8 per group). The effect of sensory ablation and close arterial infusion of $hCGRP_{8–37}$, an antagonist of calcitonin gene-related peptide (CGRP), on the gastric hyperaemic effect of capsaicin and EGF was evaluated in a gastric chamber preparation. Gastric mucosal damage was assessed by planimetry and light microscopy.Capsaicin, EGF and their combination reduced ethanol-induced gastric mucosal damage in rats with intact innervation. In contrast, they did not afford any protection in capsaicindesensitised rats. Sialoadenectomy had no effect. Administration of capsaicin, EGF or their combination increased gastric mucosal blood flow in rats with intact innervation but not after capsaicin desensitisation. Close arterial infusion of $hCGRP_{8–37}$, an antagonist of calcitonin gene-related peptide (CGRP), abolished the hyperaemic effect of both capsaicin and EGF.Our results suggest that capsaicin and EGF may exert their gastroprotective effects via stimulation of capsaicin sensitive afferent neurones with release of CGRP. "P P 38 0866"P 38 0866**Central Effect of Pacap on Gastric Secretion and Gastric Mucosal Blood Flow in Anesthetized Rats**

*M. Ozawa, M. Aono, K. Mizuta, M. Moriga, M. Okuma

The First Department of Internal Medicine, Faculty of Medicine, Kyoto University, Kyoto, JapanPACAP is a neuropeptide originally isolated from ovine hypothalamic tissues and has two amidated forms, PACAP38 and PACAP27. We examined the effects of centrally administered PACAP38 on gastric secretion and gastric mucosal blood flow (GMBF) in anesthetized rats.Male Wistar rats were anesthetized with a urethane injection after 24 hr fast. A stainless steel cannula was implanted in the right lateral ventricle. The gastric secretion study was performed using Ghosh-Lai's rat preparation. PACAP38 or PACAP27 (2, 4, 8 nmol/rat) was administered ICV. Acute cervical vagotomy or atropine injection (10 ug/kg i.v.) was performed 15 min before ICV PACAP38 to examine the vagal pathway. PACAP antagonist PACAP6-38 (4 nmol/rat) was injected ICV to examine the role of PACAP receptor. The effect of ICV or IV bolus injection of PACAP38 on GMBF was examined by a laser doppler flowmeter.ICV PACAP stimulated gastric secretion dose-dependently. PACAP38 was 1.5–2 times more potent than PACAP27 on gastric secretion. By contrast, IV bolus injection of PACAP38 had no effect on basal gastric secretion. PACAP6-38 by itself at higher doses (8, 16 nmol/rat) stimulated gastric secretion. ICV PACAP6-38 at a dose (4 nmol/rat) that had no effect on gastric secretion, atropine or vagotomy pretreatment suppressed the stimulatory effect of PACAP38. ICV PACAP38 increased GMBF continuously, whereas IV bolus injection of PACAP38 increased GMBF transiently.These results suggested that centrally administered PACAP may have a regulatory role in gastric secretion through PACAP receptors and the vagal pathway and modulate GMBF. Hormones and receptors: Brain gut axis }" "Central Effect of Pacap on Gastric Secretion and Gastric Mucosal Blood Flow in Anesthetized Rats"

*G. Rodier[1], R. Magous[2], T. Mochizuki, J. Martinez, D. Le Nguyen[1], J.P. Bali[2], D. Bataille[1], C. Jarrousse[1]

[1] INSERM U 376, CHU Arnaud de Villeneuve, 34 295 Montpellier, France

[2] INSERM CJF 9210, Biochimie des Membranes, Facult\'e9 de Pharmacie, 34060 Montpellier, FranceGlicentin (GLIC) and oxyntomodulin (OXM), two peptides coreleased from ileum and large intestine during digestion which are related to the enteroglucagon concept and represent the main circulating oxyntomodulin-like immunoreactants. Both hormones contain the whole glucagon sequence and a C-terminal octapeptide. Moreover, GLIC has a 32 amino-acids N-terminal extension. GLIC and OXM activities differ from that of glucagon. They are directed towards the digestive tract: inhibition of gastric acid secretion in vivo in rat and man, inhibition of gastric emptying and duodenal motility for OXM in man and inhibition of the antral motor activity at high doses for GLIC in dog.The effect of GLIC and OXM on gut motility prompted us to analyse their activity on the model of smooth muscle cells isolated from rabbit antrum after enzymatic digestion and mechanical stirring. The preparation contained 95% circular muscle cells. Human GLIC and OXM were obtained by chemical synthesis.GLIC or OXM induced a clear shortening of the cells, their maximal contraction corresponding to 13.9 – 0.8% and 15.5 – 0.9% of decrease in mean length. The contraction induced by GLIC and OXM was dose related, the observed EC50 were 5 and 83 pM respectively. The effect of two C-terminal fragments, OXM (19–37) and OXM (30–37), known to inhibit acid secretion, was also studied. The extent of maximal contraction was maintained (13.7 – 0.5% and 14.9 – 1.1% respectively) but OXM (30–37) was 1800 less potent (EC50 = 10420 pM) than GLIC whereas OXM (19–37) was as potent as OXM (EC50 = 72 pM). By contrast, glucagon or tGLP exhibited no contractile effect.In conclusion, it is the first time that a target cell is described for glicentin or oxyntomodulin. These results pointed out the effect of these two coreleased hormones on digestive motility in addition to their well established role on gastric acid secretion. "P P 38 0868"P 38 0868**Effect of Epidermal Growth Factor, Capsaicin and Chilli Ingestion on Haemorrhagic Shock-Induced Gastric Mucosal Injury**

*C.H. Teng, J.Y. Kang[1], A. Wee[2], K.O. Lee

Department of Medicine, National University of Singapore, Singapore

[2] Department of Pathology, National University of Singapore, Singapore

[1] James Paget Hospital, Norfolk, UKWe, and others, have shown that epidermal growth factor (EGF), chilli, and its pungent ingredient, capsaicin, are protective against ethanol- and aspirin-induced gastric mucosal injury in animals. In the present study, we further investigated the effect of EGF, capsaicin, and long term ingestion of chilli, on haemorrhagic shock-induced gastric mucosal injury.Fasted, anesthetised rats (n = 8 per group) were subjected to 60 minutes of haemorrhagic shock by withdrawing the blood, 1.7 ml/100 g body weight, followed by 45 minutes of reinfusion of shed blood. Using an ex-vivo gastric chamber preparation, superficial, white abnormal areas were observed on the gastric mucosa during haemorrhagic shock, and upon reinfusion of shed blood, bleeding occurred at these areas resulting in lesion formation. Gastric mucosal damage was assessed by planimetry and light microscopy.Topical application of EGF (25 \'b5g) to the gastric mucosa prior to haemorrhagic shock significantly reduced the gastric mucosal injury from 30% to 10% ($p < 0.05$). Similarly, administration of capsaicin (5 mg) prior to haemorrhagic shock reduced the damage to 7% ($p < 0.05$). The use of EGF and capsaicin after haemorrhagic shock, however, did not produce any beneficial effect. Chilli intake for four weeks (360 mg daily) reduced gastric mucosal injury from 21% to 11% ($p < 0.05$). Pre-treatment of rats with subcutaneous high dose capsaicin (125 mg/kg body weight) to achieve desensitisation of capsaicin-sensitive afferent neurones abolished the gastroprotection afforded by EGF, capsaicin and four-week chilli intake.Epidermal growth factor, capsaicin and long term chilli intake protect against haemorrhagic shock-induced gastric mucosal injury and that this protection may be mediated by capsaicin-sensitive afferent neurones. Hormones and receptors: Growth factors }"

[2] Dept. of Pharmacology (FCM), UNICAMP, Campinas, SP; BrazilThe production of peptic ulcers is a clinically important side-effect of non-steroidal antinflammatory drugs (NSAIDS). Sucralfate is a basic aluminum salt of sucrose sulfate that polymerizes in an acid medium to form a viscous substance capable of binding to the gastric and duodenal mucosa. This is thought to accelerate ulcer healing; however, the healing mechanism(s) remains to be fully defined. The objectives of the present work were to study the influence of sucralfate on the pharmacokinetics of diclofenac in eighteen healthy male volunteers.*Methods:* Potassium diclofenac suspension (Cataflam, Ciba-Geigy, 105 mg) was administered orally with or without a five-day pre-treatment with Sucralfate (2000 mg *bid;* phases SUC+ and SUC{ -}, respectively), and blood samples were collected before and 0.5, 1.0, 1.5, 2, 3, 4, 6, 8, 12, and 24 h after diclofenac administration. The serum concentrations of diclofenac were quantified by reverse-phase HPLC with U.V. detection. The maximum plasma concentration (C_{max}), the time taken to reach this (T_{max}), a first-order terminal elimination rate constant (K_e), the half-life ($T_{1/2}$), the area under the time-concentration curves from 0–24 h ($AUC_{0–24}$) and the value $AUC_{0–24}/T_{1/2}$ as an index of diclofenac clearance, were determined.*Results:* Pre-treatment with sucralfate significantly decreased the amount of diclofenac absorbed (75% of the AUC during the SUC- phase) and the C_{max} (62%) with no significant effect on diclofenac elimination.*Conclusion:* Pre-treatment with sucralfate leads to decreased bioavailability of potassium diclofenac*Financial support: CNPq, FAPESP* Clinical practice: Management strategy }" "Short-Term Sucralfate Administration Alters Potassium Diclofenac Absorption in Healthy Human Volunteers"

"P P 38 0871"P 38 0871**Bacterial Endotoxin Lipopolysaccharide (LPS) Protects Gastric Mucosa Via Endogenous Prostaglandins (PG), Nitric Oxide (NO) and Sensory Nerves**

*T. Brzozowski, P.Ch. Konturek, Z. Sliwowski, S.J. Konturek

Inst. Physiol., Univ Sch Med, Krakow, Poland

Dept Med I, University Erlangen, FRG*Purpose:* LPS induces endotoxemia by releasing various cytokines and NO synthesis but its effects on gastric secretion and mucosal protection have not been tested.*Methods:* We determined the effects of bacterial *(E. coli)* LPS on gastric secretion, acute gastric lesions induced by 100% ethanol, gastric blood flow (GBF) using laser Doppler flowmetry and expression of constitutive (cNOS) and inducible NO synthase (iNOS) messenger RNA in gastric mucosa using RT-PCR. Four series (A–D) of tests were performed on rats; A – with suppressed PG generation by indomethacin (5 mg/kg ip), B – with inhibited NO synthase by N^G-nitro-L-arginine methyl ester (20 mg/kg iv), C – with deactivated sensory nerves with capsaicin (125 mg/kg sc) and D – with vehicle treatment (control).*Summary of results:* LPS (0.01–1.0 mg/kg) applied intragastrically was ineffective but when given intraperitoneally (ip) it reduced dose-dependently both gastric acid secretion and ethanol-induced mucosal lesions. The dose inhibiting by 50% (ID_{50}) these lesions was 0.8 mg/kg and it was accompanied by a significant rise in the GBF. The protective effect of LPS persisted over 6 h, similarly as after exogenous dimethyl PGE_2 (10 \'b5g/kg ip). Pretreatment with indomethacin significantly reduced the gastroprotection and hyperemia afforded by LPS. Intense signals for expression of cNOS and iNOS were detected by RT-PCR in the gastric mucosa of LPS-treated rats. Suppression of NO synthase by L-NAME also significantly reduced the protective and hyperemic effects of LPS against ethanol damage. Addition of L-arginine (300 mg/kg iv), a substrate of NO synthase, restored the protective and hyperemic action of LPS. Deactivation by capsaicin of sensory nerves reduced significantly the protection and hyperemia caused by LPS.*Conclusion:* LPS protects gastric mucosa from acute ethanol-induced damage via the mechanism involving endogenous PG, arginine-NO pathway and sensory nerves. "P P 38 0872"P 38 0872**Effects of Pyrilamine on Secretions of Gastric Acid and Gastrin in Rats After Long-Term Acid Suppression**

*Takaoka Toru, Chen Gang, Kashiwagi Kideyuki, Omura Nobuo, Aoki Teruaki

Department of Surgery (II), The Jikei University School of Medicine, Tokyo, Japan*Aim.* Long-term acid suppression is known to induce hypergastrinemia, but the underlying reasons why there is no increase in acid secretion, so-called acid rebound, after the treatment is widely debated. Acid secretion is known to be regulated by many factors, and long-term acid suppression may produce the change of other regulatory factors. Histamine H_1 and H_2 receptor subtypes are reported to locate on gastrin-immunoreactive cell (G-cell). This study investigates the effects of pyrilamine (an H_1 receptor antagonist) on gastric acid and gastrin secretions in rats after 4-week acid suppression.*Method.* Famotidine (H_2 receptor antagonist 15 mg/kg/day p.o.) was administered in drinking water for four weeks. On the 3rd, 5th and 7th day after cessation of famotidine treatment, the gastric juice pH, acid output, and serum gastrin level were measured in rats 5 hours after pylorus-ligation with or without pretreatment of pyrilamine (50 mg/kg, i.p.). If administered, pyrilamine was given prior to 30 minutes before pylorus-ligation.*Result.* After the cessation of famotidine, the gastric juice pH, acid output and serum gastrin level were not significantly different from those of the control group. However, pretreatment of pyrilamine significantly increased the acid output and the serum gastrin level in the famotidine-treated group, but not in the control group.*Conclusion.* These results suggest that gastric acid and gastrin secretions don't increase after long-term treatment with H_2 receptor antagonist because they become inhibited via the H_1 receptor. Oesophageal gastric duodenal disorders: GD disorders, acid pepticOesophageal gastric duodenal disorders: Secretion: mechanism, regulation }" "Effects of Pyrilamine on Secretions of Gastric Acid and Gastrin in Rats After Long-Term Acid Suppression"

"P P 38 0873"P 38 0873**Gastric Blood Flow Changes May Differ in the Mucosa and the Extramural Arteries in Response to Different StimuliM. Casadevall, A. M\'e9ndez, C.H. Watcher, A. Heinemann, J.I. Elizalde, M. del Rivero, P. Holzer, E. Quintero, J.M. Piqu\'e9**

University of Barcelona, Spain

University of La Laguna, Spain

University of Graz, AustriaAlthough flow to the mucosal layer mainly depends on the supply from extramural arteries of the stomach, a certain degree of autoregulation may probably takes place with changes on flow resistance in the submucosal arterioles. *Aim:* To compare the gastric mucosal blood flow (GMBF) and the left gastric artery blood flow (LGABF) responses to pharmacological, physiological and pathological stimuli. *Methods:* In urethane anesthetized rats, GMBF and LGABF were measured by hydrogen gas clearance and perivascular ultrasonic transit time respectively. In separate groups of rats measurements were conducted in baseline conditions and after vehicle administration (n = 5), vasopressin infusion (1 mU/min, n = 9), isovolemic hemodilution by exchanging 3 ml of blood by a plasma expander (n = 6), pentagastrin infusion (40 \'b5g/kg/h, n = 8) or HCl-taurocholate gastric perfusion (n = 7). In additional groups of rats submitted to hemodilution, pentagastrin infusion or HCl-taurocholate gastric perfusion pretreatment with L-NAME (10 mg/kg) was administered.*Results:* Vasopressin induced a significant reduction in both GMBF and LGABF, but the percent decrement was greater ($p = 0.05$) in LGABF (47 – 7%) than in GMBF (30 – 4%). Isovolemic hemodilution was followed by an increase in both GMBF and LGABF, the percent increment being significantly ($p < 0.05$) higher in LGABF (105 – 14%) than in GMBF (60 – 8%). This increment in blood flow was significantly ($p < 0.05$) attenuated by L-NAME in both the GMBF (78% attenuation) and the LGABF (89% attenuation). In rats infused with pentagastrin, a significantly ($p < 0.05$) greater increment was observed in GMBF (80 – 9%) than in LGABF (29 – 7%), both increments being attenuated by L-NAME. A similar gastric hyperemic response was seen in the GMBF and the LGABF when gastric mucosa was challenged by HCl-taurocholate perfusion, an effect that was significantly attenuated by L-NAME.*Conclusions:* Gastric mucosal and left gastric artery blood flows changes may differ under certain pharmacological, pathological or physiological stimuli. This illustrates the autoregulatory capability of the vascular tone at the mucosal-submucosal level. In addition, hyperemic responses induced by pentagastrin, hemodilution, and HCl-taurocholate injury are modulated by nitric oxide inhibition in a similar manner in the left gastric artery and in the mucosal microcirculation. }" "Gastric Blood Flow Changes May Differ in the Mucosa and the Extramural Arteries in Response to Different Stimuli"

"P P 38 0874"P 38 0874**Expression of Epidermal Growth Factor (EGF) and Transforming Growth Factor Alpha (TGF{ a}) during Recovery from Stress Damage**

*P. Konturek, T. Brzozowski, J. Majka, Z. Sliwowski, H. Ernst, E.G. Hahn, S.J. Konturek

Dept. Med I, Univ Erlangen-Nuremberg, Germany

Inst. Physiol, Jagiell. Univ. Med. Sch. Krakow, Poland*Background:* Stress is known to produce gastric mucosal damage but the mechanism of the recovery of gastric mucosa after stress exposure has not been fully explained. EGF and TGF{ a} are potent mitogenic and growth promoting factors involved in the protection of gastric mucosa against stress-induced damage but expression of these growth factors during mucosal healing after stress exposure has been little evaluated. This study was designed to determine the rate of cell proliferation, changes in the gastric blood flow (GBF) and the expression of EGF and TGF{ a} during mucosal repair after stress. *Material and Methods:* Rats were exposed to 3.5 h of water immersion and restraint stress and sacrificed at 0, 2, 4, 6, 8 and 12 h after stress. The number and area of gastric lesions was determined by planimetry and the GBF was measured by laser Doppler flowmetry. The gastric content was collected for the measurement of luminal release of EGF by radioimmunoassay. The mucosal sections were stained immunocytochemically for proliferating cell nuclear antigen (PCNA) – an index of cell proliferation and for EGF and TGF{ a} with monoclonal antibodies. Expression of EGF and TGF{ a} mRNA in fundic mucosa was determined by reverse-transcriptase polymerase chain reaction (RT-PCR). The first-strand cDNA was synthesised from total RNA and then amplified with specific primers by PCR method. PCR products were separated on 1.5% agarose gel by electrophoresis and then visualised under UV. *Results:* The number of gastric lesions induced by stress averaged 18 – 4 and declined at 2, 4, 6, 8 and 12 h by 9%, 15%, 33% 62% and 85%, respectively. This was accompanied by a significant rise in GBF by 8%, 15%, 26%, 32% and 35%, respectively and a marked increase of the luminal EGF immunoreactivity. PCNA labelling index increased gradually after stress and reached the maximum at 6 h. The immunohistochemical expression of EGF rised time-dependently and reached a peak at 4 h, whereas expression for TGF-{ a} increased gradually from 0 h to 12 h after stress. EGF mRNA was not detectable in intact mucosa but expressed at 0, 2, 4, 6 and 8 h with the maximal signal at 4 h after stress. Expression of TGF{ a} mRNA was present in intact mucosa and during all intervals after stress exposure. *Conclusion:* gastric hyperemia and an increase in cell proliferation are involved in mucosal repair after stress damage and this appears to be mediated by luminal release of EGF and an overexpression of EGF and TGF{ a}.

"P P 38 0875"P 38 0875**Role of Endogenous Nitric Oxide on Water Immersion Stress-Induced Gastric Lesions in Rats**

*K. Tachi, H. Goto, S. Hase, T. Arisawa, Y. Niwa, N. Ohmiya, M. Hisatomi, T. Watanabe, N. Okada, M. Tsukamura, Y. Hisanaga, T. Hayakawa[1], S. Sugiyama[2]

[1] Second Department of Internal Medicine, Nagoya University School of Medicine, Nagoya, Japan

[2] Department of Clinical Biochemistry, Institute of Applied Biochemistry, Mitake, Kani-gun, Gifu, Japan*Background.* Gastric mucosal microcirculation is an important factor in the genesis of gastric lesions and nitric oxide (NO) plays a crucial role in the regulation of regional blood flow. This study was designed to evaluate the effect of cetraxate, an anti-ulcer drug, on water immersion stress-induced gastric lesions in relation to the changes in NO synthase activity.*Methods.* Gastric lesions were induced in rats by water immersion stress. The effects of cetraxate on NO synthase activity with or without stress was determined enzymatically. Changes in gastric mucosal prostaglandin (PG) contents with or without stress were also determined using high performance liquid chromatography. Gastric mucosal blood flow was measured by hydrogen gas clearance technique.*Results.* Water immersion stress induced gastric lesions. Cetraxate mitigated significantly the lesions but N^G-monomethyl-L-arginine (L-NMMA), a specific inhibitor of NO synthase, exacerbated the lesions. The favorable effect of cetraxate was remarkably diminished by administration of L-NMMA. NO synthase activity increased significantly 30 min. after stress and decreased significantly 6 hr. after stress. Cetraxate treatment increased NO synthase activity throughout the experiment in rats with or without stress treatment. Water immersion stress decreased all PGs detected, *i.e.*, 6-keto-PGF_{1a}, PGF_{2a}, PGE_2 and PGD_2. Cetraxate prevented stress-induced decreases in PG contents. L-NMMA showed no significant effect on PG contents. Cetraxate increased gastric mucosal blood flow significantly and L-NMMA cancelled out cetraxate-induced increase in blood flow.*Conclusions.* The pharmacological efficacy of anti-ulcer drugs such as cetraxate might be attributable to the enhancement of NO synthase activity resulting in an increase in gastric mucosal blood flow.

"P P 38 0876"P 38 0876**Novel Evaluation Method for Drug Induced Gastropathy Using Endoscopic Sprayed Powder Drug Delivery System (IV)T. Hoshino,**

*T. Kishi, K. Abiko, K. Nakazawa, H. Nabana, M. Nunamo, K. Kusakari, M. Ishida

St. Marianna University School of Medicine, Kawasaki, Japan*Aim:* Previously, we have reported that administration of powdered drugs using an endoscopic compressed air drug delivery system technique was useful for the investigation of direct effects of drugs on the gastric mucosa, and demonstrated the direct irritant action of anti-inflammatory drugs. In this study, the direct irritant actions of antibiotics powder studied in canine gastric mucosa using this technique.*Methods:* 2.5 mg/kg of powder drugs were administered at target sites (about 10 mm { f}) on the gastric mucosa of five dogs by endoscopically, followed by observation of changes in the character of the gastric mucosa after 24 hours.*Results:* Minocycline hydrochloride induced mucosal lesions were limited to the target site of gastric mucosa in all dogs. However, no lesions was observed at any other site. Amoxicillin 2/5 dogs (40%) induced superficial gastritis at the antrum, but did not appear to spray sites. Erythromycin did not induced mucosal lesions. The control study of powdered NaCl produced gastric mucosal lesion at the site of administration in all dogs. No lesions were induced by lactose.*Conclusions:* We could observe the experimental gastric mucosal lesion at the target site of the gastric mucosa by an administration of a small amount of powdered drugs via an endoscope. Minocycline hydrochloride induced direct irritant action on the gastric mucosa. Amoxicillin and erythromycin did not induce direct mucosal lesions.

"P P 38 0877"P 38 0877**Gastroprotective Properties of Aminosugar Glucosamine and its Derivates**

*I.A. Zupanets, V.P. Chernych, V.V. Propisnova

Department of Clinical Pharmacy, Department of Organic Chemistry, Ukranian Academy of Pharmacy, Kharkov, UkraineDuring the last 5–7 years aminosugar glucosamine has been attracting the research workers close attention, as it is an integral element of biological membranes and, included in composition of mixed biopolymers and, being a natural metabolite of human organism, is absolutely harmless. In the field of gastroenterology there's an opportunity of appliment for glucosamine, conditioned by existence of target-organs — stomach in the mucus of which its own glucosamine of neutral glycoproteides is contained, according the data of the literature. In the course of experiments and clinical testing we proved the sudden lowering of endogenous glucosamine in target-organs in pathology of gastrointestinal tract. In the connection of above mentioned material the suggestion about the efficiency of glucosamine in gastric ulcer desease was brought up.The experiments were held on white rats of Wistar line. Gastric ulcer desease was induced by combined intragastric putting of prednyzolon and 80% aethylic spiritus. This model gives the 100% development of gastric ulcer affections of stomach in control animals. The antiulcer activity of the substances was valued at the following features: the ulcer area, the percentage of animals with ulcer, ulceral index. Besides that the contents of endogenous glucosamine was studied in blood serum and gastric tissue. During the experiment, the following substances were studied: glucosamine hydrochloride, N-acetylglucosamine, glucosamine acid, glucosamine pentaacetas, glucosamine disulfatis (""SIGMA"", USA), and the original substances, that are the oxalic acid derivates: oxaglucamine with one molecula of glucosamine and dioxaglucamine with two moleculas of glucosamine. The studied substances were putting on before 1 hour of ulcer modeling and 3 hours after of ulcer modeling per os.Experiments that were made shows the gastroprotective properties of all studied substances. The highest antiulcer activity had glucosamine hydrochloride and it synthetic derivates, that lowered the ulcer index in 10, 5 and 30 times, respectively, in comparison with the control group. The contents of endogenous glucosamine in blood serum and gastric mucosa restored to the level of intact rats under the influence of above mentioned substances. Received data makes it possible to propose glucosamine hydrochloride, oxaglucamine, dioxaglucamine for the further investigation on antiulceral activity in order to clinical using. }" "Gastroprotective Properties of Aminosugar Glucosamine and its Derivates"

"P P 38 0878"P 38 0878**Involvement of Endogenous Nitric Oxide in the Gastroprotective Activity of Ebrotidine in Rats**

*D. Palop, L. Conejo, A. Sacrist\'e1n, J.A. Ortiz

Department of Pharmacology, Centro de Investigation Grupo Ferrer, Barcelona, SpainEbrotidine is a novel H_2-receptor antagonist with marked antisecretory potency which affords a remarkable gastroprotective activity against ethanol. In a previous study, we demonstrated that the administration of N-nitro-L-arginine methyl ester (L-NAME), inhibitor of nitric-oxide synthase (NOS), antagonized significantly the gastroprotective activity of ebrotidine. The aim of this study was to investigate the influence of L-arginine and D-arginine on the antagonism exerted by L-NAME in the gastroprotective action of ebrotidine. Two groups of male SD rats received saline (i.v.) 10 min prior to ebrotidine (100 mg/kg i.g.) or the vehicle, while two other groups were given L-NAME (10 mg/kg i.v.) instead of saline under the same conditions. Then, other two groups of rats received L-arginine (200 mg/kg i.v.) or D-arginine (200 mg/kg i.v.) immediately prior to L-NAME and 10 min before ebrotidine. Thirty minutes after ebrotidine or the vehicle all the groups were administered with 100% ethanol (1 ml/rat i.g.) and after 60 min they were sacrified. Results showed that mucosal damage in the control group in the absence and in the presence of L-NAME was 78.06 – 4.28 mm and 143.71 – 8.61 mm respectively. The lesion inhibition rate was 85% for ebrotidine in the absence of L-NAME. Pretreatment with L-NAME reduced the inhibition rate of ebrotidine to 24%. Finally, L-arginine, natural substrate for NOS, counteracted the reduction in the gastroprotective action of ebrotidine caused by L-NAME, the lesion inhibition rate being 69%, while D-arginine was ineffective and the inhibition afforded by ebrotidine was only 14%. Our findings indicate that nitric oxide plays a crucial role in the gastroprotective activity of ebrotidine. Hormones and receptors: Molecular biology }"

"P P 38 0879"P 38 0879**Neural Mechanisms and Gastroduodenal Resistances to Saline Flow Activated by Acute Blood Volume Expansion in Anaesthetized RatsJ.R.V. Gra\'e7a, D.I.M. Cavalcante, F. de A.A. Gondim, G.R. Oliveira, M.C.V. R\'eago, H.M.P. Alencar,**

*F.H. Rola

Department of Physiology and Pharmacology, Federal University of Cear\'e1, BrazilAcute blood volume expansion increases the gastroduodenal resistance to the flow of saline in rats (Xavier-Neto, J. *et al* Gut, 34, 235, 1990). In this study, we searched out the possible gastroduodenal site(s) of resistance and neural mechanisms involved on the phenomenon. Four gut circuits were prepared (gastroduodenal, gastric, pyloric and duodenal) and perfused under barostatically controled pressure (4 cm H_2O) on male Wistar rats (n = 64, 200–300 g). Perfusion flow rates did not change in time control euvolaemic animals. Blood volume expansion (i.v. Ringer-bicarbonate infusion, 1 ml/min up to a 5% of body weight) reduced perfusion rate in gastroduodenal (10.3 – 0.5 to 7.6 – 0.6 ml/min – $p < 0.05$), pyloric (9.0 – 0.6 to 5.6 – 1.2 ml/min – $p < 0.05$), duodenal (10.8 – 0.4 to 8.0 – 0.6 ml/min – $p < 0.05$), but not in gastric circuit (11.9 – 0.4 to 10.4 – 0.6 ml/min – $p > 0.05$). The threshold for blood volume expansion effect for gastroduodenal flow was 4% of b.w., 2% for duodenal and 3% for pyloric flow reduction. Mean arterial pressure was not modified, but central venous pressure levels increased ($p < 0.05$). Yohimbine (3 mg/kg) and prazosin (1 mg/kg) blocked expansion effect on duodenal but not in the pyloric circuit. Atropine (0.5 mg/kg), was ineffective. The results show that blood volume expansion increases gastroduodenal resistance(s) to the flow of liquid in rat; pylorus and duodenum are two important sites of resistance and yohimbine and prazosin (alpha blockade) abolished the phenomenon, but not atropine. Coupled to decreased intestinal absorption and increased secretion rates (Duffy, *et al Gastroenterology,* 75: 413–8, 1979), these modifications on gastroduodenal flow may work as a mechanism to warrant liquid volume homeostasis.*Financial support:* CNPq, CAPES-PET, UFC e UNIMED-Ce. "P P 38 0880"P 38 0880**Diet-Induced Changes of Rat Gastric Muscle Responses to Acetylcholine, Caerulein and Cholecystokinin. An In Vitro Study**

*V. Leray, G. Shi, S. Bruley des Varannes, C. Cherbut, J.P. Galmiche

Human Nutrition Research Center, INSERM and INRA, Nantes, FranceThe influence of long-term modifications (i.e. adaptation) of diet on gastrointestinal motility is not well known. In rats, preliminary studies from our laboratory indicated that gastric emptying is delayed after 3 weeks of feeding with low protein diet. We hypothesized that this adaptation could result from changes in the smooth muscle responses to neuromediators. Consequently, we tested the effects of acetylcholine (Ach), caerulein and cholecystokinin (CCK) on fundic and antral contractility of rats chronically adapted to high and low protein diets.*Methods.* Wistar rats (n = 36, final weight: 330–350 g) were adapted during 21 days to two isocaloric diets. A group was fed with a high protein diet (56%), and the other one with a low protein diet (9%). All the rats were compared with control rats fed with standard diet containing 18% of protein (n = 12). Contraction of antrum and fundus longitudinal muscle segments, bathed in Krebs solution, was recorded by a force transducer in response to different doses of Ach (10$^{\{ -}$9} to 10$^{\{ -}$3} mol/L), caerulein (10$^{\{ -}$11} to 3.7 {\'b4} 10$^{\{ -}$8} mol/L) and CCK (10$^{\{ -}$12} to 10$^{\{ -}$6} mol/L). Results were expressed as means – SEM and compared to control by unpaired Student's t test.*Results.* High protein diet did not affect responses to Ach, caerulein or CCK. In contrast, after low protein diet fundic response to Ach (10$^{\{ -}$3} mol/L) significantly decreased: 85.6 – 6.9 g/g of fresh tissue *vs* 111.1 – 5.5 g/g of fresh tissue (control rats), $p < 0.02$. By contrast, the low protein diet resulted in increased antral response to caerulein (3.7 {\'b4} 10$^{\{ -}$8} mol/l): 26.1 – 3.6 mg/mm^2 *vs* 8.9 – 4.2 mg/mm^2 (control rats), $p < 0.02$, and CCK (10$^{\{ -}$6} mol/L): 7.6 – 1.5 mg/mm^2 *vs* 3.2 – 0.8 mg/mm^2, p = 0.01.*Conclusion.* Adaptation to a low protein diet is associated with significant changes in the motor responses of gastric motility to several mediators. These results are consistent with the delayed gastric emptying previously reported in *in vivo* conditions. The mechanisms whereby this adaptation occurs should be further investigated (up- or down-regulation of receptors?). Nutrition: Nutrients and gut functionMotility, specific: Stomach }" "Diet-Induced Changes of Rat Gastric Muscle Responses to Acetylcholine, Caerulein and Cholecystokinin. An In Vitro Study"

"P P 38 0881"P 38 0881**Adaptive Cytoprotection and Adaptation to Topical Ammonia in Rat Stomach**

*P.C. Konturek[1], T. Brzozowski[2], S.J. Konturek[2], K. Sliwowski[2], J. Majka[2], R. Pajdo[2], H. Ernst[1], E.G. Hahn[1]

[1] Dept. Med. I Univ. Erlangen, Germany

[2] Inst. Physiol. Jagiell. Univ. Med. Sch. Krakow, PolandAmmonia (NH_4OH) has been proposed to play a major role in the pathogenesis of the Helicobacter pylori (Hp)-associated gastric damage but the mechanism of this damage has not been fully explained. This study was designed to examine possible adaptive cytoprotection and the adaptation of rat gastric mucosa to the irritant action of ammonia (NH_4OH). Single application of NH_4OH alone in various concentrations (15–500 mM) caused a concentration-dependent mucosal damage starting at 30 mM and reaching a maximum at 250 mM, similar to that obtained with 100% ethanol and that was accompanied by the fall in the gastric blood flow (GBF) to about 30% of the normal value. When the mucosa was exposed first to the low, non-damaging concentration (15 mM) of NH_4OH and then insulted with 100% ethanol, the extent of ethanol damage was greatly attenuated as compared to that caused by ethanol alone. This ""adaptive"" cytoprotection was accompanied by the rise in the GBF and reversed, in part, by the pretreatment with indomethacin, an inhibitor of PG-cyclooxygenase, with L-NAME, a blocker of NO-synthase or with capsaicin deactivating the sensory nerves.Damaging concentration of NH_4OH (125 mM) caused a widespread mucosal damage after first application but with repeated insults of 125 mM NH_4OH, a gradual reduction in the mucosal lesions accompanied by an enhanced mucosal cell proliferation and overexpression of epidermal growth factor (EGF) (using immunohistochemistry) and EGFmRNA (using RT-PCR) were noticed.*We conclude that:* 1) NH_4OH alone damages gastric mucosa only at concentrations exceeding that found in Hp-infected stomach, while at lower concentration acts as ""mild"" irritant to induce adaptive cytoprotection, 2) this adaptive cytoprotection appears to be mediated, in part, by endogenous PG, sensory nerves and arginine-NO dependent pathway, and 3) repeated applications of NH_4OH induce gastric adaptation probably mediated by enhanced expression of EGF and its receptors and by an increased mucosal cell proliferation. Oesophageal gastric duodenal disorders: Helicobacter PyloriHormones and receptors: Growth factors }" "Adaptive Cytoprotection and Adaptation to Topical Ammonia in Rat Stomach"

"P P 38 0882"P 38 0882**Tumour Necrosis Factor (TNF) Induces Expression of the Transcription Factor Nuclear Factor { k}B (NF{ k}B) in a Human Gastric Epithelial Cell Line**

*D.L. O'Toole, A. Long, A.M. Murphy, D.G. Weir, D. Kelleher

Department of Clinical Medicine, Trinity Centre for Health Sciences, St James' Hospital, Dublin 8, IrelandThe transcription factor, NF{ k}B, plays a major role in the regulation of inflammatory events such as secretion of cytokines, expression of adhesion molecules and potentially cell proliferation. Regulation of expression of this transcription factor appears to occur through tissue-specific mechanisms. In these experiments, we have examined regulation of NF{ k}B by tumour necrosis factor in the human gastric epithelial cell line, AGS, using an electrophoretic mobility shift assay. TNF produced detectable induction of NF{ k}B in AGS cells at a dose of 10 ng/ml. This effect was maximal at 100 ng/ml. Time-course experiments revealed that the effect was maximal at 4 hrs with subsequent reduction at 24 hrs. The protein kinase C activation PMA produced low-level induction of NF{ k}B. Lastly, hydrogen peroxide, a product of the acute inflammatory response did not induce NF{ k}B induction.These findings indicate that TNF can regulate induction of the transcription factor, NF{ k}B, in gastrin epithelial cells. As high levels of TNF are produced by gastric mononuclear cells in response to *H pylori,* this may represent a mechanism whereby the gastric immune response to *H pylori* may modulate epiethial cell function. Oesophageal gastric duodenal disorders: Helicobacter PyloriImmunology and microbiology: Inflammation }" "Tumour Necrosis Factor (TNF) Induces Expression of the Transcription Factor Nuclear Factor [kappa]B (NF[kappa]B) in a Human Gastric Epithelial Cell Line"

"P P 38 0883"P 38 0883**Overproduction of NO Retards Wound Healing by Inhibiting Cell Proliferation in a Cultured Rabbit Gastric Epithelial Cell Model**

*Tuula Kiviluoto[1], Sumio Watanabe, Miyoko Hirose, Xiang-En Wang, Nobuhiro Sato, Eero Kivilaakso[1]

[1] Dept. of Surgery, University of Helsinki, Finland

Dept. of Gastroenterology, Juntendo Univ. Sch. of Med., Tokyo, JapanDespite the wide knowledge of different physiological effects of NO in gastrointestinal tract, there are no reports on its direct effects in gastric epithelial cells. This study investigates the role of NO in wound repair on a gastric epithelial cell monolayer culture. *Methods:* Isolated rabbit gastric epithelial cells (92% surface mucous cells) were cultured in F-12 round-shaped medium, forming a complete polarized nonolayer cell sheet in 48 h. A round-shaped wound was created by mechanical denudation using rotating silicon tip. The restoration process was monitored by measuring and photographing the wound size every 12 h up to 72 h. The proliferative cells were detected by serial staining for BrdU. NO donor, sodium nitroprusside (SNP) (10{ -4}, 3 {\'b4} 10{ -5}, 10{ -5} M), and NO-synthase inhibitor, N-nitro-L-arginine methyl ester (L-NAME)(10{ -3} {\'b4} 10{ -4}, 10{ -4}) were added to the serum-free media at the time of wounding. 0 h 12 h 24 h 36 h 48 hControl 3.3 – 0.17 1.6 – 0.12 1.1 – 0.16 0.4 – 0.10 0.2 – 0.12SNP 10{ -4} 3.3 – 0.09 1.7 – 0.04 1.1 – 0.09 1.0 – 0.08* 0.9 – 0.13*SNP 10{ -5} 3.5 – 0.23 1.7 – 0.15 1.1 – 0.07 0.4 – 0.04 0.2 – 0.02L-NAME 10{ -3} 3.2 – 0.11 1.7 – 0.11 1.1 – 0.17 0.3 – 0.25 0.1 – 0.07L-NAME 10{ -4} 3.4 – 0.12 1.9 – 0.13 1.1 – 0.14 0.6 – 0.21 0.3 – 0.21*Results.* Quantitative analysis of wound repair is shown in the table (mm^2, mean – SD, n = 5, * $p < 0.01$ compared to controls): SNP inhibited wound repair in a dose dependent manner. In controls, BrdU positive cells were detected mainly at 36 h after wounding. SNP inhibited this proliferation almost totally (BrdU-labelling index 1.5 vs. 0.02%, respectively, $p < 0.01$). This inhibition war partially reversible, if SN was removed from the culture 24 h after wounding. Inhibition of endogenous NO synthesis by L-NAME had no significant effect. *Conclusion:* The data indicate that NO has no influence on the primary cell migration during wound restoration, but excess of NO retards wound healing by inhibiting cell proliferation. "P P 38 0884"P 38 0884**The Behaviour of BCL-2 Protein during Progression of Gastric Carcinoma**

*T. Starzynska, K. Marlicz, L.S. Jones, M. Bromley, P.L. Stern

Department of Gastroenterology Pomeranian Medical Academy Szczecin, Poland

Paterson Institute for Cancer Research, Manchester, UKThe bcl-2 protooncogene, located on chromosome 18, codes for a 26 Kd protein involved in inhibiting programmed cell death (apoptosis). The role of this protein in human cancer progression remains to be defined.The objective of the present study was to investigate the behaviour of bcl-2 protein during progression of gastric cancer.Immunohistochemical staining for bcl-2 protein was performed in primary gastric carcinomas of different tumour stage, from early to advanced disease (n = 62), coexisting metastases (n = 57) and in a series obtained from recurrent tumours that had progressed to more advanced stages in the following 48–60 months (n = 5). The monoclonal bcl-2 antibody and paraffin material were used.21% of gastric tumours showed positive bcl-2 staining with protein occured already in early cancer. In most patients there was coordinate expression of bcl-2 in primary carcinomas, coexisting metastases and recurrent tumours. However, in 2 patients bcl-2 protein was subsequently detected in regional lymph node metastases.The results suggest that the bcl-2 expression is an additional factor in the cascade of molecular alterations seen in gastric cancer and might contribute in some cases to the tumour promotion and in others to tumour progression. "P P 38 0885"P 38 0885**Inhibition of Migration and Proliferation by 5-Fu,CDDP and Cepharanthin Using Cultured Human Gastric Cancer Cell Line**

*R. Iwazaki, S. Watanabe, H. Misawa, K. Ohtaka, K. Ohta, Y. Ohno, M. Hirose, N. Sato

Dept. of Gastroenterology, Juntendo Univ. School of Med. Tokyo, JapanThe mechanism of cancer cell metastasis involves cell migration which might be modulated by cytoskeleton, extracellular matrix and growth factors. However, the detail mechanism of metastasis is still unclear. We recently established a new, simple and convenient model to investigate the mechanism of metastasis in vitro using cultured human gastric cancer cell line, and also analyzed directly the role of cytoskeleton. Using this model, we assessed the migration capacity of gastric cancer cell line (undifferentiated adenocarcinoma AGS, differentiated adenocarcinoma MKN28) and also assessed the inhibition of migration and proliferation by 5-FU, CDDP and cepharanthin (CE). *Methods:* Human gastric cancer cell strain, AGS, MKN28 cells (3.5 {\'b4} 10^5 cells) were inoculated into the round enclosed area (diameter, 15 mm) by silicon fence in a plastic culture dish and cultured in each F12, RPMI 1640 medium with 10% FBS. Inoculated cells formed round shaped cell sheet in 3 h and subsequently silicon fence was removed and the cancer cell migration was monitored under phase contrast microscope. The number of migrated cells in a unit area of free space was counted after 48 hr. Antineoplastic agents 5-FU,CDDP, and cepharantin as alkaloids, were added to the medium (1 to 10 \'b5M) to investigate functional and morphological changes of the cells. The cell proliferation were detected by BrdU staining. *Result:* The number of cancer cells from the edge of the cell sheet at 48 hr after the start of experiment were presented in a table. –5 5–10 10–15 15–20 20–25 mmAGSControl 497 – 36.2 310 – 61.5 267 – 54.5 249 – 45.0 220 – 40.35-FU10 \'b5 M 101 – 0** 47 – 1.4** 40 – 5.6** 33 – 3.5** 16 – 0**CDDP10 \'b5 M 95 – 16.2** 47 – 10.2** 26 – 3.6** 26 – 5.0** 17 – 8.5**CE10 \'b5 M 59 – 3.5** 47 – 12.0** 42 – 4.2** 38 – 1.4** 47 – 0.7**MKN28Control 424 – 55.1 306 – 47.3 203 – 24.7 185 – 23.5 178 – 28.35-FU10 \'b5 M 241 – 23.3* 179 – 13.4* 148 – 6.3* 116 – 14.8* 100 – 13.4*CDDP10 \'b5 M 117 – 14.8** 94 – 8.4** 95 – 5.6** 104 – 0** 84 – 13.4*CE10 \'b5 M 184 – 34.6** 126 – 44.5* 110 – 27.5* 98 – 9.1** 114 – 26.1Data: mean – SD, n = 4, * $p < 0.05$, ** $p < 0.01$, mm: distance from the edge of cell sheetCancer cells (AGS,MKN28) were inoculated to round-shaped sheet spread concentrically over time due to migration. In controls, the number of cells in the nearest area from the edge of the round cell sheet was each 2.26, 2.38 time higher than that taken at the region 20 to 25 mm from the edge of the cell sheet. There were no differences in migrated cell number between AGS and MKN28. Spontaneous cell migration and proliferation were significantly inhibited by 5-FU, CDDP and cepharantin in both cell lines in a dose-dependent manner. The inhibited cell proliferation which was assessed by BrdU staining. *Conclusion:* Present results demonstrated that 5-FU, CDDP and cepharantin suppressed the capacity of cancer cells to metastasize. "P P 38 0886"P 38 0886**Expression of Autocrine Motility Factor Receptor and Its Relationship to Progression and Prognosis in Human Gastric Cancer**

*Y. Hirono[1], S. Fushida[1], G. Nishimura[1], Y. Yoneruma[1], K. Miwa[1], I. Miyazaki[1], A. Raz[2]

[1] Second Dept. of Surgery, Kanazawa University, Kanazawa, Japan

[2] Tumor progression and Metastasis, Karmanos Cancer Institute, Detroit, MI, USAAutocrine motility factor (AMF) is a cytokine which is produced and secreted by cancer cells and which stimulates both random and directed cell migration through binding to its receptor, a 78 kD cell surface glycoprotein (gp78-AMF receptor). Recent studies have demonstrated that increased expression of gp78 is correlated with a high incidence of recurrence and decreased survival of patients with colorectal cancer and bladder cancer. We retrospectively examined the expression of gp78 in tumor specimens from patients with primary gastric cancer and its relationship to clinicopathological factors.*Materials and Methods:* Using a monoclonal antibody against gp78 (3F3A), an immunohistochemical study of expression of AMF receptor was performed in formalin-fixed paraffin-embedded tissue sections from 221 primary gastric cancers, who were diagnosed and treated at the Department of Surgery II, Kanazawa University, during 1986 to 1991. Immunohistochemical study was performed with the labelled streptavidin biotin method.*Results:* One hundred twenty five out of 221 tumors (56.6%) expressed the AMF receptor gp78. There was not a significant association between gp78 expression and histological type or liver metastasis. Expression of gp78 was associated with macroscopic type, lymphatic invasion, venous invasion, lymph node metastasis, and peritoneal metastasis. In addition, positive rate of gp78 expression significantly raised according to increased grade of tumor penetration or histopathological stage. Patients with gp78 expression had a significantly poor prognosis than those without gp78 expression in primary gastric cancer ($p < 0.001$). To be confined to stage II and III, only gp78 expression had a significant relationship to survival ($p < 0.05$).*Conclusions:* Increased gp78 expression is correlated with tumor invasion, metastasis, and poor prognosis in primary gastric cancer. This result indicates that AMF receptor plays an important role in progression of human gastric cancer. "P P 38 0887"P 38 0887**Expression of bcl-2 Protein in Gastric Cancer and Its Relationship to Prognosis**

*S. Fushida, E. Bando, Y. Yonemura, K. Taniguchi, T. Fujimura, Y. Hirono, K. Miwa, I. Miyazaki

Second Department of Surgery, Kanazawa University School of Medicine, Kanazawa, Japan*Introduction:* The function of bcl-2 is known to prolong cell survival by preventing the onset of programmed cell death or apoptosis. Overexpression of bcl-2 gene has been found in variety of human malignancies. Here we examined the association between bcl-2 status and prognostic parameters in gastric cancer.*Materials and Methods:* A total of 118 primary gastric cancer specimens embedded in paraffin were used in the present study. Using an anti bcl-2 monoclonal antibody we analyzed immunohistochemically its expression.*Results:* bcl-2 immunoreactivity was detected in 21 cases (18%) and its tissue status was closely associated with tumor size and peritoneal dissemination. In addition, a positive bcl-2 immunoreaction was found to be significantly associated with shorter overall survival. Especially, in the group of patients without stage Ia and IVb, the prognosis of patients with bcl-2 positive tumors was significantly poorer than that of patients with bcl-2 negative tumors ($p < 0.001$).*Conclusion:* These results suggest that immunohistochemical staining for bcl-2 may be useful in evaluating metastatic potential and prognosis in gastric cancer. "P P 39 0901"P 39 0901**Palliativ Treatment of Malignant Duodenal Obstruction by Self Expanding Metal Stents Inserted through a Percutaneous Endoscopic Gastrostomy**

*U. Rosenstock, A. Schulte-Bockholt, S. Clemens, B. Pleger, A. Hofmann, M. Keymling

II. Med. Klinik, Klinikum Meiningen, GermanyMetal stents as palliativ therapy for esophageal and biliary malignant stenosis are well established. For malignant duodenal outlet obstruction bypass surgery is often performed, but results are poor. Metall stents in these patients are difficult to insert, because the delivery systems available, designed for stent placement in the esophagus, are often too short to insert the stent safely into the pylorus. We here report three patients with advanced antral carcinoma invading the duodenum, in whom surgery was thought to be inappropriate and a wall stent was inserted into duodenum through a PEG.*Material and Methods:* 3 patients with with gastric adenocarcinoma invading the duodenum (2 male, 1 female; 86, 80 and 75 years) who had gastric retention due to the outlet obstruction where treated as follows: After Midazolam sedation or in general anesthesia a 15 Fr. standard gastric pull through percutaneous endoscopic gastrostomy (PEG standard gastral; Fresenius, Germany) was inserted into the stomach. Under fluoroscopic and gastroscopic control a guide wire (Terumo, Japan) was passed into the duodenum and a 7 Fr. ERCP catheter was placed over it. The guide wire was removed and a stiffer guide was placed into the duodenum through the catheter, which was then removed. The wall stent assembly (Wall stent A-V Shunt, uncovered stainless steel, 10 cm usable length, 12 Fr. introducer, 16 mm diameter expanded, 100 mm length; Schneider, Switzerland) was then introduced over the guide wire into the duodenum and released. The expansion of the wall stent was then observed radiologically and endoscopically and it was possible to pass an endoscope through the stent.*Results:* In all three patients stent placement was possible within 30 minutes without complications, the patient was able to be fed a liquid diet or via PEG and the patients were satisfied with the achieved improvement of their quality of life. Survival was 32 and 40 weeks, and the third patient is alive 10 weeks after the stent placement. In one patient cholestasis developed due to liver metastasis and an ERCP was performed through the metall mesh in the duodenum.*Discussion:* Metall stents inserted into the duodenum for malignant outlet obstruction provide effective palliation of patients symptoms and are an alternative to surgery in elderly and high risk patients with uncurable GI malignancies. Because the delivery systems of the available metall stents are not suitable for placement into the pylorus due to their length, placement via a PEG makes it possible to insert these stents and furthermore also allows the delivery of nutrients in these patients who's food intake is often reduced by insufficient oral intake. "P P 39 0904"P 39 0904**Gastric Polyps after Stomach SurgeryC. Spiliadis, V. Vamvakousis, V. Ntelis, A. Konstantinidis, V. Balatsos,**

*K. Paraskeva, Z. Manika, C. Spiliades, N. Skandalis

Gastroenterology Department, General Hospital of Athens*Aim:* To study the incidence of gastric polyps in patients who have undergone stomach surgery.*Patients-Methods:* We retrospectively studied the records of 504 patients with a history of gastric surgery who underwent esophagogastroduodenoscopy (EGD) during the nine year period 1986–1994. These were 296 female and 208 male. The type of surgery was as follows: Billroth II 292 patients, Billroth I 78 patients, gastroenterostomy 134 patients. The indication for EGD were atypical epigastric disturbances in 243 patients, epigastric pain in 192 patients and anemia in 69 patients. The presence, histologic nature and location of gastric polyps at the time of EGD was assessed. These were compared to 16307 patients who underwent EGD during the same time period but had no history of prior surgery of the stomach.*Results:* A total of 46 gastric polyps were found in 30 out of 504 patients with history of gastric surgery, an incidence of 5.9%. By contrast only 474 polyps were found in 253 out of 16307 patients without history of surgery, an incidence of 1.5%. This difference was statistically significant ($p < 0.001$). On histological examination 42 of the polyps from operated patients were hyperplastic (91.3%) and 4 were inflammatory (8.7%). With regard to location 38 out of the 46 polyps (82.6%) were at the anastomotic margin.*Conclusion:* Gastric polyps appear with increased frequency in patients after gastric surgery, the majority are hyperplastic by histology and the most common site is the anastomotic margin. Endoscopy, specific: Stomach, duodenumEndoscopy, general: Instrumentation, diagnosis }" "Gastric Polyps after Stomach Surgery"

"P P 39 0906"P 39 0906**Open Access ^{13}C-Urea Breath Tests (OA^{13}C-UBT): Comparisons with and Impact on Open Access Endoscopy**

*P. Moayyedi, A. Zilles, M. Clough, E. Heminborough, D.M. Chalmers, A.T.R. Axon

Centre for Digestive Diseases, Leeds General Infirmary, Great George Street, Leeds, LS1 3EX, UK*Introduction:* We have recently introduced an OA^{13}C-UBT service to GPs. Patients < 40 years with dyspepsia were eligible and were given a ^{13}C-UBT at the LGI. *H pylori* positive patients are given eradication therapy and a repeat ^{13}C-UBT 2 months later. *H pylori* negative patients are referred back to their GP. We assessed patient satisfaction with this service and it's impact on referral to open access endoscopy (OAE). *Methods:* Patients completed an anonymous questionnaire grading their satisfaction with the service on a 5 point Likert scale. Referral patterns to the OA^{13}C-UBT and OAE services in patients < 40 years were evaluated retrospectively. *Results:* 251 patients < 40 years have attended the OA^{13}C-UBT service. 88/251 (35%) were *H pylori* positive. Patients attending the OA^{13}C-UBT service were similar to those attending for OAE in terms of gender, smoking history and alcohol intake but had more severe dyspepsia scores (15.8 7.6 vs. 12.6 6.7 $p < 0.001$). 145 patients completed a satisfaction questionnaire. 86% stated the service was very good, 10% good and 3% found the service satisfactory. In Aug-94 to Apr-95 321/926 OAE were performed in patients < 40 years old. In Aug-95 to Apr-96 (after the introduction of the OA^{13}C-UBT) this fell to 237/924 OAE – a 35% reduction (95% CI = 30–39% reduction: $p < 0.001$) in endoscopies in patients < 40 years old. Only 6 patients referred for an OA^{13}C-UBT have subsequently been referred for endoscopy (all *H pylori* negative). *Conclusions:* Patients are satisfied with the OA^{13}C-UBT service and it has reduced endoscopy referral. [4] Department of Surgery, College of Medicine, National Taiwan University, Taipei, Taiwan

[5] Institute of Epidemiology, College of Public Health, National Taiwan University, Taipei, TaiwanWe investigate whether the genetic alterations of several oncogenes and tumor suppressor genes could be correlated with the two histologic subtype, the diffuse and intestinal types of gastric carconoma (GC).In 60 patients with GC, the overexpression of mutant p53 and c-erbB-2 oncoproteins was studied using immunohistochemical stains. Mutations of p15 and p16 tumor suppressor genes were assessed by polymerase chain reaction, Southern blotting, and direct DNA sequencing.Overexpression of c-erbB-2 and p53 was found in 21 (35.0%) and 27 (45.0%) patients, respectively. Overexpression of the c-erbB-2 oncoprotein was more common in the intestinal type (15/32) and the advanced stage (19/45) of GC. Similarly, p53 overexpression was more frequently found in the intestinal type (19/32) and the advanced stage (24/45) of GC. Homozygous deletions of p16 in exon 1 were found in 6 patients. Neither point mutations of p16 nor alterations of p15 were detected. The frequency of alterations of p53, c-erbB-2, and p16 was not related to sex and *H. pylori* infection. No correlation of genetic changes between any two genes was observed.Alterations of p15 and p16 genes play a limited role in GC. Overexpression of c-erbB-2 and p53 is frequently encountered in the intestinal type advanced GC. The association between genetic alterations and histologic subtypes supports the notion that a distinct pathogenesis exists in different histologic subtypes. *K. Taniguchi[1], Y. Yonemura[1], N. Nojima[1], T. Kawamura[1], S. Kinami[1], S. Fushida[1], T. Fujimura[1], G. Nishimura[1], K. Miwa[1], I. Miyazaki[1], Y. Endo[2], T. Sasaki[2]

[1] Second Department of Surgery, School of Medicine, Kanazawa University, Kanazawa, Japan

[2] Experimental Therapeutics Cancer Research Institute, Kanazawa University, Kanazawa, Japan*Background:* The hepatocyte growth factor receptor (c-MET), autocrine motility factor receptor (AMFR) and urokinase-type plasminogen activator receptor (UPAR) are known to play an important role in tumor cell migration, invasion and metastasis. We have studied simultaneous overexpression of these genes in human gastric carcinoma.*Methods:* we examined immunohistochemically the relationship between tissue status of c-MET, AMFR and UPAR and clinicopathological parameters of 103 gastric carcinomas using resected primary tumor embedded in paraffin.*Results:* Among 103 cases, 44 (46%) cases showed overexpression of c-MET. AMFR and UPAR immunoreactivity was observed in 38 (37%) and 46 (47%) cases. Carcinomas were classified according to Borrmann classification. The all three genes were expressed in 1 case (3%) of early tumors, in no (0%) of localized tumors (Borrmann 1, 2), in 16 cases (39%) of infiltrating tumors (Borrmann 3, 4). Especially, in 13 cases (68%) of Borrmann 4 tumors, this occurrence was significantly higher compared with other macroscopic type ($p < 0.01$). The incidence of overexpression of three genes was also closely associated with lymph node metastasis and peritoneal dissemination. In addition, the overexpression of three or two genes were relevant to lymphatic invasion and microscopic type.*Conclusion:* These results suggest that simultaneous overexpression of c-MET, AMFR and UPAR may be correlated with the progression and invasion of gastric carcinoma, especially biological nature of Borrmann 4 type carcinoma. Oncology, general: Molecular biology, geneticsOncology, specific: Stomach }" "Simultaneous Expression of Hepatocyte Growth Factor Receptor (C-MET), Autocrine Motility Factor Receptor (AMFR) and Urokinase-Type Plasminogen Activator Receptor (UPAR) in Gastric Carcinoma. -Especial"

"P P 40 0911"P 40 0911**Immunohistochemical Investigation of Staining Development and Staining Intensity of Immunoreactivity of Sialyl-Tn Antigen in Human Gastric Cancer**

*T. Okuda, M. Onda, Y. Ozawa, T. Honjou, Y. Sumiyama

Third Department of Surgery, School of Medicine, Toho University, Tokyo, JapanA cell surface sugar chain antigen, sialyl Tn (STN), in gastric cancer lesions was immunohistochemically stained for measurement of staining development (positive area) and staining intensity (positive stain), to investigate its relationships to clinicopathological factors and assess its clinical significance as a tumor-related antigen. *Materials and methods* We studied 200 gastric cancer lesions, resected surgically in our department with preoperative STN data available. Thin sections of paraffin-embedded lesions fixed in 10% buffered formalin were immunochemically stained according to the streptoavidin-biotin (SAB) method. The biological examination was measured in Otsuka Assay Laboratory by RIA. Positive areas and positive stains developed after immunological staining of STN were analyzed with a BECTON-DICKINSON CAS-200 image cytometer. *Results* Intestinal metaplasia in the non-carcinomatous gastric mucosa was positive in immunological staining for STN, while normal gastric mucosa was not stained at all. STN staining was predominantly apical or intraluminal, with the cell surface facing the gland cavity and the extracellularly secreted substance stained. We also observed staining development of cytoplasmic type with additional staining in the cytoplasm. The incidence of STN-staining-positive regions was significantly higher in well differentiated tumors, which was also the case with positive area and positive stain. Both positive area and positive stain increased significantly with increased degree of the depth of invasion and stage progression. These values increased in cases with liver, peritoneal and lymphonode metastasis. They also correlated well with serum STN. *Conclusion* We conclude that the positive area and positive stain for STN antigen in the gastric cancer tissue are closely correlated with clinicopathological factors and reflect the degree of clinical progression, suggestive of its clinical significance as a tumor-related antigen. "P P 40 0915"P 40 0915**Molecular Mechanisms of the Formation of Peritoneal Dissemination from Gastric Cancer**

*Y. Yonemura, K. Taniguchi, T. Kawamura, N. Nojima, T. Fujimura, I. Miyazaki, Y. Endou, T. Sasaki

Surgery II, School of Medicine, Kanazawa University, Kanazawa, Japan*Purpose*A new animal model by the i.p inoculation of highly metastatic gastric cancer cell line MKN-45-P was developed, and the specific genes having a great role in the formation of peritoneal dissemination was identified.*Methods*MKN-45-P was established from a gastric cancer cell line of MKN-45 by the progressive growing of the intraperitoneal passages. By a specific detection method of metastasized human tumor cells in nude mice using PCR, a human { b}-globin-related sequence in the DNA from various parts of the peritoneum was specifically amplified and detected by gel electrophoresis and by a specific nucleotide probe. A novel *ex vivo* co-culture system using human greater omentum was developed. The differences of the expressions of metastasis related genes (MMP 2/9, uPA, uPAR, AMFR, met, erbB-2, CD-44, Integrin subunits) between MKN-45 and MKN-45-P were examined by RT-PCR.*Results*Greater omentum showed a strong signal of human { b}-globin gene from the 1st day and the signals gradually increased. The signals in the gonadal fat, mesentery and ovarium could be weakly detected on the 1st day, transiently decreased on the 3rd day, and then increased from 7th day. In the diaphragm, and abdominal wall, signals could be detected from the 7th day. In contrast, small intestine and colon did not show any human { b}-globin signals. MKN-45-P cells were found to adhere on the naked areas of the submesothelial connective tissue. In *ex vivo* culture system, cancer cells adhered only to the naked area of the submesothelial basement membrane. The expressions of integrin { a}2 and { a}3 subunits in MKN-45-P were extremely elevated than those in MKN-45. Integrin { b}1 subunit expression did not change during the intraperitoneal passages. Anti-{ b}1 integrin subunit antibody significantly inhibited the adherent number of MKN-45-P on the omentum. Other metastasis associated genes were not overexpressed in MKN-45-P. From these results, we conclude that the major metastatic rout of the peritoneum may be through milky spots and by the adhesion to the naked connective tissue exposed after shrinkage of the mesothelial cells. In this process, VLA 2 and VLA 3 have a great role in the formation of the peritoneal dissemination from gastric cancer. "P P 40 0916"P 40 0916**The Change and Reflection of Curative Operation for Gastric Cancer Patients in every Decade**

*Y. Mikami, M. Mikami, H. Kawasima, R. Hada, H. Suzuki, Y. Sugiyama, Y. Ebina, M. Konn

Department of Surgery II Hirosaki University School of Medicine, Hirosaki, 036, Japan*Aim:* The operative curative cases for gastric cancer patients past 34 years were divided into three groups by every decade. The clinical characteristics and the results of each group was retrospectively analyzed. We also examined whether extension of gastric cancer surgery could improve its prognosis.*Patients and method:* The 1238 patients with primary gastric cancer except residual or multiple cancer were divided into the following three groups: the former era: 367 patients from April, 1961 to December, 1974 (the former); the mid era: 377 patients from January, 1975 to December, 1984 (the mid); the late era: 494 patients from January, 1985 to December, 1994 (the late). In the general rules of gastric cancer study in Japan, the curative operation included \lquoterelative non-curative, relative curative or absolute curative resection\rquote. The Kaplan-Meyer method was used for calculation of the postoperative survival rate, and the Chi-square test and generalized Wilcoxon test were used to determine the statistical significance of difference.*Result:* The change of each era in stage and curability was that the rate of stage I and absolute curative resection increased, however, that of stage III or IV and relative non-curative resection was decrement. Ten (or five) year survival rate of curative resection in \lquotethe late\rquote was 79.8 (83.3)%. There was no significant difference between \lquotethe late\rquote and \lquotethe mid\rquote in 76.5 (78.8)% although that of \lquotethe former\rquote was significantly low in 44.2 (56.5)%. When 10 (5) year survival rate by grade or number of lymph node metastasis was examined, there was a significant better prognosis in patients with n0 lymph node metastasis (n0) and the n2 group positive between in \lquotethe former\rquote and in \lquotethe mid\rquote or \lquotethe late\rquote ($p = 0.02$). It means that in stage III there was a significant difference between them. There was no difference in survival time by the number of lymph node metastasis between in \lquotethe mid\rquote and in \lquotethe late\rquote. In the group of n0 lymphnode metastasis and of 4 to 9 lymph node metastasis positive, the survival rate in \lquotethe former\rquote was significantly worse than that in \lquotethe mid\rquote ($p < 0.001$) or that in \lquotethe late\rquote ($p = 0.03$). In the group of metastasis positive more than 10, there was no significant difference between both eras.*Conclusion:* There was a marked prolongation of the survival time in the curative surgery with R2-dissection after \lquotethe mid\rquote in comparison with R1 lymphnode dissection in \lquotethe former\rquote although the ratio of the gastric cancer patients in early stage has been relatively increasing. R3-dissection for the advanced gastric cancer patients was introduced into the operation after 1985 aiming at better prognosis in the curative surgery, however, there was no significant improvement of prognosis. Lymphnode dissection up to R2 level as the standard curative surgery for the gastric cancer patients prolonged the survival time rather than R1 level. Furthermore the curative operation for lymph node metastasis with n0 or at most 4 to 9 was in good prognosis. "P P 40 0917"P 40 0917**Re-Evaluation of Surgical Therapy for the Primary Gastric Malignant Lymphoma Patients**

*Y. Mikami, M. Mikami, H. Kawasima, T. Ito, A. Murata, H. Suzuki, R. Hada, Y. Sugiyama, M. Konn

Department of Surgery II Hirosaki University School of Medicine, Hirosaki, 036, Japan*Introduction and aim* Gastric malignant lymphoma (ML) is different from the lesion of lymphnodes origin and generally localized close to the primary lesion. Recently there are increasing more reports that even chemotherapy could cure gastric ML patients in early stage. The surgical treatment was retrospectively evaluated on the basis of prognosis and clinicopathologic findings of gastric ML removed surgically. The clinicopathological findings of ML depends on the Japanese general rules for the gastric cancer study.*Patients and results* The 48 primary gastric ML patients by the end of 1995 from 1975 were analyzed. The ratio occupied in gastric malignancy of primary malignant lymphomas was 1.5%. Ten cases were histologically diagnosed as MALT lymphomas, however, two cases as only benign RLH (Reactive lymphoid hyperplasia). The ratio of sex was almost equal with 25 (M) to 23 (F). Mean age is 59-year-old. The survival time of giant rugae type, superficial type and protruded type were 100%, however, that of Borrmann 2 type 82.5% and Borrmann 3 type 44.4%. Significant difference was recognized in survival rate by macroscopic type. The correlation between lymph node metastases and prognosis was examined. Twenty one cases were alive in 24 cases with n0, and, three cases were dead and 8 alive in 11 cases with lymphnode metastases more than n2-group. But 3 cases were dead in 7 cases with n1-group positive. The 5 year survival rate was 90.9% in n0 group, 76.9% in the cases more than n2-group positive, however 64.3% in n1 group positive. The prognosis of resected ML was better than that of operated gastric cancer patients, but there was no correlation in the grade of lymphnode metastasis. Histopathology of 29 cases was diffuse type and that of 5 follicular type. The six cases with diffuse large cell type were dead in 16. All of MALT lymphoma patients was alive, so this disease was in good prognosis and may present macroscopical superficial type. The 5 year survival rate of follicular type and MALT lymphoma was 100%, and that of diffuse type was 74.7. There were no dead cases with stage I and III. There were five patients dead in 9 cases with stage II, 4 dead in 5 with stage IV. Five year survival rate in stage I and III was 100%, 66.7% in stage II and 33.3% in stage IV, but wasn't correlated. When 5 year survival rate in surgical curability according to the general rules of the gastric cancer study was examined, the ratio in curability C was 42.5%, 81.5% in B and 95.8% in A. Each survival curve by the curability was significantly graded.*Conclusion* The overall 5 year survival rate of resected gastric ML was 76%. Operative curability A and shallow invasion of ML up to proper muscle (mp) were decisive factors to regulate the prognosis. Histological classification is important factors predicting prognosis. The patients in low grade ML such as follicular type or MALT lymphoma after operation was all alive in extremely good prognosis. As for MALT lymphoma and ML in early stage such as I or II of Japanese classification for gastric cancer, surgical treatment should be first performed. "P P 40 0918"P 40 0918**High-Dose 5-FU/FA in Advanced Gastric Cancer**

*T. Berns[1], P. Preusser[1], J. Kocik[1], J. Wilke[2]

[1] Klinik und Poliklinik f\'fcr Allgemeine Chirurgie der Westf\'e4lischen Wilhelms-Universit\'e4t M\'fcnster

[2] Tumorzentrum EssenThe palliative treatment of advanced gastric cancer has been proven before in 5 studies. Palliative chemotherapy has a better effect in comparison to best supportive care according to survival and quality of life. 5-FU, folinic acid (FA) and Cisplatinum (C) are active drugs in advanced gastric cancer with a different mode of action. The continuous infusion of 5-FU with folinic acid for 24 h once weekly determines a higher dose intensity and less toxicity as 5-FU bolus therapy. Patients with advanced gastric cancer were treated in a desease orientated phase II study.*Treatment:* FA 500 mg/m^2, 2 h inf. d 1, 8, 15, 22, 29, 36, 5-FU 2000 mg/m^2, 24 h inf. d 1, 8, 15, 22, 29, 36, C 50 mg/m^2, 1 h inf. d 1, 15, 29, Repetition at d 50. Depending on response and toxicity up to 6 cycles were planned.*Pts.-characteristics:* male/female 29/21, age (years 51 (24–72), measurable/evaluable dis. 33/17, locally advanced disease (LAD) 8, M1 42, 1–2 TU-sites 32, > 2 TU-sites 18, malignant ascites 14*Results:* CR 4 (8%), PR 21 (42%), maR 8 (16%), CR + PR + maR 33 (66%), stable disease 14 (28%), progression 2 (4%), toxicity related death 1 (2%)CR + PR + maR in: LAD 63%, M1 67%, 1–2 TU-sites 69%, > 2 TU-sites 61%, malignant ascites 63%Median remission duration 8 mts, median survival time all pts. 14 mts, M1 13 mts.*Toxicity:* (grade): leucocytopenia 2 26%, \'be 9%, nausea/vomiting 2 35%, \'be 4%, mucositis/stomatitis 2 7%, \'be 0%, alopecia 2 10%, \'be 2%*Conclusions:* HD-FU/FA/C with cont. inf. is an active regimen for advanced gastric cancer with lower toxicities as regimen with FU-bolus-infusion. Other regimens with cont. inf. proven are ECF and ELFI with comparable results. Because of these good results these forms of therapy with 5-FU in continuous infusion seem to be good alternatives for future trials. Therefore this regimen is one arm in a new randomised phase II study of the EORTC and AIO. Oncology, general: TherapyOncology, specific: Stomach }" "High-Dose 5-FU/FA in Advanced Gastric Cancer"

"P P 40 0919"P 40 0919**Development of a Neuroendocrine Carcinoma and Multifocal Carcinoidosis in the Stomach of a Patient with Chronic Atrophic Gastritis**

*R. Eissele, E. Weihe, R. Arnold

Depts. of Gastroenterology and Anatomy, Philipps University, Marburg, GermanyMultifocal carcinoids (MC) are benign neoplasias of the stomach and frequently occur in patients with chronic atrophic gastritis (CAG). Hitherto, no association has been reported between CAG and neuroendocrine carcinomas (NC). We present a case report of a patient with the coincidence of MC and NC in the oxyntic stomach. Furthermore, the cellular origin of both types of tumors were investigated histologically. *Case report:* A 63 year old female patient was admitted to the hospital with upper GI bleeing. An ulcerous tumor in the oxyntic mucosa was found by endoscopy and histologically a NC (G3) was diagnosed. In addition, biopsies of several small polyps in the oxyntic mucosa revealed multiple carcinoids with infiltration of the submucosal layer. In the remaining oxyntic mucosa argyrophil cell hyperplasia (diffuse, linear, micronodular) and severe CAG (type-A) were present. H. pylori infection was absent. Numerous metastasis of the NC could be found in the liver and the net. Serum gastrin levels exceeded 2000 pg/ml. Antibodies against parietal cells and H+/K+-ATPase were detectable. *Treatment:* Local removal of the NC was necessary because of recurrent tumor bleeding. Serum gastrin levels could be suppressed to near normal values with octreotide (SMS 3 {\'b4} 200 \'b5g). Since liver metastasis progressed rapidly, chemo-embolization was performed, which resulted in a partial response. *Histological investiations:* Global endocrine markers (NSE, chromogranin-A, Grimelius silver stain) were positive in both types of tumors (NC and MC). Recently, the vesicular monoamine transporter 2 (VMAT2) was found be a selective marker of ECL-cells in the stomach (J Mol Neurosci 1994; 5: 150). Immunohistology with a polyclonal VMAT2 antibody showed a positive immunoreaction in the MC and the argyrophil cell hyperplasia but not in the NC and the metastasis. *Conclusion:* Neuroendocrine carcinomas and multiple carcinoids can occur simultaneously in patients with chronic atrophic gastritis and hypergastrinemia. It seems unlikely that both tumor types derive from the same cell population. "P P 40 0920"P 40 0920**Immunohistochemical Study of Laminin, Vitronectin and Tetranectin in Gastric Cancer**

*H. Kaneko, K. Miyachi, M. Namba, E. Takada, M. Sunagawa

First Department of Surgery, Dokkyo University School of Medicine Tochigi, JapanThe purpose of this study is to clarify the localization of laminin (LN), vitronectin (VN) and tetranectin (TN) in gastric cancer by means of immunohistochemistry and to make a comparison with pathological findings to determine their significance in gastric cancer invasion and metastasis. *Methods:* Sixty-two cases of gastric cancer patients were examined. Tissue specimens were obtained from both normal and cancer tissue of resected stomach. These specimens were examined by immunohistochemical staining. *Results:* Positive staining of LN was observed in basement membrane. It was observed in 24 cases of 29 (82.8%) in differentiated type of adenocarcinomas and in 8 of 33 (24.2%) cases in undifferentiated type of adenocarcinomas. Positive staining ratio for LN was significantly higher in differentiated type than undifferentiated type. Immunoreactivity for VN was observed in internal elastic membrane of blood vessel. The relationship between venous invasion and positive rate of VN staining was examined. Positive staining for VN was observed in 1 of 11 (9.1%) in invasive ({ -}) group and 22 of 51 (43.1%) cases in invasive (+) group. VN positivity was significantly high in the cases with venous invasion. TN staining was observed in the cytoplasm of cancer cells. In differentiated type, the cytoplasmic positive staining was observed in 23 of 29 (79.3%) cases, while in undifferentiated type, positive staining was observed in only 12 of 33 (38.4%) cases. TN positivity was significantly high in the cases of differentiated type. *Conclusion:* The results suggested that positivity of LN and TN were related with histological differentiation of gastric cancer and VN staining was related with venous invasion. "P P 40 0921"P 40 0921**Adenosine Deaminase Activity in Patients with the Intestinal Type of Gastric Carcinoma**

*Z. Namiot, J. Stasiewicz, A. Namiot, A. Kemona, M. Kralisz, J. G\'f3rski

Department of Gastroenterology, J. Sniadecki's Regional Hospital and Departments of Physiology and Pathomorphology, Medical Academy, Bialystok, PolandOur previous study has shown that adenosine deaminase activity is lower in the intestinal than diffuse type of gastric carcinoma (Cancer Lett., 1994). The proposed explanation for that was the rate of tumor growth.The aim of the present study was to analyse only those patients who had recognized the intestinal type of gastric carcinoma either in the non-operated or partially resected stomach.40 subjects were included in the study; 26 partially gastrectomized and 14 non-operated. Adenosine deaminase activity was determined in the gastric cancer and surrounding unchanged gastric mucosa by means of ammonia liberated from the substrate during 10-min. incubation.We have found that the enzyme activity in the advanced gastric cancer (ascites, metastases) of non-operated stomach as well as that developed in partially resected stomach due to duodenal ulcer was significantly lower than in recurrent cancer of the gastric remnant (no ascites and metastases) (36 – 18.0 and 20.9 – 17.5 vs. 75.8 – 46.8 nmol NH_3/mg of protein/min, $p < 0.05$). We have also noticed a significantly lower enzyme activity in the unchanged gastric mucosa surrounding the neoplastic lesion of non-operated stomach than in the unchanged gastric mucosa of partially resected stomach due to malignancy (57.8 – 30.2 vs. 86.5 – 30.2 nmol NH_3/mg of protein/min, $p < 0.05$).The other factors than histological type of the tumor are also involved in the regulation of adenosine deaminase activity in the gastric cancer and surrounding cancer unchanged gastric mucosa; one of them may be cancer progression. Oncology, specific: Stomach }" "Adenosine Deaminase Activity in Patients with the Intestinal Type of Gastric Carcinoma"

"P P 40 0922"P 40 0922**Early Gastric Cancer: Relapse and Prognostic Outcome**

*I. Claro, J. Mid\'f5es Correia, P. Lage, A. Suspiro, C. Chagas, R. Pinto, P. Chaves, L. Gl\'f3ria, A. Dias Pereira, C. Nobre Leit\'e3o, F. Costa Mira

Servi\'e7o de Gastrenterologia, Instituto Portugu\'eas de Oncologia, Lisbon, Portugal*Background:* Patients with Early Gastric Cancer (EGC) are known to have a good prognosis with a low rate of relapse at five years. *Aims:* To prospectively evaluate prognostic variables in a group of patients in whom curative surgery was performed for EGC between 1983–1995. *Patients and methods:* 90 patients, 48 male and 42 female with a mean age of 58.9 – 13.1 years (22–82) were included in the present study. We have analysed clinical and histopathologic features of the tumor as well as survival curves and percentage of relapses. *Results:* From a histophatologic point of view, 58 patients (64.4%) had an adenocarcinoma and 32 of them (35.6%) presented as signet ring cell carcinoma. TNM staging (UICC) in the surgical specimens was the following: T1N0M0 { -}78 (86.7%), T1N1M0 { -}10 (11.1%), T1N2M0 { -}2 (2.2%). According to the Japanese classification 13 (14.4%) tumors were type I, 8 (8.9%) type IIa, 27 (30%) type IIb, 28 (31.1%) type IIc and 14 (15.6%) type III. During a follow-up period of 52.6 – 42.9 months (1–154), 5 patients relapsed, two of them earlier than 6 months and the remaining three at 30, 43 and 59 months after surgery, respectively. Only one of these patients was re-operated. There were 18 deaths – 5 relapses, 4 peri-operative deaths and 9 patients for others causes. Rate of relapse (5.5%) was not related to histologic features although they were all N0 (TNM). Nonetheless, all these relapses occurred in patients who were operated before 1988 when an extended lymphadenectomy was not routinely performed. In all these patients the number of resected lymph nodes was lower than 5. No metachronous tumors were observed. *Conclusions:* It is possible that limited lymph node resection performed in the eighties was the main responsable for relapses observed in the present series. Therapeutic possibilities of the relapses are limited and therefore, intensive surveillance is probably not advised. [1] University of Tartu, Estonia

[2] University of Lund, Sweden

[3] IRIS, Siena, Italy*Purpose.* To evaluate the presence of antibodies to CagA protein associated with the risk of developing gastric cancer (GC) in Estonian adult population with high prevalence (87%) of H. pylori (HP) infection and to compare it with presence of antibodies to CagA in GC patients.*Subjects and Method.* 199 subjects (86 M, 113 F, median age 41) as a representative sample of adult population (1461 persons) from the South Estonian town of Karksi-Nuia and 45 patients (22 M, 23 F, median age 67) with gastric adenocarcinoma (14 in antrum, 17 in corpus or cardia, 14 in antrum & corpus; types: 17 intestinal, 8 diffuse, 20 indeterminate) operated at the Oncological Clinic in Tartu were studied. HP status was determined using serological evaluation of IgG antibodies to glycine extracted proteins of HP (NCTC11637) as reported previously (Eur. J. Gastroenterol & Hepatol. 1994, 6, 529–533). Anti-CagA IgG were determined by ELISA using a recombinant fragment of CagA antigen of HP CCUG strain (1.25 \'b5g/ml). The absorbance value 0.300 OD was taken as a cut-off level based on a study in 25 HP negative sera (histology, serology).*Results.* IgG antibodies to HP strain NCTC 11637 were revealed in 169/199 (85%) of the population, and in 41/45 (91%) of GC patients ($p > 0.05$). Anti-CagA IgG were seen in 126/199 (63%) of the population sample (in 120/169 of HP positive persons). In GC patients the prevalence of anti-CagA IgG was significantly higher, 39/45 (87%), than in the whole population ($p = 0.002$) in all age groups except 20–29-year old (76%; $p = 0.25$).*Conclusions.* Seropositivity to HP strain NCTC 11637 was similarly high in Estonian adult population and in GC patients. The prevalence of anti-CagA IgG was significantly higher in GC patients than in the population studied. In population, persons aged 20–29 with the highest prevalence of anti-CagA IgG should be given further attention with respect to cancer development. "P P 40 0924"P 40 0924**Cimetidine Might Affect Gastric Carcinogenesis in Rats Subjected to Gastrojejunostomy**

*G.S. Hortemo, H. Maartmann-Moe, O. R\'f8kke, A. Viste

Department of Surgery, the Gade Institute of pathology, University of Bergen, Haukeland Hospital, Norway*Introduction:* There is some evidence that cimetidine by immunomodulation increases survival in cancer patients. This study was performed to investigate if cimetidine reduced occurence of gastric cancer following gastrojejunostomy.*Material and methods:* Duodenogastric reflux was established by gastrojejunostomy in 132 male rats (PGV/Mol rats). Half of the animals were postoperatively for a minimum of 38 weeks given cimetidine (100 mg/kg/day) in their drinking water. The animals were killed after 52 weeks of observation and the stomach macroscopically and microscopically investigated. Blood was drawn for analysis of TNF and Il-6.*Results:* In the cimetidine fed group 39.6% (19/48) of the animals developed cancer versus 27.9% (12/43) (p = n.s.) in the control group. We found no correlation between TNF and Il-6 versus cancer and cimetidine.*Discussion:* Although not statistical significant, we found tendency towards an increased rate of cancers in the cimetidine treated group. This effect might be caused by a reduced hydrochloric acid production superimposed on a duodenogastric reflux. Evaluated by TNF and IL-6 we found no immunomodulative effect of cimetidine. Oncology, specific: Stomach }" "Cimetidine Might Affect Gastric Carcinogenesis in Rats Subjected to Gastrojejunostomy"

"P P 40 0925"P 40 0925**Gastro-Intestinal Sarcomas: Prognostic Significance of the F.N.L.C.C. Histological GradingC. Genestie[1],**

*J.-C. Sabourin[1], A. Auperin[2], Ph. Lasser[3], P. Duvillard[1]

[1] Department of Pathology, Institut Gustave Roussy, Villejuif, France

[2] Department of Medical Statistics, Institut Gustave Roussy, Villejuif, France

[3] Gastro-Intestinal Oncological Department, Institut Gustave Roussy, Villejuif, FranceThe FNCLCC (F\'e9d\'e9ration Nationale des centres de Lutte contre le Cancer) histological grading system has a well established prognostic significance when it is used on smooth tissue sarcomas. Gastro-intestinal (GI) sarcomas are rare and of uncertain behaviour. Mitosis count is the only method for pathologists to evaluate the prognosis of such tumours.The purpose of this work was to evaluate the FNCLCC grading system on a retrospective series of 19 GI sarcomas treated at the IGR Institute. There were 10 women and 9 men (mean age 51 years). The tumour was located in the stomach in 10 cases, in the small intestine in 8 cases and in the anal canal in 1 case. The treatment consisted of surgical removal of the tumour followed in 5 cases by radio or chemotherapy. Histologically, all cases were leiomyosarcomas. The average survival rate was 23 months, with a 5 year survival rate for 22%. All cases were reviewed by two pathologists and the 3 items of the FNCLCC grading system (differentiation, mitosis count, necrosis) were noted in each case.The results shows: the FNCLCC grading system has a significant prognostic value ($p = 0.03$) as well as the differentiation item and as the mitosis count item. The necrosis item has no significant value.In conclusion, this preliminary study seems to demonstrate that: (1) the FNCLCC grading system is applicable to GI sarcomas, and (2) a new grading system with only two items (differentiation & mitosis count) could be used on such tumours. "P P 41 0926"P 41 0926**Gastric Smooth Muscle Tumours (SMT): Long Term Results of Surgery in 52 PatientsD. Quinaux,**

*J.C. Vaillant, N. Dehni, S. Prevot, C. Huguet[1], R. Parc

Hospital Saint Antoine, 75012-Paris, France

[1] Centre Hospitalier Princesse Gr\'e2ce, MonacoSMT of the digestive tract are of 3 types: leimyoma (LM), leiomyosarcoma (LMS) and leiomyoblastoma (LMB). They are characterized by their rarity, a difficult diagnosis of malignancy, and therapeutic controversies concerning the extent of resection and the efficacy of chemo- and radiotherapy. We report here about the features and the results of surgery in a series of 52 gastric SMT.From 1981 to 1995, among 105 mesenchymal tumours of the digestive tract operated on in two institutions, 83 (79%) were SMT. Of those, 52 (63%) were gastric and were divided in 14 LM, 26 LMS and 12 LMB.There were 32 males and 20 females, 26 to 85 yr old (mean: 55). The mean delay between the first symptom and the diagnosis was 8 mos (0–60). The most frequent symptoms were: bleeding (41%), palpable mass (41%) and pain (38%), whereas 6 patients (pts) (12%) had no symptoms. The most frequent endoscopic findings were ulcerated (45%) and submucosal tumour (33%). The tumour could be demonstrated by ultrasound and CAT-scan of the abdomen in 27/30 and 22/22 cases, respectively. Its gastric origin was shown in 5 and 8 cases, respectively. Preoperative biopsies (n = 26) were contributive in 11 cases (42%). The mean size of the tumour was 11 cm (1–30) and was larger for LMS. The site of the tumour compared to the angulus did not differ between 3 types. In LMS, contiguous tumour spread of LMS was present in 12 pts (46%), and liver metastases and peritoneal carcinomatosis in 5 pts each. Lymph node metastases were not observed. Complete resection (elective: 45, urgent: 7) with curative intent was achieved in 44 pts (including 18 LMS). Sixteen of 17 total gastrectomies were done for LMS. Extended resections for contiguous spread were done in 14 LMS pts. One patient had only exploration. After pathologic examination of surgical specimens, there were: 16LM, 12LMB, and 24LMS divided in 24 malignant, 24 benign, and 4 intermediate prognosis SMT. Operative mortality was nil and the morbidity rate was 6%. One patient (LMS) was lost to follow-up. During a median follow-up of 6.2 yrs (n = 51), 11 cancer deaths and 4 unrelated deaths (2LM, 1LMS, 1LMB) were observed. After curative resection, 8 pts are alive free of disease (mean follow-up: 5 yrs), and 9 had relapse (mean delay: 28 mos) among whom 4 had liver resection. The mean survival after palliative resection was 1 yr. For LMS, the overall 2-, and 5-yr survival after resection of LMS were 55%, and 43% with a mean survival time of 38 mos. In 3 pts, despite an initial diagnosis of benign SMT, the appearance of distant metastases after 22, 24, and 101 mos switched the diagnosis to malignancy.A prolonged follow-up is needed after resection of so-called benign SMT since the outcome may contradict the initial diagnosis. The type of gastrectomy has to be adapted to the size and the site of the lesion. Extensive lymphadenectomy is not mandatory due to scarcity of nodal invasion. Resections extended to adjacent organs or of metastases with curative intent are worthwhile since no other efficient treatment is available. Oncology, specific: Stomach }" "Gastric Smooth Muscle Tumours (SMT): Long Term Results of Surgery in 52 Patients"

"P P 41 0927"P 41 0927**Surgical Treatment of Duodenal Adenomas in Familial Adenomatous Polyposis**

*C. Penna, N. Bataille, R. Parc

Service de Chirurgie Digestive, Hopital Saint-Antoine, Paris, FranceIn familial adenomatous polyposis (FAP) duodenal adenomas are found in 80% of patients and duodenal cancer accounts for the majority of cancer-related death after colectomy. Duodenal adenomas are not amenable to drug or conventional endoscopic treatment. In case of multiple, large, villous and severely dysplastic adenomas (stage IV disease), prophylactic measures to prevent malignant change may become necessary.The aim of this work was to assess the results of surgical treatment of stage IV duodenal polyposis in FAP.Duodenotomy and clearance of duodenal adenomatous polyps was performed 6 times in 5 patients. In no case was the polyp histology more severe than that found at endoscopy. There was 2 duodenal leaks, one which necessitate reoperation. After a mean follow-up of 53 months (36–72) duodenal adenomas recurred in all patients and 4 had stage IV disease.Pancreatoduodenectomy with pylorus preservation and pancreatico-gastric anastomosis was performed in 7 patients. Histology of the specimens revealed 2 unsuspected duodenal carcinoma at an early stage. There was 1 pancreatic leak that was treated medically. After a mean follow-up of 33 months (9–108), 1 patient died of rectal cancer, there was no case of jejunal polyposis and the operation did not affect the bowel function.In FAP, stage IV duodenal polyposis seems to carry a high risk of malignant change. Surgical polypectomy failed to guarantee a polyp-free duodenum and carried a risk of post-operative complications. Duodenopancreatectomy had a low morbidity, revealed cancers at early stages and did not affect bowel function.In colectomized FAP patients, duodenopancreatectomy should be offered in some selected cases of stage IV duodenal polyposis. Oncology, general: Screening, preventionOncology, specific: Small bowel }" "Surgical Treatment of Duodenal Adenomas in Familial Adenomatous Polyposis"

"P P 41 0928"P 41 0928**Role of Surgery in Localized Primary Gastric Lymphoma (PGL): Long Term Results of a Prospective Multicenter Study of 45 Patients**

*J.C. Vaillant, A. Ruskon\'e9-Fourmestraux, P. &AEllig;gerter, B. Gayet, J.C. Rambaud, P. Valleur, R. Parc

Groupe d'Etude des Lymphomes Digestifs, Fondation Fran\'e7aise de Canc\'e9rologie Digestive, France*Aim:* The role of surgery in the treatment of PGL is still controversial and must be discussed according to the grade of malignancy and the chemosensiblity. Most series are retrospective and mix both high-grade (HG) and low-grade (LG) lymphomas. We aimed to study prospectively a therapeutic strategy based on surgical tumour reduction followed by chemotherapy (CT) adapted to the histological subtype and the radicality of the resection in localized PGL.*Patients and Methods:* As part of the multicenter study of the french cooperative group collecting gastrointestinal tract lymphomas, localized PGL, either HG (large cells) or LG (small cells), were studied. Primary surgical resection was recommended whenever possible for HG and when reasonable for LG. At this time, total gastrectomy was not systematically mandatory. Surgery was followed, or, when not performed replaced by CT: COP regimen in LG and AVmCP after radical (R) resection or M-BACOP after non radical (NR) resection in HG.*Results:* From 1984 to 1990, among 54 PGL, we enrolled 45 localized PGL: M/F = 27/18; median age 54.2 yrs; 18 LG and 27 HG; stages I_E, (n = 30) and II_E, (n = 15). The median interval between the first symptom and diagnosis was 4.6 mos. Endoscopic biopsies permitted final diagnosis in 78% of cases. Diagnosis was made at emergency laparotomy in 2 patients (pts). There were no differences between the 2 grades of malignancy concerning: site, size, depth of wall invasion, and nodal involvement. Primary laparotomy was undertaken in 40 pts (13LG, 27HG). Thirty five had tumour resection (11LG, 24 HG) either R (4LG, 19HG) or NR (7LG, 5HG). Exclusive CT was given to 10 pts (7LG, 3HG). One anastomotic leak and one jejunal perforation were observed during M-BACOP after NR surgery. The median follow-up was 7 yrs. Among 18 LG, 6 pts did not achieve complete remission (CR) after initial treatment (5 exclusive COP, 1 NR resection). For these pts, CR was achieved after secondary R resection (3), or radiotherapy (2), and second-line CT (1). Among the 12 LG who achieved CR after initial treatment, we observed 1 locoregional relapse (initially NR) after 9.7 yrs and 1 unrelated death. Thus, 16 pts (89%) with LG are alive free of disease (of whom 2 exclusive COP, 6 R, 2 radiotherapy). In HG, 24 pts (89%) achieved CR after initial treatment and 3 pts undergoing laparotomy without resection died within 10 mos despite CT. The overall 5-yr survival (product-limit method) was 91.1% for all pts, 94.1% for LG, and 89% for HG. R resection was associated with better survival rate either in the whole population (p = 0.04) or in HG (100% when R, p = 0.01).*Conclusion:* In localized PGL, initial CR and long term disease-free survival were obtained each time primary or secondary radical surgery were performed in association with CT. Compared to surgery, the roles of radiotherapy in LG or exclusive CT in HG should be evaluated in larger randomized trials. Oncology, specific: StomachOncology, specific: Lymphoma }"

"P P 41 0929"P 41 0929**Blood Gastrin Level, Stomach Stump Acid-Formating and Evacuatory Functions in Patients with Postgastroresectional Disease (PGRD): Aspects of Pathogenesis**

*O.O. Abrahamovych, M.P. Pavlovsky, E.S. Abrahamovych, M.O. Abrahamovych

Medical Institute, Lviv, UkraineThe aim of the investigation was to study blood gastrin level, stomach stump acid-formating function (SSAFF) and evacuatory function (EF) of esophagogastrointestinal system (EGIS) and their role in PGRD pathogenesis in long terms (5–33 years) after gastric resection. The study included 241 patients (pts) with PGRD: 91.2% men, 8.8% women; age from 28 to 73 years; 29.4% after Billroth-I, 70.6% – Billroth-II; 17.6% – resection of 1/2, 73.5% – 2/3, 8.8% – 3/4 stomach. Radioimmunologic study of basal blood gastrin concentration, intragastral pH-metry of stomach stump, radiographic and radionuclide evacuatory esophagogastrointestinography (RNEGIG) were performed to all the pts. The results show that in 77.3% pts basal free HCL was absent; normochlorhydry – in 9.7%. The acid-formating function after submaximal histamine stimulation was characterized by absence of free HCL in 33% pts and hyperchlorhydry in 16.4% pts. The correlation between SSAFF and gastrin level was weak (r = 0.27). Before stimulation achlorhydry was evident in the majority of cases and didn't depend on basal gastrin level; after stimulation the pts with normal HCL-diminate. 55.0% pts with hypergastrinemia were with hyper – (15%) or normochlorhydry (40%), only 10% – with achlorhydry. Hyperchlorhydry was established in 14.3% pts with normal gastrin level, achlorhydry – in 38.1%. 16.2% pts with low gastrin had high HCL concentration. Complicated mechanisms of SSAFF disorders can be connected with disorders of parietal cells function, second-rate messengers, especially Ca2+ and Ca-poliphosphoinosid system, ensuring gastrin action through alfa-adrenoreceptors. Evacuatory function of EGIS was significantly accelerated ($p < 0.001$): the time of evacuation beginning 1.9 – 0.5 min, the duration of half-evacuation 27.4 – 4.3 min, overall evacuation 62.0 – 6.3 min. Gastroesophageal reflux was diagnosed in 79.4% pts, duodeno (jejuno) gastral reflux – in 97.1%, duodenostasis – in 76.5% pts. The results showed also that RNEGIG hasn't advantages in comparison with radiographic method in study of evacuation from stomach stump. Nevertheless, it was much more useful to reveal refluxes and duodenostasis.*Conclusions:* The established changes indicate the importance of gastrin metabolism, stomach stump acid-formation and evacuatory function disorders in the pathogenesis of postgastroresectional disease, which must be taken into account in diagnostics, evaluation treatment results by secretory and evacuatory regulating drugs, and prognosis.

"P P 41 0930"P 41 0930**Prevalence of H. Pylori Infection in Subtotal Gastrectomy and Vagotomy**

*M. Tuncer, C. Uras, A. Dobrucali, I. Yurdakul, F. Hamsioglu, A. \'c7elik, S. Tuncer, N. Bagatur, E. Oktay

Gastroenterology Department of Cerrahpasa Medical Faculty of Istanbul University, Istanbul, Turkey*Purpose:* We investigated the prevalence of H. pylori infection in patients with gastrectomy plus piloroplasty, for the treatment of peptic ulcer disease.*Methods:* Fifty-five patients age: 48–72, mean: 60 yrs; 90% male) with subtotal gastrectomy and vagotomy were investigated: Billroth I (n = 32), Billroth II (n = 12) and vagotomy plus piloroplasty (n = 11). At endoscopy biopsy specimens were taken from fundus and both sides of anastomosis (H&E stain, Gram stain and culture).*Results:* The percentage of H. pylori infection was 48% in patients with.Billroth I; Billroth II: 42%; and vagotomy + pilorplasty: 92%, No differences were found between both reconstruction procedures. However, differences ($p < 0.01$) were obtained when comparing percentages of H. pylori infection between subtotal gastrectomy and vagotomy. In gastrectomized infected patients, H. pylori was detected in 76% of cases at gastric fundus, and in 96% of biopsies form the anastomotic region ($p < 0.05$).*In Conclusion:* The prevalence of H. pylori infection was low (44%) in patients with subtotal gastrectomy and no differences were observed between both reconstruction procedures. H. pylori infection after vagotomy plus piloroplasty was significantly higher (92%). In gastrectomized infected patients, H. pylori was detected with a higher frequency at anastomotic region, than in biopsies obtained from the gastric fundus. "P P 41 0931"P 41 0931**Cathecolamines in Gastric Juice and Tissues before and after Vagotomy**

*A.V. Shaposhnikov, K.M. Islam, Y.S. Sidorenko

Rostov Research Oncology Institute, Rostov-on-Don, RussiaThe purpose of the study was to reveal influence of vagotomy on local concentration of cathecholamines in gastric tissues and in nonstimulated basal juice.*Methods.* The levels of epinephrine (E), norepinephrine (NE) dopa (DO) and dopamine (DE) were investigated in gastric juice of 10 patients with duodenal ulcer disease before and at 2nd, 14th and 30th days after combined posterior truncal with anterior seromuscular vagotomy by Taylor. The same substances were also investigated in gastric tissues of 50 white rats at 1st, 2nd, 7th and 14th days after the same operations. For identification of cathecholamines were used spectrofluorometry method.The results of the study of patients gastric juice are given below (in ng/ml). Before After operation (days) 2 14 30Epinephrine 0.39 +{ -} 0.1 +{ -} 0.2 +{ -} 0.3 +{ -} 0.03 0.03 0.02 0.09Norepinephrine 2.5 +{ -} 1.5 +{ -} 1.8 +{ -} 1.9 +{ -} 0.05 0.02 0.02 0.02Dopa 1.3 +{ -} 2.4 +{ -} 2.7 +{ -} 2.1 +{ -} 0.02 0.03 0.03 0.01DOpamine 4.5 +{ -} 6.0 +{ -} 9.1 +{ -} 7.5 +{ -} 0.03 0.03 0.04 0.05Concentrations of E and NE decreased by 0.8–3.9 times, especially at 2nd and 14th day after operation. On the contrary, levels of DO and DE were increased. The same pic-pure was revealed in gastric tissues of experimental rats.*Conclusion:* Vagotomy leads to activation of sympathetic nerve system with local liberation of cathecholamines in gastric tissues and then into gastric juice. Low levels of E and NE may be explained by negative feedback mechanism of their production. These changes may influence at gastric motility and regional hemodynamics after vagotomy. "P P 41 0932"P 41 0932**Systemic Vascular Changes in Early Dumping Syndrome**

*J. Vecht[1], M. Winter[1], P. Chang[2], C.B.H.W. Lamers[1], A.A.M. Masclee[1]

[1] Dept. of Gastroenterology, University Hospital Leiden, The Netherlands

[2] Dept. of Nephrology, University Hospital Leiden, The NetherlandsEarly dumping after gastric surgery has been attributed to systemic hypovolemia caused by redistribution of blood into the splanchnic vascular bed. The somatostatin analogue octreotide effectively prevents the occurrence of dumping symptoms. We have explored the systemic hemodynamic changes in early dumping that occur after provocation with glucose. Six patients with proven early dumping (partial gastrectomy n = 6, age 31–75 yr) 6 patients after gastric surgery (partial gastrectomy n = 6, age 35–70 yr) without dumping (disease-controls) and 6 healthy volunteers (n = 6, age 25–64 yr) were studied on two separate occasions. After an overnight fast 50 g glucose was given orally 15 min after s.c. administration of 25 \'b5g octreotide or placebo in random order. Heart rate (HR) was measured and mean arterial blood pressure (MAP) was monitored by Dynamap; forearm blood flow (FBF) and forearm vascular resistance (FVR) were measured with plethysmography.Results are presented as peak increments after glucose provocation relative to basal values (* $p < 0.05$). Dumping Disease controls Healthy controls{ D}HR (bpm) 17 – 4* 1 – 2 { -}3 – 2FBF (%) 141 – 19* 107 – 14 90 – 14FVR (%) 75 – 8* 85 – 11 107 – 17Baseline MAP was 92 – 7, 91 – 4 and 82 – 2 mmHg resp.; MAP after glucose provocation was 89 – 5, 86 – 2 and 79 – 2 mmHg resp. Octreotide prevented the increases in HR and FBF and decrease in FVR after dumping provocation. After glucose provocation patients with early dumping showed increases in HR and FBF, however without a drop in blood pressure, indicating acute peripheral vasodilatation. *Conclusions:* In patients with early dumping a glucose challenge does not induce a hypovolemic state as assumed previously but causes a peripheral vasodilatation and hyperdynamic state. Octreotide completely prevents these changes. Intestinal disorders: Splanchnic circulation, ischemiaNutrition: Nutrients and gut functionIntestinal disorders, absorption: Pathophysiology of diarrhea }" "Systemic Vascular Changes in Early Dumping Syndrome"

"P P 42 0933"P 42 0933**Lactulose/Mannitol (L/M) Test: Clinical Usefulness in Crohn's Disease (CD) Patients**

*V. Di Leo, R. D'Inc\'e0, C. Venturi, M. Minotto, A. Ferronato, G.C. Sturniolo

Division of Gastroenterology, University of Padua, ItalyWe studied intestinal permeability in 181 CD patients (78 female, mean age 42 years, range 15–72), 52 with ileal disease and 54 with colonic disease, in order to determine its clinical significance. In each patient L/M test, CDAI and acute phase reactive proteins (APRP: ESR, RCP and acid-alpha1 glicoprotein) were evaluated. L/M test was considered positive when > 0.030, clinical remission when CDAI < 150 and inflammatory activity (IA) present when 2 of the 3 APRP were above the normal value.CD patients underwent 450 evaluations: clinical remission was found in 340 occasions, while CDAI > 150 was found in 110. IA was present in 73% of the occasions of clinical activity. L/M test was positive in 72% of active ileal or ileocolonic disease and in 37% of active colonic CD, with a 63% overall concordance of positive L/M test and CDAI > 150. Sensitivity, specificity, PPV and NPV of L/M test and IA with respect to CDAI are as follows: L/M test IASensitivity 62% 72%Specificity 78% 87%PPV 49% 64%NPV 87% 87%No statistical significant difference was found between the two parameters. L/M test together with IA increased sensitivity to 85% and NPV to 94%.In our study, L/M test performed as IA in defining clinical activity. It may improve the evaluation of the clinical status of CD patients and could be proposed as an useful adjunctive and/or alternative to biochemical parameters, being less invasive and expensive. Intestinal disorders: IBD diagnosis, monitoring }" "Lactulose/Mannitol (L/M) Test: Clinical Usefulness in Crohn's Disease (CD) Patients"

"P P 42 0934"P 42 0934**Assessment of Clinical Disease Activity in Crohn's Disease Patients with IleostomyS. Acciuffi,**

*S. Ghosh, A. Ferguson

Gastrointestinal Unit, Department of Medicine, University of Edinburgh, Western General Hospital, Edinburgh EH4 2XU, Scotland*Purpose:* Assessment of clinical disease activity is difficult in patients with Crohn's disease (CD) and ileostomy. The CDAI has not been validated in such patients and generally these patients are excluded from therapeutic trials of new drugs. In CD patients without ileostomy, whole gut lavage fluid (WGLF) IgG concentration correlates very well with CDAI. Other markers of gut protein loss such as WGLF albumin and { a}$_1$-antitrypsin also correlate with CDAI. We therefore aimed to perform a prospective study in CD patients with ileostomy, comparing a modified CDAI with WGLF IgG, albumin and { a}$_1$-antitrypsin concentrations.*Methods:* 10 patients with Crohn's disease and ileostomy were recruited. Their symptoms comprised of a combination of increased stomal output, abdominal pain, and tiredness. They prospectively filled in a CDAI diary card for 7 days prior to having a whole gut lavage with a polyethylene-glycol electrolyte solution (Klean-Prep, Norgine UK). In their CDAI diary, the patients recorded the number of times they emptied their bags, instead of the number of loose motions. The clear fluid obtained after complete gut cleansing was collected, filtered, processed by the addition of protease inhibitors and stored at { -}70\'b0C. IgG was assayed by an ELISA, and albumin and { a}$_1$-antitrypsin by immunoturbimetric assay.*Results:* The CDAI in the 10 patients ranged from 67 to 468. Seven patients had CDAI > 150. WGLF IgG ranged from 0 to 40 \'b5g/mL. There was no correlation between the modified CDAI and WGLF IgG concentrations (r = 0.06; p = NS). Similarly, WGLF albumin (r = { -}0.15; p = NS) and { a}$_1$-antitrypsin (r = 0.37; p = NS) did not correlate with the modified CDAI. An experienced physician's global assessment and decision as to active or inactive disease corresponded to WGLF IgG concentration (and generally to albumin and { a}$_1$-antitrypsin concentrations) but not to modified CDAI.*Conclusion:* A modified CDAI is not a valid instrument in assessing clinical disease activity in patients with CD and ileostomy. Objective markers of mucosal inflammation using the technique of WGLF may be useful in these patients. Intestinal disorders: IBD diagnosis, monitoring }" "Assessment of Clinical Disease Activity in Crohn's Disease Patients with Ileostomy"

"P P 42 0935"P 42 0935**Cyclosporine Therapy and Fistula Closure in Crohns Disease**

*J. O'Neill, S. Pathmakanthan, J. Goh, S. Costello, P. MacMathuna, R. O'Connell, J. Crowe, J. Lennon

Gastrointestinal Unit, Mater Hospital, Dublin, IrelandUse of Cyclosporine A (CyA) has been proposed in Fistulous Crohns disease but its efficacy is unclear. We report use of CyA in 8 patients with active fistulous Crohns disease who had failed standard therapy.The 8 patients (1 M 7 F) with a mean age of 29 (range 24–45) had a total of 10 fistulas (5 perianal, 2 rectovaginal, 1 enterocutaneous, 1 enterovaginal and 1 enterocolic). All patients continued maintenance medical therapy of salicylates, azathioprine and oral steroids which were not altered during treatment period. Intravenous CyA was commenced at a dose of 4 mg/kg/day for up to 10 days. 7 patients were subsequently maintained on oral CyA commencing at a dose of 8 mg/kg/day with doses adjusted to reach trough levels of 150 ng/ml. Oral therapy was continued for a mean 12 weeks (range 4–32) with serum CyA and renal indices monitored weekly.Of the 8 patients, 7 showed an initial response after a mean of 4 days as defined by improvement of Crohns Disease Activity Index (median decrease 48, 7/7 < 150); symptomatic improvement evidenced by decreased discharge from fistula, decrease in perifistular inflammation and improvement in patient comfort. One patient required immediate fistulotomy after no response to intravenous CyA was observed. Two patients (25%) had a sustained response while on oral CyA, one of whom has maintained a partial response after discontinuing CyA for 6 months. Fistulotomy was delayed in 5/8 patients and performed electively after a mean 5.2 months (range 2–24). Follow up (mean 8 months) in these patients has shown no recurrence.Mild side effects were observed in 4 patients including diarrhoea (1), nausea and vomiting (1) and hirsutism (2). No renal impairment was noted and no patient was withdrawn from therapy due to side effects.Temporary remission of fistula activity through CyA therapy allows for subsequent elective fistulotomy in more favourable conditions.

University of L'Aquila, L'Aquila, Italy

Gruppo Italiano per lo Studio del Colon e del Retto (GISC)*It is commonly accepted that the most accurate diagnosis of post-operative recurrence is obtained by endoscopy or barium meal. The availability of laboratory parameters or clinical indeces would be of great value for this purpose. Aim of this study was therefore to assess the ability of CDAI score and some laboratory parameters to detect recurrence. The study was performed in 110 pts who entered the Italian multicentre randomised controlled trial on the effectiveness of 5-ASA in the prevention of post-operative endoscopic recurrence (R. Caprilli and GISC. Aliment Pharmacol Ther 1994; 8: 35–43).ESR, Hb, Ht, RBC, WBC, iron, proteins, albumin, and CDAI score were assessed at 6, 12, 24, and 36 months after surgery. At the same intervals colon-ileoscopy was performed in all pts. The association between these variables and the presence of recurrence, diagnosed by colon-ileoscopy was analysed. The mean value of each laboratory variable and CDAI was compared in the two groups of pts, those with and those without recurrence. *Results:* None of the laboratory parameters was significantly different between the two groups. The mean value of CDAI score tended to be higher in pts with endoscopic recurrence compared to those without recurrence, but the difference was significative only at six months of follow-up: 119 – 98 (\'b1SD) and 75 – 62 respectively ($t = 2.66$; $p < 0.05$) although remaining in the normal range. In order to achieve a better evaluation of CDAI ability to discriminate between the two groups of pts, it was performed the ROC (Receiver Operating Characteristic) analysis, that plots the conjunctive behaviour of sensibility and specificity for each possible cut-off of CDAI score. The area under ROC curve is considered as the best index of discriminant capacity of the test (area under curve = 1.00 indicates a perfect discriminatory capacity of the test). The area under ROC curve was 0.65, indicating that CDAI is capable to disciminate pts with and without recurrence only in 65% of the cases. Considering a cut-off value of the CDAI as 150, this figure corresponds to 89% specificity and 30% sensitivity. *In conclusion* the results of this study indicate that CDAI and routine laboratory features are not of practical value in predicting recurrence. The low sensitivity of CDAI is due to the fact that about 50% of the recurrences are asymptomatic in the first years following surgery. Colonscopy remains the best method to diagnose post-operative recurrence of CD. Results of clinical trials based on CDAI to assess post-operative recurrence should be reconsidered..* G. Latella, G. [1] Divisione di Gastroenterologia, Ospedale Mauriziano, Torino, Italia

[2] Servizio di Radiologia, Ospedale S Lazzaro, Torino, Italia*Purpose* Ultrasound scanning (US) is a non-invasive method for the diagnosis and for monitoring the effects of therapy in CD. Aim of the study is to evaluate the overall accuracy of US versus clinical data, laboratory, radiology, endoscopy and surgical specimen in the detection of post-operative recurrence.*Patients and Methods* Starting from 1986, 208 US were performed in the follow-up of 92 patients operated because of Crohn's disease complications. US was made at six months and then once a year after surgery or when clinically indicated. Clinical recurrence was defined following commonly accepted criteria. Surgical recurrence was confirmed by the specimen available for patients re-operated during the follow-up. Ultrasound recurrence was defined by the presence of 1) bowel thickening (more than 5 mm) with or without 2) bowel stenosis 3) bowel dilatation.*Results* Accuracy of ultrasound Examinations Accuracy % US+ only % US{ -} %versusLaboratory recurrence 206 46 67 3.4Clinical recurrence 208 63 69 4.3Colonoscopy 62 81 14.5 4.8Radiology 54 93 3.7 3.7Re-operation 22 100 0*Accuracy:* agreement between US and any of the other methods. *US + only:* percentage of recurrence detected by US and not by the compared method. *US* { -}: percentage of recurrence seen by one of the other methods but not by US.*Discussion* US scanning is more sensitive than any other method in detecting post-operative recurrence in operated Crohn's disease. Given the low sensitivity of laboratory and clinical data US is a promising non-invasive and convenient method for detecting recurrence in the post-operative follow-up of these patients. [1] IVth Department of Medicine, Charit\'e9 Medical School, 10098 Berlin/Germany

[2] Institute of Medical Genetics, Charit\'e9 Medical School, 10098 Berlin/Germany*Purpose:* As the genetic basis of IBD is being uncovered, association studies are playing an important role in the fine mapping especially of minor risk loci. Accurate predictions of sensitivity and specificity of specific designs are of pivotal importance for the later interpretation of data. However, the theoretical basis of these studies in polygenic disorders is still incompletely understood. In order to provide guidelines for a robust and sensitive design, the properties of different strategies were evaluated using a computer simulation.*Methods:* We developed a computer program ""popsim"" (C programming language), which allows for the simulation of genetic transmission in populations up to 3 million individuals under a polygenic model (prevalence: 0.05%, $\{ 1\}_s = 20$). Non-overlapping generations and random mating were assumed. The population is propagated according to Mendelian laws, no further theoretical assumptions are made.*Results:* Estimates on the persistence of initial associations originating from founder populations were obtained as a function of the recombination fraction { Q}. Only tightly linked markers were found to become fixed on rare disease alleles and thus could persist over several hundred generations. In the presence of population heterogeneity, case-control studies were found to be susceptible to false positive results, whereas parental control designs performed well under these conditions, although at a slightly lower sensitivity.*Conclusion: Choice of markers:* Only makers tightly linked to suspected risk genes, e. g. intragenic polymorphisms, should be considered for association studies ($\{ Q\} \ll 0.5$ cM).*Choice of study design:* Unless the sample can be shown to be homogenous, only a parental control design should be chosen and evaluated by one of the appropriate tests (TDT: ""transimission-disequlibrium-test"", or HRR: ""haplotype relative risk"") Intestinal disorders: IBD, etiology and geneticsIntestinal disorders: IBD, basicImmunology and microbiology: Inflammation }" "Association Studies in Crohns Disease: Approaches in Choosing the Right Design"

"P P 42 0940"P 42 0940**Impressive Histologic Improvement after TNF Antibody (cA2) Therapy in Active Crohn's Disease**

*F.J. Baert, G.R. D'Haens, K. Geboes[1], N. Ectors[1], M. Peeters, P.J. Rutgeerts

Dep of Gastroenterology, University of Leuven, Belgium

[1] Dep of Pathology, University of Leuven, BelgiumTNF-{ a} is an important mediator of inflammation in Crohn's disease (CD). We studied the histologic effects of cA2 therapy in a detailed and systematic way. Biopsies of 13 patients with active CD before and 4 weeks after a single placebo or cA2 infusion (5, 10 or 20 mg/kg) were reviewed by one blinded pathologist. A minimum of six biopsies were taken per patient at every occasion in the most inflamed areas. If ulcers were present, biopsies were taken in the vicinity. Seven pts had colitis, four ileocolitis and two ileitis only. Assessment of the severity of inflammation was based on epithelial alterations (architecture and cytology), inflammatory changes (granulocyte, lymphocyte and plasma cell infiltration), the presence of ulcerations and/or granulomas and the number of biopsies affected. A score from 0–3 was given for each item according to severity. The minimal score was 0, the maximum score 16. In addition to classical H&E, immunohistochemical stainings for HLA – Dr, CD68 (activated macrophages), ICAM-1 and LFA-1 were performed using an indirect immunoperoxydase method.*Results:* The mean total activity score in the cA2 treated group dropped from 6.7 (2–12) to 3.0 (0–7) in ileitis and from 7.6 (2–12) to 3.0 (0–8) in colitis compared to 11 (10–12) before and 9 (6–12) after in placebo pts. The changes in the inflammatory components of the score were most pronounced. The enhanced epithelial HLA-Dr and endothelial ICAM-1 and numbers of CD68+ monocytes and LFA-1+ lymphocytes observed at week 0 markedly decreased along with the classic components of inflammation in CD pts treated with cA2 but not in the placebo group.*Conclusion:* Monoclonal TNF-{ a} antibody therapy markedly improves histologic disease activity in active Crohn's ileitis and colitis. The improvement is mainly due to a dramatic decrease of the inflammatory infiltrate parallel to a reduction of HLA-Dr expression and the number of CD68+ and LFA1+ cells, whereas the architectural changes grossly remain unchanged 4 weeks after treatment. Intestinal disorders: IBD, therapyImmunology and microbiology: Inflammation }" "Impressive Histologic Improvement after TNF Antibody (cA2) Therapy in Active Crohn's Disease"

"P P 42 0941"P 42 0941**Suppression of Bone Formation by Methylprednisolone But Not by Budesonide CIR in Active Ileocolonic Crohn's Disease**

*G. D'Haens, A. Verstraete, F. Baert, M. Peeters, R. Bouillon, P. Rutgeerts

Depts of Gastroenterology and Endocrinology, University of Leuven, BelgiumOne of the most severe long-term side effects from prolonged corticosteroid use is osteopenia with an increased fracture risk. Bone formation can be assessed by *osteocalcin,* a noncollagenous protein synthesized by osteoblasts, while bone resorption can be measured with urinary (deoxy)pyridinolines (collagen cross-links). *Aim:* to compare the effect of conventional oral glucocorticosteroids and oral Budesonide CIR (Entocort', Astra) on bone metabolism in active ileocolonic Crohn's disease (CD). *Methods:* 29 pts with active CD (CDAI > 200) were randomly treated with either methylprednisolone (MP) 32 mg/day PO for 3 weeks and then tapered by 4 mg/week (total 10 weeks) (13/29 pts), or budesonide CIR (BU) 9 mg/day PO for 10 weeks (16/29). Six pts with quiescent CD on 5-ASA were used as controls. We measured serum calcium (Ca), phosphorus (P), alkaline phosphatase (AP), osteocalcin (OC) levels and urinary (deoxy)pyridinolines before the start and at week 4 and 10 of therapy. *Results:* Neither in the MP group (n = 13, 5 M/8 F, age 39.5 – 3.3 yrs), nor in the BU group (n = 16, 4 M/12 F, age 39.3 – 3.4 yrs), any changes in serum Ca, P or AP were observed. OC, however, decreased from 50.8 – 22.1 ng/ml at w0 to 20.0 – 1.8 ng/ml at w4 (p = 0.05) and 18.1 – 1.9 ng/ml at w10 (p = 0.05) in the MP group versus from 32.0 – 23.9 ng/ml at wo to 29.6 – 4.9 ng/ml at w4 and 37.0 – 5.4 ng/ml at w10 (NS) in the BU group. OC in the control group (n = 6, 1 M/5 F, age 36.2 – 4.5 yrs) was comparable to w0 in the MP group and w0, w4 and w10 in the BU group. Urinary (deoxy)pyridinolines remained unchanged in all groups throughout the trial. *Conclusions:* Osteoblast function is suppressed with conventional steroids but not with budesonide CIR, while bone resorption appears unaffected. Topical steroids are probably safer for long-term use with regard to bone metabolism. "P P 42 0942"P 42 0942**Colorectal Cancer in Colonic Crohn's Disease — High Frequency of DNA-Aneuploidy**

*R. L\'f6fberg, R. Befrits, U. Sj\'f6kvist, P. Karl\'e9n, A \'d6st, C. Rubio, B. Tribukait, P. Rutgeerts, K. Geboes

Huddinge University Hospital, Karolinska Hospital, S\'f6der Hospital, Karolinska Institute, Stockholm, Sweden

University Hospital, Leuven, Belgium*Aim:* The risk for colorectal cancer (CRC) in colonic Crohn's disease (CD) seems to be of the same magnitude as in extensive, longstanding ulcerative colitis (UC) and colonoscopic surveillance has been advocated. Mucosal dysplasia and DNA-aneuploidy are early warning markers of malignant transformation in UC. Data are scarce concerning the occurrence of such premalignant lesions in colonic CD. This study aimed at investigating the DNA ploidy pattern in CD-patients with manifest CRC.*Methods:* Biopsies and surgical specimens from patients with colonic or ileocolonic CD who presented with CRC between 1988 and 1995, were scrutinized histologically and analysed by flow cytometry (FCM) for assessment of DNA-ploidy pattern. CRC type, site and presence of distant mucosal dysplasia/DNA-aneuploidy was determined as were patient characteristics.*Results:* 17 CRC:s in 14 patients (7 men) were analysed. Median age at diagnosis of CRC was 55 years (range 21–70) and median duration of CD was 11 years (1–45). 11 (65%) of the cancers were found proximal to the splenic flexure. DNA-aneuploidy was found in 13/17 (76%) of the cancers. Concomitant dysplasia/DNA-aneuploidy was found in 5/14 patients and preceded the finding of CRC in 3/3 patients having been subjected to prior colonoscopic surveillance.*Conclusion:* A right-side predominance of CRC in longstanding ileocolonic/colonic CD was found, and DNA-aneuploidy was a common feature. Since the findings of DNA-aneuploidy may precede the development of invasive carcinoma, inclusion of FCM analyses of colorectal biopsies may therefore be a valuable complement to assessment of dysplasia in trying to identify high-risk CD-patients prone to develop CRC within the frame of colonoscopic surveillance programs. "P P 42 0943"P 42 0943**Use of Heparin in the Treatment of Chronically Active Crohn's Disease**

*J.L. Dupas, F. Brazier, T. Yzet, J.C. Duchmann, B. Roussel, F. Iglicki

Department of Gastroenterology, University Hospital, Amiens, FranceIt has been suggested that the combination of hypercoagulable state and vasculitis may contribute to the pathogenesis of Crohn's disease (CD). Heparin, acting by its anticoagulant and immunodulatory properties, may be effective in the treatment of active inflammatory bowel diseases. *Aim:* To evaluate effects of heparin in the treatment of patients with chronically active CD who failed to respond to corticosteroid and azathioprine. *Methods:* 10 patients (6 F, 4 M; mean age 30 yrs; range 16–66) with chronically active Crohn's disease (CDAI > 200) were included in this open label study. Disease was confined to the colon in 4 patients and extended to colon and ileum in 6 patients. All patients were treated with either prednisolone 20–50 mg/d (n = 7), or prednisolone 25–35 mg/d plus azathioprine 1–2 mg/kg/d (n = 3). Doses of previous treatments were unchanged in the 3-weeks period before and during heparin therapy. Patients were administered heparin, either intravenously 3000 UI/4 hrs for 1 week then subcutaneously 2500 UI/10 kg bid for the following 1 to 3 weeks (n = 4), or subcutaneously 2500 UI/10 kg bid for 1 to 4 weeks (n = 6). All patients were clinically and biologically evaluated every week during the study then every 2 weeks after the end of heparin treatment. *Results:* Mean duration of heparin treatment was 21 days (7–28). 6/10 (60%) patients fulfilled remission criteria (CDAI < 150) and 1 patient reported significant clinical improvement ({ D}CDAI > 100) within 2 to 4 weeks; 3 patients failed to respond. The mean CDAI decreased from 304 (95% CI 239–369) before to 161 (95% CI 89–234) ($p < 0.05$) after heparin treatment. The mean C-reactive protein decreased from 82 mg/l (95% CI 38–125) before to 43 mg/l (95% CI 14–73) ($p < 0.05$) at the end of heparin treatment. After discontinuation of heparin, prednisolone tapering was resumed in 5/7 responders. All of these patients were still in remission after 3 months follow up. *Conclusions:* These results suggest that heparin may be useful in the treatment of patients with chronically active Crohn's disease who failed to respond to conventional treatments. Intestinal disorders: IBD, therapyImmunology and microbiology: Inflammation }" "Use of Heparin in the Treatment of Chronically Active Crohn's Disease"

"P P 42 0944"P 42 0944**Crohn's Colitis in Stockholm County**

*A. Lapidus, O. Bernell, G. Hellers, G. L\'f6fberg

Department of Medical and Surgical Gastroenterology and Hepatology, Huddinge University Hospital, Sweden*Background:* The annual incidence of Crohn's disease (CD) in Stockholm County increased from $1.4/10^5$ in 1955–59 to $4.6/10^5$ as mean 1970–89. The proportion of colonic disease doubled during the study period from 14% to 32% as mean 1980–89.*Aims:* To describe the natural history of Crohn's colitis over time with regard to incidence, extent at diagnosis, initial treatment, age and gender.*Material and Methods:* Retrospectively, registers for in- and outpatients were investigated for possible cases of CD according to Lennard-Jones' criteria. All patients who got the diagnosis of Crohn's colitis in 1955–89 and were residents in Stockholm County at time for diagnosis were included into the study. Data for extent of colitis at diagnosis, initial treatment, clinical course within the first year of diagnosis and time for surgery were registered.*Results:* 512 cases of Crohn's colitis were included into the study. The annual incidence of colitis increased from 0.2 in 1955–59 to 1.6 in 1985–89 with an increasing proportion of distal colonic disease during the latter study period (23% vs. 33% $p < 0.05$). Clinical remission was achieved within one year after diagnosis in 75% of the cases. 78% had at least one relapse. The risk for surgery within the first year of diagnosis decreased from 25% to 14% during the study period. The overall risk for surgery was 52%. The cumulative risk for surgery was higher among the patients with chronic continuous disease compared to those who achieved remission within the first year. Patients with distal colonic disease run a lower risk for surgery compared to the other patients. Except for a higher propensity for distal disease among those aged > 60 years at diagnosis, there were no differences according to age or gender.*Conclusion:* While the incidence of Crohn's disease remained stable during the last 20 years, the incidence of Crohn's colitis (particularly distal disease) increased. Half of the patients with colitis required surgery with highest risk for those why chronic continuous disease and lowest risk for those with distal disease. Clinical practice: Epidemiology (non cancer)Intestinal disorders: IBD, basic }" "Crohn's Colitis in Stockholm County"

"P P 42 0945"P 42 0945**Therapy of Refractory Crohn's Disease by 7S-ImmunoglobulinsCh. Schmidt**

Medizinische Poliklinik, Bonn, GermanyAbout 10 to 20% of patients with inflammatory bowel disease are resistant to usual drug therapy. As immunoregulatory disturbances play an important role in pathophysiology we tried to improve the situation in therapy-resistant cases of Crohn's Disease by additional intravenous application of 7S-immunoglubulins.In an open cotrolled trial 20 patients with therapy-resistant Crohn's Disease received 10 g 7S-immunoglobulin (Venimmun’) per day for 10 days. Mean duration of illness was 10.3 – 1.4 years and 9 patients had one or more operations in the past. Mean CDAI was for more than 6 months higher than 200. Patients received prednisolone (16.4 – 4.0 mg/die) and 5- ASA (2.2 – 0.3 g/die). Before and after therapy CDAI, laboratory data and immunoglobulins were checked.Activity index (CDAI) decreased during therapy from 201 – 17.7 to 99 – 8.6 ($p < 0.0001$). Frequency of diarrhia was reduced from 4.5 – 0.8 to 1.8 – 0.3 ($p < 0.001$). At the end of therapy CDAI was in all patients lower than 150. In 9 patients CDAI decreased by more than 100 points. Follow up was done in 11 patients up to 6 months. 73% of patients were in remission even after a period of 6 months. BSR increased during therapy from 27.9 – 5.2 to 37.6 – 7.8 mm/h ($p < 0.03$). Leucocytes decreased and lymphocytes increased (13.3 – 3.0 vs. 23.3 – 2.8; $p < 0.008$). Alpha-2-globulin decreased by 1.8% ($p < 0.01$). IgG, IgG1, IgG2, IgG3, IgG4 and even IgA increased significantly during therapy ($p < 0.001$). Flow cytometry of perpheral lymphocytes showed different results with increasing B-lymphocytes and decreasing CD4-cells.Additional therapy of refractory Crohn's Disease by 7S-immunoglobulins was effective in our study. Immunoregulatory effects seem to be responsible for successful immunoglobulin therapy in Crohn's Disease. However mechanisms of acting of immunoglobulins are not identified. Further investigations are necessary. Immunology and microbiology: Inflammation }" "Therapy of Refractory Crohn's Disease by 7S-Immunoglobulins"

"P P 42 0946"P 42 0946**A Prospective Randomized Trial in Active Crohn's Disease Comparing Prednisolone, a Polymeric Diet and a Polymeric Diet Plus Prednisolon**

*G.J. Mantzaris, E. Archavlis, P. Amberiadis, D. Kourtessas, G. Triantafyllou

A' Gastroenterology Clinic, Evangelismos Hospital, Athens, GreecePolymeric diets may be useful in active Crohn's disease but their effects in conjunction with steroids have not been adequately studied. In this prospective trial, 35 patients were randomized to receive intravenous prednisolon (0.75 mg/kg of body weight) (group I, N = 11), a polymeric diet [Nutrison High Energy, 1.5 l/day delivered via a nasoduodenal tube (group II, N = 11), or the previously described polymeric diet plus prednisolon (group III, N = 13). All patients received mesalazine (Salofalk 500 mg three times a day). The three treatment groups were similar with respect to sex, age, age at disease onset, anatomic site of disease, disease activity (Crohn's Disease Activity Index, CDAI), nutritional status, and previous medical or surgical treatments. Seven patients (two in groups II, III and three in group I) were undergoing the first attack of disease. Three patients had complicated disease (one in group I, two in group III). A satisfactory response to treatment was defined by a fall of CDAI by 100 points or below 150. After 4 weeks of treatment, there were 8 responders in group I (72.7%), 5 responders in group II (45.5%) and 10 responders (77%) in group III; differences were not significant. However, patients who received prednisolon (groups I and III) showed a better response than did patients who received only a polymeric diet whereas the combination therapy increased only marginally the effect of prednisolone. In addition, the time to response was significantly higher in patients receiving polymeric diet alone (18.9 – 3.5 days *versus* 5.9 – 2.1 days in group I and 5.2 – 1.5 days in group III, $p < 0.01$). Polymeric diet did not increased body weight or other indices of nutritional status. Irrespective of treatment, all patients undergoing the first attack of disease were responders. Of the six failures in group II, 4 patients responded to prednisolone. Thus, polymeric diets should not be considered as a substitute for steroids at least in patients presenting with a relapse of Crohn's disease. Intestinal disorders: IBD, therapy }" "A Prospective Randomized Trial in Active Crohn's Disease Comparing Prednisolone, a Polymeric Diet and a Polymeric Diet Plus Prednisolon"

"P P 42 0947"P 42 0947**Restricted T Cell Receptor V{ b} Regions in Crohn's Disease Patients Suffering from Joint Complications**

*N. L\'fcgering, T. Kucharzik, W. Domschke, R. Stoll

Department of Medicine B, University of M\'fcnster, M\'fcnster, GermanyLittle is known about the mechanisms triggering both the development and perpetuation of extraintestinal complications in Crohn's disease (CD). The aim of the present study was to test the hypothesis that the T-cell immune response in CD patients with joint complications may be altered when comparing with patients without extraintestinal manifestations.We used a semiquantitative polymerase chain reaction assay to analyse the T-cell antigen receptor repertoire in peripheral blood T cells from eight CD patients suffering from peripheral arthritis and ankylosing spondylitis, twelve CD patients without extraintestinal manifestations, and from seven non-CD patients with ankylosing spondylitis showing typical changes on joint radiographs. Being concerned that different patterns may be seen in different phases of the inflammatory disease process, we have also taken care to analyse sequential samples at various time points of the disease.Expression of all 22 V{ b} genes was found in each healthy control and in each CD patient without extraintestinal manifestations and showed no major variation over time. Southern hybridization analysis of amplified products revealed a highly restricted V{ b} repertoire in all CD patients suffering from peripheral arthritis and ankylosing spondylitis. In contrast, non-CD-patients with ankylosing spondylitis without signs or symptoms of gastrointestinal problems demonstrated the presence of the entire V{ b}-repertoire. Our longitudinal studies confirmed variable V{ b} usage over time, as certain transcripts were found only in distinct temporal phases of disease.Our data are not directly suggestive of a common super-antigen model of CD, but instead emphasize a specific decrease in signals throughout the TCR V{ b} repertoire in CD patients suffering from joint complications. Intestinal disorders: IBD, basicImmunology and microbiology: Inflammation }" "Restricted T Cell Receptor Vß Regions in Crohn's Disease Patients Suffering from Joint Complications"

"P P 42 0948"P 42 0948**Effect of Mild Exercise on Ileal Crohn's Disease (CD) in Remission**

*R. D'Inc\'e0, C. Mestriner, M. Varnier, D. Martines, A. D'Odorico, M. Bortolami, M. Minotto, S. Pigozzo, G.C. Sturniolo

Division of Gastroenterology, University of Padua, ItalyWe investigate the possible noxoius effects of mild exercise in CD patients in remission by examining gastrointestinal transit time and permeability, lipid peroxidation and inflammatory cells function.Six male CD pts were evaluated before and after exercise (1 hr at 60% VO2 max), with lactulose breath test and lactulose/mannitol (L/M) test, malondialdehyde (MDA) levels, neutrophyl activity and IL-6 production. Seven healthy volunteers served as controls. Sugars were measured by spectrophotometry, MDA by fluorimetry and neutrophyl activity by chemiluminescence after PMA, fMLP and zymosan stimulations. Oro-caecal transit time and urinary L/M recovery were unchanged after exercise both in CD pts and in controls. MDA levels significantly increased in CD pts after exercise (1.77 – 0.4) with respect to baseline (1.62 – 0.4) ($p < 0.05$). Respiratory burst activity of isolated neutrophyls was significantly increased after exercise in CD pts with fMLP (65 – 20.2) and zymosan (238.9 – 35.6) stimulations compared to controls (22.7 – 4.3 and 133.88 – 37.15 respectively, $p < 0.05$) while PMA did not affect neutrophyl function in both groups. Exercise significantly decreased basal IL-6 production of isolated lymphocytes both in CD pts (2.7 – 3.5 vs 0.7 – 0.5) and controls (8.1 – 7.1 vs 2.7 – 4.2) while LPS response was similar in both groups. In conclusion, mild exercise may have detrimental effects in CD since it increases lipid peroxidation and turns on inflammatory cells while it does not seem to affect gastrointestinal transit time and permeability. Intestinal disorders: IBD diagnosis, monitoring }"

"P P 42 0949"P 42 0949**Change from Ulcerative Colitis to Crohn's Disease: Two Features of the Same Disease?M. Dinca, W. Fries, A. Cecchetto[1], A. Martin**

Divisione di Gastroenterologia, Universit\'e0 di Padova, Italy

[1] Istituto di Anatomia Patologica, Universit\'e0 di Padova, ItalyAnecdotal reports have raised the possibility that a change from Ulcerative Colitis (UC) to Crohn's Disease (CD) or vice versa may occur during the course of IBD.Aim of this study was to assess the frequency of this change and the role of associated factors.*Methods:* we reviewed the files of 1114 patients with IBD who attended the outpatients clinics of our Institution from 1979 to 1995. We defined the clinical, endoscopic and histological criteria for an ""unequivocal"" diagnosis, in order to exclude cases in which the diagnosis was indeterminate at the time of first assessment. For a diagnosis of CD we used as endoscopic criteria the presence of aphthae, skip lesions and/or stenosis and histological criteria were the presence of follicles, granulomas and/or full thickness inflammation.*Results:* we found only 5 cases where a ""real"" (i.e. endoscopy and histology confirmed) change in diagnosis occurred, all of whom had an initial diagnosis of UC. All were young males and the change took place within two to five years from the onset of disease in four of the patients and in three months in the fifth. Four were smokers or ex-smokers and 3 had been treated with several courses of high doses of steroids. None had familiar cases of IBD.We conclude that a change in diagnosis, always from UC to CD is rare (7.9/thousand cases of UC). It affects young males and takes place within few years after the initial diagnosis of disease. We could not demonstrate any causal relation with steroid intake. Intestinal disorders: IBD diagnosis, monitoring }" "Change from Ulcerative Colitis to Crohn's Disease: Two Features of the Same Disease?"

"P P 42 0950"P 42 0950**Bone Mineral Density and Its Evolution in Patients with Crohn's Disease****M. Dinca, W. Fries, L. Leone, G. Luisetto[1], F. Bottega[1], F. Peccolo[1], A. Martin**

Divisione di Gastroenterologia, Universit\'e0 di Padova, Italy

[1] Istituto di Semeiotica Medica, Universit\'e0 di Padova, ItalyLow bone mineral density has been demonstrated in patients with Inflammatory Bowel Disease.Aim of our study was to assess the prevalence of osteopenia and the rate of bone loss in patients with Crohn's Disease (CD).*Methods:* We studied 32 patients (19 men and 13 women), mean age 37 years (range 18–69), 14 of whom had CD limited to the colon and 18 with ileocolonic involvement. Bone mineral density was measured by dual-energy x-ray absorptiometry of the lumbar spine. In 21 patients (65.6%) the measurement was repeated after a mean of 23 months (range 9–48). During the follow-up period 8 patients (25%) received steroid therapy and 6 (18.7%) calcium and vitamin D supplements. Osteopenia was defined as z-score below { -}1.5. The fracture threshold was considered bone mineral density (BMD) of 0.8 g/cm^2. Results were related to site and extent of disease and type of medication.*Results:* Osteopenia was present in 18 patients (56.2%) with values below the fracture threshold in 5 (15.6%). In the 21 patients in whom we measured BMD twice, no significant changes were observed, not even in those treated with steroids.We conclude that osteopenia is frequent in patients with Crohn's disease but is a slow-evolving process and, at least in the short interval of our observation, independent of disease localization and of steroids intake. Intestinal disorders: IBD diagnosis, monitoring }" "Bone Mineral Density and Its Evolution in Patients with Crohn's Disease"

"P P 42 0951"P 42 0951**Low Skinfold Thickness Predicts Osteoporosis in Crohn's Disease**

*R. Robinson, F. Al-Azzawi, S.J. Iqbal, K. Abrams, J. Mayberry

Gastrointestinal Research Unit, Leicester General Hospital, Gwendolen Road, Leicester, U.K.The aims of this study were to investigate the relation of skinfold thickness (SFT) to bone mineral density in Crohn's disease (CD), and to evaluate SFT as a screening test for osteoporosis in CD.*Methods:* 117 patients with confirmed Crohn's disease were studied (Male = 49). Pregnancy, ankylosing spondilitis, medical conditions or medication affecting bone density were exclusion criteria. Bone mineral density was measured at lumbar spine (L2–L4) and left hip (femoral neck, trochanter, Ward's triangle) by dual energy X ray absorptiometry (DEXA). SFT was measured over the dorsal aspect of the right hand using Holtain Tanner Whitehouse callipers. The thickness of a longitudinal skinfold over the 4th metacarpal was measured 3 times by a single observer and the mean calculated.*Results:* Osteoporosis was present in 14 (12%) of the patients. Mean SFT was significantly lower in patients with osteoporosis than patients with normal bone density (Difference in means = 0.74 mm, 95% CI 0.33 to 1.15, $p < 0.001$). There was a strong correlation between SFT and bone mineral density at all measured sites: Lumbar spine ($r = 0.41$, $p < 0.0001$, 95% CI 0.25 to 0.55), femoral neck ($r = 0.38$, $p < 0.0001$, 95% CI 0.21 to 0.53), Ward's triangle ($r = 0.38$, $p < 0.0001$, 95% CI 0.21 to 0.53) and trochanter ($r = 0.33$, 0.16 to 0.48, $p < 0.0001$). SFT was associated with bone mineral density independent of age, BMI and lifetime steroid use ($p < 0.05$). If a significantly low SFT is taken as > ISD below the mean normal value (2.64 (0.71) mm), then subjects with an SFT less than 1.9 mm were at significantly greater risk of osteoporosis ($p < 0.05$, odds ratio 5.48, 95% C.I. 1.36 to 22.0). As a diagnostic test for osteoporosis, an SFT of 1.9 mm has 93% specificity and 29% sensitivity. Using 2.5 mm as the \lquotecut off\rquote, specificity falls to 54% and sensitivity increases to 93%.*Conclusions:* In patients with CD there is a strong correlation between SFT and bone mineral density at the hip and lumbar spine. Measurement of hand skinfold thickness is a simple clinical marker of bone mineral density in CD, and will be a useful screening test to in determine which patients need DEXA. "P P 42 0952"P 42 0952**Crohn's Disease — A Hyperreactivity of the Tight Junctions?**

*J.D. S\'f6derholm, G. Olaison, L. Hedman, L. Franz\'e9n, C. Tagesson, R. Sj\'f6dahl

Dept's of Surgery, Pathology and Occupational Medicine, University Hospital, Link\'f6ping, SwedenPatients with Crohn's disease (CD) have a disturbed intestinal permeability. The epithelial tight junctions (TJ) regulate the mucosal barrier to hydrophilic molecules. The dynamics of TJ permeability during exposure of the mucosa to modulating substances has not been studied previously in CD.*Purpose:* To study paracellular permeability and electrical parameters in inflamed and non-inflamed ileal mucosa from patients with CD and controls patients during exposure to sodium caprate (C10), a fatty acid found in dairy products with effects on TJs in cell lines, and cytochalasin B (CytB), a well established TJ modulator.*Methods:* Five cm of the ileum was taken from 7 patients with CD and 8 patients operated for colonic cancer. The mucosa was dissected from the muscular layer and the specimens were mounted in Ussing chambers. Transepithelial potential difference (PD), electrical resistance (ER), short circuit current (I_{SC}) and permeation of ^{51}Cr-EDTA and ^{14}C-mannitol was studied for 90 min in control segments and in segments modulated with C10 or CytB with washout at 10 min and 45 min, respectively.*Results:* Both CytB and C10 induced a partly reversible increase in tight junction permeability. Non-inflamed mucosa from CD patients showed a more pronounced decrease in PD, ER, I_{SC} and a larger increase in ^{51}Cr-EDTA permeability during modulation with C10 than did control mucosa. In inflamed CD mucosa permeability in unmodulated specimens was increased compared to controls, whereas the effect of modulators was less pronounced.*Conclusions:* The results indicate a hyper-reactivity of the tight junctions in non-inflamed ileal mucosa in CD. This may be of importance for the pathogenesis in Crohn's disease.

"P P 42 0953"P 42 0953**Is ANCA Positivity in Crohn's Disease (CD) Associated with Particular Clinical Features?**

*E. Louis, V. Mommens, D. Franchimont, J. Salmon, P. Mahieu, J. Belaiche

Departments of Gastroenterology and Immunology, CHU Sart Tilman, 4000 Liége, BelgiumAccording to different studies, 10 to 20% of CD patients are ANCA +. The significance of that positivity is still unknown. The aim of our study was to compare ANCA + and ANCA { - } CD populations on the basis of several clinical features. *Patients and methods:* ANCA were searched, using an immunohistochemical method, in a sample of 180 CD patients. Twenty one of them (11.6%) were ANCA +. They were compared to a group of 41 ANCA { -} CD patients, matched for gender, smoking and duration of the disease. Comparisons on certainty of the diagnosis, type and location of the disease, systemic manifestations, age at onset, family history of IBD, need for surgery or immuno-suppressive treatment, were made using, either Fisher's exact test, or t test. *Results:* the frequency of gastro-duodenal location of CD was significantly higher in ANCA + CD patients (33.3% vs 4%; $p < 0.01$). There was also a trend to an increased frequency of inflammatory disease and to a decreased frequency of stenosing disease among ANCA + CD. The need for surgery tended to be less frequent in ANCA + CD, but the need for immuno-suppressive drug tended to be more frequent in the same population. Finaly, the age at onset tended to be higher in ANCA + patients (37.4 vs 28.5 years; $p = 0.053$). *In conclusion,* a minority of CD patients are ANCA +. This may represent a particular subset of CD, characterized by an increased frequency of gastro-duodenal location, and perhaps later onset, more inflammatory and less stenosing disease. Intestinal disorders: IBD, etiology and geneticsIntestinal disorders: IBD diagnosis, monitoring }" "Is ANCA Positivity in Crohn's Disease (CD) Associated with Particular Clinical Features?"

"P P 42 0954"P 42 0954**Familial Crohn's Disease: Study of 18 Families**

*D. Franchimont, S. Simon, E. Louis, C. Gower-Rousseau, P. Latour, J. Belaiche

Soci\'e9t\'e9 Li\'e9geoise de Gastroent\'e9rologie, CHU Sart Tilman, 4000 LiégeThe most recent data from epidemiology and molecular biology in Crohn's disease are consistent with a multifactorial, polygenic inheritance with a possible genetic heterogeneity. The aim of our study was, first to evaluate among families, the concordance rate for the type and location of the disease, and second, to compare familial and sporadic CD on the basis of the type and location of the disease, and age at diagnosis. *Patients and methods:* 16 families with 2 affected first degree relatives (n = 32), 2 families with 3 affected first degree relatives (n = 6), and 155 sporadic CD were studied. The expected numbers of concordant cases among families were calculated using the binomial law and compared to the observed numbers by a Chi2 test. Comparison between familial and sporadic CD was done by a Chi2 or a Kruscall-wallis test. *Results:* 1) There was a significant increase in concordance rate for stenosing disease and a decrease for inflammatory disease, among the families. 2) Age at diagnosis was the same in sporadic and familial CD. There was an increased frequency of ileal (p = 0.022), and stenosing (p = 0.005) CD and a decreased frequency of colonic (p = 0.006) and inflammatory (p = 0.028) CD, in familial CD. *In conclusion,* 1) Among families, the concordance rate for stenosing CD was higher than expected, which may reveal the genetic inheritance of that feature. 2) Ileal and stenosing diseases were more frequent in familial than in sporadic CD, which may suggest some heterogeneity in CD.

"P P 42 0955"P 42 0955**Low Symptomatic Load in Crohn's Disease with Surgery and Medicine as Complementary Treatments**

*P. Andersson, G. Olaison, G. Bodemar, S. Almer, J. Dabrosin-S\'f6derholm, R. Gotthard, P.O. Nystr\'f6m, K. Smedh, M. Str\'f6m, R. Sj\'f6dahl

Dept of Medico-Surgical Gastroenterology, University Hospital, Link\'f6ping, Sweden*Background:* The treatment of Crohn's disease has changed due to the recognition of its chronicity. Maintenance medical treatment and limited resections has evolved as major concepts of management. Medicine and surgery are complementary, their indications being related, and both aim to reduce symptoms. The study aimed at to investigate how these treatment concepts influenced the symptomatic load in Crohn's disease.*Patients and methods:* An unselected population-based cohort of 202 patients from our primary catchment area and 119 referred patients were investigated. Symptoms were evaluated by a symptom-index, the physician's global assessment and the patient's perception of health by means of visual analogue scale.*Results:* Of catchment area patients 53% were on medication and the annual rate of abdominal surgery was 5.7%. Corresponding figures for the referred patients were 63% and 8.2% respectively. According to the symptom-index 75% were in clinical remission, 16% had mild, 8% moderate and 1% severe symptoms. Corresponding figures according to the physician's assessment were 63, 26, 10 and 1 percent. Patient's perception of health was 82% in normal health. Symptoms and perceived health were similar in referred patients.*Conclusion:* The large majority of patients with Crohn's disease can live in remission or have only mild symptoms.

"P P 42 0956"P 42 0956**Osteoporosis in Crohn's Disease in a Danish Out-Patient Clinic: Bone Mineral Measurements and Biochemical Markers**

*H. Andreassen, M. Rix, E. Hylander

Departments of Internal Medicine and Gastroenterology, Roskilde County Hospital K\'f8ge, Denmark*Methods:* BMD was measured at the lumbar spine (L2–L4), the hip and of the forearm, using the Hologic 2000 DEXA-scanner. Biochemical markers of bone formation (osteocalcin) and bone resorption (urinary pyridinoline) were analyzed.*Patients:* 56 unselected patients (33 females, 23 men) with Crohn's disease, mean age 41 years (SD 14.6), mean BMI 23.6 kg/squarem (SD 4.0 kg/squaremeter), half of whom had a bowel resection, were studied.*Results:* Osteopenia (defined as a T-score (mean BMD value for the young adult) less than { -}1 SD)) was found in the lumbar spine, the hip (neck-region) or the forearm in 52%, 64% and 46% of patients, respectively. Osteoporosis (defined as a T-score less than { -}2.5 SD) was observed in 14%, 16% and 16% of patients, measured in the same areas. In 25% of cases osteoporosis occured at any of those sites. Increased urinary pyridinoline was found in 16% of the patients (mean value for the whole group: 46.6 nmol/mmol creatinine, SD 28.0, normal values 38.8 – 10.8), elevated urinary deoxy-pyridinoline in 4% (mean: 11.1 nmol/mmol creatinine, SD 7.2, normal values 13.0 – 4.6). Nine % of the patients had serum-osteocalcin above normal range (mean value for the group 9.0 – 4.4).*Conclusion:* In a Danish cross-sectional study of unselected patients with Crohn's disease, attending an out-patient clinic, osteoporosis is found in 25% (WHO-criteria). Biochemical markers of bone turnover indicates increased bone resorption.

"P P 42 0957"P 42 0957**Bone Metabolism and Remodelling in Crohn's Disease**

*J. Bures, V. Palicka, L. Pl\'edskov\'e1, J. V\'e1vrov\'e1, P. Zivn\'fd, S. Rejchrt, M. Sirok\'fd, P. &Rbreve;ehorkov\'e1

Charles University Teaching Hospital, Hradec Kr\'e1lov\'e9, Czech Republic*Purpose of the study* was to evaluate bone metabolism and remodelling in Crohn's disease.*Methods.* Thirty-five patients with Crohn's disease entered the study (17 men, 18 women, aged 17–64, mean 37, median 38). The diagnosis was based on typical endoscopic, radiological and histological findings (including 17 persons with previous history of bowel surgery). Bone metabolism was assessed by measuring serum osteocalcin (by EIA), collagen-I carboxyterminal propeptide [PICP] (by EIA), parathyroid hormone (using immuno-chemiluminiscence), 1,25-OH-vitamin D_3 (by RIA), urine hydroxyprolin (using spectrophotometry) and urine free deoxypyridinoline (by EIA). Bone density was measured by peripheral broadband ultrasound attenuation (using CUBA, McCue, UK). Data were statistically treated (t-test, Mann-Whitney, Spearman Correlation) using Jandel Scientific.*Results.* Peripheral bone density was decreased in 22/35 patients (63 per cent). Serum osteocalcin was increased (mean 6.66 – std. dev. 3.15 \'b5g/l) as well as the urine excretion of deoxypyridinoline (median 6.90, interquartile range 5.43–11.08 nM/mM of creatinine). Serum PICP was in the upper part of reference values (mean 121.7 – 47.53 \'b5g/l). Serum 1,25-OH-vitamin D_3 (mean 33.3 – 14.4 ng/l) and parathyroidal hormone (mean 24.6 – 14.6 ng/l) were within normal range (except 3 patients). There was no significant correlation between bone density, biochemical markers of bone turnover, disease duration and cummulative dose of corticosteroids.*Conclusions.* The bone metabolism is often heavily disturbed in Crohn's disease. The incidence of osteopenia and osteoporosis is high in these patients. Intestinal disorders: IBD diagnosis, monitoringIntestinal disorders: IBD, therapyNutrition: Metabolism }"

"P P 42 0958"P 42 0958**Low Body Fat and Risk for Osteoporosis in Crohn's Disease**

*E.J. Schoon[1], A.B. van Nunen[1], G. Heidendal[2], B.J. Geerling[1], M.G. Russel, R.W. Stockbr\'fcgger[1], R.J. Brummer[1]

[1] Department of Gastoenterology, University Hospital Maastricht, The Netherlands

[2] Nuclear Medicine, University Hospital Maastricht, The NetherlandsReduced bone mineral density (BMD) has a reported prevalence of 13 to 31% in patients with Crohn's disease (CD). Several risk factors and risk conditions have been proposed. The aim of the study was to estimate whether body composition is correlated to bone mineral density (BMD) in patients with CD.*Methods:* Fifty-seven out-patients with CD (17 M, 40 F, age 18–72, mean 43 yrs.) were investigated using total body dual X-ray absorptiometry (DXA). Total body BMD (TBBMD), lumbar spine (LS) BMD and hip BMD (neck, Wards triangle (WT), trochanter (Troc)), and body fat percentage (% BF) were measured. BMD was expressed in T-and Z-score. Body mass index (BMI) was calculated. Serum 25-OH-vitamin D (vit D) levels were determined.*Results:* The prevalence of osteopenia in this group of patients, defined as Z-score < { -}1 SD, was 54% (31/57). BMI was correlated with TBBMD-T (r = 0.35, p < 0.01), and TrocBMD-T (r = 0.37, p < 0.025). There was a significant correlation between % BF and and TBBMD-T (r = 0.59, p, 0.001), TBBMD-Z (0.31, P < 0.05), TrocBMD-T (r = 0.32, p < 0.025) and WTBMD-T (0.29, p < 0.05). There was a significant correlation between % BF and vit D levels (r = 0.43, p < 0.025).*Conclusion:* Crohn's disease patients with low BMI and low body fat percentage are at higher risk for osteopenia. Body mass index is a simple clinical parameter which can be helpful in selecting patients at risk for osteopenia in Crohn's disease. "P P 42 0960"P 42 0960**Change of Clinical, Laboratory Parameters and Clearance-Alpha-1-Antitrypsin in the Chronically Active Patient's with Crohn's Disease****Nj. Jojic, D. Necic, B. Dapcevic**

Zvezdara University Center, Gastroenterology Unit, Belgrade, YugoslaviaPractical value of clinical, laboratory and intestinal parameters for the estimation of the total activity, was analyzed in the group of chronically active patients with Crohn's disease. Forty patients were tested, 16 with Crohn's colitis, 12 patients with extensive small bowel disease and 12 patients with ileocolonic disease. Clinical parameters were measured by modified Best index (CDAI), laboratory parameters with acute phase reactants (CRP and orosomucoid) and intestinal activity with Clearance-alpha-1-Antitrypsin (Cl-{ a}-1-At). All parameters were determined at the beginning of testing and after 3, 6, 9 and 18 months. Initially, all patients were clinically active (CDAI > 200) as well as laboratory active (CRP, orosomucoid and Cl-{ a}-1-At were above the normal values). Mean values of CDAI in each quarater were statistically different significantly (Freedman test; $\{ ?\}^2 = 13.4$; which is higher than 13.27; $p < 0.01$). Relapse was considered when the patients bad CDAI values 50 points higher compared to previous measurements. Mean values (*&Xbar; – SD*) of orosomucoid (1.7 – 0.2 g/l) and Cl-{ a}-1-At (82 – 12 ml/24 h) were increased during entire period, but there was no significant difference statistically during relapse. Mean CRP values were statistically much higher during relapse ($t = 2.91$; $p < 0.05$). These results mean that constantly increased values of orosomucoid and Cl-{ a}-1-At indicate chronically activity in this group of patients. Increase in CRP values indicated relapses. Intestinal disorders: IBD diagnosis, monitoring }" "Change of Clinical, Laboratory Parameters and Clearance-Alpha-1-Antitrypsin in the Chronically Active Patient's with Crohn's Disease"

D\'e9p. d'H\'e9matologie-Immunologie, CH Valenciennes, France*Bakground/aim:* A search for serological tests to differentiate between CD and UC has been underway for a long time. Antineutrophil cytoplasmic auto-antibodies (ANCA) are well recognized marker for UC. We have recently shown that antibodies to oligomannosidic epitopes of the yeast *Saccharomyces cerevisiae* (ASCA) were associated with CD [1]. The aim of this study was to evaluate the value of detecting ANCA in diagnosing UC and ASCA in diagnosing CD by single or combined use of these tests. *Methods:* Serum samples were obtained from 68 patients with CD (40 F, 28 M, mean age 30 yrs) and 81 patients with UC (43 F, 38 H, mean age 42 yrs). Determination of ANCA was performed using the standardized indirect immunofluorescence technique. Determination of ASCA was performed using ELISA [1].*Test results* for determining either UC or CD in patients with inflammatory bowel disease (IBD) are given in the following table: Se = sensitivity, Sp = specificity, PPV = positive predictive value. Test UC CD Se Sp PPVASCA + 12 45 68% 85% 88%ANCA + 44 11 65% 83% 72%ASCA +/ANCA { -} 2 36 55% 97% 97%ASCA { -}/ANCA + 39 3 57% 95% 89%No relationship was observed between the presence of ASCA and ANCA and any clinical parameters including UC or CD activity and location. *Conclusion:* ASCA and ANCA either used single or combined may help diagnosis of IBD. The remarkable PPV observed when combining both tests might be particularly useful in patients with unclassified colitis and should be confirmed in a prospective study.

"P P 43 0962"P 43 0962**Role of the Viscosity of Therapeutic Milk on Digestibility and Tolerance of Lactose in Adults with Hypolactasia**

*T. Vesa, P. Marteau, F. Briet, A. Briend, B. Flouri\'e9, J.C. Rambaud

INSERM U290, Hospital Saint Lazare, Paris, FranceSubjects with lactose maldigestion including malnourished children digest more efficiently lactose from fermented milk than from milk. It has been hypothesised that differences in viscosity could play a role. Therapeutic enriched milks are developed for the nutrition of malnourished children, but a problem often encountered in rehabilitation is lactose intolerance. *The aim* of this study was to evaluate whether increasing the viscosity of a therapeutic milk would enhance the digestibility of its lactose content. *Methods:* Thirteen healthy adult volunteers with hypolactasia ingested three different test milks in random order with one week interval between each test. The therapeutic milks were prepared from the same milk formula to which rice starch and/or maltodextrin were added to modify the viscosity without modifying the caloric content. Viscosity ranged from that of usual milk (TM1) to approximately that of stirred yoghurt (TM3). Each test milk (500 ml) contained 14 g protein, 21 g fat, 50–55 g carbohydrates including 18 g lactose, and 1886–1969 kJ (450–470 kcal). Test milks were ingested in the morning after a 12-hour fast. Digestion of lactose was measured by hydrogen (H_2) breath test during 6 h, and intolerance symptoms were recorded. The Wilcoxon test was used for statistical comparisons. *Results:* (means – SD): There were no significant differences between the milks concerning digestion of lactose, orocaecal transit time, nor symptoms (Table). TM1 TM2 TM3Maltodextrin content (g) 35 17 0Rice starch content (g) 0 17 35Viscosity (cps) 33 80 1892AUC H_2 (ml) 51 – 35 55 – 37 50 – 40Orocaecal transit time (min) 180 – 83 163 – 80 180 – 85Sum of symptoms 13 – 16 11 – 13 11 – 13*Conclusion:* moderate increase of meal viscosity does not enhance the digestion or tolerance of lactose from a therapeutic milk in adults. The breath H_2 excretion and intolerance signs were relatively low with the 3 milks, possibly owing to their high caloric and fat content. Other hypothesis should explain the good digestibility of fermented milks in hypolactasic subjects. Intestinal disorders, absorption: Malabsorption syndromesNutrition: Metabolism }" "Role of the Viscosity of Therapeutic Milk on Digestibility and Tolerance of Lactose in Adults with Hypolactasia"

"P P 43 0963"P 43 0963**Digestion and Tolerance of Lactose from Yoghurt and Semi-Solid Fermented Dairy Products — Is Bacterial Lactase Important?**

*T.H. Vesa, P. Marteau, S. Zidi, F. Briet, P. Pochart, J.C. Rambaud

INSERM U 290, Hospital Saint-Lazare, Paris, FranceLactase-deficient subjects digest lactose better from fermented dairy products than from milk. Three hypothesis which do not exclude each other have been proposed. Slower gastric emptying and intestinal transit (probably due to physical differences), stimulation of the endogenous residual lactase, and action of the bacterial lactase *in vivo* in the gastrointestinal tract. The specific role of each of these factors is debated. *The aim* of this study was to compare the digestibility and tolerance of three fermented dairy products with the same amount of lactose, and physical state (semi-solid), but different lactase and bacterial contents. *Methods:* 14 lactase-deficient healthy volunteers consumed, on 4 different days and in random order, after a 12-h fast, 3 semi-solid test meals containing 18 g of lactose, and 10 g of lactulose which allowed calculation of lactose malabsorption. The 3 meals were: yoghurt, a fermented milk containing *Lactobacillus acidophilus* and *Bifidobacterium* sp. (Ofilus'), and a similar product enriched with *L. bulgaricus* to increase the lactase content (Bulgofilus). The lactase contents (IU/g product weight) were 0.19 for Ofilus', 0.24 for Bulgofilus, and 0.86 for yoghurt. Breath hydrogen (H_2) concentration and clinical symptoms were measured for 6 h after consumption of the test meals. *Results:* Symptoms scores were low, indicating a good tolerance of all products. Compared with lactulose, the sum of symptoms was significantly lower for Bulgofilus ($p = 0.05$), and bloating was less severe for Ofilus' ($p = 0.06$). The area under the breath H_2 curve was significantly lower for each fermented milk when compared to lactulose ($p < 0.0001$). There were no differences in symptoms between the fermented milks. The degree of maldigestion of lactose did not differ significantly between them and was 18 – 3% (range 3–43) for yoghurt, 21 – 3% (range 6–52) for Ofilus', and 21 – 3% (range 6–44) for Bulgofilus.*Conclusion:* Despite the differences in the lactase and bacterial contents, lactose was as well digested and tolerated from the 3 different fermented milks. This argues against a major role for lactase in the digestibility of semi-solid fermented dairy products.

"P P 43 0964"P 43 0964**Lactase and Sucrase-Isomaltase Expression in the Duodenum during Development in Children**

*E.H. Van Beers, H.A. B\'fcller, E.H.H.M. Rings, A.W.C. Einerhand, J. Dekker

Pediatric Gastroenterology & Nutrition, Acad. Med. Ctr, Amsterdam, The Netherlands*Purpose:* A large number of diseases affect the integrity of the intestinal epithelium, which harbors a number of very important digestive enzymes. Particularly the brush border enzymes lactase and sucrase-isomaltase (SI) are essential for the digestion of milk-based lactose during early childhood and plant-based sucrose and starch later in life respectively. Clinical evaluation of the effects of epithelial damage on intestinal ability to digest carbohydrates is very important for diagnosis and therapy. Since the regulation of these brush border enzymes in health and disease is inherently very important for survival, we have studied the expression of both these enzymes at the mRNA and protein levels in children.*Methods:* 85 Caucasian children (3 mnth–18 y) were studied with normal or affected duodenal mucosae. Villus atrophy was scored in 3 classes. Endoscopic forceps biopsies were taken in duplicate from both proximal and distal duodenum in each child. One of these duplicate biopsies was used in immunohistochemistry (IHC) with anti-lactase or anti-SI antibodies, and the staining of the brush border membrane of the villus enterocytes was measured semi-quantitatively. The duplicate biopsies were used to isolated RNA, and the lactase and SI mRNAs were quantified. Lactase and SI mRNA levels were expressed relative to Gapdh mRNA.*Results:* The biopsies from the proximal and distal region of the duodenum of each patient yielded very similar results in every aspect. In healthy tissue the mRNA and IHC levels of both lactase and SI remained similar in all age-groups. Likewise, when the ratio lactase mRNA/SI mRNA was determined per biopsy, no differential gene expression was noted between these enzymes: The mean mRNA-ratios remained similar at all ages. However, increasing villus atrophy correlated with decreasing expression of both enzymes, measured by mRNA levels or IHC. Despite similar mean levels of lactase and SI in healthy tissue among the age-groups, a large variety was found in the individual levels of the enzymes: Individuals were found with high lactase levels and low SI levels, and vise versa. Also at the epithelial level no correlation was found between individual cells in their expression levels of lactase or SI using IHC.*Conclusions:* There are no longitudinal expression gradients in the duodenum for lactase or SI. There seems to be no age-related regulation of either enzyme in Caucasians, and the relative levels of these enzymes remain similar. Both enzymes are affected negatively during epithelial damage. Nevertheless, large varieties were observed in enzyme levels in individuals as well as at the cellular level, strongly indicating that the expression of the enzymes is largely independently regulated. "P P 43 0965"P 43 0965**Reproducibility of a Combined Lactose-^{13}C-Glycine Breath Test to Study Gastric Emptying, Orocaecal Transit Time, and Lactose Digestion**

*F. Briet, P. Marteau, T. Vesa, A. Briend, B. Flouri\'e9, J.C. Rambaud

INSERM U290, Hospital Saint Lazare, Paris, FranceGastric emptying and orocaecal transit time (OCTT) influence lactose digestion. *Our aim* was to set-up a combined test and assess its reproducibility to study gastric emptying, OCTT, and lactose digestion in lactose maldigesters.*Subjects & methods:* After an overnight fast, 13 lactose maldigesters ingested 500 ml of milk containing 18 g of lactose and supplemented with ^{13}C-glycine (99 AP). Breath gas samples were collected every 15 min for 6 h, and gastrointestinal symptoms were recorded using visual analogue scale. A second test was repeated for each subject after one week. Breath excretion of H_2 and $^{13}CO_2$ were measured using an electrochemical cell and an isotopic mass spectrometer respectively. The $^{13}CO_2$ excretion curves were fitted using non-linear regression models to calculate the gastric emptying parameters: half emptying time ($t_{\'bd}$), time of maximal gastric emptying (t_{max}), and gastric emptying coefficient (GEC) (Maes et al. 1994). The area under curve of breath H_2 excretion (AUC H_2) was calculated, and the OCTT was assessed by the appearance of H2 excretion in breath. Results were compared using the Wilcoxon test.*Results:* (means – SD) $t_{\'bd}$ (min) t_{max} (min) GEC AUC H_2 (ml) OCTT (min)Test 1 87 – 14 40 – 12 2.6 – 0.3 64 – 30 122 – 41Test 2 84 – 18 39 – 12 2.6 – 0.4 51 – 35 180 – 83p 0.60 0.78 0.79 0.17 0.06Almost significant decrease was seen between the first and second test concerning abdominal pain (4.6 – 7.5 vs 1.3 – 3.9, p = 0.05), flatulence (6.0 – 6.3 vs 3.8 – 4.4, p = 0.07), and the sum of symptoms (24.6 – 25.3 vs 12.9 – 15.6, p = 0.07).*Conclusion:* This new test allows simultaneous assessment of gastric emptying, intestinal transit time, and lactose digestion. Repeated measures showed a good reproducibility and the absence of a period effect for gastric emptying. Since there was a trend towards a period effect for the assessment of the intestinal transit time and intolerance signs, studies using repeated measures of lactose digestion and tolerance in the same subject should always randomise treatment periods. *U. Nieminen[1], M. Rautio[3], M. Saxelin[2], A. Siitonen[3], T. Vesa[4], H. Jousimies-Somer[3], R. Korpela, M. F\'e4rkkil\'e4[1]

[1] Dept. of Medicine, Helsinki University Central Hospital, Helsinki, Finland

[2] Valio Research Center, Helsinki, Finland

[3] National Public Health Institute, Helsinki, Finland

[4] Foundation for Nutritional Research, Helsinki, Finland*Purpose:* To study the correlation of duodenal mucosal lactase activity with the results of the lactose tolerance test and symptoms in patients with primary lactase deficiency.*Methods:* The study group consisted of 30 patients with primary lactase deficiency; lactase concentration half of the normal determined by duodenal lactase measurement with normal histology. The exclusion criteria were: coeliac disease, inflammatory bowel diseases, active duodenal or ventricular ulcer disease, cholecystolithiasis, diabetes mellitus, and intense symptoms suggesting of an irritable bowel syndrome.The standard lactose tolerance test was performed with 50 g of lactose liquid. The bowel transit time was determined using 1 g of carmine red to mark the lactose liquid. The symptom score during the lactose test and during the 6-hours follow-up was calculated using a questionnaire. The correlation of duodenal mucosal lactase activity with the results of the lactose tolerance test, and with the symptoms in patients during the test were analyzed using the regression analysis test.*Results:* The symptoms in the patients varied largely during the lactose tolerance test. No correlation of the duodenal mucosal lactase activity was found with patients' symptoms during the lactose test (r = { -}0.03), or with the rise of glucose in the test (r = 0.28). Moreover, there was no correlation of the mucosal lactase activity with the bowel transit time (r = { -}0.013). The symptoms in patients' did neither correlate with the rise of blood glucose during the lactose test (r = { -}0.04).*Conclusions:* The duodenal lactase activity was detected as an insignificant factor to define the result in the lactose tolerance test and the intensity of symptoms during the test.

"P P 43 0967"P 43 0967**Lactose Malabsorption Adult Type in Brazil**

*A. Sev\'e1-Pereira, A.C. Sparvoli

Department of Medicine, State University of Campinas (UNICAMP), Campinas and Department of Medicine, University of Rio Grande, Rio Grande, BrazilLactose malabsorption adult type (LMA) has different prevalences in distinct ethnic groups. Brazil has 150 million people distributed in 5 regions of different ethnic and genetic admixture. Indians are the aboriginal. Since the 16th century mixture has occurred with other races. Whites came from Europe as settlers. Negroes came from Africa since 1538 as slaves. Later on many immigrants arrived: Europeans and Orientals.The Southeast (SE) has 64 million people of an intermediate mix of Portuguese, Spanish, Italians, Syrians and Japaneses. The Northeast (NE) has 43 million people of intense interracial genetic admixture, mainly Indigenous, Negroids and Portugueses, then they are considered trihybrids. The South (S) has 23 million people with poor genetic admixture and the strongest European influence, specially German, Italian and Portuguese. The other 2 regions, North and Middle West, are less populated, only 13%. Our investigation was undertaken to clarify the LMA prevalence in the different Brazilian regions, thus establishing a complete picture of our country.A lactose tolerance test consisting of the administration of 50 g lactose as a 10% aqueous solution was applied to healthy adults, nonconsanguineous, with no secondary lactase deficiency: 80 (40 Caucasoids, 20 Negroids and 20 mongoloids of Japanese ancestry) born in SE; 70 (48 Caucasoids and 22 Negroids) from S and 37 (trihybrids) from NE.The results of prevalence of LMA are summarised in the table: Brazilian Population Caucasoids Negroids Japaneses Trihybridregion (n) (%) (%) (%) (%)SE 64 000 000 45 85 100NE 43 000 000 76S 23 000 000 37.5 68Total 130 000 000 41 76 100 76We conclude that Brazilian Caucasoids have an intermediate prevalence of LMA, whereas Negroid, Japaneses and trihybrid Brazilians have a high prevalence of LMA. "P P 43 0968"P 43 0968**Lactose Intolerance: Role of the Colon and of Changes in Motor Activity in the Occurrence of Symptoms**

*P. Jou\'ebt, J.M. Sabat\'e9, B. Flouri\'e9, Y. Bouhnik, B. Coffin, C. Franchisseur, J.C. Rambaud

INSERM U290, Hospital Saint Lazare, 75010 Paris, FranceIn lactose intolerance, symptoms are attributed to the colonic fermentation of unabsorbed lactose. However, in the small bowel unabsorbed lactose could also produce symptoms via its osmotic load. Mechanisms of symptoms are unsettled. They could be related to the occurrence of motor events induced in the small intestine by the osmotic load and/or in the colon by the bacterial fermentation of unabsorbed lactose. *We compared* in healthy volunteers the effects of lactulose, a nonabsorbable sugar biochemically similar to lactose, taken orally or directly infused into the colon in order to bypass its possible effects on the small bowel. *Methods:* During two periods separated by one month, 8 healthy volunteers swallowed a multilumen tube consisting of 9 perfused catheters, and 1 infusion catheter. After migration of the tube, the infusion catheter was in the cecum, at least 3 perfused catheters were in the jejunum, and 3 in the colon. After an overnight fast, subjects ingested a 500 kcal liquid meal containing either 40 g lactulose or 40 g saccharose; in this last case, the 40 g lactulose was infused directly into the colon 45 min after the beginning of the meal for 4 hrs at flow rates pre-established in 2 ileostomized patients. Motor activity was recorded for 5 hours. Symptoms were also recorded and graded hourly for 10 hrs and their occurrence was marked on the motility records.*Results:* Neither the score for each symptom, nor the overall score (29 – 6 vs 30 – 4; p = 0.7; mean – SEM) were significantly different between the 2 periods. Out of the 48 reported symptoms, only 18, i.e. 38%, (11/25 borborygmi, 4/14 abdominal pains, 3/9 flatus) coincided in time with a particular colonic motor event: propagated contractions were associated with borborygmi (8), abdominal pains (3) and flatus (3), waves of localized contractions were associated with borborygmi (2), whereas prolonged waves of contractions that occurred simultaneously on several catheters were associated with borborygmi (1) and pains (1). No symptom coincided with a particular small bowel motor event.*Conclusion:* In healthy subjects, symptoms induced by a nonabsorbable sugar are similar when this sugar is ingested orally and when it is infused directly into the colon. This shows that symptoms originate from the colon. However, symptoms were not clearly correlated with particular motor events. This suggests that nonrecorded motor events (for example tonic variations) or other factors could be involved in the occurrence of symptoms. Motility, specific: Small bowelMotility, specific: Colon, anorectumIntestinal disorders, absorption: Malabsorption syndromes }" "Lactose Intolerance: Role of the Colon and of Changes in Motor Activity in the Occurrence of Symptoms"

"P P 43 0969"P 43 0969**Intestinal Mucosal Permeability to Lactulose, L-Rhamnose in Adult Patients with Chronic Diarrhoea****Mohamed A. Nafeh[1], Ahlam M. Ahmed[1], Soad M. Abdel-Ghany[2],**

*Nabilah M. Rashwan, Abdel-Ghany A. Soliman[1]

[1] Department of Tropical Medicine, Assiut University Hospital

[2] Department of Biochemistry, Faculty of Medicine, Assiut UniversityIntestinal permeability to lactulose (La) and rhamnose (rham) was studied to show integrity of the small intestine in chronic diarrhoea. Thirty-six patients with chronic diarrhoea as well as 14 healthy controls were studied. The aetiologic diagnosis of diarrhoea was settled through a set up for management of chronic diarrhoea in the Department of Tropical Medicine, Assitt University Hospital.According to the histopathological changes in the proximal intestine, patients were classified into 2 groups. A group with normal histological appearance (9 patients); showed a significant increase in La/rham ratio in comparison to controls (0.07 – 0.02 vs. 0.04 – 0.02). On the other hand, those with histopathological changes in the proximal intestine (27 patients), showed significant increase in the mean La/5 h (23.3 – 9.9 vs. 11. – 7.8) and highty significant decrease in rham/5 h (23.6 – 12.9 vs. 51.1 – 14.5) compared with controls. All patients had higher la/rham ratios without overlap with the normal range and the mean ratio was statistically highly significant (0.25 – 0.17 vs. 0.044 – 0.022 for controls).We conclude that the la/rham permeability test — in addition to being non-invasive technique — is a sensitive index of small intestinal integrity. We hope that it may replace the endoscopic biopsy and histopathologic study or at least decreases the need for such invasive procedures. "P P 43 0970"P 43 0970**Longitudinal Mapping of Sodium-Glucose Transport and Disaccharidase Activity in Human Small Intestine**

*A. Garner, R. Dib, I. Chandranath, E. Mensah-Brown, M. Nur-E-Kamal, K. Broadbent, A.J.W. Sim

Faculty of Medicine & Health Sciences, United Arab Emirates University, Al Ain, U.A.E.*Purpose:* We have used vesicles prepared from resection specimens to map the profile and properties of some brush border membrane proteins along the length of human small intestine *Methods:* Sodium-dependent glucose uptake and sucrase-isomaltase activity were determined in brush border membrane vesicles (BBMVs) prepared from duodenum, jejunum, mid and terminal ileum by differential centrifugation and Mg precipitation. A potential role of ras in regulating non receptor-mediated transport of glucose was investigated by conversion of membrane-bound ras to the GDP form by treatment with neurofribromin. All tissues use had normal histological appearance and were obtained fresh from patients undergoing surgery for non-inflammatory benign disease or localized malignancy.*Results:* BBMVs prepared from all 4 regions had comparable diameter (142–160 – 9 nm) and a similar appearance on EM examination. Purity was confirmed by the 7–12 fold enrichment in alkaline phosphatase and 3–5 fold depletion in basolateral membrane potassium-stimulated ATPase. Recovery and enrichment of sucrase ranged between 17–29 fold and 27–47% respectively. Vesicles from all four regions of small bowel supported sodium-dependent transport of ^{14}C-labeled D-glucose as revealed by a substantial overshoot in the presence of NaSCN. Diffusional uptake of D-glucose was not influenced by KSCN. Peak rates of D-glucose uptake in the duodenum, jejunum, mid and terminal ileum were 168, 829, 352, and 169 pmol/mg protein respectively. Corresponding values for the specific activity of sucrase were 0.3, 1.6, 3.6 and 2.4 \'b5mol/mg protein/min. Vesicles prepared in the presence of an excess of neurofibromin displayed rates of glucose uptake similar to control.*Conclusions:* These data reveal the regional differences along the human small intestine with respect to membrane-bound disaccharidase and transmembrane monosaccharide transport. Sucrase activity was maximal in the mid ileum but substantial activity was still present in the terminal ileum. Sodium-dependent glucose uptake was maximal in the jejunum (initial rate 126 – 9 pmol/mg protein/sec) and was unaffected by inhibition of ras. "P P 43 0971"P 43 0971**Celiac Disease and Autoimmune Thyroid Disease**

*M.T. Passaleva, G. Macr\'ec, G. Romano, M. Orsini, A. Calabr\'f2

GI Unit, Dept. of Clin. Pathophysiology, Univ. of Florence, ItalyThe association of Celiac Disease (CD) and Thyroid Disease (TD) has previously been described. However, being most of the published data based on retrospective studies or case note review, the exact frequency of thyroid disorders in CD is as yet unclear. We prospectively examined a cohort of adult CD patients drawn from a defined geographical area in Central Italy. *Patients and methods:* the study group comprised 92 CD patients diagnosed between April 1992 and March 1996 (26 M, 69 F; mean age at diagnosis 38.3 yr, range 15–78). The diagnosis of CD was based on the clinical history, laboratory and histological findings, and a good clinical response to a gluten free diet. Age and sex matched controls were selected from among outpatients with HCV-related chronic hepatitis, consecutively referred to our center for interferon therapy. Total and free T_3 and T_4, and TSH were measured by standard RIAs to assess thyroid function; thyroid microsomal (TM) and thyroglobulin (TG) antibodies were determined by indirect immunofluorescence and agglutination techniques. *Results:* an associated thyroid disorder was found in 15.2% of patients and 2.3% of controls (Chi square, $p < 0.001$): 7 patients (7.6%) were hypothyroid, 3 (3.3%) were hyperthyroid, and 4 (4.3%) had TG and/or TM antibodies with a normal thyroid function. The mean age of patients with both CD and TD was significantly higher than that of those with just CD (49.1 vs. 29.5 yr: Student's *t* test, $p < 0.001$). In 6 of the 14 patients with both diseases the TD had presented first: 2 patients with Grave's disease and 3 with hypothyroidism had received adequate treatment and were euthyroid at the time of examination; in a further hypothyroid patient chronic diarrhoea was thought to be a complication of thyroxine supplementation. Moreover, in 3 patients a prior diagnosis of CD delayed the recognition of the symptoms of hypothyroidism (2 cases) or hyperthyroidism (1 case). All the others were found to have overt TD or TG and TM autoantibodies at the time their CD was diagnosed. *Conclusions:* we have shown that the association of CD and TD is clinically important and more frequent than previously recognized. Since both diseases can present with similar clinical manifestations, we believe that thyroid function and autoantibodies should be checked routinely in all celiac patients at presentation. Intestinal disorders, absorption: Gluten enteropathy }" "Celiac Disease and Autoimmune Thyroid Disease"

"P P 43 0973"P 43 0973**Immunoglobulin Deficiency in Coeliac Disease: A Single Institution 25 Year Experience**

*M.A. Heneghan, E. Cryan, R. Warner, F.M. Stevens, C.F. McCarthy

Department of Medicine, Clinical Science Institute, University College Hospital, Galway, IrelandImmunoglobulin deficiency, especially deficiency of IgA has been described in coeliac patients. Between 1971 and 1996, over 700 coeliac patients have been treated at this institution. Immunoglobulins have been measured on at least one occasion in 604 of these. Case notes of these patients were reviewed to determine the prevalence of Immunoglobulin deficiency states in this population.*Aims:* To examine the clinical characteristics of coeliac patients found to be deficient in IgA, and to compare them with a group of age and sex matched coeliac patients with normal IgA levels.*Results:* 14 cases (8 women and 6 men) were identified as being selectively deficient in IgA. One man had common variable immunodeficiency. Mean age at diagnosis was lower in the IgA deficient group (17.52 versus 26.12 yrs.). Anaemia was present in 8/14 IgA deficient patients compared with 3/14 controls, $p = 0.121$.Abdominal pain was more prevalent among coeliac controls, (5/14) versus (1/14) IgA deficient coeliacs, ($p = 0.167$). Recurrent infection and an increased prevalence of autoimmune conditions was noted in the IgA deficient group, but the difference was not significant. Response to gluten free diet was similar in both groups. No difference was found in the prevalence of HLA B8 and DR3 among the two groups. No IgA deficient coeliac was deficient in any IgG subclass.*Conclusions:* The prevalence of IgA deficiency in west of Ireland coeliacs is 2.31/100. This is similar to other coeliac groups and 13–18 times greater than the general population. These are a distinct group of coeliac patients with unique characteristics, and should be followed closely. We also suggest that all coeliacs be monitored for this state. Intestinal disorders, absorption: Pathophysiology of diarrheaIntestinal disorders, absorption: Gluten enteropathyIntestinal disorders, absorption: Malabsorption syndromes }" "Immunoglobulin Deficiency in Coeliac Disease: A Single Institution 25 Year Experience"

[1] Ist. di Scienze Mediche, IRCCS-Ospedale Policlinico, Universit\'e0 di Milano, Italy

[2] II Servizio di Anatomia Patologica, IRCCS-Ospedale Policlinico, Universit\'e0 di Milano, Italy

[3] Ist. Chirurgia Generale, IRCCS-Ospedale Policlinico, Universit\'e0 di Milano, Italy*Background and aims.* LG has been associated with H. pylori infection and with celiac disease. The prevalence of LG in adult celiac patients from the Mediterranean area is still unknown. The aims were to correlate GIEL concentration and the prevalence of LG and H. pylori infection in adult celiac patients.*Patients and methods:* Two or more antral gastric biopies were taken prospectively in a consecutive series of 49 celiac patients (37 on free diet, 12 on gluten free diet for 6 months at least) and compared with those from 22 non celiac patients comparable for sex and age. Biopsies were examined separately by 2 observers and assessed for the presence of gastritis and H. pylori infection. LG was diagnosed if 25% GIELs were counted in at least 300 surface epithelial cells per biopsy. GIELs were also identified by antibody anti-CD3 and anti-CD20.*Results.* LG was not diagnosed in any patient or control. Mean (range) GIEL concentration was 3 (1–20)% in celiac patients on free diet, 2 (1–10)% in those on gluten free diet and 1 (0–6)% in controls ($P < 0.001$). H. pylori infection was observed in 25% patients and 32% controls.*Conclusions.* LG may be rare in adult celiac patients from the Mediterranean area. Genetic factors may affect the immunological status of these celiac patients. Whether patients with and without increased GIELs differ in response to gluten free diet and in risk of intestinal lymphoma should be investigated. [3] Depts. of Dietetics and Nutrition, Hogeschool Nijmegen, The Netherlands

[4] Dutch Down Syndrome Foundation, The NetherlandsChildren with Down syndrome (DS) frequently have feeding problems which can predispose to an inadequate dietary intake. *Aims:* 1. To study the eating habits and nutrient intake of 44 children with DS (0–4 year). 2. Compare them to that of 37 healthy control children, matched for age and sex. 3. Investigate whether the Recommended Dietary Allowances (RDA) (1) are appropriate for these children. *Methods:* The food intake was assessed by the dietary history method. Data from patients and controls were compared using the ANOVA analysis. The data from the children with DS were compared to the RDA by means of the Student-t test. *Results:* The mean weight of the children with DS was 9.7 – 2.7 kg (P25) versus 11.7 – 3.6 kg (P50) in the controls. The mean height of the children with DS was 78.5 – 10.5 cm (P50) versus 83.6 – 13.4 cm (P25) in the controls ($p < 0.01$). The median age at introduction of bread, of hard pieces of fruit and of warm meals was significantly older among the children with DS (12, 30 and 24 months respectively) than in the controls (8, 12 and 12 months respectively). No significant differences were found in the energy intake from macronutrients. The daily intake of vitamins B2, B6 and calcium of the children with DS was significantly lower than in the controls, but in agreement with the RDA. The energy intake per kg body weight of the children with DS reaches the RDA. *Conclusions:* The most important difference in the eating habits of children with DS versus controls is the age at introduction of solid food. The fact that the energy intake per kg body weight of the children with DS reaches the RDA can be explained by the significant lower body weight of the children with DS compared to the controls ($p < 0.01$). Dietetic advise to DS children should be based on the body weight and on the developmental age of the child and not on their chronological age. (1). The Netherlands food and Nutrition Council. [4] Dept. of Medical Statistics, Leiden University Hospital, The Netherlands

[3] Dutch Down Syndrome Foundation, The NetherlandsThe board of the Dutch Down syndrome Foundation (DDF) suspected children with trisomy 21 (DS) to have cow's milk allergy (CMA) more often than children in the general population (1.7–2.8%) [1]. *Aim.* The DDF asked us to establish the frequency of CMA in their young members. *Design.* Experimental, prospective, double-blind, food intervention study. *Patients.* All 109 families living in the western part of the Netherlands were invited. Inclusion criteria: having a child with DS, age 0–4, home-reared, not diagnosed as having CMA, not being breast-fed. *Methods.* The diagnosis of CMA was based on the gold standard of double blind food intervention: improvement of symptoms on cow's milk protein (CMP) elimination and worsening of the same symptoms on CMP introduction. A positive elimination-introduction-re-elimination test was considered diagnostic. During the whole study the children followed a CMP-free diet based on an adapted hypo-allergenic whey hydrolysate milk formula (Nutrilon Pepti Plus, Nutricia Nederland BV). CMP was double-blind introduced by adding 1.5 g CMP per 100 ml CMP-free formula. Before and after each food intervention the symptoms compatible with CMA (respiratory, dermatological, gastrointestinal) were scored. *Results.* Data on CMA before the study were available in 92 children: in 3 of them CMA had already been diagnosed, but not according to the elimination-introduction-re-elimination principle. 44 children participated in our study (41%, 22 boys. Mean age: 21 – 11 months). The main reason to participate (63%) was to exclude CMA. Reasons for not participating were too great a burden on the family (13%), no suspicion of CMA (12%), a critical clinical condition (7%) and unknown reasons (27%). CMA was proven in 1 child (2.8%; 95% CI: 0.1%–14.5%). *Conclusion.* In a selected group of children with DS (meanly parents suspecting their child to have CMA participated) we found CMA only in 1 of 109 children (1%; 95% CI: 0%–5.1%). The frequency of CMA in children with DS seems to be similar to the one reported in the general Dutch child population.

"P P 43 0979"P 43 0979**Acute Diarrhoea in France Probably Due to Rotavirus during Winter: A Case-Control Approach**

*L. Letrilliart[1], J.C. Desenclos[2], L. Beaugerie[3], A. Flahault[1]

[1] I.N.S.E.R.M. U444-Institut F\'e9d\'e9ratif Saint-Antoine de Recherches sur la Sant\'e9, Paris, France

[2] R\'e9seau National de Sant\'e9 Publique, Saint-Maurice, France

[3] D\'e9partement de Gastro-enterologie, Hospital Rothschild, Paris, France*Background*—The surveillance data gathered from the *Sentinelles* Network at a national level indicates that acute diarrhoea (AD) occurs with an endemic pattern usually including an epidemic winter outbreak [1]. We estimate that 670 000 cases of AD were diagnosed in general practice in January 1996. However the determinants of AD during the winter period are not well established in France. *The aim* of this study was to ascertain risk factors of AD: mode of transmission (consumption of shellfish, of soft water; recent contact with a case of diarrhoea) and facilitating factors (drug consumption; association with influenza or ear infection; underlying chronic disease).*Methods*—A case-control study was conducted with incident cases matched to controls for age class; 588 cases and 568 controls were included among the patients of sentinelle practitioners between December 24, 1995 and January 31, 1996. Conditional logistic regression was used for statistical analyses.*Results*—There was no association between AD and any shellfish consumption — e.g. raw oysters (OR = 1.1 [0.9; 1.4]) — or soft water drinking (OR = 0.7 [0.5; 1.0]). Factors significantly associated with AD were: an intra-familial contact with a case of diarrhoea within the last ten days (OR = 4.4 [3.0; 6.3]); an estimated delay inferior to 3 days between the time of contact and the date of consultation (OR = 10.8 [4.9; 23.8]); and cohabitation with a child under two (OR = 1.9 [1.3; 2.7]).*Conclusion*—These results stress the major role of person-to-person transmission in the occurrence of winter acute diarrhoea epidemics. The nature of the factors significantly associated with the risk of AD is suggestive of a viral etiology. Rotavirus, because of its infantile epidemiology and its incubation period usually inferior to 3 days, is one of the most plausible causes of winter diarrhoea.

[6] Brest, Paris, France

[7] Janssen Cilag, Paris, FranceAlthough acute diarrhoea is a common problem, little is known about its epidemiology, management and socio-economic impact.*Method:* 6-month survey, using 2 previously validated questionnaires (Q) via Minitel: this system allows real-time follow-up and validation of data. 176 of 277 practitioners (Gps) who initially agreed on participating throughout France, completed [1)]over 6 months: *phase-1* Q in all patients (pts) (> 15 yrs) presenting with acute diarrhoea ({\'b3} 3 stools per days, max 72 hrs) and [2)]during 2 defined periods: *phase-2* Q on outcome of diarrhoea in 5 consecutive pts (4 – 3 days after phase 1).*Results.* Information was generated in 4200 patients by 176 GPs (age 42 (15–98) yrs, ratio M/F 42/58, 48.4% had profession). Seasonal variations were not observed. The main associated symptom was abdominal pain (84%). Vomiting was reported in 39%, fever in 33%, mucus in stools in 9% and dehydration in 3%. The cause was thought to be viral in 51%, alimentary 23%, drug-induced 8%, bacterial 6.5% and parasitic 0.7%. The duration of episode varied mostly 1–3 days. Self-medication was initiated by 1 of 3 pts prior to consultation. Management was mainly handled by GP's, with few investigation (8% stool culture; 3.5% other), rare referral (2%) or hospitalisation (– 1%). Medication was prescribed in 95% of pts. Diarrhoea (mainly high stool frequency, fever and severe symptoms) lead to absenteeism at work in 1 of 3 pts, usually of short duration (– 3 days). Direct costs of management were the lowest in case of Imodium prescription, but indirect costs (days of sick-leave) appeared not to be affected by type of medication prescribed.*Conclusion.* Diarrhoea is a common condition, leading to relatively low direct health care costs per pt, but frequent work loss of short duration. Clinical practice: Epidemiology (non cancer)Clinical practice: Management strategy }" "A French Survey on Epidemiology and Management of Acute Diarrhoea"

"P P 43 0981"P 43 0981**Comparison of Loperamide-Oxide and Acetorphan in Acute Diarrhoea**

*J. Frexinos[1], J.-R. Sallenave[2]

[1] Hopital Rangueil, Toulouse, France

[2] Janssen-Cilag and GP's Cooperative Group, FranceLoperamide-oxide (LOX), a new loperamide derivative with higher mucosal (antisecretory) than myenteric (motility-inhibiting) properties, was compared with acetorphan (ACE), an antidiarrheal without effects on gut peristalsis and thought to give less constipation than loperamide.*Method:* Randomized, double-dummy placebo (PLA)-blinded study in 574 adult outpatients (pts) with acute diarrhoea (lasting {\'b3} 12 hrs and {\'a3} 72 hrs; {\'b3} 3 (semi-)liquid stools/day). Pts received LOX, 2 tabs of 1 mg at start and 1 tab after each unformed stool (max 8 tabs/day), plus 3 PLA caps identical to ACE, or ACE 100 mg tid, plus LOX-identical PLA tabs. Hospitalization, blood in stools, fever (> 38.5\'b0C), severe infection, chronic diarrhoea, IBD, and intake of antibiotics or other antidiarrhoeals were excluded. Treatment lasted until the end of diarrhoea or max 96 hrs.*Results.* Diarrhoea was resolved in 53% LOX pts, vs 48% ACE pts within 24 hrs, and in almost equal % within 48 hrs (– 87%) and 96 hrs (– 98%). There were no significant differences in mean duration of diarrhoea (26.8 hrs for LOX, vs 28.9 hrs for ACE) or daily number of unformed stools. The number of unformed stools, however, was lower with LOX than with ACE during the total 3-day period ($p < 0.03$), until resolution of diarrhoea ($p < 0.06$) and in the responding pts ($p < 0.01$). Overall response was in favour of LOX when rated by physicians ($p < 0.01$), a difference not found among the pts' assessments. Both drugs were well tolerated, but less aggravation of bloating occurred with LOX ($p = 0.02$). Quality of life was comparable in both groups during the 1st and 2nd day, but in favour of LOX during the 3rd day (less pts with incapacitating symptoms or interrupting work, $p < 0.05$).*Conclusions.* Overall, LOX and ACE are almost equally effective and tolerated; results for some limited parameters slightly favour LOX. Motility, general: Functional GI disordersClinical practice: Management strategy }"

"P P 43 0982"P 43 0982**Bacterial Overgrowth of the Small Bowel (BOSB) and Malabsorption of Low Weight Sugars in Isolated IgA DeficiencyM. Romeo, G. Balducci, G.F. Sasso, G. Mattiacci, F. Lintas, B. Ceccanti, P. Santini, M. Ceccanti**

Dept. Clinical Medicine, University of Rome ""La Sapienza""In isolated deficiency of IgA patients BOSB is frequent, leading to chronic diarrhea. The reference method for BOSB was the demonstration of a large number of microbial colonies (> 2 {\'b4} 10^5/ml) in cultures of jejunal fluid. Recently, H_2-breath test (HBT) was found useful: a good correlation between jejunal-fluid culture data and the fasting basal levels of H_2 in expired air (> 10 ppm) was reported. Relevant lactose malabsorption was demonstrated by our group in chronic alcoholics, frequently affected by diarrhea and impairment of IgA function. In this study, a series of patients affected by primary IgA deficiency was tested by HBT, to confirm the relationship between fasting basal overproduction of H_2 and BOSB, and to assess the frequency of low weight sugars (LWS) malabsorption. *Materials and methods.* A series (A) of 27 patients (14 male, 0.13 female; age 33–46 y., m – SD = 39.9 – 17.16) affected by primary IgA deficiency, without any detectable parasite in the gut were investigated. Controls (C) were 38 healthy people, matched for age, sex and dietary habits. All the subjects were taken at a low-fiber diet for two days before the test. Body weight and height were measured. HBT was performed in the morning (starting about at 8 a.m.) after a 12-hour fasting. Basal H_2-level in expired air was assayed; lactose (20 g/H_2O 100 ml) was administered; samples of expired air were taken each 30 min for 4 hours. The diagnosis of lactose malabsorption was established if in at least 3 consecutive samples the H_2-levels were > 20 ppm higher than basal levels. Statistical evaluation was performed by { ?}^{2}-test and Tau-C Kendall's test, for Area Under Curve (AUC) evaluation, by Mann-Witney's test. *Results.* Basal H_2-level was 8.5 – 9.0 ppm [confidential interval (ci) = 3.9 \'f7 7.2] in group A and 5.6 – 5.2 ppm (ci = 4.99 \'f7 12.08) in the group C. The frequency of malabsorption was 78.6% in group A and 41.0% in group C: H_2-AUC was 12,741.72 – 11,497.15 (ci = 8,283.30 \'f7 17.199.56) in group A and 3.185.77 – 3,617.92 (ci = 2,012.97 \'f7 4,358.56) in group C. Body Mass Index (BMI, body weight/body height^2) was 22.96 – 3.17 (ci = 21.73 \'f7 24.19) in group A, 24.18 – 3.28 (ci = 23.12 \'f7 25.25) in group C. *Conclusions.* According to our data, basal H_2-levels are increased in IgA deficiency respect to controls, suggesting BOSB (p < 0.001). Also the frequency of malabsorption is increased in IgA deficiency, as confirmed by AUC values (p < 0.001). LWS malabsorption leads to lowered BMI in IgA deficiency, suggesting impaired LWS utilization. These clinical findings may be related to: 1) modifications of intestinal microenvironment, specific for IgA deficiency (both congenital and acquired), leading to H_2-consuming bacteria decrease and to saccharolytic bacteria increase, producing the increased H_2-levels in the colon; 2) small bowel mucosa impairment, frequent in IgA deficiency patients, leading to reduced activity of brush border enzymes, promoting increased frequency of malabsorption; 3) increased osmolarity of stool and increased production of volatile fatty acids (with cathartic activity) in the colon, leading to increased frequency of diarrhea, promoting the BMI decrease (p < 0.001) observed in IgA deficiency patients. Intestinal disorders, absorption: Malabsorption syndromes }" "Bacterial Overgrowth of the Small Bowel (BOSB) and Malabsorption of Low Weight Sugars in Isolated IgA Deficiency"

"P P 43 0983"P 43 0983**Efficacy of Two Antibiotics and a Probiotic in the Treatment of Small Intestinal Bacterial Overgrowth**

*A. Attar, Y. Bouhnik, B. Flouri\'e9, C. Franchisseur, P. Crenn, F. Briet, J.C. Rambaud

Department of Gastroenterology, Saint-Lazare, Paris, FranceAlthough antibiotics are widely used in the treatment of small intestinal bacterial overgrowth (SIBO), no controlled trial has been performed to test their efficacy. *In this study* we compared 3 treatments: 1) amoxicillin-clavulanic acid (Am-c) which is *in vitro* the most efficient antibiotic against aerobic and anaerobic bacteria isolated from jejunal contents of patients with SIBO (Bouhnik et al., Gastroenterology, 1993, 104, A237), 2) norfloxacin (Nor) which is only efficient against aerobic bacteria, 3) *Saccharomyces boulardii (Sb),* a probiotic agent whose efficacy has been reported in children with SIBO. *Methods:* Ten patients suspected to have SIBO (predisposing conditions, chronical diarrhea, malabsorption syndrome) and a positive H_2 breath test (H_2BT) were enrolled and received for five 7 days periods no treatment (basal period), a *placebo (Pla)* and then, in a random order and double blinded fashion, Nor (800 mg/d), Am-c (1500 mg/d) and *Sb* (1500 mg/d). The main criteria of efficacy was the mean daily number of stools reported on the last 3 days of each periods. When the treatment was considered efficient, patients were followed until worsening of diarrhea and were then included in the next period. A H_2BT was performed on the first and the last day of each period. *Results:* (m – SD) compared to basal period, Nor and Am-c led to a significant reduction in the mean daily number of stools (4.2 – 2.2 vs 2.3 – 1.2 and 3.0 – 1.5; P < 0.01, respectively) whereas *Pla* and *Sb* had not effect (3.9 – 1.9 and 3.8 – 1.6). Benefit of Nor and Am-c occurred after respectively 2.0 – 1.4 and 1.2 – 0.4 days and was maintained for 6.1 – 3.7 and 14.2 – 23 days after withdrawal; however, H_2BT became negative in only 30 and 55% of patients during Nor and Am-c periods respectively. Nor and Am-c reduced the number of stools in 9 and 6 patients out of 10. Hydrogen excreted in breath decreased during Nor and Am-c periods (from 37 – 24 to 12 – 14 ml/2 h, P < 0.01 and from 24 – 19 to 8 – 14 ml/2 h, P = 0.01) but was not modified during *Pla* and *Sb* periods. *Conclusion:* Norfloxacin and amoxicillin-clavulanic acid are effective in the treatment of diarrhea induced by SIBO but more patients responded to norfloxacin in spite of a narrower spectrum and inefficiency against anaerobic bacteria. The improvement of diarrhea is associated with a reduction in the abnormal bacterial metabolic activity in the small intestine, but not necessarily with its removal. Intestinal disorders, absorption: Malabsorption syndromesClinical practice: Management strategy }" "Efficacy of Two Antibiotics and a Probiotic in the Treatment of Small Intestinal Bacterial Overgrowth"

"P P 43 0984"P 43 0984**The Ursodeoxycholic Acid–p-Aminobenzoic Acid Loading Test, a New Diagnostic Tool in the Bacterial Overgrowth Syndrome**

*Zs. F. Kiss, J. W\'f6lfling[1], S. Cs\'e1ti, F. Nagy, T. Wittmann, Gy. Schneider[1], J. Lonovics

First Department of Medicine, Albert Szent-Gy\'f6rgyi Medical University, Szeged, Hungary

[1] Department of Organic Chemistry, J\'f3zsef Attila University, Szeged, Hungary*Introduction:* Contaminated small bowel syndrome (CSBS) is frequently associated with different clinical symptoms, among which meteorism and diarrhoea are common. Meteorism is due to excessive gas formation, while diarrhoea is a result of bacterial toxins and pathological fermentative processes. These mechanisms include abnormal splitting of carbohydrates, and deconjugation and dehydroxylation of bile salts. Some bacteria capable of metabolizing bile salts have been shown to release *p*-aminobenzoic acid (PABA) from an ursodeoxycholic acid (UDCA)–PABA conjugate. The present aim was to determine the possible complementary role of the UDCA-PABA test in the diagnosis of intestinal bacterial overgrowth. *Patients and methods:* The H_2 breath and UDCA-PABA tests were performed simultaneously in 68 patients with suspected CSBS, and in 5 healthy control subjects. The H_2 breath test involved was performed by oral loading of 25 g lactose and or 10 g lactulose. The UDCA-PABA test was carried out by the oral loading of 250 mg UDCA-PABA conjugate, followed by measurement of the amount of urinary excreted PABA. The diagnosis of bacterial overgrowth was considered to be established when either the H_2 breath test or the UDCA-PABA test yielded proved pathological results. *Results:* 35 of the 68 patients proved to have CSBS. In 13 of the 35, only the enhanced urinary PABA excretion (11.7 – 1.42 mg vs 3.6 – 0.68 mg) indicated the bacterial overgrowth. 15 of the 35 gave only a positive H_2 breath test, and in the remaining 7 cases the results of both tests were pathological. In 8 CSBS patients, the urinary excretion of PABA decreased significantly following a 10-day Tinidazole treatment (5.5 – 1.29 mg vs 13.1 – 2.07 mg). *Conclusion:* The UDCA-PABA test is to be a valuable clinical adjunct to the H_2 breath test for the detection of intestinal bacterial overgrowth: the H_2 production alone failed to reveal bacterial overgrowth in 37% of the cases. Intestinal disorders, absorption: Pathophysiology of diarrheaIntestinal disorders, absorption: Malabsorption syndromes }" "The Ursodeoxycholic Acid-p-Aminobenzoic Acid Loading Test, a New Diagnostic Tool in the Bacterial Overgrowth Syndrome"

"P P 43 0985"P 43 0985**Bacterial Colonisation of the Upper Gastrointestinal Tract Is Related to Severity of Illness**

*C.J. O'Boyle, A. Gilliam, R. Williamson, P. Buckley, C.J. Mitchell, J. MacFie

Combined Gastroenterology Unit, Scarborough General Hospital, Scarborough, North YorkshireThe upper gastrointestinal tract is usually regarded as being sterile. The occurrence of bacterial colonisation in the upper gastrointestinal tract may predispose to septic morbidity. It has been suggested that this occurs more frequently in critically ill or immunocompromised patients. The aim of this study was to assess changes in gastric flora and to attempt to relate these to severity of illness.We have prospectively evaluated proximal gut microflora in 279 surgical patients by culturing aspirates obtained aseptically from indwelling nasogastric suction tubes. Severity of illness was assessed using the \lquotePOSSUM\rquote physiological scoring system.Eighty five (31%) aspirates yielded no growth, eighty four (30%) patients grew one organism type and 110 (39%) grew multiple organism types. Candida albicans was the most abundant organism cultured and was present in 104 (37%) of aspirates. This was followed by E. Coli 38 (14%), Strep. Sp. 33 (12%), Lactobaccillus 27 (10%) and Strep. Fecaelis 23 (8%). Forty eight percent (175) of bacteria isolated would not commonly be associated with intestinal colonisation. Multiple organism colonisation occurred in significantly fewer patients with low (< 20) POSSUM scores than those with high (> 30) scores (35% vs 67%, $p < 0.02$, { ?}^{2} = 7.09) and was associated with an increase in septic morbidity.We conclude that upper gastrointestinal tract colonisation is common in surgical patients and that bacterial overgrowth is related to the degree of physiological stress and may predispose to septic morbidity. "P P 43 0986"P 43 0986**Prophylaxis of Mucosal Damage with Sucralfate During Cancer Therapy**

*L. Franz\'e9n, G. Edbom, B. Zackrisson, R. Henriksson

Dept. of Oncology, Umea University Hospital, S-901 85 Umea, Sweden*Purpose.* Radiotherapy and chemotherapy of different malignancies may be complicated by a variety of side effects, some of which may be related to mucosal damage. The value of sucralfate in the prevention of radiation induced symptoms was suggested by the results of two open studies one with prostate and urinary carcinomas and the second with gynaecological cancer treated with radiotherapy.*Methods.* A double-blind randomised placebo-controlled study in patients treated with curative intent for prostate and urinary bladder cancer with external radiotherapy and the study included 70 patients. The other study also double-blind, placebo-controlled included 50 patients receiving irradiation against the head and neck region with curative intent.*Summary of the results.* For the head and neck patients the mucosal reactions were significantly worse for the placebo group at week 1, 2 and 3, but at other observation times the differences did not reach statistical significance. The results of the pelvic treated patients showed that the frequency of diarrhoea, stool consisting and the number of patients requiring symptomatic therapy with loperamide were significantly in favour of sucralfate group.*Conclusion.* The studies demonstrated that sucralfate can be of value in reducing radiation induced bowel and oral symptoms during and following radiotherapy of the head and neck and pelvic region. "P P 43 0987"P 43 0987**H_2 Starch Breath Test in the Study of Functional Gastrointestinal Disorders**

*M. Ventrucci, G.M. Ubalducci, A. Cipolla, E. Roda

Dept. of Gastroenterology, University of Bologna, ItalyMany patients with irritable gut experience gastrointestinal distress after starch ingestion. We studied the orocecal transit and absorption of starch by means of a H_2 breath test in 121 H_2 producers: 106 patients with functional gastrointestinal disorders (72 with dyspepsia, 17 with constipation, and 17 with diarrhea) and 15 healthy volunteers. Breath samples were taken every 30 min for 9 hours after ingestion of 100 g of starch in the form of white bread. H_2 breath tests with lactulose (10 g), lactose (20 g) and fructose (25 g) were also carried out in 34, 76 and 67 subjects, respectively. Results are expressed as medians and interquartile ranges (25–75%). *Results:* Incomplete absorption of starch (peak rise in breath $H_2 > 10$ ppm) was present in 11/15 healthy controls (73%) and in 76/106 patients (72%). Starch ingestion caused gastrointestinal symptoms in only 11 patients of whom 7 showed starch malabsorption. The 9 hour H_2 excretion (area under the curve) after starch ingestion was significantly lower ($p < 0.05$) in patients (42 ppm{\'d7}h, 26–82) than in controls (82 ppm{\'d7}h, 36–126). The orocecal transit time of starch did not significantly differ between the two groups (330 min, 270–390 in patients and 300 min, 180–300 in controls), but was significantly lower ($p < 0.01$) in patients with diarrhea (240 min, 180–330) when compared with those suffering from dyspepsia (330 min, 270–405). An inverse relationship was found between H_2 output and transit time in patients (rho = { -}0.65), but not in controls (rho = { -}0.22). No relationship was found between the H_2 excretion or transit time measured after starch and those after lactulose. The H_2 excretion after starch was not significantly different between the 36 patients with lactose malabsorption (43 ppm{\'d7}h, 29–82) and the 40 patients with normal lactose response (35 ppm{\'d7}h, 15–78). In the 33 patients with fructose malabsorption in the H_2 excretion after starch was higher (55 ppm{\'d7}h, 29–96, p = 0.06) than in the 34 with a normal fructose breath test (36 ppm{\'d7}h, 17–75). *Conclusions:* The H_2 starch breath test needs further investigation before it can be used for the diagnosis of functional gut disorders. According to our results gastrointestinal distress after starch ingestion in patients with irritable gut cannot be attributed to excessive H_2 intestinal production. Motility, general: Functional GI disordersIntestinal disorders, absorption: Malabsorption syndromes }"

*S. Taoka[1], T. Okahisa, M. Sogabe, S. Hayashi, H. Matunaga, Y. Ohkita, A. Tsutsui, T. Fukuda, N. Muguruma, M. Yasuda, T. Yokoi, S. Okamura, H. Shibata, S. Ito, T. Sano[2]

[1] Second Department of Internal Medicine, School of Medicine, The University of Tokushima, Tokushima, Japan

[2] First Department of Pathology, School of Medicine, The University of Tokushima, Tokushima, Japan*Purpose:* Neuropeptides liberated from enteric neurons have been suggested to contribute to the inflammatory process in ulcerative colitis (UC). Furthermore, inhibitory effects of lidocaine on the responses elicited by neuropeptides were also studied. We studied the efficacy of lidocaine gel enema (LG), reported in 1989 by Bjork, for UC. *Methods:* The subjects of this study were 10 patients who underwent LG at our department. Eight of 10 patients were the left colitis type and two were proctitis type. The conditions before the start of LG were the followings. Seven patients had poorly controlled on sulfasalazine. One became in worse condition during progressive reduction of steroid dosage. One could not reduce the dose level of steroid. One had to stop the steroid therapy because of the side effect. LG was performed as follows. 40 ml (10 ml in the morning, 10 ml in the daytime and 20 ml at night) of 2% lidocaine gel was administered into the rectum. Endoscopy was carried out immediately before and 2 weeks after the start of LG, and biopsy samples of the rectum were examined histologically. *Results:* In all cases, rectal discomfort disappeared within 5 days, and viscous bloody feces disappeared within 2 weeks after the start of LG. Endoscopically, the disappearance of rectal ulcers and a reduction in rectal erosion were observed after 2 weeks of LG. The numbers of crypts and goblet cells were increased, and the inflammation was reduced after 2 weeks of LG. Substance P immunoreactive for nerve fibers slightly increased after 2 weeks of LG. None of the patients complained about any side-effects of LG. *Conclusion:* LG is easy to do and is expected to reduce inflammation, probably through suppressing the release of neuropeptides. LG will be a promising new therapy for UC. Intestinal disorders: IBD, therapy }" "Treatment with Lidocaine Gel Enema for Ulcerative Colitis"

"P P 43 0989"P 43 0989**Interleukin-8 Induced Neutrophil Activation is Suppressed by the Thiol Modulating Anti-Colitis Agent OR-1384**

*E. Nissinen, J. Kaivola, I.-B. Lind\'e9n

Orion Pharma Research, Espoo, FinlandThe extensive infiltration of neutrophils into the inflamed mucosa plays a major role in the pathogenesis of inflammatory bowel disease. One of the most powerful inflammatory mediators responsible for the attraction and activation of neutrophils is interleukin-8 (IL-8). OR-1384 {3-[(4-methylsulfonyl)phenyl]methylene-2,4-pentanedione} is a novel locally acting agent, which is protective in various animal colitis models at doses of 0.3 { -} 10 mg/kg. OR-1384 forms reversible adducts with free thiol groups, which are essential for the proper function of the specific IL-8 receptor on the surface of neutrophils. *The aim* of this study was to evaluate how the reversible thiol modulating compound OR-1384 can affect IL-8 binding and subsequent neutrophil activation.*Methods:* Human neutrophils were isolated from buffy coats. The neutrophils (2 {\'b4} 10^6 cells) were treated with different doses of OR-1384 or reference compounds and incubated with ^{125}I-IL-8. The free and bound ^{125}I-IL-8 were separated and the specific binding of ^{125}I-IL-8 to the neutrophils was measured. The nature of OR-1384 binding to the IL-8 receptor (IL-8R) was evaluated by adding glutathione to the incubation mixture containing OR-1384. Elastase release from the neutrophils (20 {\'b4} 10^6 cells) was used as an IL-8 induced functional assay.*Results:* OR-1384 dose-dependently prevented IL-8 binding to the neutrophils (IC_{50} = 70 \'b5M) while the analogue of OR-1384 without thiol modulating properties was ineffective. The reversible nature of OR-1384 binding to the IL-8 receptor was confirmed by the addition of glutathione. The neutrophil functional assay showed that elastase release was effectively inhibited by OR-1384 (IC_{50} = 18.9 \'b5M). 5-ASA did not inhibit IL-8 binding but showed some effect on elastase release at high mM concentrations.*Conclusions:* The thiol modulating compound OR-1384 was shown to prevent IL-8 binding to neutrophils and interfere with the neutrophil activation process determined as inhibition of elastase release. The effects were clearly dependent on the thiol modulating properties of OR-1384. However, unlike other thiol reactive compounds the effect was reversible. In addition to the previously shown suppression of cytokine formation in inflammatory cells, OR-1384 is likely to exert its effect by inhibiting IL-8 induced neutrophil-mediated deleterious effects in the inflamed gut. "P P 44 0990"P 44 0990**A Pair of Twins with Myo-Neuro-Gastrointestinal Encephalopathy (MNGIE) Syndrome**

*D. Katsaros[1], A. Papadimitriou[2], R. Divari[2], N. Rossolimos[1], K. Goumas[1]

[1] Gastroenterology Dept., Red Cross Hospital, Athens, Greece

[2] Neurology Dept., Red Cross Hospital, Athens, GreeceMNGIE syndrome is a rare multisystem mitochondrial disorder affecting the nervous system and Gastrointestinal (GI) tract.Here we report a pair of male twins, 45 years old, suffering from this syndrome. Both were short, thin, almost cachectic (35–40 kgs) and stated intermittent diarrhoea since childhood, leading to malabsorption, which deteriorated recently.The one of them had been treated for coeliac disease, without success, until we considered his neurological findings, which had gradually become prominent and consisted in bilateral eyelid ptosis, neurosensory hearing loss, nasal speech and mild limb weakness.Laboratory GI investigation did not reveal specific pathological findings, except malabsorption. However brain MRI showed severe leucoencephalopathy. Muscle biopsy showed scattered ragged red fibers and denervation. Mitochondrial enzyme analysis showed significant deficiency of cytochrome-c-oxidase. Southern blot analysis and PCR showed no deletion of mitochondrial DNA. Investigation of the second patient revealed similar findings.Both patients died recently, within 3 months the one from the other. Their parents, two older brothers and one sister are alive in good health.MNGIE syndrome seems to be a separate nosological entity in the spectrum of mitochondrial encephalomyopathies affecting also the GI tract. However, although gastrointestinal symptoms are firstly presented and last for years, this syndrome has been reported only in the neurological literature, in four cases only, and never in twins. Intestinal disorders, absorption: Malabsorption syndromes }" "A Pair of Twins with Myo-Neuro-Gastrointestinal Encephalopathy (MNGIE) Syndrome"

"P P 44 0991"P 44 0991**Vasoactive Intestinal Peptide Is Involved in the Interleukin-1{ b} Inhibitory Action on the Acetylcholine-Induced Jejunal Contraction**

*A.C. Aub\'e9, H.M. Blottiére[1], C. Cherbut[1], J.P. Galmiche

Human Nutrition Research Center: INSERM, Nantes, France

[1] Human Nutrition Research Center: INRA, Nantes, FranceWe have previously shown that interleukin-1{ b} (IL-1{ b}) decreased the acetylcholine (ACh)-induced intestinal contractility through an action on the enteric nervous system. However, the neuromediators potentially involved are poorly known.The aim of the present study was to determine the possible involvement of the three main noncholinergic, nonadrenergic relaxant mediators: nitric oxide (NO), vasoactive intestinal peptide (VIP) and adenosine triphosphate (ATP) in the inhibitory effect of IL-1{ b} on the ACh-induced intestinal contractility.*Methods.* Isometric contraction of rat jejunum longitudinal muscle-myenteric plexus (LM-MP) preparations, bathed in Krebs solution was recorded by a force transducer. IL-1{ b} (10 ng/ml) was added to the bath for 90 minutes. The effect of potentially inhibitory agents on the LM-MP jejunal motor response to ACh ($10^{\{ -}$5} M) was investigated before and after exposure to IL-1{ b}. The following drugs were used: N^G-nitro-L-arginine methyl ester (L-NAME); N^G-amino-L-arginine (L-NNA); N^G-monomethyl-L-arginine (L-NMMA); vasoactive active intestinal peptide (VIP) 10–28; [4-Cl-D-Phe^6, Leu^{17}] VIP and suramin to inhibit NO synthase, VIP and ATP effect respectively.*Results.* L-NAME (3 {\'b4} $10^{\{ -}$4} M), L-NNA (3 {\'b4} $10^{\{ -}$4} M) and L-NMMA (3 {\'b4} $10^{\{ -}$4} M) did not prevent the inhibition of ACh-induced jejunal contraction caused by IL-1{ b}, but increased the ACh response of smooth muscle when administrated alone. Moreover, suramine (3 {\'b4} $10^{\{ -}$4} M) failed to affect the inhibition induced by IL-1{ b}. On the contrary, addition of VIP 10–28 ($10^{\{ -}$5} M) or [4-Cl-D-Phe^6, Leu^{17}] VIP ($10^{\{ -}$5} M) to the bath abolished the inhibitory effect of IL-1{ b}. The effect of IL-1{ b} on the ACh-induced jejunal contraction was partly reproduced by VIP ($10^{\{ -}$6} M).*Conclusions.* In LM-MP jejunal preparation, neither NO nor ATP are involved in the inhibitory effect of IL-1{ b} on ACh-induced contractility. This inhibitory effect seems to be mediated by VIP. "P P 44 0992"P 44 0992**Is Small Bowel Motility Induced by Duodenal Enteral Nutrition Dependent on Osmolality?**

*T. Schmidt, T. Wandersleb, A. Pfeiffer, H. Kaess

Department of Gastroenterology, Hospital Bogenhausen, Munich, Germany*Background/Aim:* Recently, we have demonstrated that upper small intestinal motility induced by duodenal nutrition with an isoosmolar nutrient solution is not dependent on the amount of calories administered (Gastroenterology, May 1996: abstract). The aim of the present study was to investigate, whether the intestinal fed pattern induced by duodenal enteral nutrition is dependent on osmolality.*Methods:* Duodenal infusion (5 ml/min) of an enteral nutrition (2.64 kcal/min; 17% proteins, 59% carbohydrates, 24% lipids) at 3 different osmolalities (160, 300, and 600 mosmol/kg obtained by the addition of sodium chloride) on three consecutive days in a randomized order in 8 healthy volunteers. Duodenal infusion started 10 min after a phase III activity and was continued for 90 min. Motility was recorded with a digital data logger and 6 catheter-mounted miniature pressure transducers located around the duodenojejunal flexure. Recordings underwent visual and computer-aided analysis (Scand J Gastroenterol 1994; 29: 1076–82).*Results* (means – SEM): Osmolality [mosm/kg] 160 300 600Contraction frequency [min{ -1}] 1.95 – 0.21 1.94 – 0.28 1.92 – 0.27Contraction amplitude [mm Hg] 20.7 – 0.3 21.3 – 0.9 20.6 – 0.6Propagated contractions [%] 36 – 3 37 – 4 34 – 5Propagation distance [cm] 4.1 + 0.2 4.2 + 0.2 4.1 + 0.2*Conclusion:* Small intestinal motility induced by duodenal enteral nutrition is not influenced by osmolalites ranging from 160 to 600 mosm/kg. "P P 44 0993"P 44 0993**Enteric Dysmotility Revealed by Computer Analysis of Prolonged Small Bowel Manometry**

*D.L. Wingate, F.D. Castillo, D.F. Evans, M.J. Benson

GI Science Research Unit, St Bartholomew's and The Royal London School of Medicine & Dentistry, London, UKProlonged ambulant small bowel manometry (PSBM) has been shown to discriminate *groups* of patients (Chagas' disease, HIV) from *groups* of normal controls, and the precision of PSBM is increased by comoputer analysis. However, its value in the diagnosis of *individual* patients remains to be determined.. We analysed PSBM in 37 patients who were tertiary referrals. The commonest cause of referral was suspected chronic idiopathic intestinal pseudo-obstruction (CIIP), with differential diagnoses of CIIP, mechanical obstruction, irritable bowel syndrome, or chronic intractable abdominal pain. Three patients with intractable post-vagotomy diarrhoea and 4 diabetic patients with diarrhoea and abdominal pain were included in the cohort. After intubation with a multi-channel pressure-sensitive catheter under fluoroscopic control, recording on a portable datalogger continued for 17–24 hours with the patient freely ambulant at home or in hostel accommodation. In 5 patients, all with CIIP, endoscopic assistance was required to position the catheter; recording was unsuccessful in 2 patients with disabling CIIP because the recording catheter was not retained in the proximal small bowel. The fasting data recorded from each patient was characterised by computer analysis, and the values obtained were compared with control values derived from 47 comparable recordings in healthy volunteers.Abnormal motor activity was found in 13/28 patients with suspected CIIP, in 4/4 diabetics and in 3/3 vagotomised patients. The commonest abnormality was increased nocturnal contractile activity. There was a significant ($p = 0.005$) excess of prolongation and/or diminished migration velocity of Phase 3 of the migrating motor complex (MMC) in CIIP, suggesting myenteric plexus damage: this was not seen in the other groups where there was, however, a significant ($p = 0.05$) excess incidence of accelerated Phase 3 migration velocity. We conclude that systematic analysis of prolonged small bowel manometry promises to be an important clinical tool in the diagnosis of enteric neuropathology. "P P 44 0994"P 44 0994**Computer Programmes Disagree in Measurement of Small Bowel Contractions Recorded by Ambulatory Manometry**

*R. Widmer[1], K. R\'fctz[2], L.M. Jensen[3], H. Andersson[4], E. Husebye[5], SAGIM Workteam

[1] Bogenhausen Hospital, Munich, Germany

[2] Odense University Hospital, Odense, Denmark

[3] GateHouse ApS, N\'f8rresundby, Denmark

[4] Synectics Medical AB, Stockholm, Sweden

[5] Ulleval Hospital, Oslo, Norway*Introduction:* Computer analysis of small bowel manometry has been shown to give discordant results for different programmes with regard to qualitative recognition of contractile events [1]. It is unclear to what extent different programmes agree with regard to quantitative measurement of contractions.*Methods:* Six ambulatory test records with normal intestinal motility patterns including fasting and postprandial motility were analyzed by three computer programmes: SBMA 1.41, (Krankenhaus M\'fcnchen-Bogenhausen), Motan 3.3 (Gatehouse ApS), Multigram 6.31 (Synectics Medical AB). The method of comparison has previously been described [1]. Amplitude, area under the curve (AUC) and duration of contractions, that were recognized by all programmes, were subjected to analysis. Correlation coefficient (r) and slope of linear regression with confidence intervals (CI) were calculated for each pair of programmes.*Results:* 2385 contractions were recognized by all programmes, and thus subjected to analysis, out of a total of 4287 contractions recognized by at least one of the programmes. Programmes SBMA vs Motan* Motan vs Multigram* Multigram vs SBMA* r slope L.CI U.CI r slope L.CI U.CI r slope L.CI U.CIAmplitude 0.81 0.55 0.54 0.56 0.82 1.51 1.49 1.53 0.94 1.09 1.08 1.09AUC 0.66 0.36 0.36 0.37 0.63 3.25 3.15 3.35 0.88 0.55 0.54 0.56Duration 0.39 0.90 0.89 0.91 0.28 1.78 1.75 1.81 0.21 0.52 0.51 0.53*first programme y, second programme x for regression; L. and U.CI: lower and upper 95% confidence limits*Conclusion:* The degree of agreement between different computer programmes in measuring contractions is unexpectedly low, showing that the outcome depends critically on the algorithms applied. Difficulties are encountered particularly in the analysis of duration of contractions.

"P P 45 0995"P 45 0995**The Importance of Immune Genetic Test in the Study of the Pathogenesis of Chronic Pancreatitis**

*N.B. Gubergrits, Y.A. Zagorenko, A.V. Khadakovsky, L.V. Klimova, T.B. Tishenko, Y.Y. Cherevatskaya

Donetsk State Medical University, Donetsk Diagnostic Centre, Donetsk Station of Blood Transfusion, Ukraine*Aim.* To deepen knowledge about the pathogenesis of chronic pancreatitis (CP), its use in the diagnosis and treatment of the disease.*Task.* To study the immune genetic predisposition to CP in connection with the specialty of its manifestation.*Material.* The frequency of occurence of erythrocyte antigens (AB0-system and rhesus-factors – CcDEe) and leucocyte antigens (HLA-system) with a calculasion of the risk of the disease was studied on 52 patients of CP and 56 non-patients.*Results.* The risk of the development of CP was high in those belonging to blood group A0 by 3.23 times. Antigens of the HLA-system A_1, B_8, B_{18}, Bw_{22} rise of the risk in the development of the disease in 2.79, 3.51, 3.52 and 3.44 times correspondingly. These antigens were associated with disregulation between the T- and B-branches of the immune system with a deficit of T-suppressors with a marked cell autosensibilisation to pancreas tissue. In the presence of the phenotype Bw_{40} the risk of developing CP rose by 6.47 times which was connected to a rise in the blood concentration of natural killers. Antigen B_{13} was associated with a fall in the debit part of lipase and B^{27} with a rise in the echogram of pancreas in sonography i.e. with fibrosis of the tissue of the organ. The risk of developing CP in patients having the phenotype of the antigens rose correspondingly by 3.17 and 3.38 times. Antigens protectors were A_2, B_5, Cw_4.*Conclusion.* In part of the patients with CP immune genetic predisposition to the development of the disease has a place, and separate antigens were associated with its pathogenetic branches. This information in perspective can be used in the diagnosis and treatment of CP. "P P 45 0996"P 45 0996**Comparison of the Preventive Effects of Somatostatin and SMS 201-995 in ERCP-Induced HyperamylasemiaG\'f6rg\'fcl Ahmet, Kayhan Bur\'e7ak, Mentes B\'fclent, Ak\'e7ali Zafer, \'dcnal Selahattin**

G\'dcTF Ankara, T\'fcrkiyeThe aim of this study was to compare the preventive effects of SMS 201–995 and somatostatin in ERCP-induced hyperamylasemia.*Materials and Methods:* 120 patients who underwent ERCP were included in our study and were divided in to 3 equal groups. After an overnight fast, the patients were sedated with 10 mg midazolam and duodenal relaxation was achieved with 40 mg hyoscine-n-butylbromide, intravenously (iv). Group I was treated with SMS 201–995 (3 {\'b4} 100 \'b5g/day sc on the ERCP day) and the second group was treated with somatostatin (3.5 \'b5g/kg iv bolus with the start of ERCP, and then 250 \'b5g i.v infusion for 4 hours). The control group received only iv saline. Contrast material was same in all groups. Serial blood samples were withdrawn pre-ERCP and at timed intervals after ERCP (4th hour, 24th hour, 48th hour). Serum amylase and isoamylase levels were determined.The results are shown in the table. GROUP Pre- Post- Post- Post- Pre- Post- Post- Post- ERCP ERCP ERCP ERCP ERCP ERCP ERCP ERCP amylase amylase amylase amylase iso- iso- iso- iso- SU/dl at 4th at 24th at 48th amylase amylase amylase amylase hours hours hours U/dl at 4th at 24th at 48th hours hours hours1 116 + 44 186 + 44 220 + 28 202 + 36 69 + 11 107 + 12 99 + 7 81 + 112 94 + 7 147 + 42 116 + 17 149 + 26 55 + 9 81 + 2 73 + 12 73 + 93 152 + 69 232 + 44 236 + 88 186 + 37 88 + 45 195 + 74 145 + 40 109 + 24*Conclusion:* According to this study, somatostatin was more potent than SMS 201–995 for inhibiting ERCP-induced hyperamylasemia. "P P 45 0998"P 45 0998**Prognostic Factors in the Therapeutic Approach to Pseudocysts of the Pancreas**

*M. Duvnjak, M. Dodig, L. Smircic-Duvnjak, V.N. Simicevic[1]

Dept. of Gastroenterology, University Hospital ""Sestre Milosrdnice"", Crotia

[1] Pliva Pharmaceutical Co., Research Institute, Biomedical Dept., Zagreb, Croatia*Purpose:* This study was performed to test the prognostic value of etiology, location and the amount of liquid in the pancreatic pseudocyst (PC), as well as the concentration of biochemical parameters (LDH, glucose, proteins, sodium, potassium, bilirubin and lipase) of the PC contents and the serum of the patients regarding the efficiency of ultrasound (US)-guided percutaneous evacuation (PE) as a possible method of therapeutic approach.*Methods:* After obtaining informed consent, a total of 43 patients with histories of acute pancreatitis and PCs persisting for more than 6 weeks were included in the study. The diagnosis was made by US examination and CAT scan. The PC content samples were obtained using a Chiba needle of 21-gauge under US control. Biochemical parameters were determined by standard laboratory methods.*Results:* Concerning the various etiologic factors, no differences were noted in the outcome of PE. PE was a successful method of treatment for the PCs located in the tail of the pancreas, while those located in the head of the pancreas had a significantly lower healing rate. The amount of liquid taken during the PE was significantly lower in patients successfully treated by PE (median 96.5 ml) compared to the PC liquid amount in the patients with the failed treatment (median 222 ml). Concerning the biochemical parameters, unlike the serum data, significantly lower values of proteins, potassium and lipase in the PC liquid were found in successfully treated patients.*Conclusion:* It can be concluded that the analysis of the mentioned parameters (location, the amount of liquid, proteins, potassium and lipase concentrations in the evacuated material) can allow an early decision concerning the therapeutic approach to patients with PC. "P P 45 0999"P 45 0999**Long-Term Effects of ONO-3403, A New Oral Protease Inhibitor, on Experimental Chronic Pancreatitis in Rats**

*M. Shiozaki, Y. Takeda, T. Itabashi, K. Katsu

Second- Department of Internal Medicine, Osaka Medical College, Takatsuki City, Osaka, Japan*Purpose:* ONO-3403 is a potent newly developed oral protease inhibitor. In rats, long-term administration of ONO-3403 has a pancreaticotrophic effect. We therefore evaluated the protective effect of chronically administered ONO-3403 against the development of pancreatic fibrosis in a rat model of chronic pancreatitis.*Methods:* Rats were injected intraductally with zeinoleic acid solution. After three days in the acute phase, there was progressive pancreatic atrophy, leading to diffuse fibrosis by day 28. Some of the rats were fed a diet containing 0.1% ONO-3403 from day 2 or 4 until day 28. Histologic findings and pancreatic enzyme contents of ONO-3403-treated rats were compared with untreated controls.*Results:* On day 2 there was no acinar cell loss and the fibroblasts appearing in the interstitium were immature. On day 4 acinar cell loss and proliferation of stromal fibroblasts were evident. ONO-3403 given from day 4 did not significantly prevent pancreatic fibrosis by day 28. However, in the group given ONO-3403 from day 2, acinar cells showed regeneration and interstitial fibrosis was almost absent, indicating a marked protective effect of ONO-3403.*Conclusion:* To prevent pancreatic fibrosis, chronic treatment with ONO-3403 should be started from the early stage of acute pancreatitis when there is no acinar cell loss, CCK receptors on acinar cell membranes are well preserved, and stromal fibroblasts are immature. Institution of long-term ONO-3403 therapy immediately after the attack of abdominal pain may prevent the progression of pancreatic fibrosis and consequent impairment of exocrine pancreatic function. "P P 45 1002"P 45 1002**A Randomised Controlled Trial of Antioxidants (Antoxid) in Tropical Pancreatitis***

*K.B. Leena, K.T. Shenoy

Dept. of Gastroenterology, Medical College, Trivandrum, India*Objective:* To test the hypothesis that a combination of antioxidants is effective in reducing lipid peroxides and pain relief in tropical pancreatitis.*Design:* Randomised double blind cross over trial using either Antoxid or placebo. Each capsule of Antoxid contains Beta carotene 50 mg, Vitamin A 2500 i.u., Vitamin E 10 i.u., Vitamin C 50 mg and Zinc sulphate monohydrate 27.45 mg and was given thrice daily for 30 days followed by placebo capsule or vice versa. A washout period of 2 weeks was given.*Sample size:* 15 patients with tropical pancreatitis.*Co-Intervention:* Treatment of diabetes mellitus with soluble insulin; pancreatic enzyme preparation and analgesics for relief of pain.*Measurements:* Clinical and biochemical (lipid peroxides, red cell enzymes, vitamin C and blood glucose) at the baseline and during each treatment period. Pain and global improvement were scored by visual analogue scale.*Outcome measures:* Improvement in blood glucose and reduction in lipid peroxides and other red cell enzyme changes; subjective improvement in pain and global improvement.*Compliance to treatment:* Consumption of more than 80% of capsules was assessed as good and more than 90% as excellent.*Data analysis:* Descriptive and independent \lquotet\rquote test and Mann Whitney U test to detect difference between the two groups in the basal state. Wilcoxson matched pair signed rank test to detect the treatment effect ({ a} = 0.05).*Results:* 8 received Antoxid and 7 received placebo as the first drug. Compliance was 100%. Baseline characteristics were similar. Significant reduction in lipid peroxides (P = 0.001), red cell glutathione (P = < 0.05) and pain scores (P = < 0.001) were noted with Antoxid. Surgery could be avoided in 70%. Global improvement was marked with Antoxid.*Conclusion:* Antoxid is a promising drug for pain relief of tropical pancreatitis and surgery could be avoided in majority of TP.* Study funded by American Remedies Ltd, Madras. Pancreas: Pancreatitis, chronicClinical practice: Management strategy }" "A Randomised Controlled Trial of Antioxidants (Antoxid) in Tropical Pancreatitis*"

"P P 45 1003"P 45 1003**Computed Tomography in Tropical Pancreatitis**

*K.B. Leena, K.T. Shenoy

Dept of Gastroenterology, Medical College, Trivandrum, India*Objective:* To determine the morphology of pancreas and other organs by computed tomography (CT) in tropical pancreatitis (TP).*Methods:* 102 patients with TP had CT performed. Calcification, ductal diameter and dilatation, lipomatons atrophy, fluid collection, focal and diffuse enlargement of pancreas, peripancreatic tissue planes, hepatobiliary and vascular involvement, renal changes were studied.*Results:* Calcific 64, non calcific 18 and pancreatic malignancy with TP 30 were observed. *Calcific:* Calcification was seen in 54 patients in the whole pancreas, 5 in the body and 5 in the tail. Ductal dilatation was seen in 14 patients and main ductal diameter was 5–18 mm (mean 8.8 mm). Margins of the pancreas were smooth in 38 patients and irregular in 26. Pancreas was atrophic in 20 patients and lipomatous atrophy was noted in 18. Fluid collection was noted in 18 patients, localised in 12; peripancreatic in 4 and remote in 2. Gall stones were noted in 9, choledochal cyst in 1, renal calculi in 3, horse shoe kidney in 1 and hepatic haemangioma in 1. *Non calcific:* Of the 18, 4 had calculi and 9 had ductal dilatation and lipomatous atrophy and 4 had pancreatic fluid collection as pancreatic ascites. *Pancreatic malignancy with TP:* Mass lesion with calcification and obstructed duct located in the head in 18 and difuse in 12. Involvement of the peripancreatic planes was noted. Hepatic metastasis was noted in 50%.*Conclusion:* CT is useful in studying the morphology of pancreas pathology in tropical pancreatitis. Even in non calcific cases, pancreatic calcification could be documented at CT and hence the division of calcific and non calcific by radiology may not reflect actual pathology. "P P 45 1004"P 45 1004**Elements Influenting the Evolution of the Pancreatic Pseudocysts**

*A. Tudora, C. Duta, F. Miculit, R. Sarandan

University of Medecine and Pharmacy-Timisoara, RomaniaTo assess the elements which influence the evolution of the pancreatic pseudocysts we have followed 40 patients between 1991–1995: 14 with chronic pancreatitis (CP) and 26 with acute pancreatitis (AP). The evolutive possibilities in the patients with CP were as follows: spontaneous resolution in 2 cases (14%), persistence of the pseudocysts with clinical symtoms (1 case) and appearence of complications (5 cases = 36%)-obstruction of the bowell or billiary tree (2 of these cases associated the abcesses formation). The acute pancreatic pseudocysts resolve spontane ously in 9 cases (35%), the rest presented complications that required intervention: 2 (8%) intracystic hemmorage, 11 (42%) obstruction phenonomens, 3 (11%) abcesses formation and 1 case-the portal vein thrombosis.The pseudocysts in the cephalic aria were asssociated with a spontaneously resolution (65% in the cases with AP respectivly 69% for CP).The size under 3 cm (for the acute pseudocysts), respectivly 4.5 cm was significantly correlated with the resolution.The number of the pseudocysts (single or multiple) has no influence ower the evolution.*Conclusions:* The predictive factors wich indicates the resolutive evolution in the pseudocysts during the acute and chronic pancreatitis are the size (under 3 cm respectivly 4.5 cm) and the localisation in the cefalic aria. In these cases the pseudocysts resoluted either spontaneously or persisted asymtomatic or pauci-symptomatic requering only a follow-up. "P P 45 1005"P 45 1005**Can Gastroprotected Pancreatic Extracts (GPPE) Improve Undernutrition Criteria in Elderly People? A Double Blind Anthropometric and Biochemical StudyF. Dyard[1],**

*J. Moreau[2], F. B\'e9ziat[3], S. Lauque[3], B. Vellas[3], J.L. Albareyde

[1] Solvay Pharma 42, rue Rouget de Lisle 92151 Suresnes, Cedex, Toulouse France

[2] CHU Purpan, 31054 Toulouse, France

[3] CHU Rangueil, 31054 Toulouse, FranceInvolution of pancreatic enzyme and bicarbonate secretions have been demonstrated among people over 70th and particularly when malnutrition was present. Clinical consequences of these findings are unknown and the potential benefit of pancreatic enzymes supplementation had never been assessed in this population.The *aims* of this study was thus to evaluate the effect of GPPE on anthropometric and biochemical data among undernurished elderly subjects during a 3 month follow-up period.*Methods:* 52 patients (46 women) with a mean age of 87 – 6 years were included. Their caloric intake calculated by a dietician on three consecutive days by using Euronut' program (on average 1,082 kcal/d) was 30% lower than RDA. Main inclusion criteria were BMI (kg/m^2) (< 21 – 3) and low serum albumin (32 – 3.3 g/l). GPPE 2 caps tid or placebo were administered in a randomised and double blind fashion. Patients were examined at D15, D30, D60, D90 for dietary intakes, anthropometric and biochemical assessment.*Results:* At inclusion, the two groups were similar for age, sex, BMI, albumin and other biological variables. Evolution of caloric intakes and body weight were not different between the two groups. Conversely, serum prealbumin level at D90 was higher in the GPPE group compared to placebo (0.23 – 0.06 g/l vs 0.19 – 0.06 g/l respectively; p {\'a3} 0.05). In addition, there was a trend in favour of the GPPE for retinol binding protein (0.043 – 0.0013 g/l vs 0.038 – 0.011 g/l respectively; p = 0.09).*Conclusion:* These data suggest that the administration of pancreatic extracts may improve several nutritional parameters in undernurished elderly subjects. Further studies are needed to confirm these results on a large scale. Nutrition: Metabolism }" "Can Gastroprotected Pancreatic Extracts (GPPE) Improve Undernutrition Criteria in Elderly People? "P P 45 1006"P 45 1006**Impact of Continuing Alcohol Addiction on the Results of Resective Surgery for Chronic Pancreatitis****B. Chareton, M. Foglia, O. G\'e9rard, C. Stasik,**

*G. Spiliopoulos, J.P. Campion, B. Launois

Department of Digestive Surgery and Transplant Unit, CHR Pontchaillou, Rue Henri Le Guilloux, 35033 Rennes, France*Materials and methods:* Between 1972 and 1991, 149 patients underwent resective surgery for chronic pancreatitis. Surgical procedures included 87 pancreaticoduodenectomies and 62 distal splenopancreatectomies. Excluded from the study were 5 patients lost to follow-up and 10 patients having died in the post-operative period.*Results:* 46 patients had continuing alcohol addiction (OH+) and 88 patients had been weaned for alcohol (OH{ -}). Post-operative comfort was poor in 3.5% of OH{ -} versus 30.4% of OH+ patients, medium in 26.7% of OH{ -} patients versus 30.4% of OH+ patients and good in 69.8% of OH{ -} versus 39.2% of OH+ patients. Pain was present in 8% of OH{ -} versus 57% of OH+ patients. Body weight was stable or increased in 100% of OH{ -} versus 47% of OH+ patients. 53% of OH+ patients experienced weight loss. Return to normal activity was 85% in OH{ -} versus 50% in OH+ patients. 5, 10 and 20 year survival for OH{ -} and OH+ patients was 90% vs 75%, 85% vs 60% and 70% vs 30% respectively. Following pancreaticoduodenectomy, 5, 10 and 20 year survival for OH{ -} and OH+ patients was 95% vs 70%, 90% vs 50% and 60% vs 50% respectively. Following distal splenopancreatectomy 5, 10 and 20 year survival for OH{ -} and OH+ patients was 90% vs 90%, 70% vs 70% and 70% vs 15% respectively. Late deaths occurred in 21 of 46 patients in the OH+ group: 5 oropharyngeal/oesophageal tumors, 2 cardiovascular conditions, 9 acute alcohol realted complications, 5 ""other"" causes. Late deaths occurred in 17 OH{ -} patients, 5 oropharyngeal/oesophageal tumors, 6 cardiovascular conditions, 9 acute alcohol related complications, 6 ""other"" causes.*Conclusions:* The best results of pancreatic resection for chronic pancreatitis are obtained in those patients who can be weaned from alcohol. Comfort, return to normal activities and survival are improved. Pancreas: Pancreatitis, chronicLiver and bile ducts, 1: Hepatotoxicity, ethanol }" "Impact of Continuing Alcohol Addiction on the Results of Resective Surgery for Chronic Pancreatitis"

"P P 45 1007"P 45 1007**Resection in Chronic Pancreatitis. A Retrospective Study with 154 Patients with Special Reference to 20 Years and 10 Years SurvivalB. Chareton, M. Foglia, O. G\'e9rard,**

*C. Stasik, G. Spiliopoulos, J.P. Campion, B. Launois

Department of Digestive Surgery, CHR Pontchaillou, Rue Henri Le Guilloux, 35033 Rennes, FranceWe retrospectively studied results in 154 patients who underwent pancreatic resection. *Methods:* Between September 1972 and December 1994, we performed 87 cephalic pancreatoduodenectomy (30 with pylorus conservation), 62 spl\'e9nopancreatectomy (SPC) and 4 total pancreatectomy for chronic pancreatitis. Patients with simultaneous neoplasia at histological control were not included. Mean age was 44 years (range 20–70 years). The most common reason for a resection was intreatable pain often associated with jaundice, duodenal compression, segmental portal hypertension, suspicion of pancreatic neoplasia. 140 (90%) patients were male. Chronic ethylism was the most commun aetiology. We could establish a score confort based on pain, diabetes, diarrhea and weight increase in 60% of patients. Median follow up was 10 years. Cause of death was determined in all patients. *Results:* Perioperative mortality was 4.5% in Whipple procedure, 9.6% in splenopancreatectomy and 50% in total pancreatectomy. Survival after duodenopancreatectomy at 10 and 20 years was 72 and 54%. Survival after splenopancreatectomy at 10 and 20 years was 68 and 38%. In both group 20 years survival was significantly higher among patients who stop alcool intake (62 vs 52% for Whipple and 72 vs 16% for SPC). Low confort score was clearly associated with alcool intake after pancreatic resection. Among patients who underwent Whipple operation confort score was higher with pylorus conservation than in patients without pylorus conservation but this difference deasappeared when patients who didn't stop alcool consumption were excluded. None of the patients in whom we carried out Whipple operation needed another surgical procedure for pancreatic pathology while 9% of the patients splenopancreatectomy group were operated again. ENT neoplasia (10 cases) and cardiovascular accident (8 cases) were the major causes of long term mortality. *Conclusion:* However pancreatoduodenectomy in chronic pancreatitis seems an heavy procedure its operative morbidity and mortality are low. A good and long term confort is obtained in most of the patients. As for any ethylic patient screening for ENT neoplasia should be the rule ... "P P 45 1008"P 45 1008**The Risk of Occurrence of Diabetes Mellitus is Influenced by the Type of Elective Pancreatic Surgery in Patients with Chronic Pancreatitis**

*D. Malka, P. Hammel, P. L\'e9vy, A. Sauvanet, J. Belghiti, P. Ruszniewski, P. Bernades

F\'e9d\'e9ration M\'e9dico-Chirurgicale d'H\'e9pato-Gastro-Ent\'e9rologie, Hospital Beaujon, Clichy, FranceWhether elective pancreatic surgery (EPS) in patients with chronic pancreatitis (CP) influences the occurrence of diabetes mellitus is unclear.*Aim:* to assess if patients with CP who underwent EPS had an increased risk of diabetes as compared to those who did not.*Methods:* 482 patients with CP (men: 85.3%; alcoholics: 84.6%) followed 8.0 years (1–32) were studied. Among them, 222 who underwent EPS were compared to 224 who did not. Thirty-six patients who underwent a non-elective pancreatic surgery were excluded.*Results:* prevalence of diabetes was of 40.7% (insulin-dependent: 19.9%) in the whole group of 446 patients and increased with time of follow-up [48.4% (26.8%) and 60.1% (37.2%) after 5 and 10 years, respectively]. The actuarial rate of diabetes: a) was not influenced by EPS (35.6% vs 43.3% at 15 years); b) was higher in patients who underwent pancreatic resection [n = 95 (distal pancreatectomy: n = 56)] than in those treated by derivation (n = 126) [51.8% (distal pancreatectomy: 64.3%) vs 37.4% at 15 years, $p < 0.01$ ($p < 0.001$)] and in those not operated on ($p < 0.05$); c) was lower in patients treated by pancreatic drainage (n = 42) than in those not operated on (20.9% vs 32.8% at 10 years, $p < 0.02$).*Conclusions:* distal pancreatectomy is the only procedure of EPS which increases the risk of diabetes in patients with CP. By contrast, pancreatic drainage seems to delay the onset of diabetes. "P P 45 1009"P 45 1009**Spatial Blood Flow Distribution in the Normal and Chronically Inflamed Human Pancreas**

*M.K. Schilling, C. Redaelli, P. Reber, H. Friess, M.W. B\'fcchler

Dept. Visceral and Transplantation Surgery, Univ. Berne, SwitzerlandIn experimental models many pancreatic diseases namely acute and chronic pancreatitis are accompanied by, caused or aggravated by microcirculatory changes. In this study we assessed blood flow as well as the flow curve pattern in the pancreas of patients undergoing laparotomy for non pancreatic diseases as well as patients undergoing pancreatic head resection for chronic pancreatitis by laser doppler flowmetry (LDF). *Methods:* In 13 patients undergoing laparotomy, EBF was assessed by LDF on the normal pancreas as well as in 9 patients with chronic pancreatitis. Blood flow was recorded for at least 30 seconds after a stable signal was obtained. Post sampling data processing included calculation of systolic and mean blood flow and pulse curve analysis with pulsatile index and integral under the curve calculations. *Results:* Results (for the normal pancreas) in perfusion units (upper row: systolic/diastolic flow, middle row: mean flow – SD, lower row: pulsatile index).

Discussion: A typical spatial distribution of pancreatic blood flow was found, correlating with the anatomical vascular supply and lowest flow over the mesenteric vein, the water shed area between pancreaticoduodenal sup/inf and splenic arterial blood supply. Furthermore blood flow and blood flow pattern was significantly decreased in chronic pancreatitis, most pronounced in the pancreatic head. }" "Spatial Blood Flow Distribution in the Normal and Chronically Inflamed Human Pancreas"

"P P 45 1011"P 45 1011**Transforming Growth Factor Beta Mediates Both Fibrogenesis and Hyperglycemia in Patients with Chronic Pancreatitis**

*P. Fogar, A. Floreani[1], D. Basso, C. Pasquali[2], M. De Paoli, C. Sperti[2], M.G. Piva, A. Melis[1], M. Plebani

Dipartimenti di Medicina di Laboratorio, Universita' degli Studi di Padova, Italy

[1] Gastroenterologia, Universita' degli Studi di Padova, Italy

[2] Semeiotica Chirurgica, Universita' degli Studi di Padova, ItalyTransforming growth factor beta (TGFb) has suggested to mediate liver fibrosis which can be monitored by the serum determination of the N-terminal peptide of type III procollagen (PIIIP) and laminin. Fibrogenesis is also an important phenomenon found in patients with chronic pancreatitis (CP), for which no data are available on TGFb or PIIIP and laminin patterns. The aims of our study were to compare the serum patterns of PIIIP, laminin and TGFb in patients with LC and CP and to verify is there were any correlation between these indices. We studied 81 subjects; 20 were controls (CS), 23 patients had CP, 17 viral cirrhosis (VC), 11 alcoholic cirrhosis (AC) and 10 primary biliary cirrhosis (PBC). In the sera of all subjects we measured PIIIP and laminin (IRMA and RIA assays, CIS-France) and TGFb (ELISA, Boehringer Mannheim, Germany). PIIIP and laminin increased in VC and AC in comparison with CS, CP and PBC (Anova one-way: $F = 8.86$, $p < 0.001$ and $F = 11.57$, $p < 0.001$ respectively). In CP high levels of PIIIP and laminin were found in 7/23 and 5/23 patients. TGFb significantly decreased in patients with VC (45 + 3 ng/mL, mean + SEM), AC (54 + 9) as compared to CS (101 + 6) ($F = 11.29$, $p < 0.001$). High levels of TGFb were found in 6/23 patients with CP. In patients with CP, PIIIP varied independently from laminin ($r = 0.358$, p: ns), but correlated with TGFb ($r = 0.481$, $p < 0.05$). On the contrary in LC patients PIIIP and laminin varied consensually ($r = 0.709$, $p < 0.001$) and the variations of PIIIP were inversely correlated with those of TGFb (r = { -}0.374, $p < 0.05$). In CP, a reduced exocrine function (PABA test) was associated with an increment of laminin values (r = { -}0.519, $p < 0.05$). Fasting serum glucose was correlated with TGFb ($r = 0.884$, $p < 0.001$), while HbA1c was correlated with C-peptide values (r = { -}0.570, $p < 0.01$). 18 patients with CP were followed up for a median period of 7.5 yrs (4–12 yrs range). TGFb significantly decreased during follow-up (Student's t test: $t = 3.09$, $p < 0.01$). A trend towards a decrement was found also for PIIIP. *Conclusions:* 1. biochemical markers of liver fibrosis can be considered of limited value in assessing pancreatic fibrosis; 2. in LC, the existence of a feed-back regulation of TGFb mediated by the fibrogenetic process may be hypothesized; 3. this feed-back does not seem to be present in CP, where TGFb seems to be involved in favouring fibrosis on the one hand and the development of hyperglycemia on the other; 4. pancreatic fibrotic phenomena, more marked when exocrine function is severly impaired, seem to go towards quiescence in long term follow-up. "P P 45 1012"P 45 1012**Is the Pancreas Able to Adapt to Repeated Caerulein-Induced Pancreatitis?**

*Z. Warzecha, A. Dembinski, P. Ceranowicz, J. Jaworek, J. Bilski, S.J. Konturek

Institute of Physiology, Collegium Medicum of Jagiellonian University, Krakow, PolandAcute pancreatitis with tissue damage and acinar cells loss is followed by recovery. We studied biochemical, histological and functional regeneration of pancreatic tissue after repeated caerulein-induced pancreatitis. Caerulein-induced pancreatitis was evoked in rats by s.c. infusion of cerulein (10 \'b5g/kg/h) for 5 h. After infusion, rats were divided into three groups. First group was infused with caerulein one time, in the second group infusion of caerulein was repeated 10 days later. The third group was infused with caerulein 3rd time 10 days after the 2nd infusion. Rats were sacrificed at time sequence of 0, 12, 24, 48, 72 hours and at 5th, and 10th day after last infusion. Pancreatic blood flow was measured using laser Doppler flowmeter. Plasma and pancreatic amylase, pancreatic weight, RNA and DNA contents, and histological changes were determined. We found that DNA and RNA content, as well, as histological changes in 1st group were showing progress of regeneration after 3 days. Regeneration after caerulein induced-pancreatitis was almost completed within 10 days and amylase content in the tissue and plasma amylase level returned close to normal values. Repeated infusion of cerulein caused significantly less pronounced destruction of the pancreatic tissue however regeneration occurred progressively later then after 1st or 2nd infusion. Tissue repair after 2nd infusion started after 5 days while that after 3rd infusion after 10 days. Pancreatic blood flow dropped after first induction of pancreatitis by 50% of control. Repeated acute pancreatitis was accompanied by lower and shorter decrease in pancreatic blood flow. *Conclusion:* Our results indicate that the pancreas is able to adapt to repeated induction of pancreatitis what is manifested by cumulative reduction of pancreatic damage. This effect is correlated with reduced significantly when compared to initial value and this effect is connected with the preservation of pancreatic blood flow. "P P 45 1013"P 45 1013**Studies of Exocrine Pancreatic Function in Patients with Sj\'f6gren's Syndrome**

*Y. Ito, T. Ishizuka, M. Yamamoto, K. Yasuda

Department of Internal Medicine, Matsunami General Hospital, Gifu University, Gifu JapanSj\'f6gren's syndrome (SJS) is a chronic, slowly progressive autoimmune disease, involving principally the salivary and lachrymal glands and occasionally other exocrine glands such as the gastrointestinal and pancreatic glands. The special aim of this study was to elucidate the relation between salivary or lachrymal gland destruction and diminished exocrine pancreatic function in SJS. We studied the exocrine pancreatic function in 25 consecutive patients (2 M/23 F, age 55.6 – 2.2 yrs, M – SE) with SJS (15 primary SJS/10 secondary SJS). All of the patients had xerostomia and dry eyes. Diagnostic evaluation of the salivary and lachrymal glands hyposecretion included sialography (n = 18) and Schirmer's I test (using a mean value of the both sides) (n = 24). The bentiromide test (n = 24) and secretin test (100 U, iv) (n = 9) were performed to assess exocrine pancreatic function. To evaluate the endocrine pancreatic function in SJS, a standard oral 75 gGTT was also performed in 15 of the patients. Furthermore, endoscopic retrograde pancreatography (ERP) (n = 17) was performed to obtain the pancreatic ductal images. ERP findings were classified by using the criteria of Kasugai. Epigastric pain was complained in 14 patients. None of the patients had liver cirrhosis, chronic renal failure and alcoholism. The value of Schirmer's I test was then related to the results of bentiromide test and secretin test. The bentiromide test showed abnormality in 13 of 24 patients (54%). In the secretin test, 4 of 9 patients (44%) were abnormal and the maximal bicarbonate concentration (MBC) was low in 2 patients. One showed markedly decreased 3 factors (MBC, volume output and amylase output). According to the WHO criteria, 2 of 15 patients were diagnosed having diabetes, 3 showed impaired glucose tolerance and the rest were normal. As to the ERP findings, 8 of 17 patients showed minimal pancreatitis, 7 moderate pancreatitis, 1 advanced pancreatitis and the rest was normal. Sixteen patients were diagnosed as chronic pancreatitis (8 definite/8 probable). A significantly positive correlation between the MBC in secretin test and the value of Schirmer's I test was found ($n = 9$, $p < 0.01$). In chronic pancreatitis, a good correlation between the results of bentiromide test and the value of Schirmer's I test was also demonstrated ($n = 15$, $p < 0.05$). The value of bentiromide test in the severe change of sialogram was significantly lower than that in the slight change of sialogram ($p < 0.05$). High incidence of exocrine pancreatic dysfunction was found in SJS. The exocrine pancreatic damage in SJS may be caused by an autoimmune mechanism via the common antigen between the salivary or lachrymal gland and the pancreatic gland. "P P 45 1014"P 45 1014**Detection of Macroamylase in Serum by a Rapid Assay**

*M. Ventrucci, G.M. Ubalducci, A. Cipolla, E. Pollini, R. Moratti, G.V. Melzi d'Eril, E. Roda

Dept of Gastroenterology, University of Bologna, Italy

IRCCS S. Matteo, University of Pavia-ItalySimple procedures are currently available for the determination of amylase isoenzymes in serum which are based on the specific inhibition of salivary isoamylase. Unfortunately, they are not able to detect macroamylasemia and in the majority of these cases they erroneously indicate an increase of pancreatic isoenzyme. In 1982 a new test was described which readily distinguishes macroamylase by means of a PEG precipitation technique. In the present study we combined this technique with a widely used automated assay for amylase and isoamylase determination in order to establish the clinical utility of this combination. *Methods.* We studied 18 sera previously found positive and 61 negative for macroamylase using gel filtration chromatography (Sephadex G-100); of the latter, 32 had normal and 29 elevated amylase activity. Total amylase concentration was estimated using a colorimetric method (Amyl, Boehringer Mannheim). Pancreatic isoamylase was determined after inhibition of the salivary fraction by two monoclonal antibodies (P-Amyl, Boehringer Mannheim). The precipitation of macroamylase was obtained by adding PEG 6000 followed by incubation at 37\'b0C for 10 min. *Results.* Sera positive for macroamylase showed precipitation of at least 71% of the amylase activity (89.6% – 7.2, mean – SD), while sera without macroamylase exhibited a maximum of 61% precipitated amylase activity (27.8% – 15.2). No significant difference in precipitation rates was found between sera with normal (25.4% – 15.5) and those with elevated amylase levels (30.3% – 14.7). Eleven of the 18 sera with macroamylase and 15 of the 61 without macroamylase were also tested with a precipitation technique using another chromogenic method for amylase assay (Phadebas, Pharmacia); the results were similar to those obtained using the automated method. All the sera but one with macroamylase showed an elevation in pancreatic isoamylase using the immunoinhibition test; this isoenzyme was found to be the prevalent fraction (> 50% of the total amylase activity) in 11 of these sera. *Conclusion.* The results demonstrate that PEG precipitation procedure is a simple and reliable technique for quick detection of macroamylase. This test can be easily applied to automated assays for amylase and should be carried out whenever dealing with hyperamylasemia of unclear origin. Pancreas: Pancreatitis, acute }" "Detection of Macroamylase in Serum by a Rapid Assay"

"P P 45 1015"P 45 1015**Pancreatic Secretion and Gastrin Release in Response to Intraduodenal Ammonia**

*J. Bilski, J. Jaworek, A. Dembinski, Z. Warzecha, M. Cieszkowski, W. Bielanski, S.J. Konturek

Institute of Physiology, Collegium Medicum, Jagiellonian University, Krak\'f3w, PolandRecent studies have suggested that *Helicobacter pylori* caused persistent elevations in the ammonia content in stomach leading to the development of G-cell hyperfunction and enhanced level of plasma gastrin. In patients with *Helicobacter pylori* infection, interdigestive pancreatic enzyme secretion was increased. The aim of this study was to evaluate the effect of ammonia on plasma gastrin and exocrine pancreatic secretion in conscious dogs equipped with pancreatic fistulas and *in vitro* on secretory activity of isolated pancreatic acini. Ammonia given intraduodenally (0.5, 1.0, 2.0, 4.0, 8.0 mM/L) resulted in increased pancreatic protein output, reaching respectively 9%, 10%, 19%, 16% and 17% of caerulein maximum and in a strong increase in gastrin plasma level. Ammonia (8 mM/L, i.d.) given during intravenous infusion of secretin (50 pmol/kg-h) and cholecystokinin (50 pmol/kg-h) reduced the protein and bicarbonate output by 37% and 35% respectively, as compared to control response obtained with thoses peptides alone. When pancreatic secretion was stimulated by ordinary feeding the same load of ammonia decreased the protein and bicarbonate responses by 47% and 78% respectively and has no significant effect on plasma gastrin. In isolated pancreatic acini, increasing concentrations of ammonia (10{ -7} M–10{ -4} M) produced a dose-dependent stimulation of amylase release reaching about 45% of caerulein induced maximum. When ammonia was given together with submaximal dose of caerulein (10{ -12} M) enzyme secretion was reduced by 30%. Conclusions: 1. ammonia affects pancreatic enzyme secretion; 2. Rise in gastrin plasma level may be responsible for stimulation of basal pancreatic secretion in conscious animals. 3. Effects of ammonia on pancreatic secretion may be mediated in part by its direct action on pancreatic acini. Pancreas: Acinar, duct cell functionPancreas: Secretion, regulationOesophageal gastric duodenal disorders: Helicobacter Pylori }" "Pancreatic Secretion and Gastrin Release in Response to Intraduodenal Ammonia"

"P P 45 1016"P 45 1016**Effect of Dose Escalation of Pancreatic Enzymes on Steatorrhoea in Patients with Pancreatic Insufficiency**

*J. Vecht, A. Masclee, H. Gielkens, H. Heyerman[1], C. Lamers

Dept. of Gastroenterology, University Hospital Leiden, The Netherlands

[1] Dept. of Pulmonology, Leyenburg Hospital, The Hague, The NetherlandsIn patients with cystic fibrosis increasing the dose of pancreatic enzymes will further and significantly reduce steatorrhoea. However, it is not known whether this is also true for patients with pancreatic insufficiency due to chronic pancreatitis. Therefore we have studied the effect of two different regimens of pancreatic enzyme suppletion (Pancrease', lipase 3 {\'b4} 10,000 U daily versus lipase 3 {\'b4} 20,0000 U daily) each dose for 2 weeks combined with omeprazol 40 mg/day, in a double blind, randomized cross-over study. Results were compared with those obtained during control period. Sixteen patients (13 male, 3 female; age 22–75 yr) with chronic pancreatitis (alcoholic n = 9; idiopathic n = 7) and exocrine insufficiency (fecal fat > 10 g/24 h) participated in the study. Food intake, fecal parameters (weight, fat, stool frequency) were measured and subjective abdominal symptoms were scored. *Results:* Fecal fat Fecal weight Fat absorption (%) (g/24 h) (g/24 h)control 36 – 7 400 – 70 49 – 143 {\'b4} 10,000 lipase 18 – 5* 260 – 40 75 – 5*3 {\'b4} 20,000 lipase 18 – 7* 290 – 50 75 – 6**p < 0.05 versus controlEnzyme suppletion significantly (p < 0.05) reduced abdominal symptoms: pain score from 3.2 – 0.6 (control) to 1.3 – 0.4 and 1.3 – 0.4 during low and high doses lipase respectively. General well being increased significantly from 4.8 – 0.4 (control) to 6.1 – 0.4 and 6.2 – 0.4 during low and high doses lipase.It is concluded that dose escalation from 30,000 U to 60,000 U lipase daily does not further improve fat absorption or abdominal symptoms in patients with pancreatic insufficiency due to chronic pancreatitis. "P P 45 1017"P 45 1017**Non-Alcoholic Chronic Calcifying Pancreatitis (NA-CCP): Is it Less Severe than Alcoholic CCP?R. Dani, C.E.D. Nogueira, A. Cardoso Jr., A.M.S. Reis**

Santa Casa de Miseric\'f3rdia, Belo Horizonte, BrazilNon-alcoholic chronic calcifying pancreatitis (NA-CCP) represents in our experience 11% of chronic calcifying pancreatitis (CCP) cases. Some authors claim that NA-CCP have a more benign course than alcoholic CCP (ACCP). The aim of this study is to report on the behavior of NA-CCP as observed in our service. *Material.* From 1963 to 1996 we have cared for 528 cases of CCP: 473 (89%) were alcoholics, 42 (8%) idiopathic, 10 (1.9%) nutritional, and 3 (0.6%) were cases of hereditary CCP. The mean age of the 55 cases of NA-CCP at the moment of the diagnosis was 26 – 17.3 years (range 1–75), with 34 males (61.8%) and 21 females (36.2%), from which 32 were white (58.2%), 19 (34.5%) colored and 4 (7.3%) negroes. Pancreatic calcifications were noticed in 39 cases (70.9%). Age at the beginning of the symptoms was 20.8 – 18.1 years (range 1–74). The main symptoms were weight loss in 49 patients (89%), pain in 38 (69%), diabetes in in 18 (33%), obstructive jaundice in 14 (26%), steatorrhea in 14 (26%), cysts and pseudocysts in 7 (13%), and other pancreatitis complications in 17 cases (31%). Surgery was undertaken in 28 cases at patients' mean age of 32.3 – 18.5 years (range 1–75). The main indications were clinically uncontrollable pain in 12 cases (43%) and pain associated to pancreatitis complications in 16 patients (29%). Nine patients were reoperated upon (16%) due to recurrence of pain (4 cases) or pain plus pancreatitis complications (5 cases). *Results.* From the 28 initially operated on patients 12 are dead (57%), with a mean survival of 15 months. The other 9 cases were doing well (mean follow-up of 12 years). Pancreatic carcinoma (PC) was diagnosed in 7 patients with idiopathic CCP* (17%) and in 1.7% of ACCP cases. *Conclusion.* NACCP is a severe disease, showing morbidity and mortality comparable to ACCP.All deceased. Pancreas: Pancreatitis, chronic }" "Non-Alcoholic Chronic Calcifying Pancreatitis (NA-CCP): Is it Less Severe than Alcoholic CCP?"

"P P 45 1018"P 45 1018**Portal Venous Obstruction in Chronic Pancreatitis. A Prospective Longitudinal Study of a Medical-Surgical Series of 482 Patients**

*L. Sosa Valencia, P. Hammel, J. Belghiti, P. Ruszniewski, P. Bernades

F\'e9d\'e9ration M\'e9dico-Chirurgicale d'H\'e9pato-Gastroent\'e9rologie, Hospital Beaujon, 92118 Clichy Cedex, France*Aim of the study:* a prospective search for portal venous obstruction (PVO) in a medical-surgical series of 482 patients with chronic pancreatitis who were followed up a mean time of 6.6 years. *Patients (pts) and methods:* PVO was systematically searched for using abdominal ultrasound and CT scan, and then confirmed by endoscopic ultrasound, echodoppler or angiography. Patients with cirrhosis were excluded. *Results:* PVO was found in 19 patients (4%). Only 4 patients were symptomatic and presented with fever. Obstruction involved the portal vein alone in 7 patients, the portal vein and the splenic vein in 3, the portal vein and the mesenteric vein in 3 and the portal vein and the spleno-mesenteric axis in 6. The total prevalence of PVO alone or in combination with other veins was 1.5% (7/482) and 2.5% (12/482) respectively. Acute pancreatitis and pseudocysts were the probable cause of PVO in 84% of cases. Three patients had chronic non calcifying pancreatitis and 2 had duodenal cystic dystrophy. Esophageal varices were found in five patients (grade I n = 4, grade III n = 1) occuring 6 months to 11 years after PVO diagnosis. No gastric varices were diagnosed. At the end of analysis, 16 patients had portal cavernoma, demonstrated by computed tomography and abdominal ultrasound in all cases and by endoscopic ultrasound in 11 patients. Liver biopsies were performed in 6 cases and reported 3 steatosis and cholestasis and 3 fibrosis. Liver dystrophy was shown in 10 patients, half of them with right lobe atrophy. Only one patient was operated on due to severe gastrointestinal hemorrhage from colic variceal bleeding and died, 11 were operated on for causes not related to PVO, four of then more than once (distal splenopancreatectomy n = 4, cephalic pancreatectomy n = 1, cystogastroenteroanastomosis n = 3, enteral bypass n = 4, and surgical shunts n = 2). Eighteen patients have been followed after PVO diagnosis, without bleeding. Only chronic pancreatitis and post-operated related complications were observed. *Conclusions:* PVO prevalence is 4% in this series, the risk of digestive variceal bleeding is very low and surgical treatment of portal hypertension is not indicated.Key words: chronic pancreatitis, portal vein obstruction, digestive bleeding. Pancreas: Pancreatitis, chronic }" "Portal Venous Obstruction in Chronic Pancreatitis. A Prospective Longitudinal Study of a Medical-Surgical Series of 482 Patients"

"P P 45 1019"P 45 1019**Helicobacter Pylori Infection in Patients with Chronic Pancreatitis and Duodenal Ulcer**

*T. Niemann, N. Thorsgaard

Medical Department, Herning Central Hospital, Denmark*Purpose:* The prevalence of duodenal ulcer (d.u.) is increased in ptt. with chronic pancreatitis (c.p.). Previous investigations including measurement of the pH in the upper gastrointestinal tract have not yielded a convincing explanation. Ptt. with d.u. without c.p. are mostly infected with Helicobacter pylori (H.p.), and the prevalence of IgG antibodies (IgG) against H.p. is > 90%.*Methods:* H.p. IgG was measured retrospectively in all ptt. who had their exocrine pancreas function investigated with a Lundh meal test in the period 1988–95, and in a control group with d.u. in whom H.p. were not eradicated. The Lundh meal test was done i 68 ptt.. In 35 of them the final diagnosis was c.p., and 9 of these have had d.u. (26%). In none of these 9 ptt. H.p. were eradicated. In the remaining 33 ptt. the final diagnosis was non organic dyspepsia. A control group of 21 ptt. with d.u. was included.*Results:* dyspepsia c.p d.u \'f7 d.u. +Hp+ 9 6 6 18Hp\'f7 24 20 3 3Total 33 26 9 21*Conclusion:* Patients with c.p. have an increased prevalence of d.u. compaired to a group with non organic dyspepsia. The H.p. IgG prevalence in ptt. with c.p. and d.u. was increased compaired to the group with c.p. and no ulcer (p = 0.05), but not as high as in the d.u. control group (n.s.). The H.p. IgG level in the group with c.p. but not d.u. was almost identical to the background population. Helicobacter pylori infection contributes, but may not be the only cause of duodenal ulcer in patients with chronic pancreatitis. Pancreas: Pancreatitis, chronicOesophageal gastric duodenal disorders: Helicobacter Pylori }" "Helicobacter Pylori Infection in Patients with Chronic Pancreatitis and Duodenal Ulcer"

"P P 45 1020"P 45 1020**Postprandial Release of Glucagon-Like Peptide-1 (GLP-1) with and without Pancreatic Enzyme Substitution in Pancreatic InsufficiencyS. Larsen, E.K. Philipsen, J.J. Holst**

Department of Gastroenterology F, Glostrup Hospital

Department of Medical Physiology, Panum Institute, University of Copenhagen, DenmarkSecretion of glucagon-like peptide 1 (GLP-1), a gastrointestinal hormone with insulinotropic action and inhibitory action on gastrointestinal secretion and motility is stimulated by ingestion of a meal. Both metabolizable and non metabolizable sugars may stimulate secretion, but it is unknown how pancreatic enzyme substitution affects GLP-1 release in pancreatic insufficiency.*Methods.* Eight patients with pancreatic insufficiency (meal-stimulated intraduodenal lipase and amylase < 5% of normal mean concentrations) ingested a mixed meal containing 2100 kJ with 50 g carbohydrate. Each participant were studied twice at random without or with pancreatic enzyme substitution (50 KU lipase and 45 KU amylase). Plasma GLP-1 (7–36) determined by RIA, C-peptide (ELISA) and blood glucose were measured over 300 min.*Results.* (Means – SE). No significant differences were found in meal stimulated blood glucose, C-peptide and GLP-1 responses (area under curve) with and without pancreatic enzyme supplementation. Peak GLP-1 levels were observed after 146 – 37 min and 73 – 21 min with and without enzyme supplementation, respectively (not significant). Peak glucose was observed after 69 – 12 min and 68 – 9 min and C-peptide after 116 – 9 min and 112 – 11 min with and without enzyme supplementation, respectively. Area under curve Meal without Meal with0 to 300 min. enzyme enzymeGlucose 1914 – 140 1888 – 122(mmol.min/l)C-peptide 264 – 47 260 (48)(nmol.min/l)GLP-1 4834 – 653 5727 (648)(pmol.min/l)Means – SE, no significant difference on any data*Conclusions.* In pancreatic insufficiency secondary to chronic pancreatitis meal stimulated GLP-1 release is preserved and not influenced to a greater extent by enzyme supplementation. Thus, nutritional absorptive processes may be of minor importance for GLP-1 secretion, which seems primary stimulated by the presence of nutrients in the gut lumen.

"P P 45 1021"P 45 1021**NBT-PABA Pancreatic Function Test Using a Novel Dual Isotope Technique and Gas Chromatography-Mass Spectrometry**

*B. Larsen, S. Ekelund, L. J\'f8rgensen, A. Bremmelgaard, N.T. Pedersen

Department of Clinical Chemistry, Aalborg Hospital, Aalborg

Department of Medicine, Herning Hospital, DenmarkWe present a tubeless test of exocrine pancreatic function based on a new dual isotope technique using NBT-PABA (N-benzoyl-tyrosyl-p-aminobenzoicacid) as substrate for intestinal chymotrypsin activity and the stable isotope ^{13}C-PABA (p-aminobenzoic acid) as pharmacokinetic marker.We have developed a gas chromatography-mass spectrometry (GC-MS) method for analysis of PABA and ^{13}C-PABA in serum. Ten healthy volunteers and 10 patients with exocrine pancreatic insufficiency were orally administrated 500 mg NBT-PABA and 50 mg ^{13}C-PABA together with a standard meal after an overnight fast. The test doses corresponded to 1.103 mmol PABA and 0.349 mmol ^{13}C-PABA. Blood samples were drawn at specified intervals. Serum concentrations of PABA and ^{13}C-PABA were measured and the ratio of PABA to ^{13}C-PABA was calculated.The analytical procedure showed good precision with a CV% 5.3 for the ratio. Best separation between the two groups was found 1&fract12; hour after administration of the test mixture. The average ratios were 2.64 – 0.15 (mean – SEM) and 1.26 – 0.22, respectively. The cut off limit of normal was calculated to 1.72 (mean { -} 2SD), giving sensitivity 0.90 and specificity 1.00 in this material.Introducing a stable isotope and GC-MS in the NBT-PABA test, allows a very sensitive and specific identification in serum of the test substances in serum. We found good separation between healthy controls and patients with pancreatic insufficiency. Further studies of applicability and diagnostic efficiency are justified. Pancreas: Pancreatitis, chronic }" "NBT-PABA Pancreatic Function Test Using a Novel Dual Isotope Technique and Gas Chromatography-Mass Spectrometry"

"P P 45 1022"P 45 1022**Postprandial Duodenal pH is Abnormally Low in Patients with Exocrine Pancreatic Insufficiency: A Preliminary Study**

*P. Bovo, V. Di Francesco, M. Marcori, B. Vaona, M. Filippini, G. Talamini, M.P. Brunori, L. Frulloni, M.T. Leardini, E. Dall\lquoteO\rquote, G. Cavallini

Gastroenterology Unit, University of Verona, ItalyIncreases in basal and pentagastrin-stimulated acid output and abnormally low postprandial pH (pH-metry method) have been reported in the course of chronic alcoholic pancreatitis, thought it is still debatable whether or not any correlation exists between duodenal pH and exocrine pancreatic insufficiency. The aim of this study was to assess the circadian variations in intraduodenal pH in 16 hospital patients with chronic pancreatitis (mean age: 50.2 – 7.2 years) and in 8 controls (mean age 41.4 – 12 years); pHmetry was performed by using specially designed 2- or 4-channel monocrystalline antimony electrodes (Monocrystant mod.0011) connected up to a recorder (Digitrapper Synectis MK-II and MK-III, respectively). The detectors were placed under fluoroscopic control in the gastric corpus in the duodenal bulb and/or in the second portion of the duodenum. The evaluation parameters considered, expressed as mean – SD values were: 24-h, postprandial, orthostatic and clinostatic median pH. The chronic pancreatitis patients were also submitted to the Secretin-Caerulein test (lipase output at 60–90 min) for assessment of the exocrine pancreatic insufficiency and to the Pancreolauryl test as proof of maldigestion.*Results:* 1) The chronic pancreatitis patients presented a significantly greater degree of acidification in the postprandial phase at the level both of the bulb (pH: 2.6 – 1.1; $P < 0.02$) ($n = 8$) and the second portion of the duodenum (pH: 3.4 – 1.2; $P < 0.05$) ($n = 13$) as compared to the control group (pH: 5.1 – 1.0 and 5.1 – 1.6 respectively). 2) There was a correlation between the median duodenal pH values and both output of bicarbonates ($R = 0.72$; $P < 0.04$) and Pancreolauryl test ($R = 0.61$; $P < 0.04$). *Conclusions:* Duodenal acidity, exocrine pancreatic insufficiency and maldigestion appear to be correlated in chronic pancreatitis. Pancreas: Pancreatitis, chronic }" "Postprandial Duodenal pH is Abnormally Low in Patients with Exocrine Pancreatic Insufficiency: A Preliminary Study"

"P P 45 1024"P 45 1024**Evidence for Potentiative Interaction between Vagal Cholinergic M1 Fibers and Cholecystokinin (CCK) as Mediators of the Pancreatic Protein Secretion**

*E. Niebergall-Roth, S. Teyssen, M. Hartel, D. Wetzel, C. Beglinger[1], M.V. Singer

Univ. Hosp. of Heidelberg at Mannheim, Germany

[1] Univ. Hosp. of Basel, SwitzerlandIn six conscious dogs with gastric and pancreatic fistulas we compared the effect of the muscarinic M1-receptor antagonist telenzepine (TEL; 20.25, 40.5 and 81.0 nmol/kg/h iv.), of the CCK-antagonist L-364,718 (L; 0.025, 0.05 and 0.1 mg/kg/h iv.) and combinations of both on the pancreatic protein response to graded loads of intraduodenal tryptophan (TRP; 0.37–10.0 mmol/h), given against a background of secretin (S; 20.5 pmol/kg/h iv.). The 180-min integrated protein response (IPR, g) to all loads of TRP was calculated. *Results:* All loads of TRP significantly ($p < 0.05$) increased the pancreatic protein output over that seen with secretin alone (data not shown). When given singly, the two highest doses of TEL and L significantly decreased the IPR by 70 to 97%. All combinations of TEL + L abolished the IPR before and after TV. In the case of the lowest doses of TEL and L, the inhibitory effect of their combination was significantly greater than the sum of the effects when given singly. An interaction between two agents given together resulting in a greater effect than the sum of the effects of the two agents given singly was defined as a potentiated interaction.Table: 180-min. IPR (g) to all loads of TRP TEL (20.25) + L (0.025): 0.8*Control: 25.2 TEL (20.25) + L (0.05): { -}0.2*TEL (20.25): 15.2 TEL (20.25) + L (0.1): 0.2*TEL (40.5): 7.3* TEL (40.5) + L(0.025): 0.4*TEL (81.0): 7.5* TEL (40.5) + L (0.05): { -}0.2*L (0.025): 12.6 TEL (40.5) + L (0.1): 0.8*L (0.05): 6.7* TEL (81.0) + L (0.025): 1.0*L (0.1): 0.8* TEL (81.0) + L (0.05): 0.8* TEL (81.0) + L (0.1): 0.6*Results are means (n = 6); *$p < 0.05$ vs. control*Conclusion:* Potentiation exists between the inhibitory actions of the M1 antagonist TEL and the CCK-A-antagonist L on the endogenously stimulated pancreatic protein output. We interpret these data as indicating a potentiative interaction between vagal cholinergic M1 fibers and CCK as mediators of the pancreatic enzyme response to intraduodenal amino acids. "P P 45 1025"P 45 1025**ERCP-Induced Necrotizing Pancreatitis. Is It a More Severe Disease?**

*A.S.Y. Fung, G.G. Tsiotos, M.G. Sarr

Mayo Clinic, Rochester, MN, USAAcute necrotizing pancreatitis (ANP) is a rare but serious complication of ERCP. *Aim:* To compare disease severity, clinical course, and outcome of ERCP-induced ANP versus ANP induced by other causes. *Results:* 72 patients with ANP underwent operative treatment at the Mayo Clinic. ANP was caused by ERCP in 6 patients (8%). When compared to the remaining group of 66 patients with ANP induced by other causes (gallstone – 27; alcohol – 6; postoperative – 8; familial – 1; idiopathic – 24), the ERCP-induced group had a higher admission APACHE-II score (13 – 3 vs 10 – 1; x&bar; – SEM), more extensive estimated pancreatic parenchymal necrosis (55 vs 47%), a greater rate of postoperative gastrointestinal or pancreatic fistulas (50 vs 33%), and a longer postoperative hospitalization (84 – 38 vs 53 – 5, x&bar; – SEM; $p < 0.05$). In addition, the ERCP-induced group required necrosectomy earlier in the hospital course and had a higher rate of infected necrosis (100 vs 75%). Although mortality rate of ERCP-induced ANP was lower (17 vs 29%), these patients were considerably younger (50 – 4 vs 62 – 2, x&bar; – SEM; $p = 0.02$) and all survivors had residual long-term morbidity (e.g. exocrine or endocrine pancreatic insufficiency) or decreased functional ability. *Conclusions:* ERCP-induced ANP is usually severe, presents in a more fulminant state, and carries a poorer prognosis concerning short- and long-term morbidity than ANP of other etiologies. Infection introduced during the ERCP may, in part, account for the more aggressive nature of this disease. Pancreas: Pancreatitis, acute }" "ERCP-Induced Necrotizing Pancreatitis. "P P 45 1026"P 45 1026**Obstructive Jaundice: Comparison between Spiral CT and Cholangio-MR, after Failure of ERCPG.A. Rollandi, A. Talenti,**

*E. Biscaldi, E. Bonifacino, N. Gandolfo, R. Perrone

Institute of Radiology, University of Genoa*Introduction:* In spite of improvements of CT and US techniques, the direct vision of the biliary tree is always important in case of obstructive jaundice, for a good choice of the therapy.At the moment Contrast Media for intravenous cholangiography are no more produced; conventional radiographic studies are then impossible. While ERCP and PTC are examination with high specificity and sensitivity, but they are also quite invasive and have frequent complications.Recently a new MRI technique for cholangiography has been described. It is based on the detectability of the bile by MR sequences, without any introduction of contrast medium.*Purpose:* We wanted to evaluate the diagnostic informations from Cholangio-MR (C-MR) in patients with obstructive jaundice, already examined by Spiral CT, and after failure to obtain a ERCP.*Materials and Methods:* 13 jaundiced patients, with US diagnosis of dilatation of biliary tree and with failure to obtain a ERCP (4 non successful attempts, 3 gastric resections, 6 difficulties of management in emergency) were submitted to Spiral CT of the upper abdomen and to C-MR, before surgical treatment.Spiral CTs were performed with a volumetric scan with 10 mm collimation, 3 mm of index of reconstruction, pitch 1, 300 mAs, 120 kV, i.v. injection (4 cc/s) of non ionic c.m. (370 I g/100 ml). C-MR examinations were performed with a 0.5 T magnetic strength, TR6000, TE200, ETL16, matrix 160–256, Nex5, MIP reconstruction.*Results:* In 12 cases C-MR reached the correct diagnosis; only in 1 case a little stone (2 mm) at the papilla was lost. In 6 cases (4 primary tumours of biliary tree and 2 pancreatic cancers) C-MR didn't give any more informations than CT.In 4 cases (biliary stones) C-RM provided more diagnostic information-sa than CT. In 2 cases of chronic pancreatitis, with pseudocysts of the head of pancreas only C-RM allowed the correct diagnostic identification as the cause of jaundice.*Conclusions:* C-MR has high diagnostic sensitivity and specificity in the diagnostic evaluation imaging of jaundice. Spiral CT is more useful only in neoplastic diseases. Oncology, specific: Liver, biliaryRadiology and ultrasound: Diagnosis }" "Obstructive Jaundice: Comparison between Spiral CT and Cholangio-MR, after Failure of ERCP"

"P P 45 1032"P 45 1032**Does Nonoperative Management of Pancreatic Pseudocyts Increase the Risk of Misdiagnosis?**

*U. Boggi, G. Di Candio, P.C. Giulianotti, F. Sbrana, F. Mosca

Istituto di Chirurgia Generale e Sperimentale, Universit\'e0 di Pisa, ItalyThe worldwide diffusion of nonoperative alternatives to surgical management of pancreatic pseudocysts might lead to an increase of diagnostic errors with consequent inappropriate treatment of unrecognized cystic neoplasms. The aim of this retrospective study was to ascertain the clinical incidence of diagnostic errors in a series of nonoperatively managed pseudocysts.Data from 64 patients (49 males and 19 females; mean age: 57.3 years, range: 26–80) bearing one or more pancreatic pseudocysts who underwent a percutaneous ultrasound-guided drainage were reviewed and analysed. The pre-treatment workup included: medical history, physical examination, ultrasound (US) and computed tomography (CT) scans, determination of tumor markers and pancreatic enzymes in the serum and in the cystic fluid, chemistry and cytology. All patients were entered into a combined clinico-ultrasonographic follow-up.Sixty patients underwent a percutaneous catheter drainage and 4 repeated fine needle aspirations. A total of 4 neoplastic lesions were overlooked after the initial workup (4/64, 6.2%). Two cancer-associated pseudocysts were identified within the treatment period (2/64 3.1%). Four patients died soon after the treatment while the remaining 58 where followed-up for a mean of 41 months (range: 10–132). A third cancer and a mucinous cystic tumor (2/58, 3.4%), fully communicating with the main duct, were further detected during this period.Data from our experience confirm the existence of a misdiagnosis risk in the nonoperative management of pancreatic pseudocysts and support the need for a thorough followup with continous reassessment of each patient. The nature of any pseudocyst with atypical clinical history o behaviour should questioned and, when doubts persist, the patient should be referred for surgical exploration. Oncology, specific: PancreasClinical practice: Management strategy }" "Does Nonoperative Management of Pancreatic Pseudocyts Increase the Risk of Misdiagnosis?"

OT40 1035**Sensitivity to Acid and Distension in Gastro Oesophageal Reflux Disease (GORD) and the Acid Hypersensitive Oesophagus**

*S. Bruley des Varannes, G. Shi, C. Scarpignato, J.P. Galmiche

Dept of Gastroenterology, University of Nantes, 44035 Nantes, FranceAlthough mechanical receptors are present in the oesophageal wall, the investigation of oesophageal sensitivity in GORD and some functional related disorders has been usually limited to the acid perfusion test. We therefore compared the oesophageal sensitivity to both acid and mechanical stimuli in patients with GORD and with the newly described acid hypersensitive oesophagus (AHO) syndrome (Gut 1995; 37: 457–64).*Methods.* One hundred and twenty four patients referred for 24-h oesophageal pH monitoring for symptoms suggestive of GORD were submitted to an oesophageal acid perfusion test (APT) and to an oesophageal balloon distension test (BDT). The probability that symptoms and reflux episodes occurred simultaneously by chance was calculated. APT was considered positive when perfusion induced retrosternal burning or the spontaneously reported pain. The balloon volume inducing pain (VIP) was determined; BDT was considered positive when VID was {\'a3} 7 ml (95% IC of 10 healthy subjects).*Results.* Patients were divided into 3 groups: normal acid exposure (< 4.2% of total recording time) with no significant relation between symptoms and reflux episodes (group Functional Dyspepsia (FD)), and with significant relation between symptoms and reflux episodes (group AHO), abnormal acid exposure (group GORD). The results of APT and BDT are in the table (Chi2, Mann-Whitney; P < 0.05 compared a: with volunteers; b: with GORD, c: with FD). Volunteers AHO GORD FD (n = 10) (n = 27) (n = 29) (n = 68)Age (mean yrs) – Sex (M/F) 41 – 4/6 51 – 9/18 48 – 25/4 55 – 20/48APT positive (%) 30 63c 62c 37VIP (ml, median – range) 11.2 (6 – 15) 7 (4 – 12)a 12 (5 – 15) 9 (3 – 15)aBDT positive (%) 10 59a, b, c 14 24*Conclusion.* Compared to healthy volunteers or dyspeptic patients without reflux, a) patients with GORD exhibit a high sensitivity to acid but are poorly responsive to mechanical distension, b) in contrast, patients with AHO are sensitive to both stimuli therefore suggesting that the primary disorder is rather a visceral hyperalgesia than a true motility disorder. OT40 1036**Lanzoprazole Versus Omeprazole in Long Term Maintenance Treatment of Refluxoesophagitis. A Scandinavian Multicentre Trail**

*L. Carling, C. Axelsson, H. Forsell, A. Stubber\'f6d, K. Kraglund, U. Bonnevie, P. Ekstr\'f6m

Med. Depart. of Bolln\'e4s-S\'f6derh\'e0mns Hospital, Bolln\'e4s, SwedenThis double-blind multicentre study recruited 289 patients who were treated with 30 mg lanzoprazole for 8 weeks or as most 12 weeks. When cured the patients were randomized to either treatment with 20 mg omeprazole or 30 mg lanzoprazole each day for 48 weeks or until relapse (t.i. at least grade II esophagitis or/and severe refluxsymptoms). The baseline distribution of esophagitis was: Grade II 194 (67%), grade III 74 (26%), grade IV 19 (7%). Grade II corresponds to: Erosive and exudative confluent lesions without circumferential extensions. The demographic data was similar in the two treatment groups. To the maintenance part 266 patients were recruited and 131 got lanzoprazole 30 mg o.m. and 125 omeprazole 20 mg o.m. treatment. They were followed every 12 weeks.*Results:* After 8 weeks 84% of the patients were cured and the cummulative figure after 12 weeks was 90%. Grade II patients healed to grade 0 in 82.5%. Maintenance part Lanzo 30 mg Omeprazole 20 mgPatients evaluated 124 120Relapse (total) 12 (9.7%) 11 (9.2%)week 0–12 3 4week 12–24 5 4week 24–26 3 2week 36–48 1 1p = 0.94 NSEighteen patients relapsed to grad II oesophagitis. Only two patients got a symptomatic relapse. There were no differences in adverse events in the both treatment groups.*Conclusion:* Both lanzoprazole 30 mg o.m. and omeprazole 20 mg o.m. gives low and similar relapse rates in maintenance treatment in moderate and severe refluxoesophagitis. OT40 1039**Somatostatin Prevents Meal Induced Alterations in Lower Esophageal Sphincter Function**

*J.W. Straathof, S. Tieleman, C.B.H.W. Lamers, A.A.M. Masclee

Dept. of Gastroenterology, University Hospital Leiden, The NetherlandsSomatostatin (SST) inhibits gastrointestinal secretion and motility. SST reduces gastric acid secretion and is of potential clinical interest in acid related disorders. It is not known, however, whether SST influences lower esophageal sphincter (LES) function. Therefore we evaluated the effect of SST on LES characteristics. Six healthy subjects (2 M, 4 F; age 19–53 yr) were studied after an overnight fast on 4 separate occasions in random order under fasting conditions during 1) SST infusion (250 \'b5g/h) or 2) saline i.v. (control) and after meal stimulation during 3) SST infusion (250 \'b5g/h) and 4) saline i.v. (control) for 240 min. LES pressure, transient LES relaxations (TLESR), as the most important reflux mechanism, and acid reflux were measured by combined esophageal pH metry and manometry (Dent-sleeve). The meal consisted of carbohydrates only (500 Kcal) in order to prevent gastro-intestinal hormone secretion.*Results:* under fasting conditions SST did not affect LES pressure and LES pressure during SST (range 25 – 4 to 29 – 6 mmHg) was not significantly different from control (range 23 – 4 to 26 – 1 mmHg). TLESR frequency under fasting conditions during SST infusion (2.2 – 0.6 per hour) was not significantly different from control (2.4 – 0.5 per hour). Meal ingestion significantly ($p < 0.05$) increased TLESR frequency from 2.4 – 0.5 to 4.8 – 0.5 in the first postprandial hour. However, this meal induced increase in TLESR frequency did not occur during SST infusion. Acid reflux time was low (fasting 0.1%; meal 0.2%) and not influenced by SST.It is concluded that 1) somatostatin does not affect fasting LES pressure and TLESR-frequency, 2) but meal induced decreases in LESP and increases in TLESR's do not occur during somatostatin infusion; 3) somatostatin prevents meal induced alteration in LES function that permit reflux. The effect of somatostatin in patients with reflux disease therefore deserves further evaluation. OT41 1040**{ a}-Interferon in Chronic C Hepatitis: Is Antipyrine Metabolism a Predictor of Response?**

*A. Grieco, R. Castellano, A. Matera, S. Marcoccia, A. Giancaterini, P. Di Rocco, B. Alfei, P. Marino, A. Bianco, G.B. Gasbarrini

Inst. Internal Medicine-Catholic Univ.-Rome-Italy{ a}-interferon (IFN) treatment is today the only evaluated therapy for hepatitis C able to induce a biological remission. The determination of predictive factors of response is essential in planning IFN treatment. Cirrhosis is a negative predictor of response and it is also associated with decreased antipyrine metabolism. A positive correlation has been recently observed between the liver metabolic capacity and the response to { a}-IFN in pts with chronic hepatitis C [1]. We assessed the antipyrine test in pts with chronic hepatitis C, who underwent { a}-IFN therapy.We enrolled 45 pts (22 males, 23 females, median age 47, range 25–70) with histological diagnosis of CAH; 20 were classified as having CAH with mild or no fibrosis (group A), and 25 as CAH with severe fibrosis or cirrhosis (group B). The antipyrine metabolism test (18 mg/kg in water p.o.; blood samples drawn 3 and 24 hrs after administration for spectrophotometrical analysis) was administered to all patients before treatment with recombinant { a}-IFN2b (9 MU/week/6 months). The therapeutic response was assessed in terms of ALT normalitation.We observed a complete response to IFN therapy in 19/45 pts (42%) and the response rate was higher in Group A (16/20, pts-80%) than in Group B (3/25 pts-12%). Pts of group A had significantly better clearance (0.405 – 0.1 ml/min/Kg) than those of group B (0.22 – 0.15 ml/min/Kg) ($p < 0.001$). Baseline antipyrine clearance for the group of responders (0.412 – 0.15 ml/min/kg) was significantly higher than that of the non-responders (0.242 – 0.14) ($p < 0.001$). 13/19 responders had an antipyrine clearance over a cut-off > 0.30 ml/min/Kg (78%).We confirm the relationship between hepatic drug metabolism, explored by antipyrine metabolism, and the response to IFN therapy in pts with C hepatitis. We suggest the use of this test in pts clinical baseline evaluation, especially when liver histology is not available.

OT41 1041**Therapy of Chronic Hepatitis C Non Responders to Alfa-Interferon: A Preliminary Report of Intravenous Natural Beta-Interferon (IFN)A. Cartabellotta, P. Campagna, G. Anastasi, L. Giannitrapani, M. Fulco, M. Soresi, F. Bascone, G. Montalto**

Cattedra di Medicina Interna, Universit\'e0 di Palermo*Background:* { a}-IFN has been shown to be effective in the treatment of chronic viral C hepatitis, but its efficacy remains unsatisfactory; in fact only 20–25% of patients will have a sustained response and 50% are non-responders. In these patients alternative treatment (ribavirin, ursodeoxycolic acid, phlebotomy) have not been effective. Recently efficacy of beta-IFN, ineffective when administered by I.M. route, has been proven when administered by intravenous infusion.*Aims:* To evaluate in patients with chronic hepatitis C non-responders to previous treatment with { a}-IFN, efficacy and safety of intravenous beta-IFN.*Patients and methods:* 9 patients, (8 M/1 F) mean age 36 – 1.4 SD years (range 21–50), with histologically proven chronic active hepatitis C without cirrhosis, HCV-RNA positive and non responders to previous treatment with { a}-IFN (recombinant or lymphoblastoid or leukocyte-derived), with mean basal ALT value 222 – 194 UI/L (range 65–359), received 6 MU of beta-IFN daily for 6 days a week for 8 weeks, by an intravenous infusion in 100 ml of saline.*Results:* After 8 weeks of treatment 5 pts (55%) showed complete normalization of ALT values and became HCV-RNA negative on serum. Therapy was well tolered and the beta-IFN dose did not have to be interrupted or reduced due to side effects in all patients, but one due to severe neutropenia.*Conclusion:* Intravenous beta-IFN can be a well tolerated effective treatment for patients with chronic hepatitis C non-responders to { a}-IFN. Nevertheless to define the optimum dose and schedule of treatment to achieve eradication of HCV infection, longer follow-up of these patients are necessary. Liver and bile ducts, 1: Hepatitis, viral, treatment }" "Therapy of Chronic Hepatitis C Non Responders to Alfa-Interferon: A Preliminary Report of Intravenous Natural Beta-Interferon (IFN)"

OT41 1042**Ribavirin Monotherapy in Patients with HCV Related Chronic Hepatitis or Liver Cirrhosis: A Retrospective Study of 95 PatientsF. Zoulim, J. Haem, F. Habersetzer, S. Si Ahmed, F. Bailly, C. Tr\'e9po**

Hotel Dieu Hospital, Lyon, FranceRibavirin is a purine analog which inhibits the replication of a variety of RNA viruses and was shown to have a transient efficacy in chronic hepatitis C during short term therapy. We have analyzed retrospectively its efficacy in 95 patients suffering from liver biopsy proven chronic hepatitis C. All patients had raised ALT levels and were positive for serum HCV RNA by PCR prior to therapy. Liver histology showed chronic active hepatitis in 50 and cirrhosis in 45. Sixty patients had received a previous course of IFN and 35 were na\'efve of any antiviral treatment. Patients were treated with Ribavirin with a dose of 600 mg–1200 mg/day for a mean duration of 11 months. ALT levels returned to normal values in 38 patients (40%), and decreased by more than 50% in 20 other patients (21%). HCV RNA clearance from serum was observed in 7 patients (8%). The rate of ALT normalization was higher in patients with chronic hepatitis (54% = 27/50) than in those with cirrhosis (11/45 = 24%) ($p = 0.0001$). HCV RNA clearance was observed in 5/50 (10%) patients with chronic hepatitis versus 2/45 (4%) patients with liver cirrhosis ($p = 0.03$). The delay of ALT normalization was 2.7 months in patients with chronic hepatitis and 4.4 months in patients with cirrhosis. In the group of 42 patients who were non-responders to a previous course of Interferon alpha, ALT returned to normal in 11 (26%) or decreased by more than 50% in 10 other patients (24%), and HCV RNA became negative in 1 (2.5%). Paired liver biopsy samples were available in 17 patients. The histologic activity index improved in 8/10 responders, 2/3 partial responders and 2/4 non responders. Side effects were mild but more pronounced in cirrhotic patients. In *conclusion,* the rate of ALT normalization and liver histology improvement after long term administration suggest that Ribavirin monotherapy may be beneficial in controlling HCV associated liver disease. This may represent an alternative therapy in patients contra-indicated to Interferon therapy. Liver and bile ducts, 1: Hepatitis, viral, treatmentClinical practice: Management strategy }" "Ribavirin Monotherapy in Patients with HCV Related Chronic Hepatitis or Liver Cirrhosis: A Retrospective Study of 95 Patients"

OT44 1044**Which Anastomosis Following Proctectomy and Total Mesorectal Exision TME for Rectal Cancer? Low Colorectal (LCRA) or Colonic Pouch-Anal Anastomoses (CPAA)**

*N. Dehni, J.D. Singland, R.D. Schlegel, M. Guiguet, E. Tiret, R. Parc

Centre de chirurgie digestive, Hospital Saint Antoine, Paris, FranceAfter TME for low rectal cancer, the decision to perform LCRA or CPAA is made per-operatively depending on the tumor distance from the anal verge. The functional results of these operations are thought to be equal 1–2 years after operation. This consideration led us to compare the long term functional results of these two operations. *Methods* from 87 to 92, 173 patients underwent anterior resection and TME for cancers between 2–12 cm from the anal verge. All patients alive without recurrence were contacted by telephone for their functional results. There were 47 patients with CPAA and 34 patients with LCRA. Minimal follow up was 3 years for all patients (mean 5 years). *Results* the 2 groups were well matched for sex, age, histologic stage and adjuvant therapy. Functional results figure herein Function CPAA LCRA p* n = 47 n = 34No. bowel movements/day 1.57 – 1 2.79 – 1 0.001Irregular transit 30% 71% 0.003Fragmented defecation 41% 65% 0.06Diarrhea/constipation 31% 59% 0.02Incontinence for feces 13% 12% 1.0Use of Loperamide 4% 21% 0.03Restricted diet 14% 41% 0.01*Wilcoxon or Fisher test*Conclusion* quality of life at long term follow up seems better with CPAA than LCRA after radical treatment of rectal cancer. Preservation of a short rectal segment does not offer any clinical advantages. These results are importants to be considered because of the high morbidity currently reported [1] following LCRA.

OT44 1046**Stool DNA Yield and the Detection of K-ras Mutations in Patients with Colorectal Cancer Using the Amplification Refractory Mutation System**

*N.R. Cruickshank[1], J.C. Fox[2], G. Ellison[2], N.R. Charlesworth[2], A. Jones[3], R. Cobb[3], D. Morton[1], J.P. Neoptolemos[1]

[1] Dept. of Surgery, Queen Elizabeth Hospital, Birmingham

[2] Cancer Diagnostics Research & Development, Zeneca Diagnostics

[3] Birmingham Heartlands NHS TrustMolecular analysis of stool DNA has the potential of providing a non invasive screening test for colorectal neoplasia. This study evaluates the extraction of human DNA from stool combined with the identification of K-ras mutations using the Amplification Refractory Mutation System (ARMS).35 consecutive matched stool and tumour samples were analysed. Stool samples were collected on admission to hospital prior to surgery, 2–4 gms of stool being used in each silica based DNA extraction. The human DNA extracted from stool was evaluated by serial dilution and PCR amplification using three common human specific primer sequences; exons 1 of the cystic fibrosis, { a}$_1$ antitrypsin and K-ras genes. Tumour DNA and matched stool DNA were then evaluated using ARMS allele specific amplification for 7 common K-ras mutations in codon 12 and 13.Human DNA was isolated in 55/61 stool samples and quantified by serial dilution and PCR amplification (range 1/5 to 1/1000 dilutions). 23 out of 61 tumours were K-ras positive (38%), 21 tumours had sufficient stool DNA recovered to allow analysis with the corresponding mutation identified in 13/21 stool samples (62%) and 12/17 (70%) of left sided lesions. In the K-ras positive stool samples all 8 samples which had a stool DNA quality greater than 1 in 200 had the correct mutation identified, compared to 5/15 in those samples with a stool dilution yield of less than 1 in 100 ($2p = 0.0047$ – Fisher's exact probability test).These results suggest that DNA yield is essential to successful stool DNA mutational analysis. In the presence of a high DNA yield from stool, this can provide a sensitive and specific test for colorectal cancer, but progress in this novel screening method will be dependant on developing improved extraction techniques. OT44 1047**Is It Possible to Assess the Quality of Rectal Excision for Cancer?**

*M. Poccard, Y. Panis, J. Nemeth, P. Hautefeuille, P. Valleur

Digestive Surgical and Pathology Departments, University Hospital Lariboisiére, 2 rue Ambroise Par\'e9, 75010, Paris, FranceAfter rectal excision for cancer, the great variability in the reported incidence of local recurrence (from 4 to 35%) suggests that surgery is crucial for the prognosis. To date, no objective criteria have been reported to assess the quality of proctectomy for cancer.*The aim of this work* was to assess, in patients (pts) undergoing curative resection of rectal carcinoma, the impact on survival and local recurrence rates, of the number of lymph nodes (involved or not) founded on the resected specimen.*Patients and Methods:* From 1982 to 1992, 180 pts underwent curative proctectomy (i.e. without synchronous metastase or distal lymph node invasion): 117 pts without lymph node invasion (NO) and 63 pts with proximal nodes invasion (N+). Mean follow up was 55 – 40 months (extr. 0–152). Mean number of lymph nodes on the specimen was 12 – 8 (extr. 0–42). According to the number of nodes (N), we studied the survival and local recurrence (LR) rates at 10 years, and for N+, the mean number of positive nodes (N+).*Results:* NO patients (n = 117) N+ patients (n = 63)N pts LR Survival N pts LR N+ Survival0–4 27 19% 72% 0–4 6 0% 1.8 60%5–9 32 19%[a] 70% 5–9 19 11% 2 54%> 10 58 5%[a] 77% > 10 38 34% 4.4 33%(a) $p < 0.05$; preoperative radiotherapy (29 pts NO and 12 N+) did not influence the results. Only the mean number of lymph nodes was reduced in case of radiotherapy: 7.4 vs 12.3 (NO) and 9.3 vs 13.5 (N+).*Conclusions:* a) in NO patients, local recurrence rate was significantly higher if < 10 nodes were founded. Whatever the cause (insufficient excision or carcinoma with low level of nodes reaction), the high rate of recurrence observed in these cases underline the need of a careful postoperative follow up; b) in N+ patients, a small number of lymph nodes on the specimen could suggest that the risk of nodes invasion is probably low (and that the prognosis is better) rather than an insufficient rectal excision. OT45 1049**Families with a Strong History of Colorectal Cancer but with Tumours Lacking the Mutator Phenotype**

*J.R. Jass, V. Pokos, J.L. Arnold, D.S. Cottier, P.J. Browett, I.M. Winship, M.R. Lane

University of Auckland, Auckland, New ZealandClinical and pathological features of families with a strong family history of colorectal cancer but lacking tumours with the mutator phenotype were studied with the aim of distinguishing a new syndrome of hereditary bowel cancer.In eight families fulfilling the Amsterdam criteria for hereditary non-polyposis colorectal cancer (HNPCC), at least two out of two cancers per family showed DNA repair proficiency as indicated by a lack of microsatellite instability at up to six loci. Colonoscopic findings in at-risk family members, together with clinical and pathological features in affected family members were compared with genuine HNPCC families (12).The overall tumour burden in the eight families included 38 colorectal cancers, one ovarian cancer, but no uterine, gastric, pancreatic, small intestinal or upper urinary tract cancers. Despite the fact that at least one family member was aged less than 50 years, the mean age at onset of cancer was 57 years. The majority of cancers developed in the left colon and rectum (80%). Only one subject had multiple colorectal cancer and there was no increased frequency of mucinous (14%) or poorly differentiated (10%) cancer. At-risk family members had more adenomas at colonoscopy than at-risk members of HNPCC families ($p = 0.095$) and a higher adenoma:carcinoma ratio (13:1 versus 7:1). No families showed features of attenuated FAP.The preceding data suggest that there may be hereditary colorectal cancer syndromes (?autosomal dominant) distinct from HNPCC and FAP.

OT45 1051**Thyroid Carcinoma in Patients with Familial Adenomatous Polyposis in the Netherlands**

*K. Van der Linde[1], H.F.A. Vasen[2], A.C.M. Van Vliet[1]

[1] Department of Internal Medicine, Drechtsteden Hospital, Dordrecht, The Netherlands

[2] Foundation for the Detection of Hereditary Tumours, Leiden, The NetherlandsFamilial adenomatous polyposis (FAP) is known to be associated with several extracolonic cancers. In the literature a 25–160 times higher relative risk of developing thyroid carcinoma (TC) has been reported, especially in women. The aims of the present study were to assess the incidence of TC in the Dutch FAP Registry and to evaluate the value of screening of the thyroid.*Methods:* The registry contains 155 families including 601 patients (339 men and 262 women). The diagnosis of FAP was confirmed by endoscopy, histology, mutation analysis or a medical report. For risk assessment, patients were studied with respect to their risk of developing TC from birth until date of last contact, death, date of diagnosis, or closing date of the study (January 1, 1996). The age-specific relative risk (RR) was defined as the ratio between the observed and expected number of tumours. The expected numbers were calculated by multiplying the person-years by corresponding age-specific incidence rates obtained from the Dutch National Cancer Registry of 1991.*Results:* Screening for TC revealed 5 cases which were all female. The mean age at diagnosis was 36 years (range 16–62). In 3 patients TC appeared to be the presenting symptom. Histology revealed 2 follicular carcinomas and 2 mixed papillar/follicular carcinomas. In one patient histology was not available. The RR of TC in female FAP patients was 32 (95% confidence interval 13–76). At the age of 74 the cumulative incidence in these patients was 17% versus 0.22% in non-FAP women. None of the FAP patients died from TC.*Conclusions:* Female FAP patients are more likely to develop TC especially at relative young age. Moreover, TC may be the presenting symptom of FAP. However, the prognosis remains good. Therefore, as swelling of the thyroid can easily be detected by palpation we recommend periodic physical examination in female FAP patients. Other screening procedures are not appropriate as the prognosis of TC in FAP appears to be good. OT46 1054**Early Diagnosis of Extrahepatic Bile Duct Cancer with Mr Cholangiopancreatography**

*J. Sai, J. Ariyama, M. Suyama, K. Sato, Y. Kubokawa, K. Wakabayashi, S. Asahara[1], M. Irimoto, H. Katayama[2]

[1] Department of Gastroenterology, Juntendo University, Tokyo, Japan

[2] Department of Radiology, Juntendo University, Tokyo, Japan*Objectives:* Purpose of this study was to determine the efficacy of MR Cholangiopancreatography (MRCP) in the early diagnosis of extrahepatic bile duct cancer.*Subjects and Methods:* From July 1995 to April 1996, 56052 patients visited our outpatient clinic, and 192 patients suspected of having pancreatobiliary diseases were examined with MRCP. Male to female was 114: 78, with an average age of 53 years. MRCP was performed with a 1.5 T scanner (TOSHIBA VISART). Two dimensional heavily T2 weighed MRCP images were obtained in breath-hold of 3 seconds using Fast Asymmetric Spin Echo Sequence (FASE).*Results:* In 34 patients, MRCP demonstrated extrahepatic bile duct stenosis which was confirmed by ERCP or PTC. Ten patients were eventually diagnosed to have bile duct cancer which was confirmed by surgery (n = 6) or PTCD and cytology (n = 4). Two patients were non-icteric, and one patient had no bile duct dilatation. In one patient tumor was limited to the muscular layer and in 2 patients to the perimuscular connective tissue. A curative resection based on histological findings was possible in 2 patients.*Conclusion:* MRCP is a useful method to diagnose early stage of extrahepatic bile duct cancer. OT46 1055**Combined Modality Therapy (CMT) in the Primary Cholangiocarcinoma of the Confluence: Czech Experience in 219 Patients**

*V. Dufek, J. Petrt\'fdl, R. Brůha, P. Klener

1st Medical Department, Charles University, Prague, Czech RepulicPrimary cholangiocarcinoma of the confluence (hilar cancer, HC) is the most common biliary tree malignancy in Central and Eastern Europe in the elderly. If untreated, its prognosis remains dismal, with the median survival 98.7 days.*Aims:* This study was performed to assess the feasibility of CMT in HC palliation.*Patients:* Since Jan 1990 to Jan 1996, 219 consecutive jaundiced pts with HC (121 males, 98 females, mean age 58.7 years) were entered into the prospective study. In all pts, nonsurgical stenting of the CBD was performed, followed by regional chemotherapy (RCHT) in 63 cases or by intraluminal radiotherapy (ILRT) in 36 pts.*Results:* Median survival in pts, treated by stenting alone, was 236 days. In those, treated by stents and RCHT or ILRT, median survival reached 594 days. In pts, treated by stents, RCHT and ILRT in combination, median survival was 711 days. We were not able to demonstrate any weighty side effects, either local or systemic. Early and/or late complications of stenting did not exceed 2.1%.*Conclusions:* On the basis of the results mentioned is possible to conclude, that CMT in preoperative HC palliation is the method of choice, nowadays.*Supported by grant 2227 of* IGA *MH CR* Oncology, specific: Liver, biliaryOncology, general: Therapy }" "Combined Modality Therapy (CMT) in the Primary Cholangiocarcinoma of the Confluence: Czech Experience in 219 Patients"

OT47 1056**Inhibition of Cholera Toxin-Induced Secretion by Substance P Antagonist**

*J.L. Turvill, M.J.G. Farthing

DDRC, St Bartholomew's & The Royal London School of Medicine, UK*Introduction.* Substance P (SP) is known to evoke neuronally mediated small intestinal fluid secretion accompanied by the release of vasoactive intestinal polypeptide (VIP). 5-hydroxytryptamine (5-HT) release, the activation of the enteric nervous system and VIP release are all implicated in cholera toxin (CT)-induced secretion. Since 5-HT receptors are located on sensory SP neurons we tested the hypothesis that SP antagonists would prevent CT-induced secretion.*Methods.* Anaesthetised male Wistar rats (180–220 g) were pretreated with: either (i) SP antagonist D Pro^2 D $Trp^{7,9}$ SP (PTT SP) 0.1, 0.3, 1.0 or 3.0 mg/kg ip; (ii) NK-1 antagonist (sendide) 0.1, 0.3, 1.0 or 3.0 mg/kg ip; (iii) NK-2 antagonist (GR83074) 1.0 mg/kg ip; or (iv) saline ip. 25 \'b5g CT in 2 ml saline was instilled into 25 cm segments of small intestine isolated between cannulae. After 2 h incubation, *in situ* perfusion was performed with plasma electrolyte solution (Na 140, K 4, Cl 104, HCO_3 40 mM) containing [^{14}C]-polyethylene glycol as a non-absorbable marker. 3 {\'b4} 10 min collections were made after 30 min equilibration and net fluid (\'b5l/min/g dw) and electrolyte movements were determined.*Results.* Net fluid movement (med { -}102 (IQR { -}75 to { -}147) n = 14) was reduced by 0.3 mg/kg ({ -}38 ({ -}14 to { -}67) n = 6), 1.0 mg/kg ({ -}76.5 ({ -}40 to { -}83) n = 7) and 3.0 mg/kg PTT SP ({ -}10.4 ({ -}4 to { -}42.5) n = 7); p = 0.0011 (Kruskal Wallis) but not by 0.1 mg/kg ({ -}135 ({ -}133 to { -}141.7) n = 5). The NK-1 antagonist also inhibited secretion at doses of 0.1 mg/kg ({ -}24.8 ({ -}16.1 to { -}39.7) n = 6), 0.3 mg/kg ({ -}49.4 ({ -}27.5 to { -}57.5) n = 8) and 1.0 mg/kg ({ -}29.4 ({ -}2.4 to { -}81.5) n = 8); p = 0.0017, as did the NK-2 antagonist ({ -}38 ({ -}13 to { -}39) n = 4); p = 0.0046 (Mann Whitney). Electrolytes parallel fluid movements.*Summary.* The SP antagonist PTT SP significantly inhibits CT-induced secretion. Antagonism of NK-1, which is SP's preferred receptor, similarly inhibits secretion. In addition, the NK-2 receptor is involved in the mediation of CT-induced secretion. Intestinal disorders, absorption: Pathophysiology of diarrhea }" "Inhibition of Cholera Toxin-Induced Secretion by Substance P Antagonist"

OT47 1057**Expression of the VIP 1 Receptor during Enterocytic Differentiation of Human Colon Cancer Cells (Caco-2): Regulation at the mRNA LevelA. Couvineau, J.J. Maoret, I. Carrero, C. Rouyer-Fessard, M. Laburthe**

INSERM U410, Neuroendocrinology and Cell Biology of the Digestive System, Facult\'e9 de M\'e9decine Xavier Bichat, B.P. 416, 75870 Paris Cedex, FranceThe human colon adenocarcinoma cell line Caco-2 in culture spontaneously differentiates into enterocytes and expresses the VIP 1 receptor. In Caco-2 cells, a dramatic increase of VIP 1 receptor concentration has been observed when cells undergo differentiation (Laburthe et al., 1987, J. Biol. Chem., 262: 10180–10184). Scatchard analysis of ^{125}I-VIP binding to Caco-2 cell membranes revealed an increase of VIP receptor concentration from undifferentiated cells at day 5 culture (15 fmol/mg of protein; Kd = 0.2 nM) to differentiated cells at day 28 of culture (128 fmol/mg of protein; Kd = 0.07 nM). We report here the study of VIP 1 receptor mRNA expression during enterocytic differentiation of Caco-2 cells. Analysis of VIP 1 receptor mRNA expression by 1) RNase protection assay revealed the presence of a high level of mRNA in differentiated cells (Day 25) and a very low level of mRNA in undifferentiated cells (Day 5). In contrast, b actin mRNA level was the same in both conditions; 2) RT-PCR detection of mRNA followed by southern blot using a VIP 1 receptor cDNA probe also revealed a much higher amount of VIP 1 receptor mRNA in Caco-2 cells at day 25 than at day 5. These results strongly suggested that the expression of VIP 1 receptor during enterocytic differentiation of Caco-2 cells was regulated at the mRNA level. In order to determine the half-life and transcription rate of VIP 1 receptor mRNA, the following experiment were performed: 1) cells were treated at different time with actinomycin D (a specific inhibitor of RNA polymerase II) and VIP 1 receptor mRNA was detected by RNase protection assay. The half-life of VIP 1 receptor mRNA was 10 hours in the two conditions of culture (day 5 and day 25); 2) runoff transcription was performed on isolated nuclei from differentiated and undifferentiated Caco-2 cells, showing that VIP 1 receptor mRNA were transcribed at 5-fold higher rate in differentiated cells than in undifferentiated cells. It is concluded that the expression of the VIP 1 receptor during enterocytic differentiation of Caco-2 cells is regulated at the transcriptional level. Hormones and receptors: Receptor characterizationHormones and receptors: Molecular biologyOncology, specific: Colon, rectum }" "Expression of the VIP 1 Receptor during Enterocytic Differentiation of Human Colon Cancer Cells (Caco-2): Regulation at the mRNA Level"

OT47 1058**Functional Characterisation of Neurokinin Receptors Mediating Ion Transport in Porcine Jejunum**

*J.E. Thorb\'f8ll, N. Bindslev, E. Skadhauge

Department of Anatomy and Physiology, The Royal Veterinary and Agricultural University, Copenhagen, DenmarkSubstance P (SP) and neurokinin A (NKA) are the major tachykinin neurotransmitters in the porcine small intestine. Tachykinins seem to be involved in the secretory actions of *Clostridium difficile* toxin A, and in inflammatory bowel disease, in which alterations in ion transport constitute part of the pathophysiology. Thus, tachykinin receptor antagonists might have a therapeutic potential. The aim of the present study was to characterise neurokinin (NK) receptors, involved in ion transport, in porcine jejunum, as this tissue exhibits functional similarity to human upper small intestine. *Methods:* Stripped porcine jejunal tissue preparations with intact mucosa and submucosa were mounted in Ussing chambers containing Ringer-solution. The tissue was short-circuited and corresponding values of electrical parameters (resistance and open circuit potential difference) were measured and calculated by computer. Compounds were added to the serosal side. *Results:* SP produced a concentration dependent increase in short-circuit current (SCC), the curve having a double sigmoidal form. The NK-1 antagonist CP 99,994 totally abolished the first sigmoidal response, indicating the presence of an NK-1 receptor. This was further supported by a concentration-dependent response of the NK-1 agonist [Sar^9 $Met(O_2)^{11}$]-SP (Sar^9 SP) with an EC_{50} value of 235.0 nM – 53.9. Increasing concentrations of CP 99,994 (0.1 \'b5M, 0.3 \'b5M and 1 \'b5M) produced a parallel dextral shift of the Sar^9 SP curve with a slope of the Schild regression (1.59) different from unity. Another NK-1 antagonist, RP 67,580, and the inactive enantiomer of CP 99,994, CP 100,263, did not change the response to SP. The NKA concentration response curve (EC_{50} value of 68.87 nM – 16.23) was not significantly changed by the NK-2 antagonists, SR 48,968 or GR 94,800. However, CP 99,994 totally inhibited NKA responses at 0.5 \'b5M and higher concentrations. The NK-2 agonist, [{ b}-Ala^8]$NKA_{4–10}$, caused only in \'b5M concentrations an increase in SCC, whereas the NK-3 agonist, senktide, did not elicit a response. *Conclusion:* SP and NKA mediate ion transport in porcine jejunum through NK-1 receptors. Tachykinins might also activate a new unclassified receptor. However, this needs to be further substantiated and clarified using structural studies. Species dependent heterogeneity of NK-1 receptors might explain the lack of effect of RP 67,580. OT47 1059**Effect of Continuous Jejunal Application of Soluble Fiber on Cholecystokinin and Neurotensin Release in Men**

*R. Meier[1], M. Kemen[2], M. Senkal[2], H. Schneider[3]

[1] Divison of Gastroenterology, Kantonsspital Liestal, Switzerland

[2] Department of Surgery, St. Josef Hospital, Bochum, Germany

[3] Sandoz Nutrition, Bern, SwitzerlandWe have shown, that a liquid diet with soluble guar fiber (Sunfiber [SF]) given as bolus for 7 days increase fasting cholecystokinin (CCK) concentrations (JPEN, 1993, 231–235). Whether a continuous jejunal application of the same diet also affects CCK secretion is not well defined. The aim of this study was therefore to assess the effect of continuous feeding on plasma CCK and neurotensin (NT) release.*Methods:* 23 patients after upper gastrointestinal surgery received continuously a liquid diet by jejunostomy over 16 days. 9 standard liquid diet (SLD), 14 the same diet with 20 g SF/L (SFD). At day 16 basal and postprandial (after perfusion of 500 ml diet) CCK and NT concentrations were assessed. Blood was drawn at regular intervals and CCK and NT concentrations were measured by specific radioimmunoassays (Pancreas, 1991, 260–265).*Results:* Data are in pg/ml (mean – SEM). N Basal 30 min 50 min 70 min 90 min1) CCKSFD 14 0.35 – 0.1 3.1 – 1.3 4.0 – 2.1 4.0 – 2.2 2.6 – 1.0SLD 9 1.3 – 0.4 4.6 – 1.6 4.4 – 1.6 4.3 – 1.6 4.6 – 1.52) NTSFD 14 9.0 – 2.0 78 – 15 102 – 24 104 – 19 88 – 17SLD 9 6.4 – 1.3 71 – 33 99 – 28 101 – 34 106 – 43No difference was seen for basal and postprandial concentrations between the two diets. Furthermore the area under the curve were not significantly different.*Summary:* After 16 days continuous feeding basal CCK and NT levels were similar for both diets and comparable to healthy volunteers. Furthermore the postprandial response was similar for both diets.*Conclusion:* In contrast to orally bolus feeding regimens continuous feeding of a SF containing liquid diet does not change basal CCK and NT concentrations. OT50 1061**Association of Serum Antibodies Against P53 Protein with Poor Survival in Zollinger-Ellison Syndrome Patients**

*Ph. Ja\'efs, M. Mignon[2], A. Vuagnat[3], S. Bonfils[1], B. Bressac[4], M.J.M. Lewin[1]

[1] INSERM U10 Hospital Bichat-Claude Bernard, 170 Boulevard Ney, Cedex 18, F-75877 Paris

[2] Department of Hepato-Gastroenterology, Hospital Bichat-Claude Bernard, 170 Boulevard Ney, Cedex 18, F-75877 Paris

[3] INSERM U169, F-94807 Villejuif

[4] Laboratoire de Diagnostic Mol\'e9culaire, Institut Gustave Roussy, F-94807 Villejuif*Background/Aims:* Long-term survival of patients with Zollinger-Ellison syndrome is largely determined by the presence or the absence of liver metastases. However, because of the lack of precision of this criteria, the development of further indicators is still required. The recent evidence that auto-antibodies directed against the p53 protein could predict a poor survival for some types of cancers, has prompted us to investigate the presence of such antibodies in sera from Zollinger-Ellison syndrome patients and their potential value as survival indicator. *Methods:* The detection of anti-p53 antibodies was carried out in sera from 44 consecutive Zollinger-Ellison syndrome patients using both an ELISA assay and Western-blotting. The mean follow-up of these patients was 92 months. *Results:* Anti-p53 antibodies were detected in 7 out of the 44 Zollinger-Ellison syndrome patients (16%) both by ELISA and by Western-blotting. Univariate and multivariate analysis demonstrated that the presence of anti-p53 antibodies ($P = 0.0009$ and $P = 0.017$ respectively) and liver metastases ($P = 0.0009$ and $P = 0.012$ respectively) were independently associated with a shorter survival. *Conclusions:* Our results suggest that anti-p53 antibodies are an indicator of survival and could be used in combination with staging for determining poor prognosis Zollinger-Ellison syndrome patients requiring reinforced therapy.

OT50 1062**Follow-Up Program after Curative Resection of Colorectal Carcinoma**

*P. Lage, P. Fidalgo, I. Claro, L. Manoel, J. Correia, P. Caldeira, A. Suspiro, C. Nobre Leit\'e3o, F. Costa Mira

Servi\'e7o de Gastrenterologia, Instituto Portugu\'eas de Oncologia, Lisbon, Portugal*Background:* After curative surgery for colorectal carcinoma, intensive follow-up has been implemented in many Centers. Its primary goal is the detection of recurrence in the asymptomatic stage hoping to increase the possibility of new curative resection and to prolong survival. The type and the effectiveness of such follow-up programs has been controversial. *Aims:* To evaluate the sensitivity of diagnostic methods and the efficacy of a follow-up program on recurrence detection, treatment and survival after curative resection of colorectal carcinoma. *Material and Methods:* Between 1989 and 1993, 218 patients were submitted to curative colorectal resection and underwent regular examinations according to a defined schedule which included: clinical examination, tumoral markers (TM) – CEA and CA19-9, liver function tests (LFT), chest roentgenography and abdominal ultrasonography (US) every four months during the first two years and half-year until the fifth. All patient were submitted to annual colonoscopy to detect metachronous tumors or anastomotic recurrences. Those with rectal cancer also performed computerized tomography (CT) at the fourth postoperative month for basal determination. *Results:* Tumor recurred in 54 patients (25%), with 61% of them having tumor associated symptoms. The sensivity of the diagnostic methods was: TM-85%; CT-91%; US-75%; LFT-40%. A second resection with curative intent was performed in 13 patients (24%): anastomotic-40%; hepatic metastases-29%. The five year survival rate after colorectal resection was 70% and survival was prolonged after curative resection of tumor recurrence ($p = 0.038$) but was not different between symptomatic and asymptomatic recurrences. *Conclusions:* The TM seems to be the best test for recurrence detection because of its low cost and high sensivity. Despite the elevated number of asymptomatic recurrences detected, this did not lead to more effective treatment, neither did it prolonged survival. Further controlled prospective studies are needed to confirm the efficacy of follow-up programs. [4] IRCCS Castellana, BariHereditary non polyposis colorectal cancer (HNPCC), is an autosomal dominant disorder that account for 4–13% of all cases of colorectal carcinomas. It is characterized by early age of occurrence, prevalence of proximal localization, higher risk of multiple tumors (synchronous and metachronous). For HNPCC diagnosis the so called ""Amsterdam criteria"" must be fullfilled. Frequently families or individuals are observed which do not meet the rigorous Amsterdam criteria, but are highly suggestive as having HNPCC (HNPCC like syndrome). HNPCC is due to defects in genes coding for mismatch repair system (MMR): hMSH2, hMLH1, hPMS1, hPMS2. The aim of our study is to define the clinical features and the mutational status at MMR genes, of young cancer patients with colorectal tumor not fullfilling Amsterdam criteria or without a family hystory indicative for HNPCC. Blood and paraffin embedded tumor tissue have been collected from 33 individuals who developed the disease before 40 years of age. Mutational analysis was carried out by a non radioactive single strand conformation polymorphism (SSCP) made more sensitive by a acrylamide gradient, followed by direct DNA sequencing where a aberrant migration pattern was observed. Preliminary and partial analysis demonstrates the presence of four mutations in hMSH2 (exons 5, 16, 14) and two mutations in hMLH1 (exons 5, 16) in individuals under 40 years of age.Our result indicate that mutations at MMR genes can be resposible of colorectal cancer in young patients even in situations not fullfilling Amsterdam criteria, and suggest the necessity of establishing new criteria for identifying individuals to be tested for mutations at MMR genes.

OT50 1064**K-Ras-2 Gene Mutations in Colorectal Adenomas and the Risk of Metachronous Adenomas****G. Nusko, R. Sachse, U. Mansmann, Ch. Wittekind, E.G. Hahn**

Depts of Medicine I & Pathology, University of Erlangen and Inst. of Medical Statistics, Free Univeristy of Berlin, GermanyMutations of K-ras-2 gene and tumorsuppressor genes have been found in colorectal adenomas and carcinomas. The aim of this study was to investigate the prognostic value of K-ras-2 gene mutations found in initial colorectal adenomas predicting the risk of metachronous adenomas.*Material and Methods:* Genomic DNA was extracted from the formalin fixed and paraffin embedded adenomas larger than 5 mm in diameter removed during 1980 and 1986 at the initial total colonoscopy. All patients had a colonoscopic follow-up for at least six years. The sequence of the exon 1 of the K-ras-2 oncogene was amplified using PCR and screened for mutation by single strand conformation polymorphism (SSCP). All suspected mutations were confirmed by direct sequencing. The predictive value was assessed by logistic regression analysis.*Results:* Out of 54 patients 39 (72%) were male and 15 (28%) female. At the time, where the initial adenoma was removed, 31 (57%) patients were younger than 60 and 23 (43%) were equal to or older than 60 years. Pointmutations of the K-ras-2 oncogene were found in the index adenoma of 15 (27.7%) patients. Mutations were found more frequently in large ({\'b3} 20 mm) adenomas and in adenomas with severe dysplasia (p = 0.0011 and p = 0.0310, respectively). There were no significant associations between anatomical location, histological type or number of synchronous initial lesions and K-ras-2 mutations. Mutations were found predominantly at codon 12 with transversions from GGT to GAT (36%), from GGT to GTT (57%) and from GGT to TTT in one patient. The one mutation found at codon 13 showed a transversion from GGC to GAC. There were significant associations of size ({\'b3} 20 mm) and K-ras-2 mutation of the initial adenomas and the size (> 5 mm) of metachronous adenomas (p = 0.0259 and p = 0.0265, respectively). But multivariate analysis revealed that K-ras-2 did not provide a significant additional contribution to the prognostic value of the size (odds rartio 7.62; 95% CI: 1.68–34.48) and the amout of villous structure (odds rartio 0.22; 95% CI: 0.0–0.90) of the initial adenoma.*Conclusions:* Patients with large ({\'b3} 20 mm) adenomas and adenomas harbouring K-ras-2 mutations at the initial examination are of a significant higher risk for developing large (> 5 mm) metachronous adenomas during surveillance. But the risk of metachronous colorectal adenomas can be estimated sufficiently by the size and the histological type of the largest initial adenoma. Oncology, specific: Colon, rectumOncology, general: Molecular biology, genetics }" "K-Ras-2 Gene Mutations in Colorectal Adenomas and the Risk of Metachronous Adenomas"

OT51 1065**Antibiotic Prophylaxis (AbP) for the Prevention of Bacterial Infections in Cirrhotic Patients with Gastrointestinal Bleeding (GB): A Meta-Analysis**

*B. Bernard[1], J.D. Grang\'e9[2], E. Nguyen Khac[1], X. Amiot[2], P. Opolon[1], T. Poynard[1]

[1] Sce d'H\'e9pato-Gastroent\'e9rologie, GH Piti\'e9-Salp\'eatriére, 75013 Paris, France

[2] Sce d'Hepato-Gastroent\'e9rologie, Hospital Tenon, 75020 Paris, FranceIn cirrhotic patients with GB, the AbP decreases the incidence of infections but no randomized controlled trial (RCT) showed an increase in survival. *Aim of the meta-analysis:* to assess the efficacy of AbP for the prevention of bacterial infections and the effect of AbP on survival rate in cirrhotic patients with GB. *Methods:* An overview of RCTs assessing the efficacy of an AbP for the prevention of infection in cirrhotic patients with GB. RCTs including patients without bleeding or comparing 2 antibiotics were excluded. Meta-analysis used Peto and Der Simonian methods. *Results:* Four RCTs including 414 patients, 204 treated with an AbP and 210 without AbP were identified. The AbP used oral, non absorbable antibiotics during 4 days (n = 68), or norfloxacin during 7 days (n = 60), or the association of amoxycillin-clavulanic acid and ciprofloxacin during 4 days (n = 30), or ofloxacine for 10 days with an IV bolus of amoxicillin-clavulanic acid before each endoscopy (n = 46). The end point of each RCT was the prevention of bacterial infection during 10 to 14 days. The mean percentage of patients free of bacterial infection was 85% in patients treated with an AbP vs 55% in non treated patients. This difference was significant (mean rate difference: 32%, 95% confidence interval (CI): 19–44, $p < 0.001$), without significant heterogeneity. The mean percentage of patients free of bacteremia and/or spontaneous bacterial peritonitis (3 RCTs) was 91% in treated patients vs 74% in non treated patients. This difference was significant (mean rate difference: 15%, 95% CI: 8–22, $p < 0.001$), without heterogeneity. The mean percentage of patients free of infection caused by enteric bacteria (2 RCTs) was 95% in treated patients vs 75% in non treated patients, this difference was significant (mean rate difference: 19%, 95% CI: 10–28, $p < 0.001$). The mean survival rate was 87% in patients treated with an AbP vs 77% in non treated patients. This difference was significant (mean rate difference: 9.2%, 95% CI: 2.4–16.0, $p < 0.008$), without heterogeneity. Sensitivity analysis without the RCT using non absorbable antibiotics showed similar results, but the difference concerning survival rate was not significant (mean rate difference: 7.4%, 95% CI 0–16, $p = 0.07$). *Conclusions:* In cirrhotic patients with GB, the AbP significantly decreases the incidence of bacterial infection and significantly increases short term survival rate. Liver and bile ducts, 1: Cirrhosis: portal hypertensionEndoscopy, general: GI bleeding }" "Antibiotic Prophylaxis (AbP) for the Prevention of Bacterial Infections in Cirrhotic Patients with Gastrointestinal Bleeding (GB): A Meta-Analysis"

OT51 1068**Evaluation of Portal Hypertension and Haemodynamic Risk Factors for Variceal Bleeding by Color DopplerSheir S. Baddar,**

*M. Osman, S. Shalaby, M.M. Hendi

Internal Medicine Department, Ain Shams University, Cairo, EgyptSeventy patients were included in this work. Ten normal control subjects, thirty patients with evidence of portal hypertension with no history of bleeding from oesophageal varices, and thirty patients with evidence of portal hypertension with history of oesophageal variceal bleeding. Real time US, Color Doppler examination and upper endoscopy were done for all the subjects. Color Doppler U.S. was found to be more sensitive and specific than real-time U.S. in diagnosing portal hypertension regarding increase in congestion index (CI), better visualization of collaterals and more accurate diagnosis of P.V. thrombosis. CI more than 0.09 cmXsec was 100% sp\'e9cifific and 100% sensitive in diagnosing portal hypertension, compared to 100% specificity and 93% sensitivity considering portal vein flow velocity < 12 cm/sec, 100% specificity and 85% sensitivity considering portal vein diameter > 13 mm, and 100% specificity and 88% sensitivity considering the visualization of collaterals. P.V. thrombosis was better detected by Color Doppler as 40% of the thrombosed PV were missed using real time U.S. Color Doppler allowed better visualisation of the collaterals as 70% only of the visualised cases could be detected using real time U.S. Study of the collateral haemodynamics revealed that the most reliable protector against bleeding varices was the presence of adequate splenorenal shunt with partial flow reversal in the splenic vein and incomplete flow reversal in the left gastric vein. Recanalization of para-umbilical vein was not directly related to the presence of varices, yet the larger the diameter and the more the flow the less will be the risk of bleeding. The risk factors bleeding varices were: 1) PV ""CI"" more than 0.12 cmXsec. 2) Absence of adequate collaterals specially splenorenal shunt. 3) PV thrombosis. 4) Complete flow reversal in left gastric vein. }"

OT53 1070**A Population Based Study on the Familial Aggregation of Inflammatory Bowel Disease**

*M.G. Russel[1], C.J. Pastoor[1], K.M. Janssen[1], M.A. Kruijs vd[1], C.Th. Deursen[2], J.W. Muris[3], R.W. Stockbr\'fcgger[1]

[1] Dept. of Gastroenterology, university hospital Maastricht, Maastricht, The Netherlands

[2] Dept. of Internal Medicine, St Gregorius Hospital, Brunssum, The Netherlands

[3] Dept. of General Practice, University of Maastricht, Maastricht, The Netherlands*Introduction:* Recent studies have shown variable degrees of familial aggregation in inflammatory bowel disease (IBD). In our study the prevalence of Crohn's disease (CD) and ulcerative colitis (UC) in first degree relatives of IBD patients, living in a well-defined area, was studied.*Methods:* All known prevalent IBD patients living in the study area (148.250 inhabitants) were asked about the occurrence of IBD in their first degree relatives. In case of a positive family history, medical information was requested to verify the diagnosis. A control group of 616 persons without IBD was recruited in co-operation with the Registration Network family Practice.*Results:* The family pedigrees of 245 patients consisted of 1571 first degree family members. Sufficient information was available of 1554 cases: 485 parents, 756 siblings, and 313 children. IBD was reported and confirmed in 16 first degree relatives by 11 (4.5%) patients: 7 (5.3%) of the 132 patients with CD and 4 (3.5%) of the 113 patients with UC. Prevalence of IBD was highest for siblings (1.5%) and children (1.3%) while only 0.2% of the parents were affected with IBD. Affected family members of the index patients showed a 88% disease concordance concerning either CD or UC. Among first degree relatives of the control subjects, IBD was observed in 0.8% (vs. 4.5% in IBD patients), resulting in an odds ratio of 5.7 (95% C.I. 2.0–16.7).*Conclusion:* In this population based study, the observed risk of IBD for first degree relatives of IBD patients was higher than in controls. However, the prevalence in our population is lower than has been reported by other centres, possibly reflecting the population based character of our study. OT53 1071**Inflammatory Bowel Disease in a Danish Twin Register**

*M. Orholm, V. Binder, T.I.A. S\'f8rensen, K.O. Kyvik

Medical Gastroenterological Department, Herlev Hospital, University of Copenhagen, Denmark

Institute of Preventive Medicine, Copenhagen University Hospital, Genetic Epidemiology Research Unit, Institute of Community Health, University of Odense, DenmarkPrevious population studies have shown a 10 fold increased risk of inflammatory bowel disease (IBD) among first degree relatives of patients with ulcerative colitis and Crohn's disease. To further investigate the heridity of these diseases a twin study was performed.A questionnaire was sent to all 34,076 twins included in a new twin register, which comprises all twins born in Denmark 1953 through 1982 (34,188), who had been identified and who had accepted to participate in studies. If a twin stated to suffer from IBD, the diagnosis was confirmed or excluded by applying the classical criteria to medical records from hospitals or private physicians.A total of 29,430 (86%) twins answered the questionnaire. Among these, 93 twin pairs with at least one suffering from IBD were observed (Crohn's disease: 36, ulcerative colitis: 57). In the Crohn's disease group three of 11 monozygotic pairs were concordant for the disease, while none of the 25 dizygotic pairs were concordant. In the ulcerative colitis group one of 15 monozygotic pairs and one of 42 dizygotic pairs were concordant for the disease. The proband concordance rate among monozygotic pairs was 38.5% for Crohn's disease and 6.7% for ulcerative colitis.The frequency of IBD in the twin register was 1.5 time the expected as estimated from the age-specific rates in the background population. The frequency of IBD among twins of patients with IBD was 36 times the expected.In conclusion, this study further strengthens the hypothesis of a genetic predisposition for development of IBD, a predisposition which may be stronger for Crohn's disease than for ulcerative colitis. Intestinal disorders: IBD, etiology and geneticsClinical practice: Epidemiology (non cancer) }" "Inflammatory Bowel Disease in a Danish Twin Register"

OT53 1072**Signal Transduction Role of Nuclear Factor (NF)-Kappa B in the Regulation of Pro-Inflammatory Cytokine Secretion by IL-10 in IBD Granulocytes**

*S. Schreiber, S. Nikolaus, J. Hampe, U. Schindler[1], A. Raedler, H. Lochs

IVth. Medical Department, Charit\'e9, Berlin, Germany

[1] Tularik, San Francisco, USA*Background:* Pro-inflammatory cytokines (IL-1{ b}, TNF-{ a}, IL-8, IL-1ra) are secreted in large amounts by IBD monocytes, macrophages and granulocytes (PMN, abstract 5th UEGW). IL-10 is a major inhibitor of pro-inflammatory cytokine secretion. NF-Kappa B is thought to be a major player in pro-inflammatory signal transduction. The *Aim* of this study was to evaluate mechanisms by which pro-inflammatory cytokine secretion by PMN can be regulated. *Methods:* PMN from 25 patients with ulcerative colitis (UC), 21 patients with Crohn's disease (CD) and 15 normal volunteer controls (NC) were obtained from peripheral blood by dextran sedimentation and density centrifugation. Release of pro-inflammatory cytokines (ELISA) into culture supernatants as well as mRNA (semiquantitative RT-PCR) were assessed. Formation of activated NF-Kappa B was assessed by gel shift or western Blot, respectively, from nuclear and cytosolic extracts. *Results:* In IBD patients enhanced secretion of pro-inflammatory cytokines by PMN coincides with detection of activated NF-Kappa B in nuclear extracts, which is absent in NC PMN. During in vivo (IBD) as well as in vitro activation of normal cells (i.e. by TNF, PMA or LPS) NF-Kappa B p65 is activated and translocated from cytosol to nucleus (Western Blot). In vitro treatment with IL-10 reverts those changes: NF-Kappa B is shifted back from nucleus to cytosol and can no longer be detected by gel shift in nuclear extracts. *Conclusions:* Activation and nuclear translocation of NF-Kappa B may provide a signal transduction mechanism by which IBD PMN are induced to secrete enhanced levels of pro-inflammatory cytokines. Moreover, Il-10 appears to induce deactivation of NF-Kappa B and evasion of the factor from the nucleus back to cytosolic compartment. This mechanism provides insights into signal transduction events influenced by IL-10 and may also suggest novel targets for future immunomodulatory strategies. Supported by DFG SCHR 2-1.*Graphic missing* Intestinal disorders: IBD, basicIntestinal disorders: IBD, etiology and geneticsIntestinal disorders: IBD, therapy }" "Signal Transduction Role of Nuclear Factor (NF)-Kappa B in the Regulation of Pro-Inflammatory Cytokine Secretion by IL-10 in IBD Granulocytes"

OT53 1073**No Exceeding Malignancy Prevalence in Relatives of IBD Patients: Comparison with Colon-Cancer Patients and Controls**

*G. Riegler, R. Manzione, F. Morace, M. Tartaglione, A. Arimoli, R. Carrat\'f9

Cattedra di Gastroenterologia, 2^Universita' di Napoli, ItalyThe relation between Inflammatory Bowel Diseases (IBD) and colon-cancer (CC) is not clearly defined. The colon cancer is considered to be more frequent in longstanding extensive ulcerative colitis (UC) and in Crohn disease of colon (CD). However, some investigators suggest that extensive colitis patients have a genetic predisposition to colorectal cancer and longstanding inflammation is not of primary importance in the promotion of cancer in UC.We report a prospective investigation on malignancy prevalence in relatives of an initial series of 225 IBD patients (178 UC; 47 CD), as well as 491 colon cancer pts. (CC) and 220 orthopedic pts. (ORT) as controls.In all patients (UC, CD, CC) as well as in controls (ORT) the prevalence of colon (A), extracolic digestive (B) and extradigestive (C) malignant tumours in the first degree relatives has been evaluated. Results are shown in table. number of relatives A B CUC 1194 5 (0.42%) 10 (0.84%) 27 (3.03%)CD 271 0 (0.00%) 3 (1.11%) 7 (2.58%)CC 3484 60 (1.72%) 25 (0.72%) 98 (2.81%)ORT 1489 6 (0.40%) 10 (0.67%) 36 (2.42%)In this initial series no difference in malignancy prevalence or tumours spectrum among UC, CD and ORT patients was observed. The relative risk of colon cancer in relatives of CC patients versus ORT was 4.3.Partially supported by grant of 60% MURST

[4] University of Chicago, Chicago, USA

[5] Sinai Medical Center, New York, USA

[6] Centocor Inc, Malvern, USATNF has been implicated in the pathogenesis of Crohn's disease (CD), and preliminary studies have suggested that administration of anti-TNF antibodies causes rapid clinical responses in patients with steroid-refractory CD. The present study is a double blind placebo-controlled trial in patients with active CD designed to assess the magnitude and duration of response to cA2 treatment. One hundred and eight patients with a CDAI between 220–400 were randomized to receive either placebo, 5 mg/kg, 10 mg/kg, 20 mg/kg or 20 mg/kg of cA2 as a single 2 hour intravenous infusion. Patients receiving concomitant therapy with corticosteroids, 6-mercaptopurine, or 5-ASA continued treatment throughout the 12 week trial. Patients in the different treatment groups were well matched for demographic and disease-related baseline characteristics. cA2 treatment resulted in a significantly larger reduction of the CDAI at 4 weeks ({ -}110.4 – 102.6) than placebo ({ -}12.8 – 79.3) ($p < 0.001$) and these differences were sustained throughout the study period. The number of patients achieving a clinical remission (CDAI < 150) was 16% in the placebo group versus 45.8% in cA2 treated patients ($p = 0.022$), and the number of patients responding to cA2 therapy (reduction of CDAI > 70) was 24% versus 69.9% respectively ($p < 0.001$). cA2-treated patients had a significant reduction in CRP levels, and an increase in the IBDQ scores. These data indicate that anti-TNF therapy has a high clinical efficacy in patients with CD, including those not responding to standard therapy. }"

OT54 1075**Ciprofloxacin Vs Mesalazine in the Treatment of Active Crohn's Disease**

*J.F. Colombel, M. L\'e9mann, M. Cassagnou, Y. Bouhnik, B. Duclos, J.L. Dupas, J.Y. Mary, B. Notteghem, GETAID

France*Background:* Evidence is accumulating for bacterial participation in the pathogenesis of (CD). Despite this, few controlled trials using broad-spectrum antibiotics have been conducted in CD. Ciprofloxacin (Cipro) has shown promising results in the treatment of CD with perineal disease and fistulae. The aim of this randomized controlled study was to investigate the efficacy of Cipro compared with 5-aminosalicylate (Pentasa[R]) in treating moderately active CD.*Methods:* Forty patients (25 F, 15 M, mean age 28 years) with moderate flare-up of CD (mean CDAI: 217, range 160–305) were randomized to receive Cipro 500 mg twice daily or Pentasa[R] 4 g/day for 6 weeks. Clinical remission was defined as a CDAI {\'a3} 150 associated with a decrease in CDAI ({ D} CDAI) > 75 at 6 weeks. Partial remission was defined as: 1) a CDAI {\'a3} 150 with a 50 < { D} CDAI < 75; 2) a CDAI > 150 with a { D} CDAI > 50 at 6 weeks.*Results:* Clinical remission was obtained in 10/18 Cipro patients (56%), and in 12/22 Pentasa[R] patients (55%). Partial remission was obtained in 13/18 Cipro patients (72%), and 13/22 Pentasa[R] patients (59%)(ns). C-reactive protein decreased from 32 – 29 to 9 – 5 (p = 0.027) in Cipro patients and from 33 – 22 to 21 – 16 in Pentasa[R] patients (ns). Three patients on Cipro (17%) and 7 on Pentasa[R] (32%) were considered as treatment failure because of deterioration or insufficient improvement (ns). Two patients receiving Cipro (11%) were withdrawn from the study for minimal side effects and absence of compliance. Two patients on Pentasa[R] (9%) were withdrawn because of the absence of improvement at 3 weeks.*Conclusion:* This study suggests that Cipro 1 g/day is at least as effective as Pentasa[R] 4 g/day in treating moderately active CD. Intestinal disorders: IBD, therapy }" "Ciprofloxacin Vs Mesalazine in the Treatment of Active Crohn's Disease"

OT54 1076**Balsalazide is More Effective and Better Tolerated than Mesalazine in Acute Ulcerative Colitis (UC)**

*J.R.B. Green, C.D. Holdsworth, A.J. Lobo, R. Leicester, J.A. Gibson, G.D. Kerr, H. Hodgson, K.J. Parkins, M.D. Taylor, P.D.I. Richardson, ABACUS Investigator group

Gastroenterology units in Stoke, Sheffield, London, Stafford, Shrewsbury and Astra Pharmaceuticals Ltd., Kings Langley, U.K.This study compared the tolerability and efficacy of balsalazide (mesalazine prodrug) and mesalazine (pH-dependent delayed release) in acute UC.Patients (101 total, 99 evaluable) (62 male) aged 41 – 13 years (mean – SD) with grade 2 (erythema + loss of vascular pattern + contact bleeding: 55% of patients), 3 (+spontaneous bleeding: 32% of patients) or 4 (+frank ulceration: 13% of patients) (extent > 12 cm; left-sided disease 80%) sigmoidoscopically verified, symptomatic (moderate 69% or severe 31%) UC were randomised, double blind, to receive balsalazide 2.25 g t.i.d. (equivalent to 0.78 g mesalazine) (n = 50) or mesalazine 0.8 g t.i.d. (n = 49) for 4, 8 or 12 weeks, as necessary. Rectal hydrocortisone p.r.n. was provided as relief medication. Both groups were comparable at entry.A greater proportion of patients achieved symptomatic remission (none/mild symptoms) at 2 (64% vs 43%, $p < 0.05$), 4 (70% vs 51%, $p > 0.05$), 8 (78% vs 45%, $p < 0.001$) and 12 weeks (88% vs 57%, $p < 0.001$) after balsalazide treatment compared to mesalazine. Similarly, more patients achieved complete remission (none/mild symptoms, sigmoidoscopy grade 0 (normal) or 1 (erythema with loss of vascular pattern) with no steroid use in previous 4 days) in the balsalazide group after 4 (38% vs 12%, $p < 0.01$), 8 (54% vs 22%, $p < 0.005$) and 12 weeks (62% vs 37%, $p < 0.05$) with greater patient satisfaction (12 weeks: 91% vs 63%, $p < 0.005$). Diary card analysis showed that patients taking balsalazide experienced more days with complete symptom relief (using no steroid) during the first 4 weeks of treatment (24% vs 14%, $p < 0.01$) and took less time to achieve their first completely symptom free day (median: 10 vs 25 days, $p < 0.005$) compared to those taking mesalazine. One patient in each group discontinued due to an unacceptable adverse event (AE) however, all 4 serious AEs (complications of UC) occurred in the mesalazine group and fewer patients in the balsalazide group reported AEs (48% vs 71%, $p < 0.05$). Analysis of prognostic factors identified low ulcerative colitis grade at entry ($p < 0.05$) and treatment with balsalazide ($p < 0.01$) as increasing the probability of complete remission after 12 weeks.In conclusion, balsalazide 2.25 g t.i.d. was more effective and better tolerated than mesalazine 0.8 g t.i.d. in achieving remission of acute ulcerative colitis. Intestinal disorders: IBD, therapy }" "Balsalazide is More Effective and Better Tolerated than Mesalazine in Acute Ulcerative Colitis (UC)"

OT54 1077**Ridogrel for the Treatment of Mild to Moderate Ulcerative Colitis. A Placebo-Controlled Trial**

*J. Wright, G. Schenowitz, G. Adler, H. Schneider

Groote Schuur Hospital, Cape Town, South Africa

Private practice, Nice, France

Med. Klinik und Powklinik, Ulm, Germany

Millpark Hospital, Aukland Park, South AfricaAn increased colonic production of eicosanoids has been documented in patients (pts) with Inflammatory Bowel Disease (IBD). Thromboxane (TXA_2) may play an active role in the development of chronic inflammatory lesions in the bowel. Ridogrel (RID), a combined TXA_2 synthetase inhibitor (low dose) and TXA_2/PGEND receptor blocker (high dose), might therefore be useful in IBD.*Methods:* 79 pts with mild to moderately active ulcerative colitis (UC) were randomized to 8-week double-blind treatment with either placebo (PLA) or one of three dose schedules of oral RID: 5 mg od, 25 mg bid, or 150 mg bid. Endoscopic assessments were performed every 4 weeks, with an additional assessment at week 2 in pts who had not improved clinically at week 2. Pts were subsequently withdrawn from the trial if there was no endoscopic improvement.*Results:* At endpoint, 3/20 PLA-treated pts, 9/21 RID 5 mg od treated pts, 6/17 RID 25 mg bid treated pts and 11/21 RID 150 mg bid treated pts had improvement by {\'b3} 1 grade on endoscopy. Significant differences in efficacy between RID and PLA were detected. Thirteen pts from the PLA group, 9 from the RID 5 mg od, 7 from the RID 25 mg bid and 6 from the RID 150 mg bid group had discontinued the therapy at week 2 due to insufficient response. More pts in the RID 5 mg od (n = 7) and RID 150 mg bid (n = 8) groups reached a clinically quiescent disease state at endpoint than the pts in the RID 25 mg bid (n = 4) or PLA (n = 3) groups. At endpoint the investigator rated the results of treatment as good or excellent in 3/20 of PLA-treated pts, 8/21 of RID 5 mg-treated pts, 6/17 of RID 25 mg-treated pts and 10/21 of RID 150 mg-treated pts.Adverse events, whether or not related to treatment, were reported by 9 to 11 pts in the three RID groups and in 6 pts in the PLA group.*Conclusion:* All three RID doses were well tolerated and were equally effective in relieving the inflammation associated with mild to moderate UC. Lower doses of RID, known to only inhibit TXA_2 synthetase activity without blocking the TXA_2/PGEND receptor, need to be tested for the treatment of acute exacerbations of UC. Intestinal disorders: IBD, therapy }"

OT55 1078**Three-Days Metronidazole (MET) and Clarithromycin (CLA) in Triple Therapy with Omeprazole (OME) for Cure of H. Pylori (HP) Infection**

*U. Peitz, A. Nusch, B. Tillenburg, M. Stolte[1], G. B\'f6rsch, J. Labenz

Elisabeth Hospital, Essen, Germany

[1] Institute of Pathology, Bayreuth, Germany*Purpose:* Triple therapy with OME, MET and CLA (OMC) has become a standard in our clinic for cure of HP infection, as OMC poses currently an optimum in terms of efficacy, savety and cost effectiveness. Shorter than one-week schedules of modified classic triple have proved to be effective, so we intend to test the hypothesis that the treatment with MET and CLA can be shortened to three days in OMC without loss of efficacy.*Methods:* In a prospective, randomised, and controlled ongoing study, patients with indication to HP cure are assigned to one of the following two groups:Group 3D-OMC: OME 20 mg bid on days 1–7, MET 400 mg tid on days 2–4, CLA 250 mg tid on days 2–4.Group 7D-OMC: OME 20 mg bid, MET 400 mg bid, and CLA 250 mg bid, all on days 1–7.The HP status is determined before and at least 4 weeks after OMC by urease test, histology, culture, and UBT; antimicrobial HP resistance is assessed by E-Test (AB-Biodisk, Solna, Sweden).*Results:* At present, 60 patients (mean age 51 years) were randomised into the study. 31 patients have meanwhile completed the protocol. 16 of 17 patients in group 3D-OMC had been cured of HP infection versus 13 of 14 patients in group 7D-OMC. Pretherapeutic culture and testing of resistance was successfull in 26 patients. The one patient with persisting HP infection in group 3D-OMC harboured a 'MET resistant strain.*Conclusions:* These preliminary data indicate no difference of HP cure rate between a 7-days OMC scheme and a 3-days OMC scheme with enhanced daily antimicrobial dosis. Oesophageal gastric duodenal disorders: Helicobacter PyloriOesophageal gastric duodenal disorders: GD disorders, acid peptic }" "Three-Days Metronidazole (MET) and Clarithromycin (CLA) in Triple Therapy with Omeprazole (OME) for Cure of H. Pylori (HP) Infection"

OT55 1079**Do Physicians from Different Countries Treat *H. Pylori* Positive Ulcer Disease Differently; A Comparison between America and Germany**

*T. Breuer[1], T. Sudhop[2], H.M. Malaty[1], K. Goodman[3], D.Y. Graham[1], P. Malfertheiner[4]

[1] VAMC, Baylor College of Medicine, Houston, TX USA

[3] Univ. of Texas, SPH, Houston, TX USA

[2] Univ. of Bonn, Germany

[4] Univ. of Magdeburg, Germany*Purpose:* The aim of this study was to determine the first line treatment used by two groups of physicians (gastroenterologists (GE) and family practitioners (FP)) in *H. pylori*-positive ulcer disease in two different countries. *Methods:* Cross-sectional study, mail questionnaire. *Results* (*to date*): 1125 US and 538 German physicians responded: Regimen* GE (USA) GE (FRG[\'86]) FP (USA) FP (FRG[\'86]) (n = 645) (n = 301) (n = 480) (n = 237)PPI based triple 36% 42% 14% 22%Standard triple 16% <1% 25% <1%PPI based quadruple 16% – 11% -PPI/CLA 11% 1% 8% 3%H_2 based quadruple 9% – 10% -PPI/AMO 4% 51% 5% 53%other (insufficient) 8% 6% 26% 22%*PPI (Proton pump inhibitor), AMO (Amoxicillin), H_2 (H_2-inhibitors), CLA (Clarithromycin), MET (Metronidazole) BIS (Bismuth); PPI based triple (PPI plus combination of two antibiotics (AMO, CLA, MET); Standard triple (BIS, MET, TET/AMO), PPI based quadruple (PPI plus standard triple); H_2 based quadruple (H_2 plus standard triple). [\'86]FRG (Federal Republic of Germany)*Conclusion:* The frequently used standard triple therapy based regimens in the US are almost non existent in Germany, whereas the most frequently used regimen in Germany (PPI/AMO) plays only a minor role in the US. We conclude that treatment of *H. pylori* positive peptic ulcer disease differs substantially in the two countries. This can be explained due to different recommendations of the researchers in the field of *H. pylori* treatment in the two countries. Nearly 25% of the FP in each country treat *H. pylori* positive ulcer disease with ineffective regimens. This emphasizes that knowledge acquisition of newly recommended therapies for *H. pylori* infection is not optimal. Researchers in the field have to make sure that dissemination of currently recommended therapies is a continuous process. Oesophageal gastric duodenal disorders: Helicobacter PyloriClinical practice: Management strategy }" "Do Physicians from Different Countries Treat H. OT55 1080**Eradication of Hp Infection after Triple Terapies Failure: A Quadruple Schedule Approach**

*S. Kusstatscher, M. Bortolon, A. Buda, N. Dal Bo`, S. Salandin, G. Laino, G. Battaglia[1], A. Pilotto[2], V. Savarino[3], F. Di Mario

Dept of Gastroenterology Padua, Italy

[1] Dept of Gastroenterology, Venice, Italy

[2] Dept of Gastroenterology, Vicenza, Italy

[3] Dept of Gastroenterology, Genoa, ItalyOverall triple therapies eradication rate against Helicobacter pylori infection is commonly high (about 80 to 90%). Still unsolved problem remains what to do with symptomatic patients after an unsuccessful triple therapy. Indeed microbiologic colture to test antibiotic resistance is not widely spread. The problem is even more relevant in patient with history of peptic ulcer which needs to be cured. The aim of this study was to establish an effective quadruple therapy which can be widely used without testing antibiotic resistance. *Material and Methods:* we enrolled 15 consecutive outpatients (mean age 51; range 33–69, M/F 8/7) referred to our endoscopy unit for Hp related gastritis resistant to triple therapies. Hp status was evaluated by three different test (histology, CLO test and serology). Study design: endoscopy with multiple biopsies were performed at immission time and two months after the end of the treatment (Omeprazole 20 mg b.i.d., Metronidazole 250 mg q.i.d., Amoxicillin 250 mg q.i.d. and Bismuth citrate 125 mg q.i.d. for 14 days). Hp eradication was considered successful when both histology and CLO test resulted negative. *Results:* overall results were calculated by intention to treat (ITT) and per protocol analysis (PP). Over 15 patients only 2 subjects remained Hp positive after the treatment (PP 85.7%; ITT 80%). Only one patient had side effects (diarrhea). *Conclusions:* 1) A 14 days quadruple therapy cured 85% of the Hp triple therapies resistant infected patients. 2) Side effects were less than 2% and compliance was very high (93%). }" "Eradication of Hp Infection after Triple Terapies Failure: A Quadruple Schedule Approach"

OT57 1085**Repeat Resection of Liver Metastasis from Colorectal Cancer**

*R. Adam, H. Bismuth, F. Navarro, D. Castaing, A. Abascal

Hepato-Biliary Surgery and Liver Transplant Research Center, Paul Brousse Hospital, Villejuif, FranceIt is estimated that about 60% of patients (pts) submitted to hepatic resection of metastasis from colorectal cancer will present a recurrence. This recurrence is limited to the liver in about 30% of cases. Repeat hepatectomy has been used increasingly in relation to the low mortality and morbidity of hepatic resection. However, the risk of these repeat hepatectomies, their long-term results as well as the rationale for patient selection need to be clarified. For this purpose, we have analyzed over a period of 12 years (1983–1995) the results of 57 rehepatectomies performed in 44 pts with hepatic metastasis from colorectal cancer (2 hepatectomies:44, 3 hepatectomies: 10, 4 hepatectomies: 3). These repeat hepatectomies represented 19.5% of the 282 liver resections performed during the same period for the same indication. The time interval between first and second hepatectomies was over 1 year in 23 pts (52%). Extra hepatic disease was associated to hepatic recurrence in 11 pts (25%). Major hepatectomy (> 3 segments) was performed in 50% of first resections., 36% of second resections and only 15% of third and forth resections. There was no post-operative mortality within two months. Per operative bleeding was not increased as compared to that of first resections. Post-operative morbidity was 11% (6/55) comparable to that of first resections. Overall survival after repeat resection was 44% at 5 years with no difference related to Dukes classification of initial colorectal tumor, to synchronous versus metachronous metastasis or to local versus distant hepatic recurrence.*Conclusion:* Repat resection of liver metastasis from colorectal cancer allows a long-term survival at least equal to that of first resection with no mortality and comparable morbidity. This policy is warranted when repeat hepatectomy is potentially curative. }" "Repeat Resection of Liver Metastasis from Colorectal Cancer"

OT57 1086**Liver Regeneration after Partial Hepatectomy is Depressed by Kupffer Cell Depletion**

*C. Meijer[1], H.J. Schouten[1], A.H.W. Van Maurik[1], A.P.J. Houdijk[1], N. Van Rooijen[2], S. Meijer[1], C.D. Dijkstra[2], P.A.M. Van Leeuwen[1]

[1] Department of Surgery, Free University Hospital, Amsterdam, The Netherlands

[2] Department of Cellbiology and Immunology, Free University Hospital, Amsterdam, The Netherlands*Purpose.* After partial hepatectomy, activation of Kupffer cells (KC) by circulating gut-derived endotoxin results in a rapid release of inflammatory mediators. Some of these mediators are thought to play a role in the induction and regulation of liver regeneration. We therefore hypothesized that KC are important for liver regeneration and investigated the effect of KC-depletion on liver regeneration after partial hepatectomy (phx).*Methods.* All animals (36 Wag/Rij rats, male, 200–220 gram) underwent a twothird liver resection. The rats were randomized in 2 groups: 48 hours prior to phx, KC-depletion was performed in 18 rats by intravenous (i.v.) administration of 1 ml liposome-encapsulated dichloromethylene diphosphonate (CL_2MDP). The 18 control rats received 1 ml normal saline (NaCl) i.v. Directly after phx 1/4 dosage of the i.v. treatments was readministered. One week prior to phx, splenectomy was performed in all rats to eliminate the effect of liposome-encapsulated CL_2MDP on macrophage populations in the spleen. Every 24 hours after phx 50 mg/kg bromodeoxyuridine (BrdU) was administered by 1 ml intraperitoneal injection. Animals were sacrificed at 24, 48 and 96 hours (n = 6 per group) after phx. To confirm KC-depletion, cryostat liver sections were stained with the monoclonal antibody ED2, a marker for resident tissue macrophages. Liver cell proliferation was determined by the BrdU labeling index in liver sections. Weight of the remnant liver was expressed in percent of calculated initial liver weight.*Results.* KC depletion was confirmed in sections of the resected liver. Proliferation of parenchymal liver cells 48 hours after phx was significantly depressed in KC-depleted rats when compared with control rats ($p < 0.05$). Also, weight increase of the remnant liver, determined 96 hours after phx, was significantly delayed ($p < 0.05$) in KC-depleted rats.*Conclusion.* KC are important for liver regeneration after partial hepatectomy. Immunology and microbiology: Host defense mechanismsLiver and bile ducts, 1: Cell biology, collagen, fibrosisOncology, specific: Liver, biliary }" "Liver Regeneration after Partial Hepatectomy is Depressed by Kupffer Cell Depletion"

OT57 1087**Unresectable Hepatic Metastases from Colorectal Cancer: Results of a Combined Approach by Chemotherapy and Subsequent ResectionR. Adam, H. Bismuth, Ch. Farabos, F. L\'e9vi, F. Waechter**

Hepatobiliary Surgery and Liver Transplant Center, Paul Brousse Hospital, Villejuif, FranceResection is the sole curative treatment of hepatic metastases from colorectal cancer. However, it may be achieved in only 10% of patients (pts) since most pts have at the first irresectable lesions associated with a poor prognosis. Over the past 6 years, we have managed these pts with a new protocol of chemotherapy with the aim to perform subsequent curative liver resection. From April 1988 to March 1994, 53 out of 337 pts (16%) with liver metastases initially considered as non resectable were subsequently submitted to hepatic resection with a curative intent. All pts have been treated by intravenous chronomodulated chemotherapy combining 5 Fluorouracil, Folinic acid and Oxaliplatinum, a non nephrotoxic platinum complex. To optimize dose intensities and tolerance, drug delivery was sinusoidally modulated along the 24 hour-scale with peak flow rates at 04.00 hours for 5-FU and Fol and at 16.00 hours for Oxa, using an ambulatory programmable-in-time pump. Initial non resectability was assessed by the same surgical team and was related either to technical impediment due to large (n = 8), multinodular (n = 24) and central ill-located tumours (n = 8) or to the presence of extrahepatic disease (n = 13 – Peritoneum (6), Epiploon (3), Lungs (4)). Pts received 3 to 29 courses of chemotherapy (mean = 10) for 2 to 29 months (mean = 8 months) before surgery.*Results:* An objective reduction in tumour size was observed following chemotherapy in all pts subsequently submitted to liver resection. A significant reduction of tumor markers was also demonstrated. A major hepatectomy (> 3 segments) was performed in 37 pts and a minor resection in 16. There was no operative mortality within 2 months. Post operative complications included 2 infected collections that needed non operative drainage, 1 transient biliary fistula and 1 reoperation for bleeding. Chronomodulated chemotherapy was routinely continued post operatively in all pts for 6 courses at less. Associated procedures included repeat hepatectomy (15), pulmonary resection (11), hepatic cryotherapy (8), splenectomy (1) nephrectomy (1), resection of the diaphragm (2), repeat resection of colon cancer recurrence (2). Twenty eight pts are presently alive (of whom 16 without disease) with a mean follow of 2.5 years (range 1.3–6.4). Median survival is 3.2 years with a patient survival rate of 61% at 3 years.*Conclusion:* Resection may be achieved in some unresectable pts with the help of an efficient chemotherapy. The benefit in survival seems comparable to that obtained with liver resection for initially resectable liver metastases. This therapeutic strategy involves a multimodality approach including repeat hepatectomy and extrahepatic surgery. }" "Unresectable Hepatic Metastases from Colorectal Cancer: Results of a Combined Approach by Chemotherapy and Subsequent Resection"

OT63 1088**Increased Human Gastric Endothelial Cell COX-2 Expression during Angiogenesis**

*M.A. Hull, J.L. Brough, C.J. Hawkey

Division of Gastroenterology, University Hospital, Nottingham, NG7 2UH, UK*Introduction:* Angiogenesis plays an important role in gastric ulcer healing. Prostaglandins (PGs) promote angiogenesis *in vivo* and non-steroidal anti-inflammatory drugs (NSAIDs) reduce vascularity of gastric ulcer granulation tissue and delay healing. However, it is not known whether gastric ulcer angiogenesis is associated with changes in endothelial cell cyclooxygenase (COX) expression. Therefore we investigated COX expression during *in vitro* angiogenesis using human gastric endothelial (HuGE) cells which were obtained using an immunomagnetic separation technique developed in our laboratory.*Methods:* HuGE cells were isolated from normal gastric mucosa using anti-PECAM-1 antibody-coated Dynabeads. HuGE cells were cultured routinely on 1% gelatin in Medium 199 + 30% FCS + 90 \'b5g/ml heparin + 40 \'b5g/ml ECGS until plating onto basement membrane matrix (Matrigel) or addition of 1 \'b5M phorbol 12, 13 dibutyrate (PdBu). COX-1 and COX-2 expression were investigated by RT-PCR, western blotting and indirect immunofluorescence studies. PGE2 levels in cell-conditioned medium were measured by ELISA.*Results:* PdBu induced formation of cell extensions and ""ring"" structures in HuGE cells at 4 hours which was associated with increased COX-2 expression and PGE2 production. COX-2 was localized predominantly in the nuclear envelope. At 24 hours COX-2 expression had declined. There was no change in COX-1 expression after addition of PdBu. Formation of ""tube-like"" structures by HuGE cells on Matrigel was associated with an increase in COX-2 (and COX-1) mRNA expression and PGE2 production which was maintained at 24 hours.*Conclusion:* In this model of angiogenesis, HuGE cell differentiation (formation of ""tube-like"" structures) rather than proliferation was associated with induction of COX-2 and COX-1 expression. This process may be impaired by NSAIDs during gastric ulcer healing. These findings suggest that specific COX-2 inhibitors may also impair angiogenesis and delay gastric ulcer healing. OT63 1089**Gene Expression of Metalloproteinases (MMP-1, -2, and -3) and Their Tissue Inhibitors (TIMP-1 and -2) during Experimental Gastric Ulcer Healing**

*A. Calabro', C. Grappone, G. Pellegrini, S. Evangelista, M. Tramontana[1], D. Schuppan[2], H. Herbst[3], C. Surrenti, S. Milani

GI Unit, Dept. of Clin. Pathophysiology, Univ. of Florence, Italy

[1] Malesci Pharmaceuticals, Florence, Italy

[3] Institute of Pathology, Free University of Berlin, Germany

[2] Dept. of Gastroenterology, Free University of Berlin, GermanyIncreasing evidence indicates that extracellular matrix (ECM) degradation plays a crucial role not only in tumor invasion but also in the process of wound repair. We analyzed the spatial and temporal pattern of expression of three major members of the metalloproteinase (MMP) family, namely MMP-1, MMP-2 and MMP-3, and of their specific tissue inhibitors TIMP-1 and -2, in an experimental model of gastric ulcer healing. *Methods:* chronic gastric ulcers were induced in rats by acetic acid injection and groups of 5 rats each were sacrificed before and at 1, 3, 7, 14, 28 and 56 days after the ulcerogen. Gene expression of MMPs and TIMPs was examined by in situ hybridization with ^{35}S-labeled RNA probes and the autoradiographic signal was quantified by an image analysis system. *Results:* in the normal rat stomach, there was no evidence of MMP-1 and TIMP-1 expression, while low amounts of MMP-2, MMP-3 and TIMP-2 RNA transcripts were present in some mesenchymal cells of the lamina propria, submucosa and muscularis propria. MMP gene expression was dramatically up-regulated after ulcer induction, starting at 24 h and peacking at 3–7 days (e.g. when lesions undergo transition into true ""chronic"" ulcers). With the completion of ulcer healing, MMP mRNA expression progressively returned toward normal; however, higher than normal levels of MMP-1 and MMP-3 mRNA persisted at sites of excessive ECM deposition and prominent histologic abnormalities. The spatiotemporal pattern of distribution of TIMP-1 and -2 essentially followed that of MMPs; in contrast with MMP expression, however, low amounts of TIMP-1 and -2 mRNA were also noted on some epithelial cells of gastric glands. *Conclusions:* the up-regulation of MMPs, by degrading basement membranes around migrating proliferating cells and removing the excess of matrix transitorily accumulated in the granulation tissue, may play a crucial role in gastric ulcer healing promoting the re-epithelialization of the ulcer crater, angiogenesis, and the final remodelling of regenerated tissue. OT63 1090**Acute and Chronic Gastrointestinal Effects of Selective Cyclooxygenase-2 Inhibition in Rats**

*A. Schmassmann[1], B.M. Peskar[2], T. Stroff[2], Ch. Stettler[1], P. Netzer[1], B. Flogerzi[1], F. Halter[1]

[1] Gastrointestinal Unit, Univ. Hospital, Inselspital, Bern, Switzerland

[2] Dep. of Exp. Clinical Medicine, Ruhr-University, Bochum, Germany*Background:* Non-selective cyclooxygenase (COX) inhibitors induce gastrointestinal ulcers and delay gastric ulcer healing. It has been reported that the selective COX-2 inhibitor L-745,337 causes less gastrointestinal side-effects, but this drug has not been tested in a reliable chronic ulcer model.*Methods:* Dose-response for indomethacin, diclofenac, and L-745,337 was assessed. Inflammatory PG-E2 was measured 5 hrs after implantation of carrageenin-soaked sponges. Rats (8 per dose and group) with gastric cryoulcers were treated twice daily for 15 days and delay in ulcer healing (incl. histologic changes) and intestinal perforation rate were assessed.*Results:* 5 mg/kg L-745,337 reduced ($P < 0.05$) PG-E2 concentration in inflammatory exudates (COX-2) by 88%. Indomethacin but not L-745,337 (20 mg/kg) caused severe gastric ulcerations 5 hrs after dosing. In chronic models, however, L-745,337 caused dose-dependently profound delay of gastric ulcer healing, decrease of angiogenesis/maturation of granulation tissue, and intestinal perforation comparable to traditional NSAIDs such as indomethacin and diclofenac. Indomethacin Diclofenac L-745,337Daily dose/kg (2 weeks) 2 times; 0.5 mg 2 times; 2.5 mg 2 times; 5 mgGastric 6-keto-PG-F1{ a} { -}42%* { -}88%* { -}27% n.s.Ulcer size on day 15 + 81%* +111%* + 107%*Angiogenesis in ulcer bed { -}55%* { -}59%* { -}55%*Thickness of ulcer bed +78%* +94%* +105%*Intestinal perforation rate[#] 5% 45% 36%*data compared with placebo, $P < 0.05$; [#]absolute data.*Conclusion:* L-745,337 is not ulcerogenic in acute studies but delays healing of gastric ulcers and causes intestinal perforation in chronic studies comparable to traditional NSAIDs. OT63 1091**Expression of Epidermal Growth Factor (EGF) and Transforming Growth Factor Alpha (TGF-{ a}) during Ulcer Healing-Time Sequence Study**

*P. Konturek, T. Brzozowski, H. Ernst, D. Drozdowicz, A. Ihlm, S.J. Konturek, E.G. Hahn

Dept. Med I, Univ Erlangen-Nuremberg, Germany

Inst. Physiol. Jagiell. Univ. Med. Sch. Krakow, Poland*Background:* Growth factors such as EGF and TGF-{ a} have been shown to share common receptor (EGFr) and to accelerate ulcer healing due to stimulation of cell proliferation but expression of EGF and TGF{ a} during ulcer healing has been little studied. In this study, the rate of cell proliferation, the gastric secretion and the gene expression of mRNA EGF and TGF{ a} were determined during ulcer healing. *Material and Methods:* Chronic gastric ulcers were induced in 150 Wistar rats by serosal application of 100% acetic acid (ulcer area 20 mm^2). Separate groups of rats with acetic acid ulcers were equipped with gastric fistula for the assessment of gastric secretion during ulcer healing. The animals were sacrificed at 0, 2, 4, 6 and 8 days after ulcer induction and the area of ulcer was determined by planimetry. The mucosal sections with gastric ulcer was immunostained for proliferating cell nuclear antigen (PCNA) – an index of cell proliferation, and for EGF, TGF{ a} and EGFr using specific antibodies. Expression of mRNA EGF and mRNA TGF-{ a} was determined in the ulcer margin by reverse-transcriptase polymerase chain reaction (RT-PCR). Five micrograms of total RNA extracted from gastric mucosa with ulcer was used to synthesise a first strand cDNA by enzyme MMLV-RT and then amplified by the PCR method with specific primers. RT-PCR products were stained with ethidium bromide and separated on 1.5% agarose gel. *Results:* At 2, 4, 6 and 8 days after ulcer induction, the area of gastric ulcers was gradually reduced from initial size (day 0) by 10%, 33%, 58% and 87%, respectively, and this was accompanied by rise in PCNA with the maximum at day 4. Following induction of gastric ulcers a marked decrease in gastric acid and pepsin secretion was observed at day 2, by 55% and 43%, respectively, but then secretion tended to return at day 8 to normal value. Immunohistochemical expression of EGF, TGF{ a}, and EGFr was negligible at the day 0 but increased significantly during the healing, reaching the peak at day 4. Expression of RT-PCR mRNA TGF{ a} was detected at 2, 4, 6 and 8 day, whereas RT-PCR mRNA EGF was detected at day 2, 4 and 6 after ulcer induction with the most intense signals observed at day 2. *Conclusions:* 1) Enhancement in cell proliferation and suppression of gastric secretion during ulcer healing is mediated by expression of EGF and TGF{ a}; 2) Expression of EGF and TGF{ a} mRNA precedes the overexpression of these growth factors during ulcer healing; 3) Overexpression of growth factors during healing coincides with the inhibition of gastric secretion probably mediated by these growth factors. Hormones and receptors: Growth factors }" "Expression of Epidermal Growth Factor (EGF) and Transforming Growth Factor Alpha (TGF-alpha) during Ulcer Healing-Time Sequence Study"

OT65 1092**Gliadin Specific, HLA-DQ2 Restricted T Cells are Frequently Found in the Small Intestinal Mucosa of Coeliac Disease Patients\'d8. Molberg, K. Kett, H. Scott, L.M. Sollid, E. Thorsby,**

*K.E.A. Lundin

Institute of Transplantation Immunology, Medical Department A, and Institute of Pathology, The National Hospital and University of Oslo, Oslo, NorwayCoeliac disease (CD) is an immune-mediated disorder of the small intestine with a very strong HLA association to a particular HLA-DQ2 variant. More than 90% of the patients carry this variant. We previously showed that T cells from the small intestinal mucosa of patients on a gluten-free diet could respond to gluten when presented by the disease associated HLA-DQ2 molecules (Lundin et al. J Exp Med 178: 187–196, 1993). The purpose of the present study was to examine if this is a general phenomenon in CD.Lamina propria-derived T cells from 22 consecutive patients, all being HLA-DQ2+, were studied. 19 patients had a gluten-free diet, 3 patients had a normal diet. Small intestinal biopsies were challenged in vitro with wheat flour gliadin proteins, activated T cells were isolated by an immunomagnetic method and cultured without further gliadin stimulation.We succeeded in establishing gliadin-specific T cell lines from all the 22 patients, but not from disease controls. Inhibition studies with anti-HLA monoclonal antibodies demonstrated predominant HLA-DQ2 restriction in polyclonal T cell lines from 11 of the patients. Gliadin-specific T cell clones were established from several of the patients. Nine T cell clones could be studied in detail, all of them showed HLA-DQ2 restriction.Our results indicate that presence of gliadin-specific T cells is a general phenomenon in the small intestine of coeliac disease patients. Intestinal disorders, absorption: Gluten enteropathyImmunology and microbiology: Inflammation }" "Gliadin Specific, HLA-DQ2 Restricted T Cells are Frequently Found in the Small Intestinal Mucosa of Coeliac Disease Patients"

OT65 1094**Anti-Endomysium Antibodies on Human Umbilical Cord: An Improved Method for Diagnosis and Follow-Up of Coeliac Disease****S.B. Grosso, M. Bruno, S. Grosso, G. Caula,**

*C. Sategna-Guidetti

Cattedra di Gastroenterologia, Universita' di Torino, ItalyAlthough anti-endomysium antibodies (EmA) are, to date, the most reliable serological marker of coeliac disease (CD), both the high cost of monkey oesophagus (MO) and the ethical problems connected with killing of endangered species, limit their routine application. *Aim:* In this study we investigated the use of human umbilical cord (HUC) as an alternative substrate to MO in EmA determination. *Method:* IgA EmA were appraised, by indirect IF on MO and HUC, on sera from 104 untreated biopsy proven CD patients, 40 healthy volunteers and 48 disease controls (inflammatory bowel disease and irritable bowel syndrome). One year after gluten withdrawal 44 out of 104 CD patients underwent a second intestinal biopsy and EmA appraisal. *Results:* A) IgA EmA sensitivity and specificity were 95% and 100% respectively on both substrates, with a diagnostic efficiency of 97.4%. B) One year after a gluten free diet (GFD) 38/44 (86%) patients still had histological alterations. EmA positivity on MO was found in only 10/38 (26%), while on HUC it persisted in 29/38 (76%). The agreement between histology and EmA was respectively 40% on MO and 79% on HUC.*Conclusion:* A) HUC can replace MO as substrate for IgA EmA detection with comparable diagnostic efficiency, lower costs and sparing of monkeys. B) HUC seems to be a more suitable substrate than MO in EmA detection during a GFD because of its higher agreement with histological pattern. Intestinal disorders, absorption: Malabsorption syndromesIntestinal disorders, absorption: Gluten enteropathy }" "Anti-Endomysium Antibodies on Human Umbilical Cord: An Improved Method for Diagnosis and Follow-Up of Coeliac Disease"

OT65 1095**TNF{ a} and LPS Increases Human Peripheral Blood Lymphocyte Adhesion to HIMECs Which Is Partially Blocked with Monoclonal Antibody to { a}$_4$**

*R. Thompson, J. Wilson, J.R. Rhodes, S.L. Bloom

Dept of Medicine, University of Liverpool, Liverpool, UK*Purpose* Bacterial Products may play a fundamental role in the pathogenesis of Inflammatory Bowel Disease (IBD). A weakened mucoid barrier may allow the influx of bacterial products into the lamina propria which may have a direct affect on endothelium and result in increased lymphocyte recruitment. Using Human Intestinal Microvascular Endothelial Cells (HIMECs), we measured the effect of TNF{ a}, butyrate, lipopolysaccaride (LPS) and f-Met-Leu-Phe (fMLP) on the adhesion of ^{51}Chromium labelled human lymphocytes.*Methods* Normal and inflammed colon (n = 3) obtained from patients undergoing resection for colonic cancer or IBD were used to isolate HIMECs, as described (Gut 38 (4): A635). HIMECs were plated onto 24 well plates, grown to confluency and incubated with butyrate, LPS, fMLP or TNF { a}. Peripheral blood lymphocytes (PBLs), from healthy volunteers, were isolated using \lquoteLymphoprep\rquote and labelled with ^{51}Cr. The PBLs were incubated with monoclonal antibody to { a}$_4$ (Serotec), a lymphocyte integrin which is expressed on the majority of PBLs, and incubated with the HIMECs for one hour. Gamma counts in the supernatant, the standardised washs and the monolayers, removed by detergent, were used to calculate percentage lymphocyte adhesion.*Results* The adhesion of PBLs to nonstimulated HIMEC monolayers was 27% (SD = 3) ({\'b4}3 wells) Preincubation with TNF{ a} (10 ngml$^{\{ -}$1}) and LPS (10 \'b5gml$^{\{ -}$1}) increased this to 74% (SD = 4 p < 0.01 Mann Whitney) and 52% (SD = 9 p < 0.05) though various concentrations of butyrate and fMLP had no effect. Preincubation with Anti { a}4 reduced adhesion by 25% (p < 0.05) on TNF{ a} and 15% (p < 0.05) on LPS stimulated cells.*Conclusions* TNF{ a} and LPS have a direct effect on HIMECs which results in increased PBL adhesion. Preincubation with antibody to { a}$_4$ reduced adhesion significantly but not substantially suggesting that other molecules or mechanisms may facilitate adhesion of PBLs to TNF{ a} and LPS stimulated endothelium. Intestinal disorders: IBD, basicImmunology and microbiology: Inflammation }" "TNFalpha and LPS Increases Human Peripheral Blood Lymphocyte Adhesion to HIMECs Which Is Partially Blocked with Monoclonal Antibody to alpha4"

"P P 46 1102"P 46 1102**Gastric Functions and Dyspeptic Symptoms in Reflux Esophagitis**

*B. Salvioli, V. Stanghellini, C. Tosetti, S. Mattioli, F. D'Ovidio, M. Pastina, B. Misitano, R. Cogliandro, N. Monetti, R. Corinaldesi

Depts. of Internal Medicine & Gastroent., Surgery, Nuclear Medicine, University of Bologna, ItalyThe relationship between gastric functions and dyspeptic symptoms in reflux esophagitis (RE) is poorly investigated. We evaluated scintigraphic gastric emptying of solids (GE; 638 kcal, ^{99m}Tc-chicken liver) in 68 (51 M, 51 – 13 yrs; m – SD) RE pts. Results were expressed as half-times (T\'bd min) and GE rates (k; %/h). Gastric acid secretion (BAO, PAO; mEq/h) was also evaluated in 50/68 RE pts (40 M, 49 – 14 yrs). Fifty healthy volunteers served as controls (HC; T\'bd = 101 – 20 min, k = 40 – 11%/h, BAO = 3 – 2 mEq/h, PAO = 21 – 7 mEq/h). RE pts presented delayed GE (T\'bd = 153 – 86 min, P < 0.01; k = 32 – 13%/h, P < 0.01) and increased acid secretion (BAO = 5 – 5 mEq/h; PAO = 32 – 15 mEq/h, p < 0.01) compared to HC (Mann Whitney U test). Delayed GE and increased acid secretion were observed respectively in 32% and 40% of pts. Increased acid secretion was present in 19% of pts with delayed GE and in 50% of pts with normal GE, while delayed GE was present in 15% of pts with increased secretion and in 43% of pts with normal secretion ($P < 0.05$, X^2). Epigastric pain/burning, postprandial fullness, nausea, vomiting were each graded 0 to 3 according to their influence on usual activities. Dyspepsia (total score {\'b3} 3 with at least one symptom {\'b3} 2) was observed in 64% of pts: 26% of them presented prevalent pain (pain {\'b3} 2 with any other symptom {\'a3} 1), 44% prevalent discomfort (postprandial fullness and/or nausea and/or vomiting {\'b3} 2, with pain {\'a3} 1) and 30% resulted unclassifiable. Gastric emptying (n = 68) Acid secretion (n = 50) delayed normal increased normalDyspepsia (total) 74% 58% 60% 60%Prev. pain 12% 35% 42% 17%Prev. discomfort 71%* 27% 33% 61%Unclassifiable 17% 38% 25% 22%*P < 0.005 vs normal gastric emptying; X^2.*Conclusions:* RE pts as a whole present delayed GE and increased acid secretion compared to HC, but gastric motor and secretory abnormalities are not usually associated. Dyspeptic symptoms are frequent in these patients. RE patients with delayed GE present more often prevalent discomfort compared to patients with normal GE. "P P 46 1103"P 46 1103**Recordings of Duodeno-Gastro-Oesophageal Reflux in Supine (Sleeping) *GORD* Patients with Fiberoptic Bilirubin Monitoring Are at Least as Good as 24-Hours RecordingH. Geldof**

IJsselland Hospital, Capelle a.d. IJssel, The Netherlands*Aim.* Oesophageal fiberoptic bilirubin monitoring quantifies the duodeno-gastro-oesophageal reflux (DGOR), which seems to be relevant for the pathogenesis of GORD and its complications such as Barrett oesophagus and oesophageal carcinoma. To improve this method, the value of recordings in supine (sleeping) patients (average 8 hours) is compared with that of 24-hours recordings.*Method.* Measurements were made with a fiberoptic sensor and portable dataprocessing unit (Bilitec 2000, Synectics medical Inc.). The fiberoptic electrodes were placed 5 cm above the lower oesophageal sphincter. The absorbance threshold was set to 0.14, corresponding to 10 \'b5M of bilirubin. Studies were performed in 11 patients with uncomplicated GORD, 10 patients with GORD complicated by intestinal metaplasia below the squamo-columnar mucosal junction, and in 13 patients with a Barrett oesophagus.*Results.* The table below shows the mean percentages of the recording time of oesophageal exposure to bilirubin. Total recording time Supine patientsUncomplicated GORD 11% 8%Intestinal metaplasia 55%*** 71%***Barrett oesophagus 60%*** 69%***Comparisons between uncomplicated GORD and GORD with metaplasia or Barrett oesophagus; *** $p < 0.001$*Conclusions.* Fiberoptic measurements of bilirubin concentrations shows large differences in the oesophageal bilirubin exposure between uncomplicated GORD, and GORD with metaplasia or Barrett oesophagus. Shorter recordings (average 8 hours) from patients in the supine (sleeping) position yield probably better information than 24-hours recordings. Moreover, the 8-hours supine recordings are much more convenient for the patients. "P P 46 1107"P 46 1107**Effect of White Wine on Gastroesophageal Reflux in Patients with Reflux Disease**

*C. Pehl, A. Pfeiffer, B. Wendl, H. Kaess

Dept. of Gastroenterology, Hospital Bogenhausen, Munich, GermanyWhite wine provokes heartburn in patients with gastroesophageal reflux disease (Gastroenterology 1995; 108: 125–31). In healthy volunteers, we recently demonstrated that white wine induced gastroesophageal reflux (GER) in contrast to a comparable ethanol solution and to tap water (Dig Dis Sci 1993; 38: 93–6). The aim of the present study was to investigate whether these results could be reproduced in patients with reflux disease.*Methods:* 15 GER patients (6 F, 51–86 yrs) received in a random order 300 ml white wine or tap water together with a standardised lunch. Because of the taste of wine the patients could not be blinded. Therefore, their pH-measurements were coded and analysed in a blinded fashion. The fraction time esophageal pH < 4 (FT) was calculated for three hours after ingestion of the two beverages.*Results:* Median and range; Wilcoxon test for paired data. Wine WaterFT (%) median 23.1 12.4Range 0–88.8 0–44.9significance $p < 0.01$*Conclusion:* In accordance with the results obtained in healthy volunteers (Dig Dis Sci 1993; 38: 93–6) white wine provokes an increase in GER also in patients with reflux disease. Therefore, patients with GER disease should be advised to avoid the ingestion of white wine. "P P 46 1109"P 46 1109**Apparently Life Threatening Events (ALTE) and Gastroesophageal Reflux (GOR) on Medical Treatment in InfantsF. Benkebil, P. Roy,**

*D.C. Belli

Gastroenterology Unit; Pediatric Department, HUG, Geneva, Switzerland*Introduction:* GOR is a frequent disease among infants, which may induce severe complications, such as ALTE. The prevalence of this association seems to increase with the supine sleeping position. The aim of this retrospective study was to analyze the potential association of GOR in 33 successive infants with ALTE, as well as their pH-metry and their evolution on medical treatment alone.*Patients and Methods:* 33 successive infants, median age = 28 days (3–185), were investigated by a clinical story and a 24 hr-pH monitoring (pH-m) following ALTE. They were born at a term. pH-m was realized with a DigitrapperMKIII (Synectics') on a 24 hr basis. pH-m criteria studied: % overall reflux, % sleep reflux, % awake reflux, clearance in total, pre-prandial and postprandial periods. control pH-m was performed on medical treatment (Cisapride: 1 mg/kg BW/d + Ranitidine: 300 mg/1.73 m2/d) before leaving hospital.*Results:* In medical story, 23 infants had frequent regurgitations, 6 had respiratory symptoms, 6 had previous ALTE without hospitalisation. The median duration of ALTE was 2 min (1–45). Position at the time of ALTE was similar to usual position: Supine Prone Lateral\'b0 0\'b0 30\'b0 0\'b0 30\'b0 0\'b0 30\'b0n 24 4 0 1 2 0On the total period reflux index basis, results of pH-m disclosed 2 groups: Gr A with GOR (n = 25) and Gr B (n = 8) without GOR. Both groups had no differences in clinical presentation. Gr A pH-m: % Index % Sleep % Awake ClearanceGr A 12.3 + 5.6 12.1 – 6.6 14.1 – 11.9 1.6 – 0.6Among the 33 infants, 6 had GOR only and 10 mainly in awake, 8 only and 4 mainly in sleep period. Furthermore, the vast majority of GOR was post-prandial. On medical treatment, all patients had presented a good evolution, with normalized pH-m in Gr A. With a 5-months follow-up, no patient presented with a new episode of ALTE.*Conclusion:* GOR and ALTE can be associated. GOR was observed in both awake and sleep periods. ALTE is not related to GOR in 25% of cases. Finally, a medical treatment alone can safely be proposed to resolve this problem. "P P 46 1111"P 46 1111**Helicobacter Infection in Esophageal Reflux (ER) Disease**

*O. Galimov, S. Fyodorov, M. Nurtdinov, A. Scumkin

Bashkir State Medical University, Ufa. Russia*Aim:* Establishing the conditions maintaining chronics local inflammatory process in the abdominal esophagus. *Methods.* Biopsy fibroesophagoscopy was carried out. Haematoxylin and eosin as well as Warthin-Starry staining technique was used in morphologic study of lower third mucosa biopsies. Urease test was carried out the sametime. Two groups of patients were studied: group 1 (18 patients) ER resistant to the therapy performed, group 2 (25 ER patients) in which concervative treatment appeared effective within usual therapy time.*Results.* Helicobacter pylori (HP) in group 1 was defermined in 66.7% cases and gastric metaplasia was revealed in 83.3%. The similar evidence was observed in group 2 in 16% and 24% cases respectively. Urease test was found to be positive in 16% cases (group 1) and 4% (group 2). HP revealed marked polymorphism closely adhering to the epithelial cells on the pit fundus and glands lumen. Chronic inflammatory process activation in mucosa was observed. HP was not revealed in deregeneration process and pronounced active inflammation in metaplasia mucosa as well as in areas of in stratified scaly noncornified epithelium irrespective of its state. Following the antireflux treatment in combination with antihelocobacter therapy no HP were revealed in all group 1 patients after control morphologic study. Positive therapy effect was obtained in 77.8% patients. Clinical evidence of esophagitis persisted in 22.2%.*Discussion.* Thus HP is significant in ER pathogenesis the fast that is supported by ineffective routine therapy. Therefare ER patients should undergo esophagus biopsy (1–4 cm from cardia) with subsequent morphologic study for HP presence. "P P 46 1112"P 46 1112**Serum Prolactin Levels in Childhood Gastro-Oesophageal Reflux Disease Treated with Cisapride**

*I. Korponay-Szab\'f3, J.B. Kov\'e1cs, A. Nagy, M. L\'f6rincz

Heim P\'e1l Children's Hospital, Budapest, HungaryAs serotonin and cholinergic stimuli may enhance prolactin (PRL) output, effect of cisapride treatment was studied in gastro-oesophageal reflux disease (GORD).*Methods:* Serum PRL was determined in 137 children with GORD newly diagnosed by pH-metry (age 0.15–19.8 years, mean: 5.05). 83 of them had also a prospective follow up of 6–36 months with at least one control PRL during continuous cisapride (0.2 mg/kg four times i.d.) intake > 2 months, checked between 9:00–11:00 a.m. Additional antacid/ranitidine use was allowed, but those with any therapy with dopamin antagonist drugs were excluded.*Results:* Mean PRL was 10.9 ng/ml (2.3–51.64) in the untreated pts, 17.6% (24/137) had pathologically high PRL levels (Group A) and further 8 pts (5.8%) PRL levels at the upper limit of normal range for age (Group B). Mean age of Group A was 2.15 years (0.15–13.81), $p < 0.01$ vs. Group B and the remaining pts.During cisapride treatment, there was apparently no significant change in the frequency of high PRL results (16.8%), however, in Group A and B, serum PRL level has been decreased in all but one patients to normal values, whereas other 13 pts newly exhibited high PRL. None of them had clinical signs of hyperprolactinaemia and all were well controlled regarding GORD.Continuing with the same treatment schedule and resampling after 2–3 weeks before the morning dose of cisapride, normal values were obtained in 13/13 of them. (There were no other known differences regarding fed state or time between other circumstances of samplings). Among 39 pts, who had been instructed already before the first control PRL determination to leave out the morning dose just before sampling, no high PRL occurred.*Conclusions:* High serum PRL levels are common among untreated infants and toddlers with GORD. Effective treatment normalized PRL. Cisapride did not caused long lasting hyperPRL, however, it may play some role in the still unclear PRL-related (compensative?) mechanisms. Oesophageal gastric duodenal disorders: EG RefluxOesophageal gastric duodenal disorders: EGD disorders in childrenHormones and receptors: Brain gut axis }" "Serum Prolactin Levels in Childhood Gastro-Oesophageal Reflux Disease Treated with Cisapride"

"P P 46 1113"P 46 1113**Epidemiology of Gastroesophagealreflux: Predictive Factors for the Course of the Disorder and Treatment Demand****S. Bruley des Varannes[1], J.-C. Grimaud[2], P. Ruszniewski[3], T. Vallot[4], A. Richard[5], F. Gentin[6]**

[1] Gastroenterology Department, Hospital Nord Nantes

[2] Gastroenterology Department, Hospital Nord Marseilles

[3] Gastroenterology Department, Beaujon Clichy

[4] Gastroenterology Department, Bichat Paris

[5] Gastroenterology Department, Icare Boulogne Billancourt

[6] Gastroenterology Department, Laboratoire Glaxo Wellcome ParisThe frequency of the symptoms of gastroesophageal reflux (GORD) is high and affects approximately 2/3 of individuals. The severity of the symptoms and perception by the patient obviously play a role in the request for medical care, while the reasons for medical consultation and/or following a course of treatment still remain unclear. The objective of this study was to examine the course of GORD and treatment demand, and to determine the predictive factors thereof for follow-up of a specific patient population over a period of six months. *Method:* a specific population of patients having experienced at least one episode of heartburn in the course of the past 15 days, who were consulting their general practitioner and had a history of such episodes were followed up over a period of six months. Investigation of predictive factors was conducted by multiple logistic regression and Poisson distribution.*Results:* 1115 patients were included in the study. Patients had been suffering from heartburn for 4 years and the mean duration of previous episodes was less than 1 month for 61%, between 1 and 3 months for 26% and more than 3 months for 13%. Heartburn was the main reason for consultation on DO for 86%. The mean duration of the current episode of heartburn was 3 weeks. The patients evaluated the symptoms of the current episode as causing slight discomfort (6%), discomfort (60%) great discomfort or incapacitating (34%). On D90, 4% of patients claimed they felt no discomfort due to heartburn; 51%, slight discomfort; 32%, moderate discomfort, and 6%, great discomfort. The predictive factors for discomfort on D90 were: the duration of episodes prior to DO, the frequency of the episodes and the severity of the symptoms on DO. The predictive factors for discomfort on D180 were: discomfort related to heartburn on D90, the length of time the patient had been suffering from GORD, and the main reason for consultation on DO; patients for whom heartburn was not the main reason for consultation on DO experienced a greater level of discomfort. The predictive factors for the extent of treatment demand over six months were: the levels of stress and anxiety measured on DO, age, discomfort related to heartburn on D90, severity on DO, and the frequency of episodes prior to the episode on DO.In conclusion, the severity of GORD after three and six months seems to be clearly related to the severity of previous episodes and the severity of the sympoms on DO. These criteria are not in themselves sufficient to explain the level of treatment demand. The levels of stress and anxiety of the patient appear to be closely related to future demand for treatment and further examination. Clinical practice: Epidemiology (non cancer)Oesophageal gastric duodenal disorders: EG Reflux }" "Epidemiology of

Gastroesophagealreflux: Predictive Factors for the Course of the Disorder and Treatment Demand"

"P P 46 1114"P 46 1114**Gastroesophageal Reflux Disease and Moderate to Severe Asthma. Prevalence and Clinical ManagementJ. Leit\'e3o,**

*A. Pinto, J. Canena, J. Reis, A. Santos, G. Lucas, M. Gomes, M. Quina

Cl\'ednica Universit\'e1ria de Medicina Interna e Gastrenterologia, Hospital de Pulido Valente, Lisbon, Portugal*Purpose:* To determine the prevalence of gastroesophageal reflux disease (GERD) in a population with moderate to severe asthma and the efficacy of anti-reflux therapy in symptoms, corticoid use and pulmonary function tests. *Methods:* We studied 29 asthmatic patients (\'b1 46.2 years) with moderate to serious disease (daily steroid use/bad control of symptoms). They had previous diagnosis of asthma since – 17 years, and GERD symptoms for – 8.4 years. Patients were submitted to: 1) upper gastrointestinal endoscopy with biopsy of the lower esophagus; 2) 24-hour ambulatory esophageal pH recording; 3) pulmonary function tests; 4) daily registration of symptomatic score, anti-asthma medication and peak expiratory flow. Patients with GERD defined by Richter criteria were treated for 8 weeks with omeprazole 20 mg bid. After that patients were submitted to another session of pulmonary function tests. In the following 20 weeks, treatment was changed to omeprazole 20 mg once a day. By the end of this period corticoid use was checked. Statistical analysis were made with the Wilcoxon, $\{ ?\}^2$, and the t-Student tests.*Results:* We found a prevalence of abnormal distal acid exposure in 17 (58.6%) of asthmatics. 52.9% had upright reflux, 17.7% had supine reflux and 29.4% both. In these 17 patients 53% had hiatus hernia and 41.2% esophagitis at the endoscopy. Histopathology found esophagitis in 47.1% of the 17 patients. After medical treatment all patients became asymptomatic; Symptomatic score ($p < 0.02$) and steroid use ($p < 0.03$) showed statistical improvement. Although there was some improvement in pulmonary function tests this was not statistical significant. *Conclusions:* 1) High prevalence of GERD was found in the studied asthmatic population; 2) Anti-reflux medical therapy significantly improve symptomatic score and corticoid using; 3) Results highly suggest the importance of detecting abnormal acid exposure in patients with asthma, specially in those with moderate to severe disease Oesophageal gastric duodenal disorders: EG Reflux }" "Gastroesophageal Reflux Disease and Moderate to Severe Asthma. "P P 46 1115"P 46 1115**The Role of Bile in the Genesis of Oesophageal Reflux Symptoms**

*R.E.K. Marshall, A. Anggiansah, W.A. Owen, W.J. Owen

Dept. of Surgery, Guy's Hospital, London SE1 9RT, England*Introduction.* Gastro-oesophageal reflux (GOR) of acid is known to be associated with oesophageal pathology as well as symptomatology. The role that duodenal contents play is not well known. Bilitec 2000, a spectrophotometric bilirubin detector, allows for the first time ambulatory monitoring of duodeno-gastro-oesophageal reflux, so symptoms can now be related to the presence of duodenal contents as well as acid in the oesophagus.*Methods.* 59 patients referred for investigation of symptomatic GOR underwent oesophageal manometry and combined oesophageal pH and Bilitec monitoring. No patients had a primary motility disorder. All symptom events described as regurgitation or heartburn were analysed for the presence of pH < 4 and bilirubin absorbance > 0.14 in the two minutes either side of the symptom. Total, upright and supine periods were analysed for acid (pH < 4) shift and bilirubin absorbance > 0.14.*Results.* 38 patients (64%) had significant acid reflux on pH testing, and 21 patients (36%) did not. 40 patients (68%) had significant bile reflux on Bilitec monitoring and 19 patients (32%) did not. There was good correlation between total bile and acid reflux (p < 0.05 Spearman rank correlation). 394 symptom events were identified (range 1–24 events per patient). Symptoms were associated with reflux thus: Acid reflux Bile reflux Both acid & Neither alone alone bile refluxNo. of 147 (37%) 24 (6%) 45 (11%) 178 (45%)symptomsOf the 178 symptom events that were not associated with either an acid or a bile reflux episode, 127 (71%) occurred in patients with no significant acid or bile reflux. The majority of events occurred in the upright interprandial period (173 events, 44%), 165 events (42%) occurred during the postprandial period, 42 events (10%) in the supine period and 14 events (4%) during meals.*Conclusions.* 32% of patients had no significant acid or bile reflux, so presumably there was another pathology to account for their symptoms. Despite good correlation between acid and bile reflux, acid and bile reflux episodes do not always occur simultaneously. However, symptoms are more frequently associated with acid reflux than bile reflux, and bile does not seem to be a major cause of reflux symptoms. Oesophageal gastric duodenal disorders: EG Reflux }" "The Role of Bile in the Genesis of Oesophageal Reflux Symptoms"

"P P 46 1116"P 46 1116**The Incidence of Gastro-Oesophageal Reflux Disease Based on Non-Specific Symptoms in Instituted Intellectually Disabled**

*C.J.M. B\'f6hmer, M.C. Niezen-de Boer[1], E.C. Klinkenberg-Knol[2], S.G.M. Meuwissen[2]

[1] Bartim\'e9us, Zeist, The Netherlands

[2] Free Univ Hosp, Amsterdam, The NetherlandsThe prevalence of GOR in randomly selected instituted intellectually disabled (IQ < 50) in the Netherlands is 48.2% and of oesophagitis 64.5%. In this study we investigated the incidence of GOR and RO in a population with non-specific reflux symptoms such as: behaviour difficulties as automutilation, food refusal, fear and restlessness, vomiting, regurgitation and rumination. Also predisposing factors were evaluated.In one institute 110 persons underwent a 24 hour oesophageal pH test and were scored for predisposing factors and non-specific reflux symptoms. A pathological pH test was defined as a pH < 4 > 4.5% of the measured time. Subjects with a pathological pH test (patients) were compared to those with a normal pH test (controls).In 7 cases (6.4%) the test failed for technical reasons. In 57 (55.3%) cases a pathological pH test was found, compared to 48.2% in the earlier mentioned at random population (ns). In this group non-ambulancy, the use of anticonvulsive medication, cerebral palsy and a history of GOR appear to be predisposing factors, while the suggested non-specific reflux symptoms did not discriminate for GOR. At endoscopy RO was diagnosed in 33 patients (57.9%), of which: 12 (36.4%) grade I, 15 (45.5%) gr II, 6 (18.2%) gr III/IV (Savary-Miller classification). Barrett's esophagus was found in 2 (6.1%) and 1 (3.0%) showed a peptic stricture.*In conclusion:* reflux of acid gastric contents was demonstrated in *55.3%* intellectually disabled with non-specific reflux symptoms, while *57.9%* of them showed RO. Subjects with non-ambulancy, the use of anticonvulsive medication, cerebral palsy and a history of GOR are at risk to develop GOR. But non-specific symptoms as behaviour problems and vomiting do not discriminate for GOR. This study demonstrate that GOR and RO are major clinical problems in intellectually disabled persons. [1] Bartim\'e9us, Zeist, The Netherlands

[2] Free Univ Hosp, Amsterdam, The Netherlands

[3] Antonius Hosp, Nieuwegein, The NetherlandsGOR was estimated to be present in 10–15% of the intellectually disabled population (Sondheimer '79). Therefore, we investigated the prevalence of GOR among the inhabitants, with an IQ < 50 (n = 1607), of 6 institutes in the Netherlands and Belgium.At random 435 persons underwent a 24 hour oesophageal pH test and were scored for predisposing factors, characteristic reflux symptoms and other possible risk factors. Subjects with a pathological pH test (patients), defined as a pH < 4 > 4.5% of the measured time, were compared to those with a normal pH test (controls).In 49 cases (11.3%) the test failed for technical reasons. In 186 (48.2%) cases a pathological pH test was found (median duration of pH < 4: 12.7%). As predisposing factors scoliosis, cerebral palsy, the use of anticonvulsive medication or other benzodiazepines, and an IQ < 35 were indicated, while as reflux symptoms haematemesis, rumination, depression, and restlessness were found. As other risk factors a history of GOR, the presence of Barrett's oesophagus, and Down's syndrome were significant more often present. At endoscopy RO was diagnosed in 127 GOR patients (68.3%), of which: 58 (45.7%) grade I, 44 (34.6%) gr II, 25 (19.7%) gr III/IV (Savary-Miller). Barrett's oesophagus was found in 14 (11.0%) and 4 (3.1%) showed peptic strictures.*In conclusion:* reflux of acid gastric contents was demonstrated randomly in *48.2%* intellectually disabled, while *68.3%* showed RO of which 19.7% of severe degrees or with complications. Subjects with scoliosis, cerebral palsy, the use of anticonvulsive medication, an IQ < 35, haematemesis, rumination, restlessness, depression, a history of GOR, Barrett's oesophagus or Down syndrome are at risk to develop GOR. This study demonstrate that GOR and RO are major clinical problems in intellectually disabled persons. "P P 46 1118"P 46 1118**Dental Erosions and Gastro-Oesophageal Reflux in Instituted Intellectually Disabled**

*C.J.M. B\'f6hmer, E.C. Klinkenberg-Knol[2], M.C. Niezen-de Boer[1], S.G.M. Meuwissen[2]

[1] Bartim\'e9us, Zeist, The Netherlands

[2] Free Univ Hosp, Amsterdam, The NetherlandsGastro-oesophageal reflux (GOR), recurrent vomiting and regurgitation may lead to erosions of the teeth. In the intellectually disabled population these conditions are frequently found. Therefore, we investigated the presence of dental erosions and GOR among intellectually disabled inhabitants, with an IQ < 50 (n = 409), recruited from 2 institutes in the Netherlands.At random 88 individuals underwent a 24 hour oesophageal pH test, dental screening and were scored for possible predisposing factors and reflux symptoms. A pathological pH test was defined as a pH < 4 > 4.5% of the measured time. Subjects with dental erosions (patients) were compared to those without dental damage (controls).25 individuals were toothless (28.4%). In 29 out of 63 (46.0%) cases dental erosions were found. In 19 (65.5%) patients GOR was diagnosed, compared to 9 (26.5%) controls (p = 0.04), while 16 (55.2%) patients showed had a history of GOR in comparison with 7 (20.6%) controls (p = 0.008). In patients the mean duration of pH < 4 was 15.6% compared to 6.3% in controls 9 (p = 0.02). As predisposing factor an IQ < 35 (p < 0.0001) was found, while symptoms as vomiting, rumination, regurgitation, swallow difficulties and gnashing one's teeth did not increase the risk to develop these dental erosions.*In conclusion:* in this population of 63 instituted intellectually disabled persons dental erosions were diagnosed in *46%,* while over *65%* of them had also GOR or a history of GOR. Individuals with longer duration of pH < 4 and with an IQ < 35 are at higher risk to develop dental erosions. This study shows that dental erosions are often atypical manifestations of GOR in the intellectually disabled population. "P P 46 1119"P 46 1119**Respiratory Symptoms Due to Gastro-Esophageal Reflux Disease (GERD), a Comparative Study**

*J.B. Van den Bogaerde, H. Van der Walt

Department of Surgery, & Gastroenterology, University of Pretoria, South Africa*Purpose:* This study compares patients with GERD and respiratory symptoms (RS), to GERD patients without RS.*Methods:* Patients with GERD, unresponsive to medical therapy underwent laparoscopic anti-reflux surgery. Pre-operative symptom scoring, endoscopy, esophageal manometry, 24 hour pH studies and DeMeester (DEM) scores were performed. RS included hoarseness, chronic cough, or asthma. Patients with RS were compared to age and sex matched controls with GERD but no RS. After laparoscopic surgery symptom scoring, endoscopy and manometry were performed. The two-tailed T test was used for statistical analysis and significance was defined as $p < 0.05$.*Summary of Results:* A total of 59 patients with GERD and RS were compared to 59 age and sex matched controls. The average age of RS patients and matched controls was 44.5 years (range 18–78). Mean pre-operative lower esophageal sphincter (LES) pressure in the RS group was 5.16 mm Hg and in the control group 5.66 mm Hg. This was not statistically significant. The majority of patients in the RS group had defective LES (90%) compared to 84% of control patients. Mean DEM scores were 53.08 in the RS group and 45.07 in the control group, which was not statistically significant. Clearance was normal in 40% of the RS group and in 32% of the control group (not statistically significant). Laparoscopic anti-reflux surgery was performed and LES pressure normalized in both groups. RS disappeared in all but one patient, but this patient reported a reduction of bronchodilator therapy. This confirmed that RS were caused by GERD in the majority of patients in the RS group.*Conclusion:* Patients with GERD and RS do not have significantly different acid reflux scores, LES pressures, clearance or defective sphincters when compared to those with GERD but without RS. "P P 46 1121"P 46 1121**The Presentation of Gastroesophageal Reflux Disease; A Prospective Clinical and Endoscopic StudyB. Werdmuller, A.B.M.M. v/dPutten,**

*R.J.L.F. Loffeld

Department of Internal Medicine, Ziekenhuis De Heel Zaandam, The NetherlandsA prospective study was done amongst 1432 consecutive patients referred for upper gastrointestinal endoscopy in order to assess the prevalence and severity of symptoms in patients with oesophagitis (n = 115), hiatal hernia (n = 108), Barrett's oesophagus (n = 29) and functional dyspepsia (n = 439). All patients received a questionnaire consisting 12 questions related to reflux. Eight questions were scored on a lineair scale ranging from 1 till 5 (absent = 1, severe = 5). Patients with grades I or II refluxoesophagitis were significantly younger compared with patients with grades III or IV oesophagitis ($p < 0.001$). Patients with functional dyspepsia were significantly younger than all other patients ($p < 0.0001$). A concomitant hiatal hernia was present in a substantial number of patients with oesophagitis or Barrett's oesophagus. Mean symptomscore in grade I oesophagitis was 15.3 (SD 5.8); in grade II 15 (SD 6.5); in grade III 8.9 (SD 7); in grade IV 11.4 (SD 5.1); in patients with Barrett's oesophagus 10.3 (SD 6), in hiatal hernia 12.2 (SD 6.8), and in functional dyspepsia 11.5 (SD 6.7). Symptomscore in patients with Grades III or IV oesophagitis was significantly lower compared with grades I or II oesophagitis ($p < 0.001$).Patients with Barrett's oesophagus and/or hiatal hernia and/or functional dyspepsia had significantly lower symptomscores if compared with grades I or II oesophagitis, 10.3 (SD 6) versus 15.2 (SD 6) ($p < 0.001$) and 12.2 (SD 6.8) versus 15.2 (SD 6) ($p = 0.01$), and 11.5 (SD 6.7) versus 15.2 (SD 6) ($p < 0.0001$) respectively. No difference in symptomscore was present in comparing grades III or IV oesophagitis, hiatal hernia, Barrett's oesophagus and patients with functional dyspepsia. Patients with grades I or II oesophagitis had a significantly higher number of reflux complaints, mean 5.1 (SD 1.5), compared with grades III or IV oesophagitis, mean 3.5 (SD 1.8), patients with Barrett's oesophagus, mean 3.7 (SD 1.9), patients with hiatal hernia, mean 4.1 (SD 1.9) and dyspeptics with reflux complaints, mean 4.0 (SD 1.9) ($p < 0.0001$). The prevalence of epigastric pain, retrosternal pain, nocturnal pain, belching, heartburn, retrosternal heartburn and halitosis was significantly higher in patients with grades I or II oesophagitis, while the prevalence of dysphagia was significantly higher in patients with grades III or IV oesophagitis. Patients with grades III or IV oesophagitis had a significantly shorter history compared with all other groups.It is concluded that the presence of a majority of typical reflux symptoms has a high predictive value for the presence of grades I or II oesophagitis, dysphagia is indicative for grades III or IV oesophagitis. In cases of less symptomatology or a low symptomscore it is not possible to distinguish Barrett's oesophagus, hiatal hernia or dyspeptics with reflux complaints. "P P 46 1122"P 46 1122**Oscillatory Index in Oesophageal 24 Hour pH Monitoring for Gastroesophageal RefluxA. Kostovski**

Pediatric Clinic, Faculty of Medicine, Skopje, MacedoniaVandenplas JPGN 11: 304, 1900), introduced a new parametar: oscillatory index (OI), after him Watanabe (JPGN 19: 50, 1994) used the term prolonged stable pH around 4 (PSpH4). The aim of the study was to determinate the incidence and clinical significance of the OI in children investigated for GER and to correlate it with reflux index (RI).In a prospective study were evaluated 53 children (age 52 – 54 months) for GER by 24 h. pH monitoring (24 HpHM). They were separated in three groups: Group A with vomiting and failure to thrive (age 9.7 – 6.9), group B with gastrointestial symptoms but older (142 – 120 m), and group C with pulmonary manifestations (33.3 – 31.9) GER was considered if RI was > 5%. OI and RI were analyzed, only.*Results:* In group A with RI < 5% OI was 1.23 – 0.95 and with RI > 5 was 7.93 – 4.75% (p < 0.05). In B if RI was < 5% we found OI to be 2.28 – 1.65% (within 2 hours postprandial.) and 0.66 – 0.52% (fasting). With RI > 5% OI was 3.90 – 2.91% and 0.94 – 0.56, respectively. In C with RI < 5% OI was 2.16 – 0.96 and 0.82 – 0.87%, respectively. With RI > 5% OI was 6.63 – 3.49 and 2.65 – 4.09%. If RI was > 10% OI was 9.0 – 4.03 and 3.4 – 1.72%. Five pts were with OI > 10%.*Conclusions:* We found that OI correlates with RI (bigger in C group) and with age (group A). Pts in group C with high OI treated with procinetics solved. So high OI can be a trigger for pulmonary symptoms. Oesophageal gastric duodenal disorders: EG Reflux }" "Oscillatory Index in Oesophageal 24 Hour pH Monitoring for Gastroesophageal Reflux"

"P P 46 1123"P 46 1123**Process of *Candida* Infection of the Esophagus**

*K. Hoshika[1], M. Iida[1], H. Mine[2]

[1] Division of Gastroenterology, Dept. of Medicine, Kawasaki Medical School, Kurashiki, Japan

[2] Dept. of Clinical Nutrition, Faculty of Medical Professions, Kawasaki University of Medical Welfare, Kurashiki, Japan*Purpose:* Esophageal *Candidiasis* occurs under three conditions; an immunocompromised state (leukemia, AIDS), a fungi overgrowth state (long term administration of antibiotics, diabetes mellitus), and a non-immunosuppressive state (healthy individuals). Our experimental studies using SEM have dealt with the formation (F) process and healing (H) process of *Candida* infection under a non-immunosuppressive state. The aim of the present study was to analyze the process under two other conditions.*Methods:* Antibiotics (tetracycline: TC) and/or immunosuppressive drugs (tacrolimus, prednisolone: PSL, azathioprine: AZP) were administrated to rabbits for two weeks, during or following two-week administration of *Candida albicans* suspensions, and the lesions were observed by SEM.*Results:* The F and H process of *Candida* infection was observed under all conditions. The H/F ratios of the same or post administrations of drugs were 83.3% and 80% in TC, 20% and 16.7% in tacrolimus, and 0% and 0% in PSL + AZP. In studies without drugs, there were 83.3% and 100%, respectively. Therefore, the H process was obviously suppressed only under the immunosuppressive conditions.*Conclusion: Candida* infection can be classified into two states; a state with H process suppression and one without H process suppression. "P P 47 1124"P 47 1124**Analysis of Esophageal Motility by Fast Mr Imaging**

*Y. Seki, S. Naruse, M. Kitagawa, H. Ishiguro, Y. Nakae, N. Iizuka, H. Ieda, O. Ito, T. Hayakawa[1], Y. Seo, M. Murakami[2]

[1] Internal Medicine II, Nagoya University, Nagoya, Japan

[2] National Institute for Physiological Sciences, Okazaki, JapanManometry and radiography are techniques commonly applied to analyze the esophageal motor dysfunctions. In order to find a less invasive method, we have tested a fast MR imaging to analyze esophageal motility in rabbits.^{1}H imaging of the esophagus was carried out by using a 4.7 T magnetic resonance spectrometer for animal studies (Biospec ABX 47/40, Bruker, Germany) with a bird-cage RF-coil (inner diameter of 20 cm). Japanese white rabbits (3.0–3.7 kg) were fixed firmly on an animal support in the prone position without anesthesia, and a pair of earplugs was applied to keep out noise from gradient coils. Median sagittal images were taken by a fast gradient-echo imaging (Snapshot) at 3 images/sec. Typical values used were as follows: field-of-view 22.5 cm, data matrix 96^2, spectral width 72 kHz, relaxation delay 3.4 msec, echo-time 1.9 msec, slice-thickness 6 mm, number of accumulation 1. A 6 Fr. silastic tube with a balloon at the tip was inserted nasally into the upper esophagus just distal to the upper esophageal sphincter. The balloon was then inflated to 1 cm diameter by infusion of 0.6 ml of 0.6% (w/v) ferric ammonium citrate.One to 10 sec after inflations the balloon moved from the upper esophagus to the stomach in 3–30 sec. The maximal velocity was 8.3 cm/sec. The primary peristalsis that followed the voluntary act of swallowing was also visualized.Fast MR imaging allows us to observe clearly a rapid movement of a volus along the entire length of esophagus during swallowing. [1] Service d'H\'e9pato-Gastroent\'e9rologie, CHRU Montpellier, France

[2] Service d'ORL, CHRU Montpellier, FrancePharyngeal symptoms of gastrooesophageal reflux disease (GORD) suggest existence of relations between oesophageal motricity and phonation. The aim of the study was to explore those relations in a preliminary work evaluating a new experimental method.*Patients and Methods:* Eight patients (3 m, 5 f), with dysphagia (n = 1) or GORD including 4 with pharyngeal symptoms and vocal overworking, underwent manometry with an electronic probe (GAELTEC CTG-6, diameter 3 mm) associated with vocal study of 6 phonemes, repeated 4 times with the probes studying the UES. A numerical recording of voice pronouncing test sentences was realised before and during manometry to detect a probe- induced modification of the phonation. We analysed the presence, the length and the size of the UES relaxations during phonation, in comparison with UES relaxations induced by a dry swallow. We also studied the motricity of the upper oesophageal third. The voice recordings were studied on a computerised vocal analyser called ""EVA"".*Results:* Out of 192 phonemes pronounced, 64 induced UES relaxation (33%). The falls in UES pressure were always equal or more than 50% of those induced by dry swallow, and in 25 cases more than 80% of this value. The mean length of relaxation was 1.75 s. Relaxations induced upper oesophageal motricity in 75% to 100% cases in 3 patients, never in the others. Out of 3 of these patients, 2 had no probe-induced phonation modifications. Pharyngeal symptoms didn't influence results.*Conclusion:* This study propose an original investigation method associating vocal and manometric study. It suggests existence of UES relaxations induced by phonation, of which some cases induce upper oesophagus motricity.

"P P 47 1126"P 47 1126**Does Lower Esophageal Sphincter Vector Volume Change by Chronic Obstructive Pulmonary Disease?**

*G\'f6rg\'fcl Ahmet, Kayhan Bur\'e7ak, Kayhan Mine[1], Ak\'e7ali Zafer, Kayhan Burhan[2]

G\'dcTF, Ankara T\'fcrkiye

[1] Ankara Atat\'fcrk Chest Disease Hospital

[2] H\'dcTF Ankara T\'fcrkiyeThe aim of this study was to investigate the effect of chronic obstructive pulmonary disease (COPD) on the lower esophageal sphincter (LES) vector volume, which is the anatomic and functional pressure profile of LES.*Materials and Methods:* 3 groups of patients were included. The first group consisted of 12 patients with chronic bronchitis, second group 12 patients with emphysema, and the last group 12 healthy volunteers. All the patients and healthy controls lacked gastroesophageal reflux symptoms, any gastrointestinal system disease or other systematic diseases. The smokers were also excluded. All patients underwent esophageal motility testing using a catheter with 6 distal side holes each oriented radially 60\'b0 from the other. The catheter was continuously perfused with water at 0.5 ml/min by a low-compliance pneumohydroullic capillary infusion system. Subjects were studied after an overnight fast. The patients received no drugs for 48 hours prior to this study. The LES pressure and vector volume were obtained using the rapid pull-through method and were measured at end-expiration. Serial readings (6 times) were taken from each of the six sensor channels permitting better detection of pressure changes even with asymetric sphincters. The measurements were evaluated statistically (Mann Whitney U).*Results:* No significant differences existed between the mean vector volumes of group I and group III ($p = 0.08$). The vector volume of group II was significantly less than that of group III (control) ($p = 0.01$). The mean value of group II was also lower than that of group I ($p = 0.015$). *Conclusion:* The results of this study demonstrated that COPD influenced LES vector volume. Motility, specific: Oesophagus }" "Does Lower Esophageal Sphincter Vector Volume Change by Chronic Obstructive Pulmonary Disease?"

"P P 47 1127"P 47 1127**Comparison of pH Probe Placement Determined by Manometry Vs a Combined pH and Lower Oesophageal Sphincter DetectorS. Carley, M.S. Gilleney, P. Vales,**

*R.F. McCloy

Department of Surgery, Manchester Royal Infirmary, Manchester M13 9WLThe monitoring of oesophageal pH is now widely accepted as the most accurate method of assessing gastro-oesophageal reflux. Continuous monitoring with a probe placed 5 cm above the proximal border of the lower oesophageal sphincter for 24 hours is the agreed standard. Accurate placement of the probe is essential, too low a placement will lead to false positives, too high a placement will result in false negative investigations. The proximal LOS is commonly identified using either manometry or the Acid-Alkali interface. Synectics have developed a pH probe with a water filled lumen that allows measurement of oesophageal intraluminal pressure. Pressure measurement allows the LOS to be identified. A study was undertaken to assess the accuracy of placement of the Synectics probe compared with conventional manometry. *Methods:* Twenty patients undergoing 24 hour pH monitoring were investigated. Conventional oesophageal manometry was performed to identify the LOS. Immediately afterwards the Synectics probe was intubated. The probe was withdrawn in 1 cm steps from 60 cm to 35 cm, the AA was identified at the point that the measured pH rose above 4. A second withdrawal was performed monitoring the intraluminal pressure, the LOS was identified at the point of intraluminal pressure falling below gastric pressure. *Results:* The PM of the LOS as obtained at manometry was taken as the standard, this was compared with the PM of the LOS as determined by the Synectic probe and with the AA interface. Using the LOS detector 75% of probes would be sited between 3 and 7 cm above the PM of the LOS. Using the AA interface alone 33% of probes would be sited between 3 and 7 cm above the PM of the LOS. Use of AA interface alone is significantly less likely to result in acceptable placement of the pH probe ($p < 0.01$). *Discussion:* In departments where formal oesophageal manometry is not available it has been suggested that identification of the AA interface is adequate for the placement of the pH probe. The results show that this would lead to the unacceptably low placement of 77% of probes. Use of the LOS detector reduces the error to 25%. *Conclusion:* Use of the Synectic LOS detector significantly increases the accurate placement of pH monitoring probes over identification of the AA interface alone. Formal manometry is still recommended as the standard for placement of the pH electrode. "P P 47 1128"P 47 1128**Esophageal Motor Function in Connective Tissue Diseases****S. Unal, I. Dogan, K. Ozoran[1], A. Gorgul, B. Sivri, N. Duzgun**

[1] Gazi University School of Medicine, Department of Gastroenterology, Ankara, Turkey

Ankara Numune Hospital, Clinic of Rheumatology, Ankara, TurkeyThe effect of scleroderma (Sc) on esophageal motor functions (EMF) is well known. The aim of this study was to investigate the effect of Sc, rheumatoid arthritis (RA), systemic lupus erythematosus (SLE), mixed connective tissue disease (MCTD), ankylosing spondilitis (AS), dermatomyositis (DM) or polymyositison EMF. In all patients EMF was studied by using water-perfused manometry system. Patients were diagnosed as nonspecific esophageal motor disorders (NEMD), nutcracker esophagus (NC), diffuse esophageal spasm (DES), hypertensive lower esophageal sphincter (HLES) and normal, by using the current diagnostic criteria.Table 1: Manometric findings Total Normal Abnormal Types of abnormalities (male/female) n (%) n (%) DES HLES NC NEMDRA 37 (9/28) 23 (62) 14 (38) 2 1 5 6Scl 13 (2/11) 4 (30) 9 (70) – 1 – 8AS 8 (8/-) 8 (100) – – – – -Dm 4 (1/3) 1 (25) 3 (75) – – 3 -SLE 8 (1/7) 4 (50) 4 (50) – – 2 2MCTD 1 (-/1) 1 – – – – -Total 71 (21/50) 41 (58) 30 (42) 2 2 11 16In 3 manometrically abnormal of 4 patients with dermatomyositis, low contraction amplitudes have been detected in the 1/3 proximal esophagus consistent with disease, however, it was interesting that with high contraction amplitudes in the 2/3 distal esophagus they were diagnosed as NC. Not in all of the patients with Sc the classical findings of esophagus dysmotility, characteristic for this disease were observed. Manometric findings in the group of patients with RA were heterogeneous in nature. For some of patients with RA, NEMD was diagnosed because of low contraction amplitude in the body of the esophagus. Some other patients were diagnosed as NC due to observed high contraction amplitudes.This study concludes that, as well as Sc, the other connective diseases also have effects on esophageal motor function in various ways. "P P 47 1129"P 47 1129**Placebo-Controlled Study of Cisapride in Patients with Nonspecific Esophageal Motility Disorder (NEMD) Accompanied by Delayed Esophageal Transit**

*C.W. Song, S.H. Um, C.D. Kim, H.S. Ryu, J.H. Hyun, J.G. Choe

Dept. of Internal and Nuclear Medicine, Korea University Hospital, Seoul KoreaNEMD represent a difficult therapeutic challenge because of the heterogenous nature of the esophageal motor functions. We studied the effects of cisapride (CIS) on the esophageal symptoms and esophageal motor function in a group of patients (pts.) with NEMD showing delayed esophageal transit.*Method:* 70 eligible pts. were entered into a 4-week, double-blind randomized comparison of 10 mg of CIS or placebo (PLA) q.i.d. Symptom assessment, esophageal manometry following wet swallows and esophageal scintigraphy following intake of a liquid and solid bolus were performed in each patient before and after treatment.*Results:* After 4 wks, both CIS and PLA significantly reduced the symptom scores without statistical difference between the two groups. However, the global efficacy of CIS, as rated by good and excellent responses, was significantly superior to that of PLA ($P < 0.05$). CIS significantly increased the number of esophageal peristaltic contractions ($P < 0.05$ versus baseline and PLA) and significantly improved esophageal emptying of the solid bolus ($p < 0.05$ versus PLA), while not of the liquid bolus. PLA did not have any significant effects versus baseline on these parameters. Both PLA and CIS, however, improved the distal esophageal amplitude versus baseline (no significant intergroup differences).*Conclusions:* CIS is effective and well tolerated in pts. with NEMD accompanied by delayed esophageal transit. Its efficacy may be related to its action on the esophageal body by increasing the number of peristaltic contractions and esophageal emptying of solids. Oesophageal gastric duodenal disorders: Oesophageal disorders, non reflux }" "Placebo-Controlled Study of Cisapride in Patients with Nonspecific Esophageal Motility Disorder (NEMD) Accompanied by Delayed Esophageal Transit"

"P P 47 1131"P 47 1131**Esophageal Motility and Gastric Tone in Systemic Sclerosis (SSc)**

*P. Iovino, G. Valentini, F. Sabbatini, D. Mota-Acioli, L. Tullo, G. Mazzacca

Cattedre di Gastroenterologia e Reumatologia, Universit\'e0 degli Studi di Napoli, ItalyGastrointestinal tract is frequently involved in SSc, but only few patients became symptomatic. Esophageal motility abnormalities are reported in 75–90% of patients. Gastric involvement has been poorly studied. The most common SSc classification describes either a limited or a diffuse cutaneous form. *Aims:* to evaluate the esophageal motility pattern and the compliance of the proximal stomach in patients with limited and diffuse SSc. *Methods:* in 14 consecutive patients (13 F, age 32–63, 9 with diffuse SSc) a study of the esophageal motility (constantly perfused multilumen catheter) and gastric compliance (volume/pressure relationship) was performed (electronic barostat). During isobaric distension, the intragastric pressure was increased from 0 to 20 mmHg, up to a maximum of 600 ml or to discomfort. A manometric score was calculated in each patient based on the tracing alterations (1–3). Perception was scored by a specific questionnaire. *Results:* the esophageal motility pattern was impaired in 10 patients (71%). In limited and diffuse SSc patients the manometric score was 1.2 – 0.5 and 2.8 – 0.4 (M – SD), respectively ($p < 0.05$). Volume/pressure relationship (compliance) was studied by linear regression analysis in each patient (correlation coefficient 0.95–0.99). Gastric compliance was larger in diffuse SSc patients than in both limited SSc and 6 controls (78 – 15 vs 51 – 11 e 55 – 15 ml/mmHg (M – SD), respectively; $p < 0.05$). No relationship was found between the manometric score and gastric compliance in each patient. In all patients gastric distention produced gastric symptoms and the perception score was higher than controls (8.1 – 5.4 vs 1.3 – 2.5 (M – SD), $p < 0.05$). No difference was found in perception score between diffuse SSc and limited SSc patients. *Conclusions:* in diffuse SSc patients gastric compliance was larger than limited SSc patients and controls. The proximal stomach could play a role in eliciting dyspeptic symptoms in SSc patients. "P P 47 1132"P 47 1132**Coexistence of Gastroesophageal Reflux Disease and Esophageal Dismotility in Non-Cardiac Chest Pain**

*Z. Mungan, S. Kamali, F. Besisik, G. Boztas, O. Yegins\'fc, S. Kaymakoglu, R. Sezer

Istanbul Medical Faculty, Section of Gastroenterohepatology, Istanbul, T\'fcrkiyeGastroesophageal reflux disease (GERD) is the most important etiologic factor of non-cardiac chest pain (NCCP). But not all NCCP patients with GERD respond to anti-reflux therapy. In a prospective study, we evaluated 43 patients with NCCP to investigate the etiology and the respond to medical therapy.All patients were referred to us from cardiology department. Male/female ratio was 24/19 and the mean age was 41.5 – 9. Patients were evaluated by means of upper GI endoscopy, endoscopic biopsy, 24-hour pH monitoring and conventional manometry. GERD and/or dismotility were diagnosed in 27 cases (62.8%). Dismotility disorders were non-specific, nutcracker, diffuse spasm and hypertensive LES (in 6, 3, 2 and 2 cases, respectively). Patients were treated with H2RA, omeprazole, cisapride or nifedipine where indicated. Fifteen patients had complete resolution of pain. Our results were as follows: Diagnose n (%) Respond to therapyGERD 14 (32.6) 11 (78.6)GERD + dismotility 7 (16.3) 2 (28.6)Dismotility 6 (14.0) 2 (33.3)Total 27 (62.8) 15 (55.6)Our results indicated that; 1. GERD is the most important cause of NCCP, 2. Dismotility coexistence with GER was found in 1/3 of GERD patients, 3. Respond to medical therapy is better when GERD is alone. Presence of motility disorder or association of GERD with dismotility is an indicator of poor response of medical therapy in NCCP Oesophageal gastric duodenal disorders: EG RefluxMotility, specific: Oesophagus }" "Coexistence of Gastroesophageal Reflux Disease and Esophageal Dismotility in Non-Cardiac Chest Pain"

"P P 47 1133"P 47 1133**24 Hours Oesophageal pH, Pressure Monitoring and ECG in Patients with Non-Cardiac Chest Pain**

*A. Baniukiewicz, S. Dobrzycki[1], M. Jedynak, A. Gabryelewicz

Gastroenterology Department, Medical School Bialystok

[1] Cardiology Department, Medical School Bialystok*Aim:* The aim of this study was to report the findings of simultaneous 24-hour oesophageal pH, pressure monitoring and ECG in patients with non-cardiac chest pain.*Material and methods:* The study group consisted of 23 patients (10 male and 13 female, mean age 46.2 years). Long term pH/manometry was performed (within 48 hours after admission and exclusion of ischemic heart disease), using catheter with an antimony electrode and separate catheter with three solid-state pressure transducers. The data were recorded on portable data logger with 2-MByte memory capacity. (Synectics, Sweden). Simultaneous Holter monitoring has been used in the evaluation of cardiac events (Marqeute Laser SXP). The analysis of data included: 1) percentage of propulsive, nonpropulsive and simultaneous contractions 2) mean amplitude and duration of contractions, 3) propagation of contractions, 4) time pH below 4.0 (%), 5) total number of reflux episodes (pH < 4.0), 6) total number of reflux episodes longer than 5 min, 7) symptom index for reflux and for dysmotility pain. An upper GI endoscopy and treadmill test were performed in all patients on a separate day.*Results:* A total of 46% of patients were found to have either reflux- or dysmotility- related chest pain. 36% of pain episodes were associated with gastro-oesophageal reflux and 26% with dysmotility. The pain was not related with oesophageal abnormality in 38% of cases. None of these pain episodes were associated with electrocardiogram changes.*Conclusion:* 24-h oesophageal pressure, pH and ECG recording is worthwhile and useful diagnostic tool of non-cardiac chest pain and offers the additional clinically valuable advantages of studying these patients.Partly supported by Medical Academy of Bialystok Grant No 513779 Oesophageal gastric duodenal disorders: EG RefluxMotility, specific: Oesophagus }" "24 Hours Oesophageal pH, Pressure Monitoring and ECG in Patients with Non-Cardiac Chest Pain"

"P P 47 1134"P 47 1134**Visceral Sensitivity of the Esophagus, and Its Relation to Basal Manometric Findings**

*M. B\'f6rjesson, T. Eliasson, C. Mannheimer, H. Norrsell, M. Pilhall[1], P. Rolny

Dept. of Medicine, \'d6stra University Hospital, Gothenburg, Sweden

[1] Dept. of Clinical Physiology, \'d6stra University Hospital, Gothenburg, Sweden*Purpose of the study:* Balloon distention of the esophagus is currently used for assessment of esophageal motility and visceral sensitivity. Recently, a lowered pain threshold on balloon distention could be shown in a subgroup of patients with ""non-cardiac"" chest pain. However, the relation between the increased visceral sensitivity and motility has received little attention so far. The aim of the study was to study visceral sensitivity of the esophagus and its relation to peristaltic activity as well as the effects of TENS.*Methods:* 18 patients referred for esophageal evaluation, because of chest pain of unknown origin, were investigated with routine esophageal manometry and 24-h pH measurements. A balloon (Medi Tech occlusion balloon catheter 10 ml, 65 mm, USA) was placed 6 cm above the lower esophageal sphincter (LES), and in stepwise fashion filled with air in 1 ml increments, until maximum balloon volume of pain 5/10 on the Borg scale. Basal manometry before balloon distention was compared with manometry at maximum balloon volume for each patient. As a study of the effects of TENS (transcutaneous electrical nerve stimulation) on visceral pain, the balloon provocation was done in two sessions with TENS or placebo-TENS.*Results:* As a result of balloon distention, the peristaltic wave increased proximal of the balloon and decreased distally of the balloon, as shown in earlier studies. The amplitude of the peristaltic wave proximal of the balloon was positively correlated with increased visceral sensitivity ($p < 0.05$). Likewise the amplitude of peristalsis at the level of the balloon was significantly ($p < 0.05$) correlated with increased sensibitivy, as was the duration of the peristaltic wave at the level of LES ($p < 0.05$). TENS significantly reduced symptoms during the balloon distention and also had effects on the esophageal motoric activity.*Conclusion:* Esophageal visceral sensitivity was related to basal manometric findings. TENS decreases symptoms during balloon distention and thus may have an effect on visceral sensitivity. The same motoric patterns as induced by the cholinergic drug edrophonium was related to increased visceral sensitivity, thus indicating a possible connection between increased cholinergic activity (autonomic dysfunction) and higher visceral sensitivity of the esophagus. "P P 47 1135"P 47 1135**Esophageal Manometry in Progressive Systemic Sclerosis**

*L. Correia, R. Palma, P. Ferreira, E. Pires, J. Lopes, A. Carvalhinhos

Department of Medicine II, Santa Maria Hospital, LisbonProgressive Systemic Sclerosis is a connective tissue disease characterised by esophageal involvement in up to 70%. Severe gastroesophageal reflux and dysphagia follow esophageal dysmotility. Impaired peristalsis of the distal body with low lower esophageal sphincter pressure are the distinguishing features.*Methods:* In order to evaluate the frequency and nature of esophageal dysmotility in PSS, 102 consecutive standard manometry recordings were reviewed (19 males, 83 females). The mean age was 48.9 years (range 17–82 years). Twenty-three (22.5%) patients had no esophageal complaints. Of the remaining 79 patients, 58 (56.9%) had heartburn, 31 of them also had dysphagia. Dysphagia was the main complain in 15 patients. Six patients had other symptoms.*Results:* Fifty (49%) patients showed aperistalsis of the distal esophagus; 14 (28%) of them with simultaneous low LES pressure; 37 (36.2%) had a normal or inespecific motility disorder of the esophageal body; 14 (13.7%) showed low amplitude peristaltic waves and one patient had low LES pressure alone. Fifty-five (69.6%) symptomatic patients and 10 (43.5%) patients without esophageal symptoms presented motility changes suggesting PSS.*Conclusions:* (1) Sixty four per cent (65/102) of our patients showed esophageal involvement by PSS, mainly (49%) smooth muscle aperistalsis; (2) The occurrence of esophageal complaints was highly suggestive of disease involvement, but more than 40% of the assintomatic patients also presented motor abnormalities suggestive of PSS; (3) Low LES pressure occurred in 14.7% of the patients, almost exclusively (93%) associated with impaired peristalsis of the esophageal body supporting that the primary abnormality in the pathogenesis of the GER in PSS is an abnormal clearance.

"P P 47 1136"P 47 1136**Esophageal Motor Disorders in Diabetic Patients**

*N. Pandolfo, F. Gianiorio, L. Spigno, P.L. Bozzano, F.P. Mattioli

Clinica Chirurgica R, University of Genoa, Genoa, Italy*Aim of the study* is to detect the presence of esophageal motor disorders in diabetics and to establish whether their seriousness is related to the kind of diabetes and to the presence of diabetic neuropathy.*Materials and methods:* we studied 16 patients (5 m, 11 f, mean age 44, range 19–67) affected with Diabetes Mellitus. Fourteen of those subjects were suffering from the Insulin-dependent kind of diabetes and were treated with this hormone; two patients were treated with oral antidiabetic drugs. Eight patients were suffering from peripheral neuropathy (the diagnosis was supported by cardiovascular authonomic neuropathy tests); eight subjects were complaining gastro and/or esophageal symptoms (dyspepsia and/or heartburn). A station pull-through was used to perform esophageal manometry. The Arndorfer E8M3R catheter (8 channels, 4 of them radial) was used. This catheter was connected to a computerized poligraph by means of a pneumo-hydraulic system and external transducers. The software used to compute the results was created at our Institute.*Results:* the study of esophageal motility showed the presence of alterations in all patients. In particular, mean LES pressure was lower than normal values (12.8 – 4.3 vs 20.4 – 2.4, $p < 0.01$). In neuropathic patients LES pressure was lower than non-neuropathic patients (10.3 – 4.3 vs 15.4 – 2.6, $p < 0.05$). A good correlation was found between LES pressure and neuropathic score. Esophageal peristalsis was altered in all patients: nine patients had lower-amplitude waves, four had higher-amplitude waves, twelve had multipeaked waves. The duration of the primary waves was significantly longer in all diabetic patients (5.0 – 1.1 vs 3.7 – 0.5, $p < 0.01$). Four neuropathic patients (score {\'b3} 4) had non-peristaltic waves in more than 50% of swallowings. Three of them had 20% of retropulsive waves.*Conclusion:* Esophageal manometry can be considered an useful method to evaluate autonomic neuropathy in diabetic patients.

"P P 47 1137"P 47 1137**Oesophageal Gastric and Ano-Rectal Motility Disorders in Patients with Diabetic Neuropathy**

*T. Wittmann, A. Roszt\'f3czy, A. Feh\'e9r, T.T. V\'e1rkonyi, Cs. Lengyel, I. Molnar, J. Lonovics

First Department of Medicine, Albert Szent-Gy\'f6rgyi Medical University, Szeged, HungaryThe impairment of the gastrointestinal smooth muscle function as a complication of the diabetes mellitus is well known. The incidence and the predilectory sites of the gastrointestinal motility disorders and its relationship to the autonomic neuropathy remains still poorly investigated.Our *objectives* were to examine the motor function at different levels of the gastrointestinal tract in diabetics. Second, whether the cardiovascular reflex test and/or the sensory tests, which are generally used to establish the degree of autonomy neuropathy in diabetes mellitus, can predict the severity of the gastrointestinal motor dysfunction.*Patients, methods:* 10 diabetics (6 male, 4 female) with different gastrointestinal symptoms were studied. The mean age was 59 (39–72) years. The mean duration of their diabetes was 17 (4–51) years. The gastrointestinal motor function was examined by oesophageal, gastric and anorectal manometry (Polygraph HR, Polygram 5.06C2, Synectics Medical). Parameters studied: Coordination of pharyngeal (PHX) contraction and upper oesophageal sphincter (UOS) relaxation; the amplitude, the duration, the propagation velocity, the wave morphology of oesophageal body (OB) contractions at 3, 8, 13 and 18 cm above the lower oesophageal sphincter (LOS); the mean pressure the relaxation time and rate of the LOS; the fasting type gastric MMC patterns; basal pressure of the external and internal anal sphincters (EAS, IAS), the recto-anal inhibitory (RAI) and conractory (RAC) reflexes, the voluntary contraction and the expulsion. All patients had an initial cardiovascular autonomic neuropathy (CAN) and a sensory neuropathy (SN) test.*Results:* The of the CAN (mean score: 5.1 – 0.8) and SN tests proved a moderate autonomy neuropathy in average. We did not observe any abnormalities of the UOS and the PHX function except one case. In the OB, the amplitude of contractions was frequently decreased (9/10 patients at 18 cm, 7/10 at 3 cm above the LOS) with prolonged duration in 50% of the cases. The rate of simultaneous waves was increased in 4/10 patients. LES abnormalities (pressure and relaxation time) was found in 5/10 cases. The presence of gastric motility disorders was prominent. We observed the absence of MMC phase III. activity in 9/10, of which complete paresis was found in 6 cases. The most frequent abnormality of the rectoanal function was the impairment of the voluntary contraction (7/10). Abnormalities of the baseline EAS and/or IAS pressures; RAC and RAI reflexes were less pronounced (4–5/10). We could not observe close correlation between the result of the CAN test and the alteration of the studied parameters of the gastrointestinal motility.In this small series of patients we can *conclude* that the abnormalities of the sphincters function are less pronounced, than the impairment of the oesophageal body or gastric motility. Second, the presence and/or the severity of the gastrointestinal motor dysfunction in diabetic patients can not be predicted by the standard CAN or SN tests.The study was supported by a grant of Ministry of Social Welfare (ETT: T-02 533/93). Motility, general: Functional GI disorders }" "Oesophageal Gastric and Ano-Rectal Motility Disorders in Patients with Diabetic Neuropathy"

"P P 47 1138"P 47 1138**Manometric Study of Errosive Esophagitis: Correlation of Manometric Findings with Healing and Symptoms Improvement**

*D. Kamberoglou, L. Kafadaris, A. Psichos, E. Patrikios, V. Doulgeroglou, V. Tzias, M. Lagoudakis

Endoscopy Department, 1st IKA Hospital, Athens, GreeceThe aim of this study was to correlate manometric findings with the natural history of gastroesophageal reflux (GER) disease in patients with errosive esophagitis. 33 symptomatic pts (17 F, 18 M; mean age 59, range: 28–82 yrs) underwent, endoscopy and manometry. Symptoms were scored (scale 0–9) before and after treatment. All patients were initially treated with omeprazole 20 mg for 4 weeks (regimen A). If healing was not achieved they continued on 40 mg for another 4 weeks (regimen B).*Results:* In 23 (69.7%) pts (Group A) esophagitis was healed on regimen A and in 25 (75.7%) (Group A1) symptoms were completely abolished. In 10 pts (Group B) esophagitis was improved on regimen A and in 5 of them complete healing was achieved on regimen B (overall healing: 84.8%). In 8 pts (Group B1) symptoms were improved on regimen A and 7 of them were completely asymptomatic on regimen B (overall symptoms eradication: 96.9%). Symptoms score after regimen A was significantly lower compared with the initial score (0.4 – 0.14 vs 5.3 – 0.26; $p < 0.001$). Pts as a whole had hypotensive (8.87 – 0.75 mmHg) lower esophageal sphincter (LES) and in 5 (15%) of them a nonspecific esophageal motor disorder (NEMD) was found. When comparing group A with group B and group A1 with group B1 as far as LES pressure, wave amplitude and duration and velocity of peristalsis, no significant differences were seen. Pts in group B were more likely to have NEMD compared with group A but this was not significant. In contrast pts in group B1 (symptoms improvement) had more frequently NEMD compared with group A1 (asymptomatic) ($X^2 = 4.1$; $p < 0.05$). Hiatus hernia, smoking, alcohol, age and sex did not affect natural history of GER disease.*Conclusions:* 1) In 84.8% of pts with errosive esophagitis complete healing of inflammation is achieved on two-month treatment with omeprazole although nearly all (96.9%) are completely asymptomatic. 2) The presence of NEMD significantly delays symptoms eradication. Endoscopy Department, 1st IKA Hospital, Athens, GreeceGER and its complications is a very common disease in the general population. The aim of this study was to consider manometric findings in patients with GER prior to surgery. Endoscopy and manometry were performed in 55 pts (28 F, 27 M; mean age 57, range: 28–82 yrs) with long-lasting GER symptoms and continuous use of antisecretory and/or prokinetic drugs. Endoscopy showed that 12 pts had esophagitis I, 28 II, 5 III, 7 Barrett's esophagus and in 3 esophagus was normal. 23 (51%) pts had significant sliding hernia (hernia > 3 cm). As far as lower esophageal sphincter (LES) pressure (mean of highest end-expiratory pressures) is concerned, 3 groups of pts were formed: 1) Group A with normal pressure, {\'b3} 10 mmHg: 24 (44%) pts, 2) Group B with low pressure, 6–10 mmHg: 13 (23%) pts and 3) Group C with very low pressure, < 6 mmHg: 13 (23%) pts. Patients as a whole had a mean LES pressure of 9.63 – 0.7 mmHg (range: 2–24). According to these results an anti-reflux operation (Nissen fundoplication) might benefit 31 pts (group B + C) (56%). Another 7 pts with significant hiatus hernia could also be included increasing the percentage to 69% (38 pts in total). In 8 (14.5%) pts a nonspecific esophageal motor disorder (NEMD) was diagnosed and in 5 (9%) of them who also had a hypotensive LES, an alternative type of surgery might be considered.*Conclusion:* Esophageal manometry is of great value in patients with GER disease prior to surgery since it helps distinguishing the group with normal LES pressure who are unlikely to benefit from it. Nevertheless in 9% of pts with a NEMD a different surgical approach could be considered. "P P 47 1140"P 47 1140**Correlation between Esophageal Clearance and Esophageal Motility in Patients with Gastroesophageal Reflux (GER)**

*D. Kamberoglou, A. Psichos, S. Georgiou, V. Doulgeroglou, V. Tzias, M. Lagoudakis

Endoscopy Department, 1st IKA Hospital of Athens, GreeceThe aim of this study was to examine the relationship between esophageal clearance expressed by the duration of reflux episodes and parameters of esophageal body motor function. 32 patients (13 F, 19 M; mean age 53, range 22–81 yrs) with symptomatic GER and positive 24 h ambulatory pH study who also underwent endoscopy and manometry entered the study. Mean duration of reflux episodes was calculated by dividing time in min the pH was below 4 by number of episodes (total, upright and supine position). According to motor function patients were classified in two groups: A) with normal manometry (17 pts; 5 F, 12 M mean age 44.3) and B) with abnormal manometric findings (15 pts: 8 F, 7 M, mean age 62.6). 12 pts in group B had a degree of failed peristalsis (mean after 10 wet swallows 85.5%; range 0–92%), 3 abnormal wave amplitude (mean in lower esophageal third after wet smallow < 30 or > 180 mmHg), 1 incomplete lower esophageal sphincter relaxation and 1 triple-peaked contractions. 13 pts (40.6%) had erosive esophagitis and 3 (9%) a hiatus hernia (> 3 cm). All pts had abnormal 24 h pH study (mean total time with pH < 4: 13.6%; range: 4.1–40.7%). Group B pts had significantly longer reflux episodes compared with group A (2.44 – 0.48 vs 1.57 – 0.24; Mann Whitney U test: $p < 0.05$) and this difference seems to be entirely due to the results in supine position (5.28 – 1.25 vs 2.44 – 0.45; $p < 0.05$) since no significant difference was found in upright position (1.28 – 0.12 vs 1.09 – 0.15). No correlation was found between esophageal clearance and wave amplitude ($r_s = 0.14$). Pts with dismotility were significantly older than those with normal manometry (62.6 vs 44.3 yrs; $p < 0.01$). Age correlated well with esophageal clearance ($r_s = 0.45$; $p < 0.05$).*Conclusions:* 1) Esophageal clearance is significantly prolonged in patients with GER and abnormal manometric findings. 2) Wave amplitude does not seem to affect the duration of reflux episodes in these pts. 3) Age seems to influence esophageal motility and subsequently to prolong esophageal clearance. "P P 47 1141"P 47 1141**Erythromycin Enhances Esophageal Motility in Patients with Gastroesophageal RefluxG. Tzovaras,**

*E. Xynos, E. Epanomeritakis, E. Chrysos, J. Tsiaoussis, N. Kariotakis, A. Mantides, J.S. Vassilakis

Dept of General Surgery, University Hospital of Heraklio*Background:* It has been shown that i.v. erythromycin (ER) enhances gastric and esophageal motility in both health and disease, acting either as a motilin agonist or as a cholinergic factor.The *Aim* of the study was to invastige any possible effect of i.v ER on esophageal motility in patients with gastroesophageal reflux (GER).*Patients-Method:* In 15 patients with GER, proven on 24-hour ambulatory esophageal pHmetry, standard esophageal manometry was performed after giving i.v. either placebo or 200 mg ER. lactobionate (Abbot). The calculated manometric parameters of esophageal motility were the loer esophageal sphincter (LES) pressure, the amplitude and duataion of peristalsis at 5, 10 and 15 cm proximal to LES and the velocity and strength of peristalsis at distal esophagus.*Results:* ER significantly increased LES pressure from 16.5 + 4.6 SDmmHg to 41.3 – 9.7 SDmmHg ($p < 0.001$), without though affecting the postdeglutition relaxation of LES. ER also increased the amplitude (from 78.5 – 34.3 SDmmHg to 97.1 – 39.5 SDmmHg; $p < 0.001$), the duration (from 3.4 – 0.6 SDsec to 3.8 – 0.6 sdsec; $p = 0.005$) the velocity (from 3.1 – 0.8 SDcm/sec to 3.5 – 1.1 SDcm/sec; $p = 0.0047$) and the strength (from 149 – 84 SDmmHgxsec to 200.7 – 103 SDmmHgxsec; $p < 0.001$) of peristalsis at 5 cm proximal to LES. Similarly, ER increased the amplitude of persitalsis at 10 and 15 cm proximal to LES (from 69.7 – 39.3 SDmmHg to 77.4 – 36.9 SDmmHg; $p = 0.049$ and from 35.6 – 20.4 SDmmHg to 48.9 – 36.1 SDmmHg; $p = 0.004$ respectively) and the duration of peristalsis at the same levels (from 3.1 – 0.6 SDsec to 3.3 – 0.5 SDsec; $p = 0.011$ and from 2.7 – 0.6 SDsec to 3 – 0.5 SDsec; $p = 0.003$ respectively).*Conclusion:* I.V. ER imrpoves the impaired esophageal motility in patients with GER. This observation might be of clinical use. "P P 47 1142"P 47 1142**Esophageal Motility in Patients with Gastroesophageal Reflux Disease**

*V.D. Pasechnikov, N.A. Kovaleva

Stavropol Medical Academy, Stavropol, RussiaEsophageal motility (EM) has been shown to be impaired in patients (pts) with gastroesophageal reflux disease (GERD).The aim of this study was to compare EM parameters in GERD pts with controls (ctls), and to determine the effect of different treatment on lower esophageal sphincter pressure (LESP), amplitude, duration, and velocity of esophageal peristaltic contractions (EPC).EM was studied in 30 GERD pts with and without reflux esophagitis (RE), classified as Savary-Miller grades 1–2, and in 10 healthy ctls. LESP was measured by rapid pull-through technique, measurements of amplitude, duration and velocity of EPC were made at 3, 8, and 13 cm above the LES. All measurements were repeated after resolution of symptoms in pts without RE (grade 0) and after healing of RE in grade 1 and 2 pts.All pts had a significantly lower mean LESP ($p_{1-3} < 0.05$) and EPC amplitude in distal esophagus (DEA) than ctls ($p_{1-3} < 0.05$). Grade 2 RE pts had a significantly lower mean LESP ($p_{1-3} < 0.05$) and DEA ($p_{1-2} < 0.05$), than grade 0 and grade 1 RE pts. The duration and velocity of EPC were decreased in all pts when compared to ctls ($p_{1-3} < 0.05$). The incidence of aperistaltic contractions was presented in 40–45% of test swallows (TS) in grade 2 RE pts, in 30–35% of TS in grade 1, and in 15–20% of TS in grade 0. All distinctable EM disorders did not change after resolution of symptoms in grade 0 pts or healing of RE in grade 1 pts. Cisapride (10 mg tid orally; 4 wks), but not antacids or H_2-receptor antagonists increased LESP (53%), DEA (20%), duration (8%), of EPC in GERD pts.We conclude that impaired EM in GERD pts is preexistent factor in the pathogenesis of RE. Main EM parameters in GERD pts were significantly improved after 4 wks administration of cisapride 10 mg tid orally and did not changed after treatment by antacids and H_2-receptor antagonists. "P P 47 1145"P 47 1145**Clinical and Manometric Response to Intrasphinteric Injection of Botulinum Toxin in Achalasia**

*D'Onofrio Vittorio, Giardullo Nicola, Iaquinto Gaetano

Gastroenterology and Digestive Endoscopy Service, San G. Moscati Hospital, Avellino ItalyBotulinum Toxin (Botox') has been reported to reduce successfully the lower esophageal sphincter pressure (LESP) and achieve significant symptomatic relief in patients with achalasia. Experience so far suggests that Botox is safe and efficacious at least in the short term (NEJM, 332 (12): 774, 1995). *Aim:* We examined the manometric, radiological and symptomatic efficacy of intrasphinteric Botox administration in adult achalasic patients as well as the complications and adverse effects associated with this procedure. *Methods:* 8 consecutive patients (6 women, 2 men, mean age: 59 years) without a previous history of esophageal surgery or dilatation were enrolled in the study. There were 6 classic and 2 vigorous achalasia. All patients had achalasia newly diagnosed using clinical, radiological and manometric criteria. Baseline manometry, symptoms scores, radionuclide emptying test and endoscopy were obtained in all patients within one month prior to Botox, and 4 weeks after. By endoscopy, under direct vision, 100 U of Botox (25 units/ml), were injected to the four quadrants of the lower esophageal sphincter, using a standard sclerotherapy needle. *Results:* Four weeks after the treatment all patients had significant symptomatic improvement with the mean symptom score from 7.5 – 0.7 to 1.9 – 0.3 ($p < 0.01$), and the LESP significantly decreased from 50 – 9 to 25.5 – 11 mmHg ($p < 0.05$). Reappearance of partial peristalsis was observed in 1 of 2 vigorous achalasia but none of the classic achalasia. Neither complications nor adverse effects were booked. Before AfterSymptom score 7.2 – 0.8 2.8 – 0.5Weight loss 1.6 – 0.2 0Dysphagia 3.2 – 0.4 1 – 0.2Chest pain 1.8 – 0.4 0Regurgitation 2.3 – 0.7 1.8 – 0.3LESP (mmHg) 50.4 – 16.4 42 – 8.4*Conclusions:* 1) Botox injection is safe and effective in the treatment of achalasia. 2) Botox treatment produces significant symptomatic improvement and reduction of LESP. 3) Long term randomized studies will need to compare the efficacy, safety and costs of the different treatment options in achalasia. "P P 47 1148"P 47 1148**Relationship of Manometric Changes with Symptomatic Response Following Pneumatic Dilation in Achalasia Cardia PatientsH.M. Shahi,**

*Rakesh Aggarwal, A. Misra, D.K. Agarwal, S.R. Naik

Department of Gastroenterology, Sanjay Gandhi Postgraduate Institute of Medical Sciences, Lucknow 226014, India*Introduction:* Achalasia cardia is frequently treated with pneumatic dilation, to reduce the lower esophageal sphincter (LES) pressure. Relationship of changes in esophageal manometric findings following dilation with symptom relief is however unclear. We therefore decided to study this relationship.*Methods:* 16 achalasia patients underwent esophageal manometry before and one month after pneumatic dilation. At each time, LES pressure and body motility were recorded. Mean basal esophagus to gastric pressure gradient (MIEP-MIGP), a measure of esophageal retention, was calculated.*Results:* 12 patients had good dysphagia relief (GR) and four had poor relief (PR). Manometric changes were similar (p = ns) in GR and PR groups [data as median (range) in mmHg]: Parameter Good relief (n = 12) Poor relief (n = 4) Before After Before AfterLES pressure 42 (17–51) 18 (3–39) 51 (25–68) 30 (23–42)MIEP-MIGP 5.9 { -}1.9 2.5 { -}2.9 ({ -}1.8 to 12.0) ({ -}5.3 to 3.0) (0.3 to 3.5) ({ -}5.8 to { -}1.3)In PR patients, dysphagia persisted despite reduction in LES pressure and amelioration of esophageal retention as evidenced by reversal of MIEP-MIGP.*Conclusions:* Esophageal manometric changes may not correlate with symptomatic response. Persistent dysphagia in achalasia patients who respond poorly to dilation may be related to abnormal peristalsis than to LES hypertension. "P P 47 1149"P 47 1149**Operative Treatment of Achalasia: Our Experience**

*E. Battaglia, L. Dughera, A.M. Serra, V. Debernardi, G. Buonafede, P.R. Mioli, E. Masenti, G. Emanuelli

Dept. of Clinical Pathophysiology, University of TorinoIn the period January 1985–January 1996, 168 cases of esophageal achalasia (62 m, 106 f, age range 11–85 yr) were referred to our Department for evaluation and treatment. Symptoms' onset was comprised between 3 months and 20 years, and their incidence was as follows: dysphagia (99.5%), weight loss (92.2%), food regurgitation (71.7%), non-cardiac chest pain (57%), pyrosis (30.7%), nocturnal pulmonary aspiration (29.4%), nausea (23%). Radiological abnormalities (esophageal body dilatation, ""bird's beaking"" of the lower esophageal sphincter (LES), tertiary contractions, etc) were found in 80% of patients. Endoscopic evaluation showed abnormal findings (erosive esophagitis, *Candida* esophagitis, food impaction) in 72% of cases. Esophageal scintigraphy was always abnormal, with a residual of radioisotopic compound of 80–100% after 20 minutes from ingestion. Manometry showed typical aperistaltic features and lack of LES relaxations in all patients, with an average LES pressure of 32.5 – 10 (SEM) mmHg (n.v. 10–40 mmHg): 11 patients (5.6%) had a progression to achalasia from a previous diagnosis of diffuse esophageal spasm. All patients were initially treated with sublingual nifedipine, 10–40 mg/day. Then, most of them (160 pts) underwent an operative treatment, consisting of Heller myotomy associated with anti-reflux procedures (140 pts, 83%), and pneumatic dilatation of cardia (20 pts, 12%). Pneumatic dilatation consisted of 3 sessions, carried out at one-week intervals. Post-operative course was almost uneventful, and 6 complications (4 cases of pneumonia and 2 pleural effusions) were observed; no deaths were reported. Following pneumatic dilatation, one patient underwent surgery due to esophageal perforation. After 6 months, esophageal manometry documented a return of esophageal peristaltic activity in 16 (11%) of patients undergoing surgery. After 1 yr, all patients having a surgical procedure were asymptomatic, whereas only 2 (1%) of those treated by pneumatic dilatation of the cardia were asymptomatic.In our experience, a surgical approach to achalasia is a safe and effective therapeutic option, whereas less convincing results have been obtained with pneumatic dilatation of the cardia. Clinical practice: Management strategyMotility, specific: OesophagusEndoscopy, specific: Oesophagus }"

"P P 47 1151"P 47 1151**Achalasia: Results of Esophagomyotomy in Patients Having Failed to Respond to Dilatation Therapy**

*E.P. Cosentini, G. Berlakovich, J. Zacherl, G. Stacher-Janotta, G. Stacher, E. Wenzl

Div. of General Surgery and Psychophysiology Unit, Dept. of Surgery, University of Vienna, W\'e4hringer-G\'fcrtel 18–20, 1090 Vienna, Austria*Introduction:* Balloon dilatation under endoscopic control is commonly accepted as the first choice of treatment for achalasia. However, adequate treatment results are obtained in a significantly smaller proportion of patients than with esophagomyotomy.*Patients:* We investigated the results of Gottstein-Heller myotomy with or without antireflux procedure in 19 female and 19 male patients, in whom pneumatic dilatation had failed to yield satisfactory results. At the time of investigation the patients' age ranged from 17 to 85 years (median, 54 yr), the time elapsed since the operation from 0.5 to 24 yr (M, 6 yr). In 33 patients the myotomy had been combined with a fundoplication and in 2 with a fundopexy. Before myotomy they had suffered from severe to very severe dysphagia for liquid, semisolid and solid meal constituents and had undergone 1 to 8 dilatations.*Results:* At the time of investigation 15 patients were entirely symptomfree. Eleven patients could stomach their ingesta only by drinking after each bite; before myotomy, this had been the case in all patients. Three patients had dysphagia of intermediate degree for solid meal constituents and 1 only slightly less severe dysphagia than before the operation. In one patient the operation had not yielded any positive effect. In all except of the two latter patients the body weight had increased by 5 to 45 kg (M, 13.5 kg). Each one patient suffered from reflux esophagitis, a cicatrical hernia, and a sliding hiatal hernia, all of which had arisen after the myotomy. Two patients, who postoperatively had been more or less symptomfree, had recommenced to suffer from dysphagia 2 and 3.5 yr later. Their dysphagia, however, was less intense than before the operation and their weight was markedly higher. In 24 patients the passage through the esophagus of a 10-ml water-bolus labelled with 250 mCi 99m-Tc sulphur colloid could be studied with the patient in the supine position. A normal passage was present in only one patient, and a slightly delayed passage in 2 others. In 8 patients between 23% and 84% of the bolus and in the remaining 13 the entire bolus was still present in the esophagus after 120 s. Manometric investigations performed in 23 patients revealed that the resting pressure of the lower esophageal sphincter was 23% to 29% lower than before myotomy and higher in only one patient, who also suffered from severe dysphagia.*Conclusion:* It is concluded that the surgical treatment of achalasia yields good results in a high proportion of patients, in whom dilatation treatment had failed to achieve satisfactory results. }" "Achalasia: Results of Esophagomyotomy in Patients Having Failed to Respond to Dilatation Therapy"

"P P 48 1152"P 48 1152**Is Routine Conscious Sedation or Topical Pharingeal Anesteshia Necessarily in Upper Emergency Endoscopy in Bleeding Patients?**

*S. Mosca, A. Balzano, V.P. Rocco, A. Bove, A. Sergio, T. Gigliotti

Dept. of Gastroenterology A. Cardarelli Hospital Naples ItalyUpper emergency endoscopy in bleeding is frequently performed in cirrhotic patients. A routine IV conscious sedation may complicate the status of this patients at high risk of encephalopathy because the bleeding status. *Patients:* in the last 12 months [May 1995–Avril 1996) we have performed all the upper emergency endoscopy for bleeding without any routine medication. The patient was reassured and was gently and energically requested to cooperation for the success of procedure. With the patients in the left decubitus position, gentle intubation was achieved with a endoscope (generally a 10.5 mm). During the procedure the patients was continuously reassured by the physician or by the assistant. We have performed. 583 endoscopies in bleeding patients: of these 192 were performed in cirrhotic patients: 56 patients requiered sclerotherapy and 26 patients a balloon tamponade. An injective emostasis was performed for bleeding ulcers in 77 patients. No insuccess of procedure or diagnostic or therapeutic may be imputaded to patient cooperation. *Conclusion:* Routine IV conscious sedation or topical pharingeal anesthesia is unnecessary in upper endoscopy performed for bleeding. The patient may be succesfull prepared with verbal assurance by physician and continuously reassured during the procedure or by physician or by technician. This patient preparation may have advantage especially in the group of cirrhotic bleeding patients that are at high risk of complication by IV sedation. Endoscopy, general: Preparation, managementEndoscopy, general: GI bleeding }" "Is Routine Conscious Sedation or Topical Pharingeal Anesteshia Necessarily in Upper Emergency Endoscopy in Bleeding Patients?"

"P P 48 1155"P 48 1155**Risks, but No Benefits of a Midazolam-Fentanyl Combination as Premedication of ERCP**

*C. Schwertner, M. Mayr, H. Leistert, W. Londong

2nd Medical Department (Gastroenterology), Krankenhaus Am Urban, Berlin, GermanyThe benefit of combining benzodiazepine with an opioid as premedication for more complex endoscopic procedures remains poorly defined. Therefore, we performed a double blind, randomized, placebo controlled study comparing midazolam plus fentanyl with midazolam alone as premedication of ERCP. *Method:* Consecutive in-patients (n = 115) undergoing diagnostic and/or therapeutic ERCP were randomized to receive either an intravenous combination of midazolam (5–15 mg) plus fentanyl (0.05 mg standard dose) or midazolam alone (5–20 mg); midazolam was individually titrated. Oxygen saturation (SaO_2), blood pressure, heart rate and arrhythmias were monitored continously, using a multifunction monitor. The degree of sedation during the examination and the patients' acceptance were rated. The two groups were comparable with respect to age, sex, body-weight, risk-group (ASA), initial SaO_2, indication, type, duration of the procedure and titrated dose of midazolam.*Results* are expressed as median (range). mida + fenta (n = 58) mida + placebo (n = 57) pMinimum SaO_2 (%) 88 (70–95) 90 (66–95) 0.013{ D} SaO_2 (%) 7.0 (2–22) 5.0 (3–28) 0.009Following midazolam-fentanyl SaO_2 dropped below 85% in 16 patients compared to 4 with midazolam (p = 0.004). Besides fentanyl, age and risk-groups II and III were independent predictors of hypoxemia. Transient fall of blood pressure, increase of heart rate, incidence of arrhythmias and patients' acceptance were not significantly different. There was a trend to a more effective sedation in the midazolam-fentanyl group (p = 0.063). In *conclusion,* the combination of midazolam-fentanyl increases the risk of respiratory depression in comparison with midazolam alone. There was no signifacant difference concerning the benefits, f. e. degree of sedation and patients' acceptance. The theoretical premise that fentanyl used in combination should reduce the dose of midazolam was not confirmed. Endoscopy, general: Preparation, management }" "Risks, but No Benefits of a Midazolam-Fentanyl Combination as Premedication of ERCP"

"P P 48 1176"P 48 1176**Optimal Number of Biopsy Specimens and Brush Cytology in the Diagnosis of Gastric and Colorectal MalignanciesL. Demirt\'fcrk, Y. Yazgan,**

*M. \'d6zel, A.K. G\'fcrb\'fcz, M. Danaci

GATA Haydarpasa Training Hospital, Istanbul, TurkeyRetrospective studies have indicated that endoscopic biopsies yielded a positive diagnosis in 57–86% and cytology in 71–98% of colon cancers. The aim of our study is to identify the optimal strategy of biopsies and cytology in cases with mass lesions in upper and lower gastrointestinal system. Gastric (%) Colorectal (%)Cytology alone 75.00 76.474 biopsies 52.08 79.416 biopsies 68.75 88.248 biopsies 89.86 91.0510 biopsies 93.83 94.12Cytology + 4 biopsies 87.50 89.18Cytology + 6 biopsies 93.28 92.86Cytology + 8 biopsies 94.46 93.14Cytology + 10 biopsies 95.83 94.1261 patients with gastric or colorectal masses were included in the study. Biopsy specimens were put into 4 vials, with 4 biopsies in the first, 2 in the second, 2 in the third and 2 in the fourth one. Based on our data, 9 discrete combinations of biopsies and cytologies were made and the results shown in the table were found. Lower diagnostic rate in first biopsies was found (52.08%) in gastric malignancies, when compared to the 79.41% in colorectal cancers. The percentage of cytology alone was comparable in both groups (75% and 76% respectively). When cytology was added to the first four biopsies in gastric malignancies, the rate increased to 87.50%, and to 89.18% in colorectal malignancies. There seemed to be no difference between cytology and 10 biopsies in both groups. With combination of biopsy and cytology, diagnosis could not be made in 4–6% of cases.Cytology and 6 biopsies had the same diagnostic range as 10 biopsies did and cytology added to 10 biopsies did not increase this diagnostic range significantly. We conclude that cytology and 6 biopsies appear to be the optimal strategy in the diagnosis of gastric and colorectal malignancies. "P P 48 1183"P 48 1183**Preoperative Parathyroid Imaging Using Echoendoscopy in Primary Hyperparathyroidism: A Prospective Preliminary Study**

*J.M. Raymond[1], B. Catargi[2], F. Leprat[2], V. Ledhingen[1], P. Roger[2], D. Ducassou[3], J. Drouillard[4], J.L. Latapie[2], P. Couzigou[1], M. Amouretti[1]

[1] Department of Gastroenterology, Hopital Haut-L\'e9v\'eaque, 33604 Pessac, France

[2] Department of Endocrinology, Hopital Haut-L\'e9v\'eaque, 33604 Pessac, France

[3] Department of Nuclear Medecine, Hopital Haut-L\'e9v\'eaque, 33604 Pessac, France

[4] Department of Radiology, Hopital Haut-L\'e9v\'eaque, 33604 Pessac, France*Purpose:* Parathyroid adenomas responsible for primary hyperparathyroidism (PHPT) are difficult to detect preoperatively. As most of parathyroid adenomas arise below and/or behind the thyroid gland, and as abnormal parathyroid glands are situated in the mediastinum or in a deep cervical location, we assessed the ability of echoendoscopy (EE) to localize parathyroid adenomas.*Methods:* 6 females and 3 men (age 54.4 – 16.5 years) with PHPT (calcium concentration 2.9 – 0.4 mmol/l with inappropriate parathormon levels 297.6 – 284.7 ng/l) were studied. A single eutopic parathyroid adenoma was confirmed at surgery in 7 cases. One patient became normocalcemic after a percutaneous infusion of ethanol in the adenoma. One patient had no lesion at surgery. All patients underwent ultrasonography (US), Tc 99 m sestamibi scanning, CT scanning or magnetic resonance imaging (MRI) and EE before undergoing initial neck exploration. EE was performed by a single physician, under general anesthesia, using 7.5 and 12 Mhz probe (Olympus EUM20). The duration of the exam was 15 minutes. The operative findings were recorded and correlated with the results of preoperative studies.*Results:* 6 of the 8 adenomas were correctly localized using EE and sestamibi scanning. 2 of these tumors were undetectable using CT scanning/MRI. Conversely CT scanning/MRI detected 2 adenomas that were not identified by EE and sestamibi scanning. US correctly localized only 4 adenomas. In one case; sestamibi scanning, MRI and EE visualized a lesion which was not found at surgery.*Conclusion:* the sensitivity of EE to detect parathyroid adenomas was roughly equivalent to that of sestamibi scanning or CT scanning/MRI. Thus, EE may be a useful tool for the preoperative investigation in patients with PHPT. Our results have to be confirmed in larger series of patients, especially in patients with small, and/or abnormal located parathyroid glands and above in patients with persistent or recurrent PHPT after surgery. "P P 49 1186"P 49 1186**Uncommon Locations of Hydatid DiseaseM. Safioleas,**

*E. Misiakos, Gr. Kouraklis, Chr. Manti, E. Karanikola, A. Papachristodoulou

2nd Department of Propedeutic Surgery, Athens University Medical School, Laikon General Hospital, Athens, GreeceHydatid disease is still a challenging diagnostic and therapeutical problem especially in endemic countries; the most commonly involved organs are the liver, the lung and less often the spleen. The aim of this study is to present the possibility of other locations of hydatid cysts in solid organs or other anatomic sites rarely encountered.During the last 20 years, 12 patients were operated on for uncommon locations of hydatid disease. There were 6 men and 6 women with a age range of 27 to 86 years (mean age 60.4 years). There were 2 cases with hydatid cysts located in the gallbladder, 4 cases in the pancreas, one case in the kidney, one case in the thyroid gland, one in the breast, one in the pericardium, one in the supraclavicular region and one in the thigh. Clinical symptomatology varied according to anatomic location and preoperative diagnosis was accomplished with radiological examinations, ultrasound or computerized tomography. Surgical treatment included cholecystectomy in the 2 cases with hydatid cysts in the gallbladder, omentoplasty or peripheral resection of the pancreas in the 4 pancreatic cases, nephrectomy in the kidney case, lobectomy in the thyroid case and cyst excision in the rest cases. In all cases histopathological examination of the surgical specimens confirmed the diagnosis. One patient with pancreatic resection died postoperatively, while the remaining 11 patients did not have any significant complications.In conclusion, hydatid disease should be included in the differential diagnosis of cystic masses in solid organs or other anatomic sites especially in endemic countries; hydatid cyst excision is curative and confirms the diagnosis. Radiology and ultrasound: Diagnosis }" "Uncommon Locations of Hydatid Disease"

"P P 49 1187"P 49 1187**Parasitic Liver Disease**

*A.E. Mohamed, M.A. Al Karawi, Z. Ghandour

Dept. of Gastroenterology, Armed Forces Hospital, Riyadh, Saudi ArabiaSeveral parasites infest the liver and biliary tree. Ascaris may be present in the liver or in the biliary tree and cause obstructive jaundice due to worms or associated stones. In schistosomiasis the liver may be involved early or later leading to periportal fibrosis and portal hypertension. We have studied 72 patients with hepatosplenic schistosomiasis, liver ultrasound showed periportal fibrosis in 48 and in 30 liver biopsy showed bilharzial granuloma or fibrosis.In amaebiasis tender hepatomegally may present during the acute phase while more commonly in chronic carriers, an amaebic abscess develops. We have treated 3 patients with amaebic liver abscess in two of which percutaneous drainage was done.Hydatid cysts of the liver may be large and cause pressure on the liver or rupture into the biliary tree causing obstruction. In our unit we have introduced endoscopic management for such cases and we have treated successfully 10 patients. Between 1985–1990 we have treated 22 patients with albendazole alone. After 1990 we have introduced combination therapy in 19 patients (Albendazole + Praziquantel) and was found to be more effective than albendazole alone. Ten other patients had percutaneous drainage of a huge liver cysts.Liver flukes infest liver and can cause biliary tree obstruction causing recurrent cholangitis. One of our patients from Thailand had obstructive jaundice and ERCP showed multiple Clonorchis sinensis worms and an associated cholangiocarcinoma.During 3 years we have studied 208 patients with Human Dicrocoeliasis, 16 of these patients had disturbed liver functions and 10 patients had gall-bladder or biliary tree disease. "P P 49 1188"P 49 1188**Eliza in Diagnosis of CryptosporidiosisS. El-Ghoneimy,**

*M. El-Khashab, Aboul-Maged

Faculty of Medicine Zagazig Universty EgyptMany authors considered Cryptosporidium as one of the main causes of diarrhoea in man. In the present work stool analysis and ELISA test were performed to detect Cryptosporidium oocyst and antibody in the stool and sera respectively of 206 patients with acute diarrhoeal disease and 15 healthy individuals as a normal control group.It was found that Cryptosporidium oocysts were detected in 35 cases (16.9%). Most of them aged less than 10 years, with insignificant difference between male and females. Stool of Cryptosporidium infection was offensive, watery and yellowish. ELISA was positive in 32 out of 35 cases having Cryptosporidium oocyst with 91.4% sensitivity and was negative in 32 out of 40 negative cases by stool examination with 80% specificity.Thus Cryptosporidium oocyst should be looked for in routine examination of diarrhoeal stool especially of young patients. ELISA is a simple easily performed serological test with high sensitivity and specificity in detecting Cryptosporidium infection. Association of other parasitic infections with cryptosporidiosis did not affect the optical density (O.D.) reading of infected cases and to avoid cross reaction, fractionated oocyst antigen may improve the test specificity. Immunology and microbiology: GI infections in adults }" "Eliza in Diagnosis of Cryptosporidiosis"

"P P 49 1189"P 49 1189***Salmonella Typhimurium INV* Mutants Invade Intestinal M Cells**

*M.A. Clark, B.H. Hirst, M.A. Jepson

Department of Physiological Sciences, Medical School, University of Newcastle upon Tyne NE2 4HH, UKInvasion of intestinal epithelial cells is a crucial step in *Salmonella* pathogenesis. Recent studies employing ligated murine intestinal loops have demonstrated that the specialised antigen sampling intestinal M cells are the primary site of *Salmonella* invasion. While the precise mechanisms and genetic basis responsible for *Salmonella* invasion of epithelial cells remain obscure, mutagenesis studies have identified a number of genetic loci necessary for internalisation of *Salmonella* into cultured epithelial cells. The significance of these loci *in vivo* is, however, unclear. The aim of this study was to investigate the significance of one such locus, *inv,* during *Salmonella* invasion of M cells. *S. typhimurium invA* (SB111) and *invG* (mutant 83) mutants which are severely attenuated for invasion of cultured cells and their parental strains (SR11 and TNP-5, respectively) were incubated in Peyer's patch-containing ligated intestinal loops which had been created in anaesthetised mice. After incubation, the tissues were harvested, fixed and dual stained for bacteria and M cells. Examination by confocal laser scanning microscopy revealed that both parent and mutant strains readily adhered to and invaded M cells: no difference could be detected between parent and mutant strains in their interaction with these cells. Bacterial association with M cells was accompanied by a redistribution of *Ulex europaeus 1* staining of M cells and by the formation, as detected by scanning electron microscopy, of M cell surface protrusions indistinguishable from the ""membrane ruffles"" previously described in association with other wild type *Salmonella.* These observations demonstrate that *Salmonella* invasion of murine M cells may proceed via mechanisms independent of the *inv* locus which is essential for invasion of cultured cells. The multifactorial nature of *Salmonella* invasion may account for the ability of many *Salmonella* to infect a range of hosts and to invade a variety of cell types. Immunology and microbiology: GI infections in adults }" "Salmonella Typhimurium INV Mutants Invade Intestinal M Cells"

"P P 49 1190"P 49 1190**Organ Involvement in Hepatointestinal Schistosomiasis**

*Z. Ghandour, A.E. Mohamed, M.A. Al Karawi, M.I. Yasawy

Armed Forces Hospital, Riyadh, Saudi ArabiaThe endoscopic, radiological and histological findings in several of our patients with schistosoma mansoni infection are described. Seventy two patients had hepatosplenic schistosomiasis. Endoscopic sclerotherapy was effective in 45 patients with bleeding varices.Ultrasound of the liver was suggestive of peri-portal fibrosis in 48 of these 72 patients and in 30 of whom liver biopsy demonstrated schistosoma granuloma or periportal fibrosis. Gastroscopy showed congestion erosions or ulcerations in the stomach in 40 of these patients and in 23 patients in the duodenum.Schistosoma ova with inflammatory changes were seen in endoscopic biopsies from the stomach in three out of twelve and five out of eight duodenal biopsies. The colonoscopic findings were suggestive of schistosomiasis. Eight patients had schistosomal polyps and one had colonic calcifications. Schistosoma ova were seen in surgical specimens from patients presenting with acute abdomen due to appendicitis in six, cholecystitis in three and mesenteric vein thrombosis in three, in one of which mesenteric angiogram showed a blocked inferior mesenteric vein by ova. Immunology and microbiology: GI infections in adults }" "Organ Involvement in Hepatointestinal Schistosomiasis"

"P P 49 1191"P 49 1191**Intestinal Immune Cells in *S. Stercoralis* Infection**

*A. Trajman, C.C.S. Elia, T.T. MacDonald[1]

Federal University of Rio de Janeiro, Brazil

[1] The Medical College of St. Bartholomew's Hospital, London, UK*Introduction: Strongyloides stercoralis* may cause a wide spectrum of disease in humans, ranging from a chronic asymptomatic infection to a hyperinfective, often fatal syndrome. In rodents, spontaneous expulsion of related parasites after experimental infection occurs. Mast cells, goblet cells and eosinophils have been identified as possible effectors of this expulsion. The aim of the present study was to assess the intestinal immune response in chronic mild strongyloidiasis.*Methods:* We performed a jejunal biopsy in 19 immunocompetent patients with at least one positive stool examination for *S. stercoralis* and few or no symptoms, and in 7 healthy controls. Specimens were processed for histopathological analysis and by the three-stage immunoperoxidase technique, using the following monoclonal antibodies: CD2, CD3, CD4, CD8, TcR-{ g}/{ d}, RFD1, RFD7 (macrophage markers), Ki67+ (proliferating) cells, HLA-DR and collagen IV. In addition, CD25+ cells, mast cells, IgE expressing cells, calprotectin-containing cells (Mac 387+) and neutrophil elastase+ cells were stained by the alkaline phosphatase method. Positive cells were counted using a Seescan Image Analyzer.*Results:* Jejunal morphology and the numbers of different T-cell subsets, mast cells, eosinophils and goblet cells were unaffected by *S. stercoralis* infection. Conversely, the number of mature macrophages and of dividing enterocytes in the crypts was reduced. Crypt enterocytes did not express HLA-DR in both groups. The expression of HLA-DR by villus enterocytes was similar in patients and controls. There were no activated (CD25+) cells in the mucosa of either patients or controls.*Conclusions:* Architectural damage to the mucosa and the resulting immune-mediated diarrhoea apparently do not develop due to the absence of an immune response against the parasite. On the other hand, the infection is allowed to persist for several years. Immunology and microbiology: Host defense mechanismsImmunology and microbiology: InflammationImmunology and microbiology: GI infections in adults }" "Intestinal Immune Cells in S. Stercoralis Infection"

"P P 49 1192"P 49 1192**Does Serum Angiotensin Converting Enzyme Level Raise in Familial Mediterranean Fever?**

*H. Simsek, A. Kadayifci

Hacettepe University Medical School, Ankara, TurkeyThe diagnosis of familial Mediterranean fever (FMF), which is a periodical disease of unknown origin, has usually been based on a knowledge of ethnic status, a positive family history, the exclusion of other disease entities, in addition to clinical findings of polyserositis and elevation of acute-phase reactants during periodic attacks. However, diagnosis of FMF is difficult for clinicians in some cases and there is no specific biological test for FMF. Angiotensin converting enzyme (ACE) is a carboxypeptidase that hydrolyses angiotensin I to angiotensin II and widely found in human tissues. ACE is also produced by sarcoid granulomata cells and elevated serum ACE level is a useful test in the diagnoses of sarcoidosis and monitoring the activity. Persistent raise of serum ACE level in FMF was claimed in a recent case report and FMF has been suggested another cause of raised serum ACE level. However, this claim has not been proved by another study up to now. In this study we aimed to investigate the serum ACE level in our FMF group and to clarify the idea whether ACE level may be a marker of disease or this relation was a fortuitous one. Fifteen patients (6 male and 9 female, with a median age of 27) followed at our center with a diagnoses of FMF were enrolled to the study. The serum sample was obtained in asymptomatic phase of disease in 13 patients and during an acute attack in 2 patients. Serum ACE level was measured by EIA and results expressed as U/L. The normal range of serum ACE level was 5–10 U/L and the minimum detection limit was 1 U/L in this method. The serum ACE level was found in a minimal level in all patients and no elevation was detected.*Conclusion:* This study clearly showed that serum ACE level has not been raised in FMF patients. It is well known that ACE production is increased in only sarcoidosis and certain other granulomatous diseases. Therefore, it seems that, there is no reason for the elevation of this enzyme level in FMF patients. Immunology and microbiology: Inflammation }" "Does Serum Angiotensin Converting Enzyme Level Raise in Familial Mediterranean Fever?"

"P P 49 1193"P 49 1193**Study of Antigenic Sites on the Asialoglycoprotein Receptor Recognize by Autoantibodies**

*O. Hajoui, F. Alvarez

Service de gastroent\'e9rologie, Hospital Sainte-justine, University de Montr\'e9al, Montr\'e9al, Canada*Background & Aims:* Antibodies against the asialoglycoprotein receptor are frequently found in sera of patients with autoimmune hepatitis. The study was designed to identify the antigenic sites on the receptor recognized by specific anti-asialoglycoprotein receptor antibodies.*Methods:* Isolated asialoglycoprotein receptor from normal human liver was used as an antigen in an ELISA test to detected specific antibodies in the sera of patients with autoimmune hepatitis. Positive sera were further tested against the same antigen by Slot blot, Western blot and immunoprecipitation. The mature, unglycosylated and partially glycosylated forms of the asialoglycoprotein receptor synthesized by $HepG_2$ cells were tested against positive patients' sera. The mature receptor in $HepG_2$ differs from the receptor in human normal liver by the H2 subunit sequence and the carbohydrate chains. The recognition by the same sera of the in vitro translated unglycosylated form of the H1 subunit of the receptor was also screened.*Results:* Sera from patients with autoimmune hepatitis recognized the native form of the human mature receptor. No reactivity was found when these sera were tested against the denatured human protein. In addition, neither the unglycosylated H1 subunit nor any of $HepG_2$ synthetized asialoglycoprotein receptor forms bound to the antibodies.*Conclusions:* Anti-asialoglycoprotein receptor antibodies in the sera of patients with autoimmune hepatitis are directed against conformational structures of the mature hetero-oligomeric form of the protein. The carbohydrates chain are probably part of the conformational antigenic sites. Liver and bile ducts, 1: Liver diseases, childrenLiver and bile ducts, 1: Chronic non viral hepatitis }" "Study of Antigenic Sites on the Asialoglycoprotein Receptor Recognize by Autoantibodies"

*J. Graus, R. B\'e1rcena, V. Ure\'f1a, C. Caballero

Hospital Ram\'f3n y Cajal de Madrid, Spain*Purpose:* To study the role of alfa Interferon (IFN) in antibody production during chronic hepatitis C (CHC) treatment.*Methods:* We studied 54 CHC patients measuring thyroid stimulating antibody (TSAb), antiislot cell (ICA), antiinsulin (Ai), antipituitary (Ap) and antiadrenal (Ad) antibody; 86 CHC patients measuring antimicrosomals (AM) and antithyroglobulin (AT) and 60 CHC patients obtaining antinuclear (ANA), antimitochondrial (AMA), antismooth muscle (SMA) and antiliver and kidney microsomes (LKM) antibodies every 3 months during IFN treatment.IFN dosage ranged 1 to 6 million units three times per week.*Results:* When ANA was investigated, 4 patients were found to develop it during treatment. None of the 6 patients showing ANA before treatment, did increase ANA titles with IFN. In one of these 6 patients, the antibody disappeared.No patient developed SMA during treatment. Seven patients were SMA+ before IFN treatment: titles increased in one of them while they became negative in 6 patients.Other studied antibodies (AMA, Ad, ICA, Ai, Ap, and TSAb) were not observed in any case.Six patients presented with AM and 3 with AT previously to IFN treatment showed a title increase during treatment. All of them also showed tyrotropin (TSH) changes.Six different cases develop AM and nine cases AT during IFN treatment. A coincidence was observed in two patients developing AM, AT and ANA.*Conclusions:* 1.- IFN is capable of inducing ANA frequently associated with AM and AT.2.- IFN may drop previously positive ANA and SMA.3.- IFN increase or develops AM and AT titles.4.- AMA, Ad, ICA, Ai, Ap or TSAb are not observed during IFN treatment. "P P 49 1195"P 49 1195**Glutamine Enriched Enteral Feeding Reduces Rat Plasma Nitrate Levels**

*A.P.J. Houdijk, J.J. Visser, E.R. Rijnsburger, T. Teerlink[1], P.A.M. van Leeuwen

Department of Surgery, Free University Hospital, Amsterdam, The Netherlands

[1] Clinical Chemistry, Free University Hospital, Amsterdam, The NetherlandsNitric oxide (NO) is a potent vasodilating and immune modulating agent that is produced in many cell types including endothelial cells and macrophages. It is a product of the enzymatic conversion of L-arginine (ARG) to L-citrulline (CIT) by NO-synthase. Nitrate is the stable endproduct of the NO-pathway. It has been shown that the *in vitro* production of NO in endothelial cells can be inhibited by L-glutamine (GLN). We hypothesized that GLN enriched feeding also inhibits NO production *in vivo.*To investigate this, nitrate measurements were performed in rats fed GLN enriched diets (6.25%, 12.5% and 25%) and compared to rats fed balanced control diets. The respective diets were fed for one or two weeks. Nitrate was measured in the diet, in plasma samples (day 7 and 14) and in samples of 24 hours urine collections. Plasma amino acids were determined weekly.*Results:* In a dose dependent manner GLN supplementation significantly increased plasma levels of GLN (from 630 to 1200 \'b5Mol/L; 91%, p < 0.0001), ARG (from 120 to 139 \'b5Mol/L, 17%, p < 0.001) and CIT (from 50 to 75 \'b5Mol/L; 54%, p < 0.0001). Nitrate levels in the diets did not differ ({ @} 1.70 \'b5Mol/g). Food intake ({ @} 18.0 g) and nitrate intake ({ @} 31 \'b5Mol/day) showed no differences between the groups. Glutamine supplementation resulted in significantly lower plasma nitrate levels ({ @} 50%) in all GLN fed groups ({ @} 15 \'b5Mol/L) compared to control groups ({ @} 27 \'b5Mol/L, p < 0.0001). No further reduction was observed after two weeks of feeding. Between 1 and 4 \'b5mol more nitrate was excreted compared to intake in all groups without any significant differences.*Conclusions:* The decrease in plasma nitrate levels by GLN enriched feedings indicates for the first time an inhibitory effect of GLN on NO production *in vivo.* This effect was not related to the amount of GLN supplementation. Lower nitrate levels was not due to a diminished availability of ARG as substrate for NO synthases, since plasma ARG levels were significantly increased by GLN feeding. Nutrition: Metabolism }" "Glutamine Enriched Enteral Feeding Reduces Rat Plasma Nitrate Levels"

"P P 49 1196"P 49 1196**Prophylaxis Against Pneumococcal Infection after Splenectomy**

*P. Ejstrud, J.B. Hansen, D.A. Andreasen

Departments of Gastrointestinal Surgery and Clinical Chemistry, Aalborg Hospital, 9100 Aalborg, DenmarkSplenectomy predisposes to serious infections from Streptococcus pneumoniae. The aims of the present study were to evaluate prophylaxis against pneumococcal infection after splenectomy.561 patients splenectomised from 1984–1993 were identified and the hospital records were available for 555 patients. The hospital records and the discharge letters were searched for informations on splenectomy and information about pneumococcal vaccination. General practitioners of living, apparently unvaccinated patients were asked for evidence of vaccination. To study differences in relation to the operative indications for splenectomy, the patients were classified into 5 major groups: haematological, trauma, incidental, accidental and other.The total vaccination rate was 62%, but vaccination rates from 47% to 91% in five different groups of indications were observed. Patients undergoing splenectomy during gastrointestinal cancer surgery or because of inadvertent intra-operative trauma to the spleen were particularly at risk of not being vaccinated. 64% of the patients were vaccinated at an inappropriate time in relation to the splenectomy. Recording of splenectomy was missing in 10%, and vaccination status was mentioned in 35% of the discharge letters.The pneumococcal vaccination rates in patients after splenectomy were not satisfactory. The majority of patients were vaccinated at an inappropriate time in relation to the splenectomy. The discharge letters often lacked information concerning the patients' vaccination status. More effort is needed to reach an acceptable level with respect to prophylaxis against pneumococcal infection after splenectomy. Clinical practice: Quality assurance }" "Prophylaxis Against Pneumococcal Infection after Splenectomy"

"P P 50 1207"P 50 1207**Helicobacter Pylori: Is It a Risk Factor for Hepatic Encephalopathy in Cirrhotic Patients?**

*Enas A.R. Al-Kareemy, Madeha M. Zakhary[1]

Department of Internal Medicine, Gastroenterology & Hepatology Unit, Faculty of Medicine, Assiut University, Assiut, Egypt

[1] Department of Biochemistry, Faculty of Medicine, Assiut University, Assiut, Egypt*Objective:* To determine whether Helicobacter pylori (Hp) infection is a risk factor for hepatic encephalopathy in patients (pts) with liver cirrhosis. *Methods:* 108 cirrhotic pts undergoing upper GI endoscopy for detection of oesophageal varices were included in this study: 34 pts Child-Pugh grade A, 60 pts grade B and 14 pts grade C. The aetiology of liver cirrhosis was either posthepatitic or mixed; Bilharzial fibrosis and posthepatitic cirrhosis. Diagnosis of Hp infection was done by histopathology using antral and fundal biopsies, hp fast test and serologically by estimating Hp IgG antibody titers by ELISA (more than 20 u/ml). Estimation of serum NH_3 using an enzymatic assay for all pts was done and the results were compared with that of 24 normal subjects as a control group.*Results:* Serum NH_3 is significantly higher in cirrhotics than in normal controls ($P < 0.001$) 86 cirrhotic pts with Hp +ve were similar to 22 Hp. { -}ve with regard to age, sex, aetiology of cirrhosis and Child score. Hp. +ve had significantly high NH_3 in comparison with Hp { -}ve pts ($P < 0.01$). Also significant high NH_3 in pts grade C compared with grade A ($P < 0.01$) and grade B ($P < 0.01$). Detection of Hp IgG antibodies by ELISA is a sensitive test as it was positive (more > 20 u/ml) in all pts with positive hp fast test and positive histopathology for Hp. There was a significant positive correlation between serum NH_3 levels and Hp IgG antibody titers in cirrhotic pts ($r = 0.9$, $P < 0.001$).*Conclusion:* Hp infection as ammonia producer can be considered as a risk factor for hepatic encephalopathy in cirrhotic patients and may warrants eradication. "P P 50 1211"P 50 1211**Effects of Canrenoate Potassium on Portal Hemodynamics in Patients with Compensated Liver Cirrhosis**

*Masahiko Koda[1], Yoshikazu Murawaki[2], Hironaka Kawasaki[2], Shiro Ikawa[1]

[1] Department of Clinical Laboratory Medicine, Tottori University, Faculty of Medicine, Yonago 683, Tottori, Japan

[2] Second Department of Internal Medicine, Tottori University, Faculty of Medicine, Yonago 683, Tottori, Japan*Aim:* Long-term administration of spironolactone is reported to reduce portal pressure in cirrhotic patients. We examined the effects of acute administration of canrenoate potassium, an aldosterone antagonist, on portal hemodynamics in compensated cirrhotic patients using noninvasive duplex Doppler ultrasonography.*Methods:* Baseline values were obtained in the fasting state, and then 200 mg of canrenoate potassium in 10 ml of saline solution was intravenously administered to 22 patients, whereas 10 ml of saline solution was administered as a placebo to 8 patients.*Results:* The portal cross-sectional area, portal blood velocity and portal blood flow decreased by 5.3 – 9.2, 10.4 – 8.7% and 13.0 – 12.4%, respectively at the nadir 60 min after administration and these decreases persisted until 120 min. Placebo did not affect these parameters of portal hemodynamics. Eleven responders who had a more than 10% fall in portal blood flow 60 min after administration had significantly higher levels of plasma aldosterone than 8 non responders who had less than 10% fall. The reduction rate of portal blood flow was closely correlated with plasma aldosterone level.*Conclusion:* These findings suggest that aldosterone antagonist directly causes a reduction in portal blood flow probably through inhibition of aldosterone-induced vasoconstrictive action. Liver and bile ducts, 1: Cirrhosis: portal hypertensionRadiology and ultrasound: Therapy }" "Effects of Canrenoate Potassium on Portal Hemodynamics in Patients with Compensated Liver Cirrhosis"

"P P 50 1212"P 50 1212**Cytoprotective and Cytoinjurious Factors in Chronic Liver Diseases with Bleeding Gastro-Oesophageal Varices**

*I. Mostafa, M. Hassan, F. Essawy, S. Omran

Theodor Bilharz Research Institute, 14 El-Nour Street, Dokki-Mehandeseen, Giza, EgyptPortal hypertension and subsequent bleeding gastro-oesophageal varices are frequent complications of chronic liver diseases. The pathogenesis of this bleeding is still unclear, many factors are known to be involved. The aim of this study was to evaluate the possible role of some factors in the pathogenesis of bleeding varices, in attempt to study the integrity of GIT mucosa which depends on cytoprotective and cytoinjurious factors. We measured epidermal growth factor (EGF), prostaglandinE2 (PGE2), thromboxane (TXB2), 6-ketoPGF1, leucotrienes LTC4, LTD4 and cyclic-AMP (c-AMP) in specimens from oesophageal, gastric and duodenal mucosa. This study included 10 healthy subjects (group I), 10 patients with portal hypertension without history of bleeding varices (group II) and 19 patients with portal hypertension and history of bleeding gastro-oesophageal varices (group III). Patients were classified according to Child-Pugh's system into Child A (7), Child B (11), Child C (11). Homogenization, extraction and purification of the mucosal specimens were done to allow measurement of PGE2, TXB2, 6-ketoPGF1 and LTC4, LTD4 using ELISA technique, EGF and c-AMP were assessed by RIA method. The data revealed that tissue levels (ng/mg protein) of PGE2, EGF in group I were significantly higher than those of group II ($p < 0.05$) and III ($p < 0.01$). On the other hand significant increase in TXB2, LTC4 & LTD4 in group II and III when compared to group I ($p < 0.05, 0.01$) was detected in all different biopsies. However c-AMP (nmol/mg protein) and 6-ketoPGF1 showed significant reduction in group II and III when compared to group I ($p < 0.05, 0.01$) in oesophageal biopsies only, this could explain the predominance of bleeding from oesophageal varices than gastric varices. It was concluded that there is an imbalance between prostaglandins and leucotrienes in patients with chronic liver diseases, this may be related to alteration of arachidonic acid metabolism causing mucosal damage and ulceration initiating variceal bleeding. The results may be of help in the effective intervention to control bleeding process, prevention of rebleeding and to choose the best line of treatment. Liver and bile ducts, 1: Cirrhosis: portal hypertensionOesophageal gastric duodenal disorders: Secretion: mechanism, regulation }" "Cytoprotective and Cytoinjurious Factors in Chronic Liver Diseases with Bleeding Gastro-Oesophageal Varices"

"P P 50 1213"P 50 1213**Effects of Diltiazem in Low Flow Portal Arterialization for Liver Protection**

*Y. Sumi, H. Hirose, M. Hayashi, S. Senga, M. Shibata, N. Imai, N. Futamura, K. Yamauchi, K. Kanetake, A. Onitsuka

First Department of Surgery, Gifu University School of Medicine, Gifu, JapanIschemia during hepatectomy and liver preservation of transplantation causes liver damages. We performed portal arterialization (PA) to prevent injuries caused by ischemia, and have reported energy metabolism was maintained in PA, the rate of which was 25% in total hepatic blood flow (THBF). The advantage of decreasing the flow of PA is to facilitate operative procedures and control of bleeding, but it may reduce protective effects. We studied effects of diltiazem in low flow PA for liver protection in mongrel dogs (12.2 – 2.8 kg). Portal venous flow (PVF) and hepatic arterial flow (HAF) were measured by transit-time flowmeter. THBF was calculated at sum of PVF and HAF. Low flow PA was at the rate of 15% in THBF. The portal vein was clamped and the hepatic arteries were ligated under portacaval shunt. Then PA was performed with a roller pump from the right femoral artery to the portal vein through a 6Fr. tube for 120 minutes. Dogs were divided into two groups. The diltiazem group (Group D, n = 4) was received with continuous administration at a dose of 10{ -5} mg/kg/min of diltiazem intraportally from 30 minutes before PA, and control group (Group C, n = 7) with none. Aortic pressure (AoP), portal venous pressure (PVP) and hepatic venous pressure (HVP) were measured, and portal venous resistance (PVR) was calculated with them. Oxygen extraction of the liver was calculated with oxygen saturation and hemoglobin of arterial, portal venous and hepatic venous blood. Arterial ketone body ratio (AKBR), ATP and energy charge were indexed in energy metabolism. Histological findings after PA were examined in hematoxylin and eosin (HE), and thrombomodulin (TM) stain. After PA, AoP decreased, but PVP, PVR and oxygen extraction increased. No significant differences were observed in them between two groups. AKBR was 0.52 – 0.24 in Group D at 120 minutes of PA, which was significantly ($p < 0.05$) higher than Group C (0.20 – 0.10). ATP and energy charge showed a tendency to be high in Group D. In histological findings, cytoplasm was maintained in Group D on HE stain, and sinusoid function also was preserved in Group D on TM stain. In conclusion, our results suggest that administration of diltiazem reduce liver damage due to ischemia in low flow PA. Liver and bile ducts, 1: Liver transplantation }" "Effects of Diltiazem in Low Flow Portal Arterialization for Liver Protection"

"P P 50 1216"P 50 1216**Somatostatin Effectiveness in Serious Upper Gastrointestinal Hemorrhage**

*L.G. Lambropoulos, A. Greca, T. Bakaris, C.P. Flevaris, C.L. Petrogiannopoulos, A.C. Zaharof, R. Agaritsi, I. Poulikakos

Second Dept of Medicine, Hellenic Red Cross General Hospital, Athens, Greece*The aim* of this study was to estimate the effectiveness of intravenous infusion of somatostatin in patients with serious upper gastrointestinal hemorrhage (GH).*Methods:* The study included 40 patients, 24 men and 16 women with mean age 55.4 – 8.6 years, who were admitted to the hospital because of GH. Twelve of them suffered from gastric ulcer, 27 from duodenal ulcer and 1 had had errosive hemorrhagic gastritis. All the diagnoses had been proved endoscopically. They were divided randomly in two groups A and B. The group A received somatostatin 250 \'b5g as bolus infusion initially, followed by 250 \'b5g per hour for 5 days. The group B received cimetidine 200 mg intravenously every 4 hours for 5 days. Groups A and B were computed for a) the number of patients in whom the GH stopped with medical treatment b) the duration of hemorrhage c) the number of blood units transfused. Student t-test and x^2 methods were used.*Results:* The GH stopped by medical treatment in 19 (95%) patients of group A and 14 (70%) patients of group B ($p < 0.05$). One patient from group A (5%) and 6 (30%) from group B needed surgical treatment. The GH stopped in 4.3 – 0.89 hours in group A and 9.8 – 1.31 hours in group B ($p < 0.05$). The patients of group A needed 2.65 – 0.73 blood units and those of group B 4.86 – 0.96 ($p < 0.05$).*Conclusion:* Somatostatin administration reduced statistical significantly the need of surgical treatment, the duration of hemorrhage and the number of blood units compared with those of cimetidine. Clinical practice: Management strategyEndoscopy, general: GI bleedingEndoscopy, specific: Stomach, duodenum }" "Somatostatin Effectiveness in Serious Upper Gastrointestinal Hemorrhage"

"P P 50 1217"P 50 1217**Medical Treatment of Portal Hypertension Using Verapamil, Ketanserin and Propranolol Alone and in Combinations**

*A.M. El-Sahly, M.S. Shendy, H.M. Abdel-Rahman

Department of Tropical Medicine, Faculty of Medicine, Cairo University and Theodor Bilharz Research Institute, Cairo, EgyptBleeding from oesophagogastric varices and portal hypertensive gastropathy is a major cause of morbidity and mortality in patients with chronic liver disease. The aim of this study was to evaluate the potential synergistic effect of portal hypotensive agents with different modes of action, using combinations of ketanserin and verapamil or ketanserin and propranolol and to optimize the doses used for each drug to avoid the deleterious effects of these agents.Fifty patients with portal hypertension due to cirrhosis and/or hepatic schistosomiasis were randomly allocated into four groups. Group I (12 patients) treated with verapamil 80 mg t.d.s. Group II (10 patients) treated with ketanserin 20 mg b.i.d. Group III (15 patients) treated with combination of verapamil 80 mg b.i.d. and ketanserin 20 mg b.i.d. Group IV (13 patients) treated with propranolol 40 mg t.d.s. and ketanserin 20 mg b.i.d. Clinical and laboratory assessment, upper gastrointestinal endoscopy, liver biopsy and splenic pulp pressure (SPP) measurement were done before and after one month of treatment.It was found that verapamil has produced significant increase in SPP. While, ketanserin with or without propranolol has produced significant reduction of SPP. However, addition of propranolol to ketanserin allowed the use of smaller and fixed doses of both agents avoiding the production of serious side effects.It was concluded that verapamil has no benefit in the treatment of portal hypertension. Ketanserin, in smaller doses, produced nearly the same effect of reduction of portal pressure without producing major side effect. Combination of ketanserin and propranolol proved to be better than each agent alone, particularly in comparison with propranolol. This allowed the use of smaller and fixed dose of each agent which minimized the side effects. Liver and bile ducts, 1: Cirrhosis: portal hypertension }" "Medical Treatment of Portal Hypertension Using Verapamil, Ketanserin and Propranolol Alone and in Combinations"

"P P 50 1219"P 50 1219**Effect of Verapamile on Portal and Splanchnich Hemodynamics in Patients with Advanced Posthepatic Cirrosis Using Duplex Doppler UltrasoundH. Din\'e7,**

*S. Kapicioglu, N. Cihanyurdu, G. \'c7an

Black Sea Technical University School of Medicine, Department of Internal Medicine and Radiology, Trabzon, Turkey*Purpose:* To assess the effect of verapamil (80 mg) oral administration on portal and splachnic hemodynamics in patients with advanced posthepatitic cirrhosis using duplex Doppler Ultrasound (US).*Methods:* Forteen patients with posthepatitic liver cirrhosis were included in the study. Duplex Doppler sonographic examinations were performed. Portal and splancnic hemodynamics including vessel diameters (mm), mean flow velocities (cm/sec), blood flows (ml/min), Doppler indices such as pulsatility and resistive indices (PI ve RI), were investigated before and after verapamil administration.*Results:* After verapamil administration; diameter of portal vein, splenic vein and superior mesenteric artery (SMA) showed increase of 8%, 10% and 7% ($p < 0.05 – p < 0.001$), respectively. Increases of 20%, 38% and 47% were found in blood flows ($p < 0.5 – p < 0.0001$) with respect to the above vessels. Decreases of 17%, 10%, 11% and 7% were found in SMA PI, splenic artery (SA) PI, and SA RI, respectively ($p < 0.5 – p < 0.0001$).*Conclusions:* Verapamil appears to have splanchnic, portal, splenic, portocollateral and probably intrahepatic vasodilator effect in patients with advenced posthepatitic liver cirrhosis. Verapamil should be further investigated in the treatment of patients with advenced liver cirrhosis with prospective studies measuring portal and wedged hepatic pressure. "P P 50 1220"P 50 1220**Acute Portal Venous System Thrombosis. Systemic Treatment with Heparin and Recombinant Tissue Plasminogen Activator (rt-PA) or Heparin alone in 10 Patients**

*J.P. Lagasse, M.L. Bahallah, G. Debillon[1], N. Salem, D. Labarriére, M.P. Serve, V. Advenier[1], X. Causse, J.L. Legoux

[1] Dept. of Hepato-Gastroenterology, C.H.R., Orl\'e9ans, France

Dept. of Radiology, C.H.R., Orl\'e9ans, FranceSome authors have reported successfull anticoagulation or thrombolytic therapy in some patients with acute splenoportal or mesenteric vein thrombosis. We report the efficacy of systemic rt-PA with heparin or heparin alone in the treatment of acute portal venous system thrombosis in 10 patients.*Methods:* 10 consecutive patients [9 men, 1 woman, mean age 51 years (27–71 years)] with acute extrahepatic portal vein thrombosis (5), left portal vein thrombosis (3) and superior mesenteric vein thrombosis (2) were studied. In all patients the ultrasonic diagnosis was based on the presence of an echogenic thrombus in the venous lumen. The cause of vein thrombosis was hepatic cirrhosis (4), pancreatitis (2), biliary tract infection (1), myeloproliferative disorders (1), protein C deficiency (2). Treatment with systemic infusion of rt-PA (100 mg over 2 h) with intravenous heparin were performed in 5 patients. The remaining 5 patients (asymptomatic or contraindication of rt-PA) were treated with continuous heparin systemic infusion only (2) or subcutaneous low molecular weigt heparin twice daily (3).*Results:* In 3 of the 5 patients treated with rt-PA ultrasonography showed total resolution of the thrombus 7 days (1) and 15 days (2) later. The remaining 2 had partial resolution of the thrombus. In 4 of the 5 patients treated with heparin alone (in 3 of 3 with subcutaneous heparin) ultrasonography showed total resolution of the thrombus 7 days (1) and 30 days (3) later, and partial in 1. No bleeding occured, one patient had heparin-associated-thrombocytopenia. Whereas total resolution of the thrombus was achieved, 3 patients with hepatic cirrhosis had bleeding from oesophageal varices 1 month, 6 months and 26 months later.*Conclusions:* The treatment with heparin can produce a complete recanalisation of acute portal venous system thombosis. These data suggest that systemic rt-PA seems not increase the efficacy of heparin. A prospective study should be usefull in order to confim these results. "P P 50 1221"P 50 1221**Stapler Transsection of Oesophagus for Bleeding Varices**

*S. Malinger, M. Drews, T. Kosinski, J. Szmeja

Dept. of General Surgery University School of Medicine, Poznan, PolandThis study was performed to assess the efficacy of stapler transsections of the oesophagus to stem haemorrhage from rupturedoesophageal varices.*Patients and methods.* Between 1988 and 1995-25 patients (aged from 32 to 70 years) have been operated on. Hepatic cirrhose was the main cause of variceal appearing. Child's hepatic failure evaluation showed stage A in 11 patients and stage B in 14 patients. According to the endoscopic variceal evaluation scale-stage I was observed in 2 patients stage II in 10 and stage III in 13 patients. Emergency indications for the surgical treatment were present in 3 patients, selective indications – in 22 patients.*The operation technique.* Consisted of introducing of a stapler device (ILS) by a gastrotomy to the subdiaphragmatical part of the oesophagus. Then a band was tied around the oesophageal wall upon opened stapler warking head. Fireing of the device formed a double layer end to end anastomosis transsecting and ligating the submucosal varices. When the vagal trunks couldn't be saved a pyloromyotomy was performed.*Results.* There were 4 important rebleedings and 2 anastomotic leaks postoperatively. Five patients died, 3 of them were operated on in emergency during a massive haemorrhage. After one year 11 variceal relapses were observed.*Conclusions.*1. Stapler transsection of the oesophagus should be performed after the control of massive haemorrhage.2. One half of the patients treated by this method has variceal reappearing during the first year. "P P 50 1222"P 50 1222**Portal Hemodynamics and Portal Hypertensive Gastropathy in Liver Cirrhosis**

*M. Nakajima, A. Itabashi, T. Nakajima[1]

Department of Clinical Laboratory, Saitama Medical School, Moroyama, Japan

[1] The Third Department of Internal Medicine, Saitama Medical School, Moroyama, JapanWe evaluated the association between portal hypertensive gastropathy and portal hemodynamics.The subjects were 49 patients with liver cirrhosis complicated by esophageal varices in whom the clinical course were observed for 5 years. They were classified into the group who developed a splenorenal shunt during the course (11 patients) and that who did not (38). They were no complicating with hepatocellular carcinoma and no treatment of esophageal varices. Furthermore, They had no collateral circulation of the portal system except gastroesophageal varices and spleno-renal shunt. Endoscopic findings of portal hypertensive gastropathy were divided into two criterias (mild and severe).Incidence of portal hypertensive gastropathy during the course, the splenorenal shunt group (5{'}4) was lower than non-shunt group (18 {'} 27). Grade of portal hypertensive gastro-pathy (mild:severe) at the ending of observation were portal hypertensive gastropathy were the splenorenal shunt group (3:1) and non-shunt group (14:15). Since no difference were observed in the size of spleen, the diameter of the main trunk of the portal vein, or blood biochemical findings between the two groups during the observation period.The development of the splenorenal shunt, i.e., the state of the development of the collateral circulation seems to be involved in the development of portal hypertensive gastropathy. Liver and bile ducts, 1: Cirrhosis: portal hypertensionEndoscopy, specific: OesophagusEndoscopy, specific: Stomach, duodenum }" "Portal Hemodynamics and Portal Hypertensive Gastropathy in Liver Cirrhosis"

"P P 50 1223"P 50 1223**Clinical Outcome Two Years after Implantation of a Tips for Recurrent Variceal Bleeding**

*M. Gschwantler, A. Gebauer, J. Vavrik, M. Rohrmoser, C. Schrutka-K\'f6lbl, E. Brownstone, D. Tscholakoff, W. Weiss

Department of Internal Medicine and Department of Radiology, KA Rudolfstiftung, Vienna, Austria*Objective:* At present there is only sparse data on midterm outcome after TIPS implantation. The role of TIPS in the management of portal hypertension thus remains controversial. The aim of this study was to assess clinical course 2 years after TIPS procedure.*Methods:* The study was designed as a prospective, uncontrolled cohort study. 46 patients who underwent successful TIPS implantation were followed prospectively by clinical examinations, duplex sonography and portal venography. Mean follow-up in surviving patients was 24.1 + 9.0 months. The Kaplan-Meier method was used to calculate cumulative rates of survival, variceal rebleeding, shunt stenosis or occlusion as well as rates of primary, primary-assisted and secondary patency over a 24-months period. Patients were stratified according to their CHILD-PUGH class. The Generalized Wilcoxon Test (Breslow) was performed to detect differences between strata.*Results:* The cumulative rate of survival was 80.4% at 1 year and 70.2% at 2 years. The cumulative rebleeding rate was 12.4% at 1 year and 21.3% at 2 years. The mortality rate of episodes of variceal rebleeding was 22.2%. Variceal rebleeding was associated with shunt abnormalities in all cases, and successful shunt revision resulted in control of the bleeding. The cumulative incidence of shunt stenosis or occlusion was 41.2% at 1 year and 54.9% at 2 years. 23.3% of patients without shunt abnormalities after 1 year developed shunt stenosis or occlusion during the second year after TIPS procedure. Shunt revision was successful in 96.6% of cases. Secondary patency rate was 88.1% after 2 years. The risk of variceal rebleeding and shunt stenosis did not differ significantly between CHILD-PUGH classes.*Conclusions:* Successful TIPS implantation results in a low rate of morbidity and mortality from variceal rebleeding over 2 years. TIPS creation in combination with careful follow-up examinations represents a safe and effective long-term treatment of recurrent variceal bleeding. Even in patients in whom no shunt abnormality was detected during the first year routine duplex follow-up examinations should be continued at 3-month intervals. Liver and bile ducts, 1: Cirrhosis: portal hypertension }" "Clinical Outcome Two Years after Implantation of a Tips for Recurrent Variceal Bleeding"

"P P 50 1224"P 50 1224**Artificial Neural Network Analysis of Prognostic Variables for Prediction of Early Mortality after TIPSS: Development and Validation**

*R. Jalan, M. Ala-Korpela[1], Y. Hiltunen[2], D.N. Redhead[3], A.J. Stanley[4], R.A. Elton[5], J.D. Bell[1], P.C. Hayes[4]

[1] NMR Unit, Hammersmith Hospital, London

[2] Raahe Institute of Computer Engineering, Finland

[3] Department of Radiology, Royal Infirmary Edinburgh, UK

[4] Department of Medicine, Royal Infirmary Edinburgh, UK

[5] Department of Statistics Unit, Royal Infirmary Edinburgh, UK*Background and Aims:* TIPSS is followed by deterioration in liver function tests and early mortality in about 20–30% patients. The purpose of this study was to develop and validate a model based upon artificial neural network (ANN) analysis of prognostic variables and compare this with a model based upon logistic regression (MLR).*Methods:* 82 consecutive patients undergoing TIPSS for variceal haemorrhage were studied. They were divided into two groups. Group I (66 patients) comprised the patients that were used to train the ANNs and establish the model based upon the results MLR. Group II (16 patients) comprised the patients that were used in a blinded manner to assess the trained neural network and also the MLR.*ANN:* A feed-forward fully-connected ANN with 10 hidden neurons (DynaMind') was trained with the 25 clinical variables related to clinical or biological data obtained from patients in Group I (input) to predict early mortality (output).*MLR:* Significant independent predictors (sodium; $p < 0.001$ and Pugh score $p < 0.001$) were combined using the formula: $p = e^x/1 + e^x$; where p is the predicted probability of survival and x = 13.42 { - } 0.1429 X [sodium] + 0.445 X [Pugh score].This network and the MLR model were then applied to predict early mortality of patients in Group II.*Results:* Sensitivity and specificity for predicting early mortality were 100% and 87.5% for the ANN and 25% and 93.8% for the MLR.*Conclusions:* This study illustrates that ANN analysis can be useful in the prediction of early mortality before TIPSS is inserted, using routine clinical and biochemical parameters. Moving from the assessment of outcome by current methods towards ANN analysis will require similar comparisons, prospective evaluation and an open mind. "P P 50 1225"P 50 1225**Long Term Patency of Transjugular Intrahepatic Portosystemic Shunt (TIPS): A Surgical Prospective ExperienceD. Azoulay, D. Castaing, H. Bismuth**

Hepato-Biliary and Liver Transplantation Center, Paul Brousse Hospital, Villejuif, FranceStent obstruction is the main argument against the use of transjugular intrahepatic portosystemic shunt (TIPS) for the long term management of portal hypertension. This prospective study analyses the impact of a stringent follow-up on the long term patency rate of TIPS performed by a surgical team. From November 1991 to December 1995, 122 attempts of TIPS placement were performed and successfull in 115 cases (94%). Follow-up included Doppler ultrasonography at 15 days, 1 month, every 3 months and when patients (pts) developped recurrent complication. Transjugular venography was systematically performed at 1 and every six months, when Doppler ultrasonography was doubtful and when the pts developped recurrent complication. End points for follow-up were death, liver transplantation (LT) or survival with TIPS in place. Fifty nine pts (51%) had a follow-up below 6 months (27 deaths, 16 LT, 11 recent survivors with a TIPS in place, 5 pts lost for follow-up). Fifty-six pts (49%) have a complete follow-up of at least 6 months with a TIPS in place (mean 20 + 2 months, range 6 to 55 months) and are analysed here. The primary patency rate was 36/56 (64%) with a mean follow-up of 18.4 + 5 months. Twenty four episodes of TIPS obstruction occured in 22 pts: 12 within 2 months, 4 between 2 and 6 months, 8 after 6 months. Obstruction was treated successfully by TIPS dilatation in 2 cases and coaxial TIPS deployement in 20 cases. Two cases of transjugular desobstruction failures were treated by portacaval shunt. Actuarial primary patency rate of TIPS was 77%, 70%, 60%, 56% at 6, 12, 24 and 36 months respectively. Assisted patency rate of TIPS gas 96% at 6 months and at 2 years. Actuarial survival was 90% and 83% at 1 and 2 years. Provided TIPS is performed by trained operators and followed carefully, assisted patency rate comparable to portacaval shunt may be achieved. TIPS may be considered as a long term treatment of portal hypertension. }"

*J. Bauer, U. Erhard-Plate, H. Sch\'f6nek\'e4s, H.G. Schmidt

Klinikum N\'fcrnberg, N\'fcrnberg, GermanyThis retrospective study presents the findings made in 8 patients (P) with hemobilia (H) and 4 P with hemosuccus pancreaticus (HP), which were treated at our hospital from 1/88 to 4/96.*Results:* Hemobilia: Causes for H were hemangiosarcoma of the liver in 1 P, pseudo-aneurysm of the hepatic artery in 1 P, cholezystolithiasis in 3 P, liver biopsy in 3 P. All P showed colics, 6 P icterus, 1 P hematemesis and 3 P melena. Emergency endoscopy established hemorrhage from the papilla in 2 P with the front-view endoscope and in another 2 P with the lateral-view endoscope. Blood clots in the bile duct were observed in 5 P with ERCP. After EPT these were extracted from the bile duct with a Dormia-basket. Angiography produced evidence of hemobilia in 2 P. As for therapy, embolisation failed in 1 P with arrosion bleeding from the right hepatic artery due to cholezystolithiasis. Embolisation was successful in 1 P with pseudo-aneurysm of an intrahepatic liver artery. 3 P were operated on. H stopped spontaneously in 4 P (hemangiosarcoma 1 P, state after liver biopsy 3 P). Hemosuccus pancreaticus: 2 P showed chronic pancreatitis and 2 P a pancreas-ca. 4 P displayed melena, 2 P icterus and 1 P epigastric pain. Hemorrhage from the papilla was observed in 1 P with the front-view endoscope and in 4 P with the lateral-view endoscope. ERCP demonstrated blood clots in the pancreatic duct and bile duct in 1 P, blood clots in the pancreatic duct in 1 P and blood clots in the bile duct in 1 P. Angiography produced evidence of HP in 2 P. As for therapy embolisation was successful in 1 P with chronic pancreatitis, fibrin-adhesive was successfully applied via endoscopy in the pancreatic duct of 1 P with pancreas-ca., and 1 P with chronic pancreatitis was operated on. Hemorrhage stopped spontaneously in 1 P with pancreas-ca.*Summary:* 1. As for our patient group, the ERCP method for diagnosing hemobilia and hemosuccus pancreaticus ranked higher than angiography. 2. No patient died as a result of hemobilia or hemosuccus pancreaticus. "P P 51 1258"P 51 1258**Management of Bile Duct Injuries of Laparoscopic Cholecystectomy with Endoscopic Sphincterotomy or Stenting: A Comparison**

*H. Senturk, M. Akdogan, S. Cimoglu, A. Mert, S. Ozdemir, A. Sonsuz, P. Akin

Department of Internal Medicine, Cerrahpasa Medical Faculty of University of Istanbul, Istanbul, TurkeyAlthough laparascopic cholecystectomy (LC) has several advantages over open cholecystectomy, the rate of bile duct injury is higher in the former. Several endoscopic retrograde techniques were advocated in management. We compared the efficacy of sphincterotomy with temporary stenting. The 31 patients, referred after LC with the clinical diagnosis of bile leak between Jan 94, and March 95 were studied. At endoscopic retrograde cholangiography (ERC), the patients without leak (2), with retained stones (5), with bilomas requiring percutaneous drainage (1), and with transsection (2) were excluded. The remaining 21 (12 female, 9 male with median age of 51 and range 28–74) were randomized into two treatment arms: sphincterotomy or stenting. In 12/21, leak was from cystic duct remnant. Tannenbaum stents of 8.5 FR size (Wilson Cook Company, Winston-Salem, NC, USA) were used. A prior sphincterotomy was not performed. All the patients were followed up until the resolution of the symptoms and signs in the hospital. Stented patients were called for a second endoscopy, two weeks after the first one. For the first four stented patients, ERC was performed before stent removal, to confirm the resolution of the leak. For the remaining 7 patients, removal was without fluoroscopic guidance. Leaks eventually resolved in all. Symptoms resolved more rapidly in the stent group in comparison to sphincterotomy group: 1.9 – 8, 1–3 days (mean – SD, range) vs. 2.9 – 1.0, 2–5 days; $p < 0.05$. Mean hospital stay was also shorter in the stent group: 2.7 – 0, 1–4 days vs. 3.9 – 1.1, 2–6 days, $p < 0.05$. No procedure-related complication occurred. Our study suggests that for the patients with isolated common bile duct injury or cystic duct leak, temporary moderate size stent (8.5 FR) insertion, across the site of the leak without ES is as effective as sphincterotomy and it confers faster improvement. Advantages of this new type of stent without side holes and, possibly, shorter stented periods require more studies. Endoscopy, general: Instrumentation, therapyEndoscopy, specific: BiliaryLaparoscopic surgery: Therapy }"

"P P 52 1259"P 52 1259**Increasing Prevalence of Right-Sided Colonic Polyps**

*A. Van Gossum, A. Mandieau, M. Adler, M. Cremer

Department of Gastroenterology, Erasme Hospital, ULB, Brussels, Belgium*Introduction:* Colorectal cancer is the second leading cause of cancer mortality in Europe. Actually, sigmoidoscopy is the most frequently used screening method. The aims of this study were 1. to determine in a large population the percentage of polyps which would be not detected by sigmoidoscopy; 2. to determine if there is an increasing prevalence of lesions isolally located in the right colon.*Material and methods:* All the protocols of total colonoscopy (13.500) performed at Erasme Hospital from 1983 to 1994 were retrospectively reviewed. For patients with polyps, the following parameters were recorded: age, sex, location of the polyps, size of the polyps. Patients were divided in two periods: a) from 1983 to 1989, b) from 1990 to 1994.*Results:* Polyps were detected in 1441 patients (period 1983–89) and in 1544 patients (period 1990–94). For the global population, the sex ratio male/female was 2/1 and the mean age was 61.9 y for males and 65.2 y for females, respectively. In the global series, 50.6% of patients had polyps located into the rectosigmoid (50 cm from the anal verge). The percentage of patients having polyps located only into the right colon or above the splenic flexure statistically increased between the 2 periods. Period 1983–89 Period 1990–94 (n = 1441) (1544)% of patients with polypslocated only in:the right colon 8.6% 13% $p < 0.0001$Above the splenic flexure 12.9% 21.3% $p < 0.000001$Sizes of the polyps were similar in the different segments of the colon.*Conclusions:* The sensitivity of sigmoidoscopy foe detecting patients with polyps is about 50%. Our data suggest a continuing trends in the prevalence of right-sided colonic polyps. That must be taken into account in evaluation of cost-effectiveness of screening endoscopic method. "P P 52 1262"P 52 1262**Colo-Rectal Adenomas and Flow Cytometric Analysis**

*S. Gasperoni, F. Monti, D. Tassinari, P. Rinaldi, R. Bronzetti, A. Ravaioli, A. Cardelli

Ospedale Infermi, Istituto Oncologico Romagnolo, Rimini, ItalyColorectal adenomas have a definite but unpredictable potential to become malignant. The currently accepted criteria are not sufficient to predict the transformation through the adenoma-carcinoma sequence. During this sequence the genetic instability of the epithelial cells increases resulting in structural and numerical chromosome aberrations (aneuploidy). Flow cytometry permits a measurement of DNA-ploidy and S-phase fraction; it has been suggested to use data from flow cytometry to further define biologic behaviour of colorectal adenomas. Aim of the present study was to evaluate prevalence of aneuploidy among polyps endoscopically removed and to relate DNA-index and S-phase fraction to size, histological type, dysplasia and site of polyps. Flow cytometric analysis was performed on 44 polyps of patients who underwent endoscopic polypectomy (32 M, 12 F; mean age 65, range 35–89). In our series, prevalence of DNA aneuploidy was 18.2%; in detail results are summarized in the following table. Size Histological type Dysplasia Site < 1 cm 1–2 > 2 cm tubul tub- vill low high rectum left right cm vill colon colonDiploid 17 9 10 19 10 7 31 5 7 25 4(%) (94) (75) (71) (86) (77) (78) (82) (83) (58) (89) (100)Aneuploid 1 3 4 3 3 2 7 1 5 3 0(%) (6) (25) (29) (14) (23) (22) (18) (17) (42)* (11)* (0)*S-phase 7.7 6.7 5.4 7.6 7.0 4.0 6.8 6.1 4.5 7.4 8.3m – SD – 4.8 – 5.2 – 3.1 – 5.2 – 3.7 – 2.2 – 4.7 – 3.2 – 2.7 – 5.0 – 2.9*p < 0.05 (chi-2)*Conclusions:* Our preliminary data show that the prevalence of aneuplody is significantly higher in distal polyps. Size, histological type and grade of dysplasia of adenoma were not related to data from flow cytometry. "P P 52 1265"P 52 1265**Concentration of Methane in Breath of Colonic Polyps Patients Measured with a New Technique**

*M. Bianchi, C. Papi, F. D'Amato[1], M. Koch, L. Capurso

Dpt Malattie Digestive & Nutrizionali Osp S Filippo Neri, Roma, Italy

[1] ENEA Inn-fiss Spet Frascati, ItalyMuch controversy exists regarding the role of merthan (CH4) producing anaerobic bacteria in colonic carcinogenesis. According to some authors, the presence of CH4 producing bacteria is correlated with colon cancer [1], whilst this finding were not confirmed by others [2,3]. The aim of our study was to evaluate the production of CH4 by bacterial flora in the intestine of patients with colo-rectal adenomas and in normal subjects.Forty eight consecutive patients with an endoscopic diagnosis of colo-rectal polyps (44 adenomatous/villous polyps, 4 adenomas with cancer) and 65 normal subjects were included in the study. The concentration of CH4 in breath was measured using a technique devised at ENEA in Frascati (Italy) based upon the absorption, by the CH4 molecules, of a laser beam of known wavelength emitted by a diode. In patients with polyps, gaschromatography measurements were also made. The amount of CH4 in breath was expressed in parts per millin (ppm). Individuals presenting CH4 concentration > 50% than CH4 concentration in the surrounding air were considered CH4 producers.Fifteen out 48 patients (31%) and 35/65 controls (54%) were found to be CH4 producers ($p = 0.02$). The amounts of CH4 detected in breath of patients and controls are shown in the figure below. A close correlation was found between the two breath tests (laser diode and chromatography) ($r = 0.72$) even if the latter failed to detect 4/15 (27%) of the CH4 producers revealed by the laser diode.

Data emerging from this study failed to demonstrate a higher frequency of CH4 producers in the colonic polyps patients as compared to normal controls.

"P P 52 1266"P 52 1266**Colonic Glutathione Content and Glutathione S-Transferase Activity in Patients with X-Linked A-Gammaglobulinaemia and Patients with Adenomas****M.J.A.L. Grubben[1], C.C.M. vd Braak[1], W.H.M. Peters[1], J.W.M. vd Meer[2], F.M. Nagengast[1]**

[1] Dept. of Gastroenterology, University Hospital Nijmegen, The Netherlands

[2] Dept. of Internal Medicine, University Hospital Nijmegen, The NetherlandsX-linked agammaglobulinaemia (XLA) is a primary immunodeficiency disorder. Patients with XLA have a 30-fold greater incidence of rectal cancer compared to the normal population. Glutathione (GSH) and GSH-related enzymes are involved in the metabolism and detoxification of cytotoxic and carcinogenic compounds. The glutathione S-transferase (GST) activity in the mucosa along the gastrointestinal tract is reciprocal to tumour incidence in humans.*Aim and methods:* we investigated GSH content and GST activity in normal colonic mucosa at three levels (ascending colon, sigmoid and rectum) of XLA-patients (n = 8, mean age 34 – 2 yrs) and patients with colonic adenomas (n = 25, age 60 – 12 yrs) and in rectal mucosa of healthy controls (n = 10, age 24 – 3 yrs).Statistical analyses were assessed by Mann-Whitney U test.*Results:* values are given as means – SEM. Asc. colon Sigmoid RectumGST (nmol/min/mg protein)XLA 237 – 17[#,*] 222 – 19[#,*] 143 – 17[#]Adenoma 333 – 23 316 – 27 285 – 19Control ND ND 321 – 29[&#]p {\'a3} 0.03 XLA versus adenoma. *p {\'a3} 0.02 versus XLA-rectum. [&]p {\'a3} 0.01 control versus XLA. ND: not determined.GSH content did not differ between all study groups at all levels.*Conclusion:* XLA-patients have a lower GST-activity at all levels in the colon compared to patients with adenomas. The rectal GST activity in XLA-patients also differs from healthy controls. In XLA patients rectal GST activity is lower than the proximal GST activity. The increased risk of colorectal cancer in XLA-patients might partly be explained by a lower detoxification capacity in the mucosa. "P P 54 1279"P 54 1279**p53 and Proliferating Cell Nuclear Antigen as Prognostic Factors in Colorectal Cancer**

*S. Knezevic-Usaj[1], S. Cerovic[1], Lj. Rabrenovic[1], Z. Bogdanovic[1], V. Cuk[1], V. Todorovic[2], A. Skaro-Milic[1], J. Dimitrijevic[1], V. Tatic[1]

[1] Institute of Pathology, Military Medical Academy, Belgrade, Yugoslavia

[2] Institute for Medical Research, Belgrade, YugoslaviaIn light of the role of p53 in cell proliferation, we were interested in markers of the cell cycle whose expression might be correlated with p53 protein overexpression. Formalin -fixed paraffin embedded surgical specimens of 29 CC of different Dukes' stages were analysed. Nuclear p53 protein overexpression in tumor cells and proliferative activity of tumor by identifying proliferative cell nuclear antigen (PCNA) were detected by immunohystochemistry. p53 protein overexpression was identified in 48.2% CC and found to correlate with stage of disease (22.2, 40.0 and 80.0% in Dukes A, B and C stages respectively), site of tumor (52.38% p53 positive tumor in left colon versus 37.5% positive CC in right colon) and nonmucinous histological type (61.9% of p53 positive tumor in nonmucinous e.g. 25.0% in mucinous tumor). Nuclear immunoreactivity for PCNA to a varying degree was expressed in 93% of CC. High PCNA distribution score 3 (> 50% PCNA positive nucleus) was more frequently found in p53 positive CC (71.42%) and in Dukes' C stage of disease (all 10 ceases) and the difference was statistically significant. Our results suggested that overexpression of p53 protein and higher PCNA score in later stages of CC indicate higher proliferative rate of tumor and therefore may have prognostic implications. Our results also indicate that mucinous differ from nonmucinous CC as well as proximal differ from distal CC in their genetic lesions. }" "p53 and Proliferating Cell Nuclear Antigen as Prognostic Factors in Colorectal Cancer"

[4] Hospital La\'ebnnec, 75007 Paris, FranceColorectal cancer is one of the most frequent causes of death by cancer in developed countries. Until now, few prognostic factors for colorectal cancer have been recognized and chemotherapeutic agents do not demonstrate much significant progress in the treatment of this disease.Epidemiological studies suggest that colorectal cancer can be attributed, at least in part, to carcinogens and mutagens present in diet and environment. The covalent binding of the xenobiotics or their reactive metabolites to DNA is believed to initiate chemical carcinogenesis. Using a ^{32}P-post labelling method, we investigated DNA adduct levels in control colons from patients without colorectal adenocarcinoma and in nontumoral and tumoral tissues from patients with colorectal adenocarcinoma. We showed that the DNA adduct level is significantly higher ($p < 0.001$) in nontumoral than in control or tumoral colon samples. For the first time, we demonstrated in humans that the presence of numerous abducts in colonic mucosa is associated with colorectal cancer, a finding in agreement with the importance of chemical factors in causing this disease; therefore the measurement of DNA adduct level in colon samples could constitute a useful approach to the early detection of colorectal cancer.Since human colorectal tumors are insensitive to most chemotherapeutic agents there is a need for the discovery of new drugs that would show activity against this disease. We compared the drug-metabolizing enzyme expression in human tumors and in several differentiated populations isolated from the human colon carcinoma cell lines HT-29 and Caco-2. We showed that these cells could be used as models for candidate anticancer screening. Moreover, to increase the sensitivity of these cells to anticancer drugs for which the metabolism is known we began to transfect these cells with the cDNA of the P450 implicated in the formation of the antineoplastic metabolites. This strategy, if it appears efficient, could lead to possible gene therapy. Oncology, general: Screening, preventionOncology, general: TherapyOncology, specific: Colon, rectum }"

"P P 54 1281"P 54 1281**Prognosis of Mucinous Colorectal CancerD. Lomanto, G. Dalsasso, A. De Luca, F. Giacovazzo, Meli E. Zarba, A. Salvio, L. De Angelis, G. Mennini, C. Tatarelli, V. Speranza**

II Clinica Chirurgica-University of Rome ""La Sapienza"", Italy*Purpose of the Study* was to compare recurrence and survival rate of patients with adenocarcinoma (ADK) and mucinous carcinoma (MC) of colon rectum.*Methods.* We studied retrospectively 380 pts. operated for colo-rectal cancer. We classified the pts. in two groups: in the first 36 pts. (9.5%) with mucinous carcinoma (MC), defined as a neoplastic lesion of the mucosa with elevated present of mucin (60% of the volume), and in the second group 344 pts. (90.5%) with adenocarcinoma (ADK). We analyzed in these pts. the following parameters: age, sex, localization, stage, resectability, recurrence disease, prognosis and long term survival. Mean age was 54 yrs. in MC group and 63 yrs. in ADK group.*Results.* We observed more frequently rectal localization vs. other colonic sites in both groups (50% in MC group vs. 50.8% in ADK group). As for staging data, according to Duke's classification, in both groups we observed a lower rate of stage A in MC group than ADK group (10.5%) while we didn't observe any difference in pts. with stage B and D (MC: stage B 41%; stage D 19.5%) (ADK: stage B 48.8%; stage D 20%). Pts. with stage C showed a statistical significative difference with following results: 36.1% for MC group vs. 22.6% for ADK group ($p < 0.05$). Among the pts. with recurrent disease (correcting the data for the perioperative mortality and excluding the pts. in stage D), we found that local recurrence rate was 72.7% in MC group and 46.6% in ADK group, the metastasis in MC group was 9% and 46.6% in ADK group, while the presence of both (metastasis + local recurrence) was 18.2% in MC group and 20% in ADK group. Overall survival rate at 5 yrs. was 45% for the MC group and 58% for the ADK group.*Conclusion.* Our study show a different biological behaviour between MC and ADK especially for the local recurrence. This behaviour, for us and other Authors, is related to the presence of elevated quantity of mucin. [3] Services de Radioth\'e9rapie, CHU, F 37044 ToursPC associated with CRC is considered as a pejorative factor. *The purpose of this study* was to analyse the factors influencing survival of patients seen in our institution for PC with CRC.*Patients and methods:* 23 patients (15 men, 8 women) aged 64 years (extr: 24–83) were followed from November 1993 to January 1996. In all cases PC was diagnosed either macroscopically (clinical or CT scan assessment) or by biopsies during surgery. PC and CRC diagnosis were synchronous in 7 patients and metachronous in 16 with a mean delay between diagnosis of 14.9 months (extr: 0–137 months). CRC was located in the sigmoid colon in 13 patients, descending colon 2 patients, transverse colon 2 patients and right colon 6 patients. One patient had two synchronous CRC. Eight occlusions were diagnosed in 7 patients and required a surgical treatment in 3 cases. Survival, calculated since PC diagnosis, was analysed according to age, gender, OMS performance status, occlusion occurrence, CRC synchronism and resection, liver metastasis or ascitis presence or occurrence and PC treatment (chemotherapy N = 8, palliative surgery N = 9, corticosteroids N = 11, symptomatic treatment N = 4).*Results:* Overall survival was 26% and 7.8% at 1 and 2 years respectively and median survival was 5 months. Gender, age, presence of liver metastasis, CRC synchronism and resection and occlusion had no influence on survival. In contrast, a better survival was observed in patients without ascitis or good performance status and patients treated by chemotherapy or palliative surgery. 1 year survival 1 year survival p <Absence of ascitis 42% vs ascitis 9% 0.05OMS 0–1 50% vs OMS 2–3 8% 0.05Chemotherapy 64% vs corticosteroids 0% 0.01Palliative surgery 56% vs corticosteroids 0% 0.01*Conclusion:* PC from CRC origin has a poor prognosis however absence of ascitis and a good OMS performance status allowing chemotherapy or palliative surgery are associated with a significantly longer survival. "P P 54 1285"P 54 1285**Overexpression of p53 Protein in Colorectal Carcinoids**

*Cheng Jhy-Young, Lin Jih-Chang

Division of Colorectal Surgery, Department of Surgery, Tri-Service of General Hospital, National Defense Medical Center, Taipei, Taiwan, R.O.C.*Purpose:* The overexpression of p53 protein is considered to be a potential marker for the transition to advanced stages of tumor progression in many human cancers. The frequency and prognostic significance of such events in colorectal carcinoid tumors remain unknown.*Methods:* Thirty-one paraffin-embedded specimens of colorectal carcinoid tumor were studied by immunohistochemical staining. The association of p53 with tumor site, tumor size, invasion level, tumor stage, DNA pattern and patient survival were analyzed.*Results:* p53 protein was detected in 5 (16%) of 31 colorectal carcinoid tumors. There was a correlation between p53 expression and tumor site, tumor size, tumor stage and DNA ploidy ($p < 0.05$).In addition, p53 overexpression indicated a poor prognosis in survival ($p < 0.001$).*Conclusion:* Although the overexpression of p53 protein is uncommon in colorectal carcinoid, the expression has an association with clinicopathological criteria and may be used as an associated parameter to predict patient survival. Oncology, general: Proliferation, carcinogenesisOncology, specific: Colon, rectum }" "Overexpression of p53 Protein in Colorectal Carcinoids"

"P P 54 1286"P 54 1286**Prognostic Value of P-53 Protein in Surgically Treated Colorectal CarcinomaA. Guerra, F.J. Jim\'e9nez-P\'e9rez,**

*F. Borda, B. Larrinaga, J.M. Martinez-Pe\'f1uela, C. Jimenez

Hospital de Navarra, Pamplona, SpainP.53 gene alteration with abnormal expression of P.53 protein has been reported in several malignant tumors. In some studies this abnormal expression has shown an independent prognostic value. The aim of the present study is to determine P.53 protein expression in a series of surgically treated colorectal carcinoma, analyzing its relation with overall 5 years survival and survival according to tumoral stage and differentiation grading.*Material and Methods:* 75 surgically treated colorectal adenocarcinomas were included in the study. Anti-P.53 antibody (Dako) was used for evaluation of P.53 protein expression. Kaplan Meier and Logrank tests were used for statistical analysis.*Results:* Overall 5 years survival was 63.12 – 4.8% for the whole series. Depending on P.53 protein expression, results were as follows: P.53+ P.53{ -} p (n = 31/41%) (n = 44/59%)Overall 48.04 – 9.2% 64.2 – 7.3% < 0.1Dukes A/B1/B2 62.8 – 12.7% 85.4 – 7.6% N.S.Dukes C1/C2/D 33.6 – 15.8% 42.9 – 11.4% N.S.Grade I–II 63.4 – 10.2% 66.6 – 8.2% N.S.Grade III 0% 55.5 – 18.5% < 0.05*Conclusions:* 1. Colorectal adenocarcinomas with P.53 protein expression have poorer prognosis and lower 5 years survival than tumors without this protein, although statistical significance is not achieved. 2. In poorly differentiated tumors, 5 years survival is significantly lower when P.53 protein is present. 3. P.53 protein determination might be useful in colorectal cancer in order to improve prognostic information. "P P 54 1287"P 54 1287**Does Tumor Heterogenity Influence the Staining for P53 in Colonic Adenocarcinomas and Their Lymph Node Metastases?Ataoglu \'d6m\'fcr, \'c7elik Bet\'fcl, Kayhan Bur\'e7ak,**

*G\'f6rg\'fclAhmet

G\'dcTF, Ankara, T\'fcrkiyeA high percentage of colon carcinomas show positive staining for p53 immunohistochemically. Using a polyclonal antibody for p53 (CM1-Novacastra lab.) which is specific for wild and mutant forms, we investigated whether or not the tumor heterogenity significantly affects the staining of the colonic adenocarcinomas and their lymph node metastasis with p53 antibody. In 40 colon specimens containing invasive colonic adenocarcinoma with lymph node metastases, positive staining was found in 37 carcinomas. Three cases (2 well-differentiated mucinous adenocarcinomas and 1 signet-ring cell carcinoma) showed no positive staining for p53. In these cases, the tumor positive lymph nodes also did not stain. One poorly differentiated adenocarcinoma showed positive staining for the tumor but the lymph node metastasis of the case was not positive for p53. The results show that the tumor heterogenity does not significantly influence the staining of colonic adenocarcinomas and their positive lymph nodes, and p53 expression of the colonic adenocarcinomas is retained in their lymph node metastases. Oncology, specific: Colon, rectum }" "Does Tumor Heterogenity Influence the Staining for P53 in Colonic Adenocarcinomas and Their Lymph Node Metastases?"

"P P 54 1288"P 54 1288**DNA Ploidy Pattern and P53 Expression in Some Colonic Lesions in EgyptM.A. Madwar,**

*S.M. Kamal, M.A. Massoud, R.R. Kamel, S. Eissa, S. Ismail, N.H. Ismail, H. Shaker

Departments of Clinical Tropical Medicine, Surgery, Molecular Biology, Oncology and Pathology, Ain Shams and Cairo Universities, Cairo, Egypt*Background Aim:* The assessment of premalignancy and increased cancer risk is rather difficult. Ulcerative colitis and colorectal adenomas represent important premalignant conditions in the colon. The increasing incidence of colonic cancer in these patients made the search for detection of prelamignancy of great value. This study was designed to determine DNA ploidy pattern and P53, the tumor suppressor gene, expression in some colonic lesions as ulcerative colitis, colorectal adenomas and colorectal carcinoma in Egypt.*Patients & Methods:* DNA ploidy and S phase fractions were assessed by flowcytometry together with detection of P53 by RT-PCR-SSCP method in colonic and rectal biopsies from 18 patients with ulcerative colitis, 8 patients with colorectal adenomas and 10 patients with colorectal carcinoma in addition to 20 patients with infective and nonspecific colitis as control group.*Results:* Diploid histograms were found in 12 ulcerative colitis cases, all colorectal adenoma cases and all control subjects. All colorectal cancer cases and 6 patients with ulcerative colitis exhibited DNA aneuploidy. Out of these 6 ulcerative colitis cases, four showed low grade dysplasia and two cases were indefinite for dysplasia. S phase fractions were highest in colorectal cancer (18.4 – 6.4%) followed by ulcerative colitis (17.4 – 5.0%) compared to colorectal adenoma (14.3 – 3.9%) and control subjects (13.8 – 2.1%) and a correlation was found between S phase fraction values and disease duration but not with disease activity in ulcerative colitis. P53 expression was detected in 6 (60%) of colorectal cancer and one case of ulcerative colitis all of which showed aneuploidy. Follow up of the 6 patients of ulcerative colitis showing aneuploidy without or with P53 expression (1993–1996) revealed early neoplastic transformation in one case.*Conclusion:* (1) DNA aneuploidy and P53 could be useful biomarkers of colorectal cancer risk and have a prognostic potential. (2) DNA aneuploidy and P53 can be valuable complement to endoscopy and histological examination in colonic cancer surveillance especially in high risk individuals. "P P 54 1289"P 54 1289**Long-Term Outcome Following Surgery for Malignant Large Bowel Obstruction**

*K. Yoshimura, M. Onda, N. Tanaka, H. Takasaki, K. Furukawa, K. Higuchi, T. Seya, S. Yokoyama, H. Kan, H. Maruyama, H. Sasabe, T. Yamada

First Dept. of Surg., Nippon Medical School, Tokyo, JapanThis study determined the factors causing poor prognosis of patients with obstructing colorectal cancer. Seventy-six patients with bowel obstruction who had undergone curative surgery were studied in comparison with 1,039 patients of non-obstructive colon cancers (control cases) in the period from 1976 to 1994. Poor prognosis in survival was obtained after surgery for obstructing colorectal cancers ($p = 0.025$, log rank test). Tumour differentiations were not so poor in obstructing colorectal cancers ($p = 0.181$), and outcome of poor prognosis after surgery for obstructing cancers was not related to tumour location, poor differentiation and vascular invasion. Tumour stage in Dukes' classification of obstructing colorectal cancer was more advanced than control cases ($p = 0.004$). In the respect of tumour stage, there were no significant difference in survival between obstruction and control cases of stage A and B in Dukes' classification ($p = 0.620$ and 0.904, respectively). On the other hand the 5-year survival rate in stage C obstructing cancers was 37 per cent against 57 per cent of survival rate in stage C control cases ($p = 0.065$,). Thus it was suggested from these results that lymph nodes metastasis was most influential factor for poor prognosis in obstructing colorectal cancer. To dissect lymph nodes adequately, we attempt to remove intraopreratively feces in obstructing bowel by suction or lavege through colon with saline. These intraoperative procedure led to improve in survival compared with control ($p = 0.886$, log rank test). }" "Long-Term Outcome Following Surgery for Malignant Large Bowel Obstruction"

"P P 54 1291"P 54 1291**CT Evaluation of the Resectability of Locally Advanced Rectal Cancer after Radiation and Chemotherapy**

*N. Momot, J. Solovyova, V. Berejnoy

Ukraine*Purpose:* To determine accuracy of CT in evaluating the resectability of locally advanced rectal cancer in patients who underwent radiation and chemotherapy (5FU).*Materials and Methods:* 128 patients with locally advanced rectal cancer were studied by CT both before and after preoperative treatment. Optimal distention and better visualization of rectal wall were achieved by balloon dilatation of rectum with air insufflation. CT findings were compared with surgical and histopathological specimen.*Results:* Postoperative histology confirmed complete tumor disappearance in 26 patients, considerable reduction of tumor mass (more than 50% of initial size) – in 88 patients. 106 patients of the both group underwent sphincter-saving resection and 8 – abdomino-perineal resection. Remaining 14 patients had minimal or no effect and were identified as inoperable. CT rezults were correct in 105 cases (82%), equivocal – in 15 cases (12%) and incorrect – in 8 patients (6%).*Conclusion:* CT has a high diagnostic value in determining the efficacy of preoperative radiation and chemotherapy and evaluating subsequent resectability in patients with locally advanced rectal cancer. "P P 54 1292"P 54 1292**Safety of DVT-Prophylaxis with Enoxaparin Vs. Dextran-70 and Heparin in Digestive Surgery-Play-The-Winner Designed Studies**

*G. Thorsen, T. Gerner, T. L\'f8vig, R. St\'f8rkson, P. Mowinckel, O. Reiertsen, S. Larsen

Harstad County Hospital, Norway*The aims* were to compare the safety of DVT-prophylaxis with enoxaparin vs. dextran-70 and unfractionated heparin in digestive surgery.*Materials:* In the first study comparing enoxaparin and dextran-70, 327 patients undergoing digestive surgery in two Norwegian hospitals were included. In the second study, comparing enoxaparin and heparin, 183 patients from two other hospitals were enrolled.*Methods:* In a Play-the-Winner (PTW) designed study the treatment of any next patient will depend on the outcome of the previous. If successful, the next patient receives the same treatment, if not, the comparative regimen will be given. Excessive bleeding according to specified criteria, severe adverse reaction, clinically detected DVT or pulmonary embolism (PE) were criteria for classification as ""loser"". The PTW-design will allocate most patient to the superior treatment. The main variable in PTW studies is the number of consecutive patients receiving the same treatment.*Results:* In the first study 200 patients were allocated to enoxaparin and 127 to dextran-70 ($p < 0.01$). The rate of success was 83% in the enoxaparin group and 74.8% in the heparin group. The survival analysis confirmed superiority of enoxaparin ($p < 0.01$). In the second study enoxaparin had a success rate of 80% and unfractionated heparin 81%. The survival analysis showed no significant difference between the groups.*Conclusion:* From a safety point of view DVT-prophylaxis with enoxaparin was found to be superior to dextran-70 and clinical equal to unfractionated heparin in digestive surgery. Clinical practice: Epidemiology (non cancer)Clinical practice: Quality assurance }"

"P P 54 1293"P 54 1293**Intraluminal Prothesis (SBS-Tube) Enhances Healing in One Layer Colon Anastomoses**

*N. Buch, H. Glad, P. Svendsen, H.R.W. Oxlund, F. Gottrup, C.P. Hovendal

Dept. of Surgery A, Odense University Hospital, Denmark

Biomedical Laboratory, Odense University, Denmark

Dept. of Anatomy C, Aarhus University, Denmark

Copenhagen Wound Healing Center, Bispebjerg Hospital, DenmarkIn one layer colonic anastomoses the risk of anastomotic insufficiency is approximately 6.2% (Sarin S, Lightwood RG. Br J Surg 1989; 76: 493–5). Several factors impairs healing in anastomoses. Among these are local ischemia, infection, insufficient adaption of the cut ends and insufficient surgical technique. *Purpose:* To compare healing in one layer colonic anastomoses performed with or without a new intraluminal prothesis (SBS-tube). *Method:* In 16 pigs the sigmoid colon was transected and an anastomosis was performed end-on with extramucosal continuous suturing. In the SBS-tube group (n = 8) the colon was slipped over the SBS-tube and the ends were approximated before suturing. The integrity and position of the SBS-tubes were examined post operatively by x-ray every second hour. After 96 hours the anastomoses were tested for leakage and breaking strength, and histology was performed. Measurements of tissue oxygen tension in the colonic wall at the anastomotic line, – 1 cm, and – 5 cm were performed after suturing and after 96 hours. *Results:* 75% of the tubes dissolved in less than 2 hours. Histology (see Figure): The SBS-tube group had a significantly better structure of layers (L) and mucosal epithelial covering (E). Similarly a tendency in favor of the SBS-tube group was found in tissue gap (A) and inflammation (I) but not in breaking strength (B) and amount of granulation tissue (G). Oxygen tension in the anastomotic line was also in favor of the SBS-tube group.

Conclusion: The SBS-tube facilitates the sewing of the anastomosis and seems to enhance healing parameters and restoring normal histology. This might be due to a better apposition of the cut ends and to a reduced suture tension. }" "Intraluminal Prothesis (SBS-Tube) Enhances Healing in One Layer Colon Anastomoses"

"P P 55 1294"P 55 1294**Analysis of Low Density Lipoprotein Receptor (LDLR) mRNA Expression by Polymerase Chain Reaction Assay in Colorectal CancerM. Notarnicola, M.G. Caruso, A. Cavallini, M. Bianco,**

*A. Di Leo

Lab. Biochemistry IRCSS ""S. De Bellis"" Castellana Grotte (Ba) ItalyProliferating tumour cells express increased numbers of LDLR molecules on their surface which enable them to bind and take up cholesterol-delivering LDL particles for growth and replication. Recently, the LDLR and its mRNA have been detected in 19 samples of human colon carcinoma [1]. On the contrary, in a previous study, we have demonstrated the presence of LDLR only in 17% of 53 specimens of human colorectal adenocarcinoma (CRA) [2].*Aim* of this preliminary study was to verify whether the absence of LDLR in mostly neoplastic samples was due to the loss of its transcript.*Materials and Methods:* Twenty CRA neoplastic samples without LDLR protein, previously evaluated by ELISA method, were studied. LDLR mRNA expression was investigated by the reverse transcriptase polymerase chain reaction method (RT/PCR), and the relative PCR products by HPLC.*Results:* Both LDLR and LDLR mRNA were absent in 13 of 20 CRA samples, while LDLR mRNA (1.34 pg/\'b5g total RNA), but not LDLR, was found in the remaining 7 CRA samples.*Conclusions:* The LDLR absence was due to the loss of its mRNA in 65% of cases (13/20). In the remaining 35% of cases (7/20), the absence of LDLR with high levels of LDLR mRNA may be due to a block of the translation process, with a subsequent store of mRNA within cells. Further studies will be required to detect the molecular events regulating the LDLR metabolism in neoplastic colorectal mucosa.

"P P 55 1295"P 55 1295**Polyamine Levels and Polyamine Oxidase Activity in Human Colorectal CancerM. Linsalata, B. D'Attoma,**

*A. Di Leo

Lab. Biochemistry, IRCCS ""S. de Bellis"" Spec. in Gastroenterologia Castellana G. (BA) ItalyPolyamines (putrescine, spermidine and spermine) are low molecular weight amines required for normal cellular growth. Polyamine biosynthesis is known to increase with mitogenesis, and elevated polyamine concentrations are found in tumour tissue including gastrointestinal mucosa [1,2]. As regards the mechanisms maintaining cellular polyamine levels, the regulation of biosynthesis has been already clarified, but little is known about the regulation of their degradation pathway. During catabolism, N^1 acetylpolyamines are converted back to spermidine and putrescine by polyamine oxidase (PAO). Therefore, this enzyme seems to play an important role in modulating polyamine levels in the actively proliferating tissues such as neoplastic ones. In order to obtain more information about the metabolism of polyamines in human colorectal cancer, our *aim* was to evaluate polyamine levels and PAO activity in colorectal adenocarcinoma (CRA) and in surrounding mucosa. *Materials and Methods:* Twenty-five patients (18 males and 7 females; mean age 69 yrs, range 33–87) with CRA entered the study. Polyamine levels and PAO activity in neoplastic colorectal tissue and in surrounding uninvolved mucosa were analysed by HPLC [3,4]. Data were assessed by Student's t-test for paired data. *Results:* (polyamines are expressed as nmol/gr weight tissue, PAO activity is expressed as nmol of putrescine formed for 30 minutes for mg of tissue protein). M – * p <0.01 Put Spd Spm Total PAONeoplastic tissue 32 – 31* 297 – 170* 531 – 353 859 – 533* 1.3 – 0.6*Normal mucosa 13 – 5.4 188 – 124 463 – 343 664 – 468 2.1 – 1.5*Conclusions:* Higher polyamine levels and a lower PAO activity were found in CRA samples than in normal mucosa. This suggests that PAO in neoplastic tissue is no more able to modulate polyamine levels and induces an abnormal polyamines accumulation.

"P P 55 1297"P 55 1297**Immunohistochemical Study of Peptide and Amine Cells in Human Colorectal Cancer**

*Y. Ozawa, M. Onda, T. Honjo, T. Okuda, Y. Sumiyama

Third Department of Surgery, School of Medicine, Toho University, Tokyo, Japan*Aim:* In order to clarify the histological occurrence, differentiation and development of colorectal cancer, the incidence and degree of peptide and amine cells in colorectal cancer tissue were studied relationship with its growth and progress.*Materials and Methods:* The subjects consisted of 220 cases colorectal cancer surgically removed in our department. Immunohistochemical activities were stained by streptoavidin-biotin (SAB) technique using formalin-fixed, paraffin-embedded tissue sections Haematoxylin-eosin-stained specimens were used for histological classification.*Results:* In normal colorectal tissue, many peptideYY-, moderate numbered glucagon-, small numbered somatostatin-, immunoreactive cells were shown. On the other hand well- and moderately-differentiated adenocarcinoma tissue contained moderately numbered peptideYY- and many glucagon- immunoreactive cells. Tissue of poorly differentiated regions contained small numbered peptideYY- and many glucagon-immunoreactive cells. Peptide and amine cells were recognized significantly in the following cases: high blood vessel invasion, lymphatic invasion cases, high lymph node metastasis, positive cases of peritoneal dissemination and liver metastasis. Peptide cells appeared highly in a considerably deep focus infiltrating through the mucosa.*Conclusions:* Although the precise meaning of peptide cells in the focus of colorectal cancer has remained obscure, it is suggested that peptide and amine cells may be secreted from colorectal cancer tissue, and then has strongly inference on the differentiation and development of colorectal cancer. Oncology, specific: Colon, rectum }" "Immunohistochemical Study of Peptide and Amine Cells in Human Colorectal Cancer"

"P P 55 1298"P 55 1298**Diagnostic and Prognostic Evaluation of Adenosine Deaminase Activity in Human Colorectal Tumors**

*G. Kocic, D. Pavlovic, S. Nagorni, I. Stamenkovic, T. Cvetkovic, R. Kocic, S. Zivic

Institute of Biochemistry and Clinic for Gastroenterology University Nis, YugoslaviaColorectal cancer is one of the most frequently occurring cancer in humans and there is an attempt to devise more selective nove tumor markers. High activity of adenosine deaminase (ADA) have been found during rapid growth state and/or after stimulation by growth factors. The study included patients with: colorecta carcinoma (10), polyps (8), resected colon carcinoma (4), patients without any pathological manifestation during colonoscopy (6). The ADA activity (IU/g prot.) was determinated in endobioptic samples obtained from: carcinoma or polyp adjacent tissue, anastomoses after carcinoma resection and healthy tissue farther from lesion. The ADA activity was especially high in carcinoma adjacent tissue, i.e. endoscopically looking healthy (65.49 – 24.33 vs farther healthy 10.15 – 0.18; $p < 0.001$). It means that ADA is important as early marker of abnormal proliferation, to discriminate normal and malignant colon epithelium and point to radical surgical resection. Estimating ADA activity from polyp adjacent tissue, the same trend was shown but significantly lower than in carcinoma (26.92 – 8.92 vs 14.28 – 5.87; $p < 0.05$). The enzyme activity from anastomosis varied (from 13.38 to 40.60) with mean value 31.37 – 12.69. Obtained results could be useful in assessing prognosis and clinica1 outcome of the disease. The ADA activity in patients without pathological manifestations was 15.8 – 3.8. It confirms that ADA is included in growth control, progression and invasion of human colorectal cancer and could be used as simple routine test for monitoring tissue neoplastic transformation.

"P P 55 1299"P 55 1299**Effects of Pro-Oxidant Systems on the Lipid Peroxidation and Antioxidative Capacity in Human Colon Carcinoma and Polyps**

*D. Pavlovic, S. Nagorni, G. Kocic, T. Cvetkovic, I. Stamenkovic, V. \'d0ordevic

Institute of Biochemistry & Clinic for Gastroenterology, University of Nis, YugoslaviaThere is convincing evidence that cell proooxidant state can promote to neoplastic growth, and that antioxidants are antipromoters and anticarcinogens. The study included 8 patients with colon carcinoma and 6 with polyps. Bioptates were from tissue surrounding malignant lesion and polyp as well as from normal tissue farther from alterative spot. The level of lipid peroxidation products was examined in homogenates after exposing to suspensions of prooxidant system (ascorbate + iron) measuring MDA (nmol/mg prot.). Obtained results show that used prooxidant system was capable to produce much greater effects in control healthy tissue (MDA concentration 4.14 – 0.9 and 3.37 – 0.88) than in corresponding tissue surrounding carcinoma (2.19 – 0.45; $p < 0.005$) or polyps (1.87 – 0.59; $p < 0.01$). The antioxidative capacity of bioptate was tested using model of Fe^{++} induced generation of MDA in phospholipid liposome suspension and expressed as percent of the inhibition of MDA formation. The antioxidative capacity was increased from tissue surrounding carcinoma (72.2 – 11.5%) vs control healthy farther tissue (50.7 – 13.47%; $p < 0.05$). However, there was not significant change in antioxidative capacity of polyps bioptate compared with normal mucosa. Decreased lipid peroxidation in tissue surrounding cancer and polyps is consistent with fact that transformation of normal into malignant tissue makes cells less peroxidisable. The increase of antioxidative capacity together with the decrease of lipid peroxidation in tissue surrounding carcinoma indicates that this change apparently occurs in early stage of complex sequences of malignant transformation. Oncology, general: Proliferation, carcinogenesisOncology, specific: Colon, rectumEndoscopy, specific: Colon, rectum }" "Effects of Pro-Oxidant Systems on the Lipid Peroxidation and Antioxidative Capacity in Human Colon Carcinoma and Polyps"

"P P 55 1300"P 55 1300**Dissimilar Activation Pattern of the Carcinogen Dimethylhydrazine (DMH) on Intracellular Polyamine Metabolism in Various Organs**

*Chr. L\'f6ser, F. Starp, U.R. F\'f6lsch

I. Medical Department, Christian-Albrechts-University of Kiel, GermanyPolyamines, and especially the key enzyme of polyamine de novo synthesis ornithine decarboxylase (ODC) are well known to play an important role in cell growth as well as tumour carcinogenesis. Weekly administration of the potent carcinogen dimethylhydrazine (DMH) is known to highly induce predominantly carcinoma of the colon after 6 months' treatment in rats. Simultaneous administration of the ODC inhibitor difluoromethylornithine (DFMO) highly significantly reduces DMH-induced carcinoma formation (Cancer Res 43: 1983; Anti Cancer Res 7: 1987). Furthermore, it is known that carcinogens have different activation patterns on polyamine metabolism in various organs (L\'f6ser et al., Pancreas 10: 1995).*Methods:* Male Wistar rats (180 g) were s.c. injected with a single dose of DMH (20 mg/kg b.wt.) and 5–7 animals were killed 4, 8, 12, 24, 72, 120, 168, and 240 hours after DMH or saline injection, respectively. Polyamines, ODC, SAM-DC, SAT, organ weight, DNA polymerase, and DNA were analysed in distal colon, proximal colon, small intestine, liver, and pancreas. Additionally, 7 animals were simultaneously treated with DFMO (2% in drinking water plus 3 {\'b4} 300 mg/kg b.wt. i.p. during daytime) and sacrificed 7 days after a single injection of DMH.*Results:* DMH treatment resulted in a significant increase in ODC activity and putrescine concentration in the proximal and distal colon after 7 days and DNA-polymerase after 10 days, while the other parameters were unchanged in the colon during the whole experiment. In small intestine ODC, SAM-DC, putrescine, and spermidine were in part significantly and prolonged increased between 8 and 168 hours. While in the liver SAT was significantly increased after 78 and 240 hours, no changes were found in the pancreas. DFMO treatment completely prevents DMH-induced activation of polyamine de novo synthesis in the gut.*Conclusions:* A single dosage of the potent colon carcinogen DMH resulted in dissimilar activation patterns in different organs: In the colon polyamine de novo synthesis is significantly induced after 7 days, in small intestine putrescine and spermidine de novo synthesis is increased between 8 and 168 hours, interconversion pathway is induced in liver, while no changes were found in the pancreas. Interestingly DMH activation of polyamine de novo synthesis appears late, which is different from findings in other carcinogens. These findings further contribute to a better understanding of carcinogen-induced complex intracellular biochemical mechanisms (DFG L\'f6 459/2-1; AIR 569-92) Oncology, general: Proliferation, carcinogenesisOncology, specific: Colon, rectum }" "Dissimilar Activation Pattern of the Carcinogen Dimethylhydrazine (DMH) on Intracellular Polyamine Metabolism in Various Organs"

"P P 55 1301"P 55 1301**Telomerase Expression in Colorectal Cancer**

*S. Odogwu, A.G. Morris, I.A. Fraser

Walsgrave Hospital, Coventry and Warwick University, Coventry, EnglandTelomeres are DNA sequences found at the ends of all chromosomes. They have no synthetic function, but protect chromosomal ends during cell division. The telomeric sequence shortens with each cell division and when it reaches a critical length the cell dies (senesces).Telomerase is an enzyme not expressed by somatic tissues, but found in some tumours. It replaces lost telomeric sequences, preventing cell senescence and thus rendering the cell immortal. This immortalization may be an important step in the process of tumorigenesis.There has been little work on telomerase in colorectal cancer to date. We have studied 20 patients undergoing surgical resection of malignant colorectal tumours, as well as 8 patients with premalignant lesions. The cancers varied from Duke's stage A to advanced metastatic tumours. Mean age was 72, with a range of 51 to 80. Curative resections were carried out on 14 patients while 6 had palliative surgery.Enzyme activity was studied using a polymerase chain reaction (PCR) based method. Specific oligonucleotide primers are acted on by telomerase and telomeric sequences formed. These can then be separated and visualized by tel electrophoresis.Telomerase activity was detected in 19 of 20 (95%) primary tumours. All corresponding pieces of normal mucosa were negative. Of the adenomas 3 of 8 were positive.These results show that telomerase activation occurs in a high percentage of colorectal tumours and is an early feature of tumour progression. This sensitive technique for detecting telomerase activity could be a useful tool for early diagnosis and follow up of malignant disease in the future. Oncology, general: Molecular biology, geneticsOncology, specific: Colon, rectum }" "Telomerase Expression in Colorectal Cancer"

"P P 55 1302"P 55 1302**The Value of Flow Cytometry in Colorectal Carcinoma**

*H. Akbulut[1], D. Din\'e7ol[1], O. Aydintug[2], S. As\'e7ikoca[2], F. I\'e7li[1], H. Karaoguz[1], A. Demirkazik[1], F. \'c7ay[1]

[1] Dept. of Medical Oncology, Ankara University School of Medicine, Ankara, Turkey

[2] Dept. of Immunology, Ankara University School of Medicine, Ankara, TurkeyThere has been a considerable number of conflicting reports on the role of DNA ploidy and S-phase fraction (SPF) as prognostic factors in colorectal carcinoma (CRC).Paraffin-embedded tumor specimens from 55 patients with operable CRC were studied by flow cytometry in order to determine the prognostic value of DNA ploidy and SPF.Twenty-two patients (40%) had aneuploid tumors and 33 (60%) had diploid ones. Mean SPF was calculated as 10.1% (range: 1.2%–34.8%) in all patients. There were no significant correlations between DNA ploidy and the other clinical and histological parameters used in the study. Twenty-two patients (40%) had aneuploid tumors and 33 (60%) had diploid ones. Mean SPF was calculated as 10.0% (range: 1.2%–34.8%) in all patients. There were no significant correlations between DNA ploidy and the other parameters used in this study, SPF was found to be significantly higher in aneuploid tumors and rectal tumors (p = 0.0002 and p = 0.0397, respectively) Histologic grade, age and SPF were found to be significant factors for OAS in univariate analysis (p = 0.0225, p = 0.0283 and p = 0.0256, respectively). Adjuvant chemotherapy and age ({\'a3} 60 years) yielded better DFS rates in univariate analysis (p = 0.0493 and p = 0.0074, respectively). While age and the histologic grade of the tumor were the independent significant factors for OAS (p = 0.033 and p = 0.011, respectively), DNA ploidy and histologic grade of the tumor were found as independent prognostic factors for DFS (p = 0.0046 and p = 0.0029, respectively).In conclusion, we can say that DNA ploidy status may be a weak prognostic factor for patients with CRC, whereas SPF seems to be a more important factor than DNA ploidy in the assessment of the prognosis.

"P P 55 1303"P 55 1303**Dual Nature of Colorectal Cancer Mucin and Its Significance**

*J.R. Jass, Y. Ajioka

University of Auckland, Auckland, New ZealandMucin secretions within colorectal cancers appear to be of a dual nature. MUC2 codes for the protein component of secretory mucin produced by goblet cells. MUC1 codes for the protein component of glycocalyceal material produced normally by columnar cells and upregulated in cancers. The expression of MUC1 and MUC2 apomucins was studied in a series of colorectal cancers with the aim of distinguishing subtypes with differing histogenesis and prognosis.A series of 51 colorectal cancers was stained immunohistochemically with monoclonal antibodies to the mucin protein core structures MUC1 and MUC2. Four phenotypes were recognised: MUC2+/MUC1{ -}, MUC2+/MUC1+, MUC2{ -}/MUC1+ and MUC2{ -}/MUC1{ -}. The distribution of pathobiological and prognostic features within the four groups was studied.The phenotype MUC2+/MUC1{ -} was closest to normal large bowel mucosa. Cancers with this phenotype showed a negative correlation with lymph node metastases ($p < 0.05$). MUC2+/MUC1+ cancers were associated with contiguous adenoma (villous and tubulovillous) and exhibited abundant mucin secretion ($p < 0.05$). MUC2{ -}/MUC1+ cancers were frequently accompanied by a marked peritumoural lymphocyte reaction ($p < 0.05$). Those with no lymphocyte reaction were associated with lymph node spread. MUC2{ -}/MUC1{ -} cancers were the most aggressive of the four phenotypes.The preceding data support the earlier suggestion that MUC2{ -} colorectal cancers may arise de novo and provide an approach to classification that cuts across traditional methods and may be highly relevant to aetiology, pathogenesis and prognosis. Oncology, specific: Colon, rectumOncology, general: Proliferation, carcinogenesis }" "Dual Nature of Colorectal Cancer Mucin and Its Significance"

"P P 55 1304"P 55 1304**Cathepsin B Like Activity in Colorectal AdenomasM. Laiglesia,**

*F.J. Jim\'e9nez, I. Monreal[1], P. Liso, F. Borda

Hospital de Navarra, Pamplona, Spain

[1] CUN, Pamplona, SpainCathepsin B is one of the proteinases that may play a key role in invasion and metastasis of colorectal cancer cells. It has been demonstrated that neoplastic cells possess cathepsin B at the plasma membrane whereas the enzyme is present only intracellularly in lysosomes of normal cells Increased cathepsin B activity has also been reported in serum of patients with colorectal cancer. The aim of this study is to evaluate cathepsin B activity in serum of patients with colorectal adenomas.*Material and Methods:* 57 patients (39 males/18 females; mean age 63.4 yr) who underwent endoscopic resection of colorectal adenomas and had no other disease were included in the study. Patients were divided into three groups: I (n = 20) Tubular adenomas; II (n = 20) Villous adenomas; III (n = 17) High grade dysplasia adenomas. A control group of healthy donors (n = 20) was also evaluated. Cathepsin B activity was measured in serum using L-BAPNA as substrate, adding EDTA and DTT, at a reaction pH = 6.*Results:* Control: 0.163 – 0.03 U/l; I: 0.166 – 0.04 U/l; II: 0.168 – 0.05 U/l; III: 0.178 – 0.07 U/l. Statistical significance was found between the four groups ($p < 0.01$) and when comparing group III with the rest of groups ($p < 0.05$).*Conclusions:* 1. The increase in expression of cathepsin B activity may be a sensitive marker for progression from the premalignant to the malignant state in the development of colorectal cancer. 2. It might be questionable to consider a high grade dysplasia adenoma as a local lesion, when systemic biological modifications are found.

"P P 55 1306"P 55 1306**Effect of Radiotherapy on the Potential Doubling Time (Tpot) of Rectal Cancer**

*P. Michel[1], J. Hemet[2], M. Paresy[2], S.H. Seng[1], C. Iasci[1], A. Fran\'e7ois[2], B. Paillot[1]

[1] Centre des Tumeurs Digestives, Hospital Charles Nicolle, F76031 Rouen Cedex, France

[2] Laboratoire d'Anatomie Pathologique, Hospital Charles Nicolle, F76031 Rouen Cedex, France*Aim:* The benefit of radiotherapy in adjuvant treatment of rectal cancer is demonstrated. However many questions remain about the modalities of this treatment which could be improved by a better understanding of the biological effects. We have evaluated the influence of radiation (34.5 Gy in 15 fractions and 3 weeks) on Tpot of rectal cancer.*Methods:* Four hours after infusion of 250 mg of bromodeoxyuridine (BrdU) endoscopic biopsies of the tumor were taken and we have studied the following kinetic parameters: labelling index (LI) of BrdU, duration of the S phase (Ts) and Tpot, with Begg's method. 36 measures have been done: 19 in patients with colonic cancers without prior chemotherapy or radiotherapy (group 1), 10 in patients with rectal cancers after radiotherapy (group 2) and 7 out of these 10 have been also investigated before radiotherapy (group 3). The means values of LI, Ts and Tpot were compared with Mann-Whitney's U test.*Results:* The LI, Ts and Tpot values (mean – SD) were: LI in % Ts in hours Tpot in daysGroup 1 11.7 – 6.0 14.3 – 4.4 5.1 – 2.7Group 2 8.5 – 8.8 15.0 – 4.1 12.6 – 8.7Group 3 10.3 – 5.2 13.1 – 4.2 5.5 – 3.3The comparison between these groups suggests a decrease of Tpot value in the radiotherapy group (1 *vs* 2, p = 0.048) however no difference was shown neither between group 2 and 3 (p = 0.097) nor between colon and rectum cancers (p = 0.81). No difference were significant for LI and Ts. In the subgroup of diploid tumors a significant difference has been found for Tpot (1 *vs* 2 = 0.001; 2 *vs* 3 p = 0.008) and LI (1*vs* 2 p = 0.008).*Conclusion:* These results suggest a decreased of kinetic activity of rectal cancer after radiotherapy, mainly in diploid tumors. Department of Gastroenterology, Royal Postgraduate Medical School, Hammersmith Hospital, Du Cane Road, London 12 ONN, England

[1] Department of Histopathology, Royal Postgraduate Medical School, Hammersmith Hospital, Du Cane Road, London 12 ONN, England*Purpose:* To investigate the effects of soya bean, peanut, mushroom, wheat germ and broad bean (BBL) lectins on the differentiation, proliferation and adhesion of colorectal carcinoma cell lines (SW1222, HT29, LS174T, S480, SW620).*Methods:* Cells were cultured in the presence or absence of each lectin at serial concentrations. Differentiation was determined in 3D-collagen gel, cell-cell adhesion by a homotypic cell aggregation assay and proliferation by tritiated thymidine incorporation and MTT assay. The role of molecules involved in cell-cell adhesion and epithelial differentiation was investigated using blocking antibodies to Epithelial cadherin (HECD-1), carcinoembryonic antigen (PR3B10) and EGP-40 (AUA1).*Results:* BBL which binds to mannose groups caused LS174T cells to differentiate markedly into organised glandular structures. Both gland formation and cell-cell adhesion induced by BBL was specifically inhibited by the monoclonal antibody AUA1. BBL also inhibited the proliferation of LS174T cells.*Conclusion:* BBL promotes differentiation and inhibits proliferation of LS174T cells and the adhesion molecule EGP-40 seems to be involved in this effect. These results point to a novel mechanism controlling the differentiation of colonic cancer cells. Oncology, specific: Colon, rectumOncology, general: Proliferation, carcinogenesisHormones and receptors: Growth factors }" "Broad Bean Lectin Increases Morphological Differentiation and Inhibits Proliferation of Colon Carcinoma Cells"

"P P 55 1309"P 55 1309**Determination of the RER Status in Tumor Cells by a Single Microsatellite GenotypingJ.M. Hoang, P. Cottu, B. Thuille, S. Olschwang, R.J. Salmon, G. Thomas,**

*R. Hamelin

INSERM U434, G\'e9n\'e9tique des tumeurs, Institut Curie, Paris, France*Background and Aims.* Inactivation of mismatch repair (MMR) genes has been involved in tumorigenesis, leading to rapid accumulation of replication errors at microsatellite loci in tumor cells, called RER+. Microsatellite instability has been first described in colorectal tumors associated with hereditary non-polyposis colorectal cancer (HNPCC) syndrome. Somatic inactivation of MMR genes accounts for 15% of sporadic cases, that do not exhibit extended losses of heterozygosity, thus allowing to define two alternative pathways in colorectal carcinogenesis. Significative difference in prognosis has been shown between these two types of tumors, giving rise to a systematic determination of the RER status.*Methods.* 134 primary tumors and 27 cell lines derived from colorectal cancers were typed for at least 20 microsatellite loci. All but one were highly polymorphic dinucleotide repeats; the last one was a constant mononucleotide repeat.*Results.* 35 tumors exhibited instability at more than 50% of tested dinucleotide repeats loci and were thus classified RER+; 99 tumors did not show instability at more than 6% of the tested loci; 8 out of 27 cell lines were RER+.Genotyping of the mononucleotide repeat locus gave similar information for 160 out of the 161 samples. In RER{ -} samples, the size of the PCR product did not differ from that observed in normal matched DNA and in 70 DNAs of unrelated CEPH individuals. All but one RER+ samples were shown to carry an additional smaller allele, that could be resolved by non denaturing polyacrylamide gel electrophoresis and ethidium bromide staining.*Conclusion.* Genotyping of a single mononucleotide repeat microsatellite enables to unambiguously determine the RER status of colorectal tumor cells, even in the absence of matching normal DNA in the vast majority of cases. This simple, low-cost and rapid approach could be implemented in a routine hospital laboratory. Oncology, general: Molecular biology, geneticsOncology, general: EpidemiologyOncology, specific: Colon, rectum }" "Determination of the RER Status in Tumor Cells by a Single Microsatellite Genotyping"

"P P 55 1310"P 55 1310**The Human Gastrin/Cholecystokinin Type B Receptor Gene: Study of Its Spliced Expression in Healthy and Tumoral Colon Samples, Associated Hepatic Metastases and Colonic Cell Lines**

*Ph. Biagini[1], D. Parriaux[2], J.F. Cantaloube[1], Ph. De Micco[1], G. Monges[2]

[1] Regional Center for Blood Transfusion, Marseille, France

[2] Paoli Calmettes Institute, Marseille, France*Purpose* – The hypothesis that the growth of some gastro-intestinal cancers may be regulated by hormones requires the presence of receptors. The gastrin/cholecystokinin type B receptor (CCK-B receptor) are clearly recognized by gastrin, which is known to be involved in the development of some gastro-intestinal cancers. Variable splicing of exon 4 of the human receptor gene results in the presence of 2 different mRNA isoforms, the exact significance of which still remains to be elucidated. Here we investigated the expression of the 2 isoforms of the receptor on a series of healthy and tumoral colon samples, the associated hepatic metastases and four colonic cell lines. Gastrin mRNA expression was also investigated*Methods* – We performed reverse transcription-nested PCR using primers for the gastrin/CCK-B receptor; after Southern blotting, the long isoform was distinguished by hybridization with a specific probe and revealed by chemiluminescence.*Summary* – The short isoform was detected in all tumour and metastasis samples, in 8/10 normal colon and 3/4 colonic cell lines; whereas the long isoform, presumably functional, was expressed in 40% of the colon tumours, 43% of the hepatic metastasis, 50% of the normal colon samples, and 1 cell line (Sk-Co15). However, while gastrin transcript was detected in 90% of the tumours tested, only 30% also expressed the long isoform of the receptor.*Conclusions* – The implication of the gastrin/CCK-B receptor in an autocrine proliferative loop seems to be plausible in some colonic tumours and cell lines. "P P 55 1311"P 55 1311**The Role of Transforming Growth Factor Alpha on Kinin Stimulated Ion Transport and Barrier Function in Human Colonic Epithelial Cells**

*J. Beltinger, W.A. Stack, C.J. Hawkey

Divison of Gastroenterology, University Hospital, Nottingham NG7 2UH, UK*Introduction:* Enhanced PG synthesis has recently been shown after activation of EGF receptors with TGFa on the basolateral cell surface of HCA-7 cells. Bradykinin has been shown to stimulate electrogenic chloride secretion both by a Ca^{2+} dependent pathway and via eicosanoid production which can be attenuated by a cyclooxygenase inhibitor. We used the colonic epithelial cell line HCA-7, colony 29 to study the modulatory effect of TGFa on bradykinin induced chloride secretion and to show the possible interaction with local PG synthesis.*Methods:* HCA-7 cells were grown in DMEM (10% FCS), seeded on Snapwell filters and formed confluent monolayers within 10–12 days. Cells were either treated with TGFa (10 ng/ml) for 24 h in the presence or absence of NS398 (10{ ¯5} M), a specific cyclooxygenase-2 (COX-2) inhibitor, added two hours before removing cells from the wells. The filters were placed into an Ussing chamber bathed in oxygenated Krebs-Henseleit solution and voltage clamped by continous application of a short circuit current (SCC). Basal SCC (\'b5A/cm^2) and resistance ({ W}cm^2) was measured and after an equilibration period bradykinin (BK) (10{ ¯6} M) was added. All drugs were added to the basolateral side of the monolayer. Data are expressed as mean – SEM.*Results:* TGFa 10 ng/ml significantly increased baseline resistance (control 138 – 9.9 vs TGFa 169 – 16.2 { W}cm^2, n = 20, p = 0.03). The COX-2 inhibitor NS398 did not affect basal resistance of controls but enhanced resistance of TGFa pretreated monolayers (TGFa 169 – 16.2 vs TGFa+NS398 178 – 17.2 { W}cm^2, n = 13, p {\'b9} s). { D} SCC due to BK was attenuated by TGFa (control 13.3 – 2.7 vs 9.2 – 1.8 \'b5A/cm^2, n = 11, p = 0.03,). { D} SCC to BK was further reduced by NS398 in basal and TGFa pretreated cells (control vs control + NS398: 13.3 – 2.7 vs 6.6 – 1.4 \'b5A/cm^2, n = 6, p = 0.049; TGFa vs TGFa+NS398: 9.2 – 1.8 vs 4.4 – 1.3 \'b5A/cm^2, n = 6, p = 0.03).*Conclusion:* These data provide evidence of the regulatory role of growth factors on resistance and BK stimulated ion transport in intestinal epithelial cells with a central role of PG synthesis which may have important implications in pathogenic conditions such as inflammatory bowel disease.*Acknowledgment:* J Beltinger is supported by a grant from the Swiss National Foundation Hormones and receptors: Growth factors }" "The Role of Transforming Growth Factor Alpha on Kinin Stimulated Ion Transport and Barrier Function in Human Colonic Epithelial Cells"

"P P 55 1312"P 55 1312**Nonsteroidal Anti-Inflammatory Drugs Inhibited Human Colonic Cancer Cell Migration in Culture**

*K. Ohtaka, S. Watanabe, Y. Ono, K. Ota, R. Iwazaki, H. Misawa, M. Hirose, N. Sato

Dept. of Gastroenterology, Juntendo Univ. School of Med. Tokyo, JapanRecently, it was reported that nonsteroidal anti-inflammatory drugs (NSAIDs) inhibited carcinogenesis in the colon, possibly inhibiting cyclooxgenase (COX). Intake of NSAIDs is believed to reduce the relative risk of colorectal cancer in human. The mechanism of reduction is not clear, but as NSAIDs are potent inhibitor of tumorigenesis in rodent models of colon cancer, inhibition of COX may be involved in the mechanism for its antitumor activity. Recently, we established a new, simple and convenient model to analyze the cancer cell migration using a human colonic cancer cell line. Using this model, we assessed the migration capacity of colonic cancer cell line (Human rectal adenocarcinoma: SW837) and assessed the effects of aspirin (ASA) and indomethacin (IND) treatment. *Method:* SW837 cells (3.5 {\'b4} 10^5 cells) were inoculated into the round enclosed area (diameter, 15 mm) by silicon fence in a plastic culture dish and cultured in L-15 medium with 10% FBS. Inoculated cells formed round shaped cell sheet in 3 h and subsequently silicon fence was removed and then the cancer cell migration was monitored. The number of migrated cells from the cell sheet in a unit area of free space was counted after 48 h. The effects of ASA (0.1 {\'b4} $10^{\{-}$2}, 0.2 {\'b4} $10^{\{-}$2}, 0.3 {\'b4} $10^{\{-}$2} mM) and IND treatment (0.01, 0.03, 0.1 mM) were assessed. Cell growth of the controls, ASA and IND treatment groups were detected by using monoclonal anti-5-bromodeoxyuridine antibody (BrdU) and BrdU labeling index (BrdU positive cell number/total cell number {\'b4} 100) were calculated randomly selected unite area. *Result:* After the removal of the fence, cancer cells started to migrate and spread to all directions from the edge of the cell sheet. The number of cancer cells migrated from the cell sheet 48 h after the start of migration was presented in a table. Data: mean – SD, * p < 0.05, ** p < 0.01, n = 4, mm: distance from the edge of cell sheet. 0 – 5 mm 5 – 10 mm 10 – 15 mmControl 971 – 76 812 – 61 483 – 30ASA 0.1 {\'b4} $10^{\{-}$2} mM 781 – 68 707 – 52 419 – 190.2 {\'b4} $10^{\{-}$2} mM 712 – 59* 503 – 31** 303 – 11**0.3 {\'b4} $10^{\{-}$2} mM 520 – 41** 276 – 21** 178 – 12**IND 0.01 mM 830 – 72 794 – 57 425 – 26*0.03 mM 688 – 62** 589 – 50* 388 – 32*0.1 mM 490 – 38** 377 – 38** 322 – 21*The migrated cell number decreased in relation to ASA and IND dose. BrdU labeling index of ASA and IND treatment groups were lower than that of the control groups. *Conclusion:* Our data suggest that ASA and IND inhibit not only colon cancer cell growth but also cancer cell migration, thus possibly exhibiting the antitumor effects in the colon. "P P 55 1313"P 55 1313**Regulation of RXR{ a} is not the Mechanism by which 9-*cis* Retinoic Acid Modulates Vitamin D Action in Two Human Colon Cancer Cell Lines**

*K.F. Kane, E.A. Walker, G.R. Williams, M.J.S. Langman

The University of Birmingham, Birmingham, U.K.1{ a},25$(OH)_2$ vitamin D_3 (D_3) protects against colorectal cancer and has been proposed as a potential therapeutic agent in the treatment of this malignancy. D_3 action is mediated by a high affinity nuclear receptor (VDR) that regulates target gene transcription by binding to specific sequences of DNA known as D_3 response elements (VDREs). VDR may bind to VDREs as a homodimer or as a heterodimer with a retinoid X receptor (RXR). The ligand for RXR is 9-*cis* retinoic acid (9-*cis*RA) which has the potential to modify D_3 action. 9-*cis*RA has been proposed as a chemotherapeutic agent in its own right. We have previously demonstrated VDR and RXR{ a} and { g} mRNA expression in both normal and malignant human colorectum and the presence of functional VDR in primary cultures. In addition, 9-*cis*RA differentially modifies D_3 action in two human colon cancer cell lines. The aim of the present studies was to determine the mechanisms by which 9-*cis*RA modifies D_3 action in HT-29 and Caco-2 cells.HT-29 and Caco-2 cells were treated with D_3 and 9-*cis*RA ($10^{\{-8\}}$ M) and RXR{ a} protein was assessed by Western analysis. Nuclear extracts from human tissues also underwent Western analysis. Caco-2 cells were transfected with reporter genes containing VDREs from two D_3 responsive genes (24-hydroxylase or calbindin D_{9K}) and treated with D_3 or 9-*cis*RA.A 55 kDa RXR{ a} protein was expressed in both cell lines and was not regulated by either D_3 or 9-*cis*RA. RXR{ a} was also expressed in both normal mucosa and malignant tissue from 15 human specimens. In transfection studies, D_3 caused a modest activation of both VDRE constructs (– 1.5 fold) although this did not reach significance. Treatment with 9-*cis*RA resulted in a response of similar magnitude (– 1.4 fold activation, not significant).We demonstrate that RXR{ a} protein is present in malignant and normal human colorectum and two colonic carcinoma cell lines. Hormonal treatment did not alter RXR{ a} expression and regulation of RXR{ a} does not account for the differential responses of the two cell lines to 9-*cis*RA. Early transfection studies suggest that 9-*cis*RA may have a direct effect on the transcription of D_3 responsive genes but further investigations are necessary to elucidate these pathways. It is important to determine the action of 9-*cis*RA on D_3 signalling before it can be considered as an antiproliferative agent. "P P 55 1314"P 55 1314**Establishment and Characterization of a New Human Rectal Neuroendcrine Carcinoma Cell Line**

*T. Yamada, M. Onda, N. Tanaka, T. Seya, Y. Kanazawa, K. Furukawa, K. Higuchi, H. Takasaki, K. Yoshimura, S. Yokoyama, H. Kan, H. Maruyama, H. Sasabe

First Dept. of surg. Nippon medical school, Tokyo, JapanHuman colorectal neuroendcrine carcinomas (NEC) are rare, and there are a few reports of NEC cell lines available for study. We have reported rectal NEC xenograft in nude mice at 4th UEGW (1995). This tumor derived from a metastatic inguinal lymph node of a 58-year old Japanese female. We succeeded in establishing of a human NEC cell line from this tumor. This cell line has been maintained in culture for more than 1 year. The cells grew in a monolayer, thereafter tended to pile up and formed a cluster. The doubling time was approximately 44 hours at the 10th generation. Immunohistochemical studies of these cells showed positive reactivity for somatostatin, chromograninA, NSE, S-100, gastrin, glucagon, pancreatic peptide, CEA, p53, and PCNA, although negative reactivity for serotonin and VIP. These results were similar to formalin-fixed, paraffin-embedded tissue samples of the original tumor and xenograft tumor. CEA p53 SS CgA NSE S-100 gas. glu. PP PCNA Ser. "P P 55 1315"P 55 1315**Gastrointestinal Hormone mRNA Expression in Human Colonic Adenocarcinomas, Hepatic Metastases and Cell Lines**

*Ph. Biagini[1], D. Parriaux[2], J.F. Cantaloube[1], Ph. De Micco[1], G. Monges[2]

[1] Regional Center for Blood Transfusion, Marseille, France

[2] Paoli Calmettes Institute, Marseille, France*Purpose* – To investigate the expression of four main hormones of the digestive tract by performing reverse transcription polymerase chain reaction (RT-PCR) on a series of samples including both tumoral and healthy colonic tissues, hepatic metastases and colonic cell line samples, as well as to study the patterns of labelling obtained with serological and morphological markers.*Methods* – After extraction and reverse transcription, gastrin, somatostatin, cholecystokinin (CCK) and transforming growth factor alpha (TGF { a}) mRNA were detected by performing PCR and nested PCR using specific primers. Immunohistochemical assays against the corresponding proteins were also performed.*Summary* – The cell lines expressed all four mRNAs. Gastrin mRNA was present in most of the tumoral and metastatic samples, while the somatostatin transcript was detected in all the samples and was frequently over-expressed in the normal colon. TGF { a} mRNA was systematically expressed in tumours of the right and transverse colon, but not in those located in the left colon; the expression of CCK mRNA was systematically absent in the left colon.*Conclusions* – The data presented here shed some light on the transcriptional events involved in the production of the various hormones present in the gastrointestinal tract, in both healthy and tumoral tissue. The various mRNAs which are expressed in cell lines are therefore not systematically expressed in the human pathology. "P P 55 1316"P 55 1316**The Distribution of *Kirsten-ras* Mutations within Early Colorectal Adenocarcinomas**

*H.J.N. Andreyev, S.A. Sampson, D. Cunningham[1], J.V.T. Tilsed[1], P.A. Clarke[2]

[1] CRC Section of Medicine, The GI Unit, The Royal Marsden Hospital & Institute of Cancer Research, Sutton, Surrey, UK

[2] CRC Section of Medicine, Centre for Cancer Therapeutics, The Royal Marsden Hospital & Institute of Cancer Research, Sutton, Surrey, UK

[3] Dept of Histopathology, The Royal Marsden Hospital & Institute of Cancer Research, Sutton, Surrey, UK*Background:* We have previously shown that detection of mutations in codons 12 or 13 of *Ki-ras* in whole tissue samples from early colorectal adenocarcinomas do not predict relapse. However, tumours may not be homogeneous for *Ki-ras* genotype and a few mutated cells may be responsible for subsequent relapse. Therefore, would microdissection of specific areas of colorectal tumours increase the rate of detection of mutations and are there differences between regions within the tumour?*Methods:* Blocks were retrieved from patients who had undergone apparently curative resection for early colorectal adenocarcinoma but subsequently developed tumour recurrence. Blocks from patients with no relapse after more than 5 years follow up were also used. PCR amplification and direct sequencing to determine *Ki-ras* status was used firstly, in whole tissue samples, secondly, in microdissected samples prepared from the 1 mm leading edge of tumour and thirdly, in microdissected samples from the central tumour core at least 2 mm away from the leading edge.*Results:* Eighteen patients with relapse and 5 long term survivors were identified. Astler-Coller modification of Dukes staging was stage A in 2, B1 in 18 and B2 in 3 patients. A sequence was obtained in all 23 whole tissue samples, in 22 of the leading tumour edges and 20 of the tumour centres. The same genotype was always found in both microdissected samples from the same tumour. In 4 tumours these were mutated. No mutation was found in a microdissected sample which was not detected in the whole tissue sample. In 1 patient, a mutation was detected in the whole tissue sample, but not in the microdissected samples. It is likely that this mutation arose from the epithelium surrounding the tumour rather than from the tumour itself.*Conclusions:* These findings suggest that colorectal tumours are homogeneous for *Ki-ras* genotype and that using PCR amplification followed by direct sequencing of whole tissue samples is accurate, so microdissection of tumours is not necessary. These results also support the hypothesis that the *Ki-ras* status of a colorectal adenocarcinoma is determined early during it's development.(Dr. H.J.N. Andreyev is supported by the British Digestive Foundation) Oncology, general: Molecular biology, geneticsOncology, general: Proliferation, carcinogenesisOncology, specific: Colon, rectum }" "The Distribution of Kirsten-ras Mutations within Early Colorectal Adenocarcinomas"

*P. Hol\'e9czy

Ist. Dept. Int. Med., Faculty Hospital Mickiewiczova 13, 813 69 Bratislava, SlovakiaThe etiopathogenesis of colon cancer (CC) seems to be multifactorial. Hormonal imbalance may be involved Somatostatin (S) has an antiproliferative influence on mucosal cells. The main antimitogeniceffect of S is the inhibition of cell proliferation via inhibition of phosphorylation. Gastrin (G) stimulates DNA synthesis in large bowel epithelial and tumorous cells. Cortisol (C) as a stress-catabolic hormone may be involved in development of some malignant diseases. In 11 patients suffering from CC S, G and C circadian rhytmicity was studied. Seven blood samples were withdrawn during 24 hours for RIA analysis, Fisher's periodogram and Halberg's cosinor analysis was applied for each individual set of measurement. A 24-hour endogenous circadian rhythm of S, G and C was confirmed. The results were compared to the circadian rhythm of the hormones observed in healthy subjects (N) (n-12), patients with ulcerative colitis (UC) (n-10), and colon polyps (P) (n-9). Higher 24 hours amplitude of S compared to N ($p < 0.05$), higher mesor (p, < 0.05) of G compared to all other groups and lower 24 hours amplitude, ($p < 0.01$) of C compared to all other groups were found. These findings may reflect the role of G in the etiopathogenesis of CC and results of C secretion could indicate a reduced responsiveness in patients with malignant diseases. S blood levels probably do not reflect its antitrophic effect at cellular and subcellular levels. }" "Colon Cancer and Git Hormones"

"P P 55 1318"P 55 1318**Edible Mushroom (Agaricus Bisporus) Lectin, a Cell Growth Inhibitor, Stops Growth of HT29 Colon Cancer Cells in G_1 and Decreases the Expression of*C-myc***

*L.G. Yu, S. Ward, R.C. Evans, R.V. Giles[2], J.M. Rhodes

Department of Medicine, University of Liverpool, Liverpool, UK

[2] Department of Biochemistry, University of Liverpool, Liverpool, UK*Purpose:* The Thomsen-Friedenreich (TF) antigen (Gal{ b}1-3GalNAc{ a}{ -}) is a common onco-fetal carbohydrate antigen in intestinal epithelia. Our previous work has shown that the non-cytotoxic TF-binding lectin from the edible mushroom *Agaricus bisporus* (ABL) inhibits proliferation in a range of malignant and normal epithelial cells (Cancer Res. 1993; 53; 4627) and has to be internalized to produce its inhibitory effect (Gastro. 1995; 108 (4); A558). The present study was designed to assess the relationship of this inhibitory effect by ABL to cell cycle and the expression of protooncogenes *c-myc* and p53.*Methods:* 1) HT29 colon cancer cells were cultured in Dulbecco's Modified Eagle's Medium (DMEM) with 5% fetal calf serum (FCS). The cells were partially_synchronized by culturing in 0.5% FCS for 2 days. ABL (80 \'b5g/ml) or PBS (control) was added for 8 hours at 37\'b0C. 4% FCS was added to stimulate cell growth. Cells were fixed at various times in ethanol and stained with propidium iodide. Total DNA content per cell was assessed using a flow cytometer. 2) Subconfluent HT29 cells were precultured in serum-free DMEM for 1 day before addition of ABL (30 \'b5g/ml). RNA was extracted at different time by the guanidinium thiocyanate-phenol-chloroform method. Northern blots were probed with cDNA for *c-myc* or p53.*Results:* After 21 hours addition of FCS, the proportion of ABL treated cells in G_1 had increased from 81.1% to 90.6% compared with a decrease to 70.8% (n = 3) in control. The expression of c-myc MRNA was decreased by 48 – 7% (n = 3) in the presence of ABL and this effect on *c-myc* of ABL was abolished by coincubation with asialo fetuin which expresses GalGalNAc. No significant effect on p53 mRNA expression was found.*Conclusion:* Mushroom lectin inhibits proliferation by holding cells in G_1. The decrease of *c-myc* MRNA expression may provide a partial explanation for the anti-inhibitory effect. Surg. of Shitaya Hp., Nippon Medical School, Tokyo, Japan

[1] 1st Dept. of Surg., Nippon Medical School, Tokyo, Japan

[2] 2nd Dept. of Patho., Nippon Medical School, Tokyo, JapanTransforming growth factor { a} (TGF{ a}) which is structurally homologous to epidermal growth factor (EGF) binds to epidermal growth factor receptor (EGFR) and is implicated in the growth and proliferation of colorectal cancer. To evaluate the role of TGF{ a}, EGF and EGFR in colorectal cancer progression, we investigated their expression in colorectal cancer and its liver metastasis.*Materials and method:* Immunohistochemical staining was performed on paraffin-embedded specimens of 32 colorectal cancer and 40 liver metastasis. EGFR, EGF and TGF{ a} expression were evaluated semiquantatively.*Results:* Overall expression of TGF{ a}, EGF and EGFR in primary lesion were 40.6%, 75.2% and 78.3%, respectively. In metastatic liver lesion, a significantly higher rate of TGF{ a} and EGFR expression was found (77.5% and 87.5%), but there was no difference in the expression of EGF (67.5%). Synchronous expression of TGF{ a} and EGFR occurred in 52.5% in liver metastasis compared with 34.1% in primary lesion. And overexpression of TGF{ a} and EGFR in the hepatocytes surrounding metastatic cancer cells were observed.*Conclusions:* These results suggests that autocrine/paracrine interaction of TGF{ a} and EGFR play an important role in liver metastasis of colorectal cancer and hepatocytes are also involved in these interaction. "P P 56 1320"P 56 1320**Role of Proximal Stomach and Pylorus on Gastric Emptying and Gastrointestinal Transit Delays Elicited by Acute Blood Volume Expansion in Awake Rats****M.C.V. R\'eago, J.R.V. Gra\'e7a, F.A.A. Gondim, R.B. de M. Gondim, R.P. Dantas,**

*F.H. Rola

Departament of Physiology and Pharmacology, Federal University of Cear\'e1, BrazilAcute blood volume expansion delays gastric emptying (GE) and gastrointestinal (GI) transit rates of liquid in awake rats (Gondim, F. de A.A., *In VIII European Symposium on Gastrointestinal motility,* 1996). In this study, we investigated the proximal stomach and pyloric roles on the phenomenon. Male Wistar rats, 180–220 g were fasted for 16–24 h, with water *ad libitum,* anaesthetized with thiopental and a proximal gastrectomy (n = 22) or Heineke-Mikulicz pyloroplasty (n = 20) performed 7 days before GE and GI transit measurements. Blood volume expansion was performed by Ringer-Bicarbonate, i.v. infusion (1 ml/min up to 5% of body weight). Before the experiment, the animals were fasted for 24 h, with water *ad libitum* until 2 h before the intragastric intubation – 1.5 ml of a phenol red solution, 0.05 g/ml with 5% glucose. The animals were sacrificed by thiopental overdose 10 min or immediately after meal (standards). Data (mean – SEM) were analyzed by One-Way ANOVA and Student Newman-Keuls test. Analogous to intact controls GE and GI transit rates were decreased in SHAM operated (laparotomy) animals after 5% expansion ($p < 0.05$). Proximal gastrectomy increased both GE and GI transit rates ($p < 0.05$), blocked blood volume expansion affect on GE but not on GI transit rates. Pyloplasty increased GE and GI transit rates, but did not block blood volume expansion effect. Subdiaphragmatic vagotomy blocked blood volume expansion effect on GE and GI transit of liquid in SHAM and animals submitted to piloroplasty. Mean arterial pressure was not modified, but central venous pressure levels increased and haematocrit rates decreased ($p > 0.05$). Pyloroplasty did not block blood volume expansion effect on GE and GI transit. The proximal stomach plays a role on GE delays elicited by blood volume expansion. However, GI transit delays can be accomplished without its participation, probably by an increase on the intestinal resistances as part of the mechanisms that acutely balance blood volume excess.*Financial support:* CNPq, CAPES-PET, UFC e UNIMED-Ce. "P P 56 1321"P 56 1321**Increased Gastric Emptying of Liquids in Rats Is Induced by *""H. helmanii""* Type I Infection**

*I. Duval-Araujo, D.M.M. Queiroz, C.J.R. Simal, V.S.P. Marino, A.G.P. Magnago, S.D. Carvalho, L.A.S. Machado

Laboratory of Research in Bacteriology & Post-Graduate Surgery Laboratory, Faculdade de Medicina, UFMG, BrazilIt has been demonstrated that *H. pylori* infection induces somatostatin and gastric secretion alterations, which could be associated to gastric motility alterations. However, this hypothesis has not yet been experimentally validated because of the lack of an appropriate animal model. It was recently demonstrated that *""H. helmanii""* type I (Hh), a spiral bacterium that infects the stomach of both humans and pig, easily colonizes and induces an inflammatory response in the gastric mucosa of rodents. Therefore, we aimed to study the relationship between gastric motility and gastrin and somatostatin levels in rats experimentally infected by Hh. Twenty Wistar female rats were included in this study. They were divided in two experimental groups: A, 10 non-infected animals (control group) and B, 10 animals inoculated *per os* with 0.2 ml of gastric mucus of a Hh positive swine. After 56 days of inoculation, the animals were anesthetized with ketamine chloride (50 mg/Kg body weight) and gastric emptying was studied by scintigraphy after oesophageal administration of 0.2 ml 99mTc-fitate diluted (1:1) in 2.5% peptone solution. After the scintigraphic study, blood samples were collected for serum gastrin contents measurement and fragments of the gastric antrum were obtained for somatostatin contents evaluation. Hh infection was confirmed by urease test and carbolfuchsin-stained smears examination. The results were analyzed by the Kruskall-Wallis test and the level of significance was set at $p < 0.05$. All animals of the group B were Hh-positive. There was an decrease in the gastric remnant in group B when compared to the group A (72.7 – 17.7% vs. 47.7 – 13.9%, p = 0.01). Serum gastrin levels of the group B were higher than in the group A (7.7 – 5.7 pg/ml vs. 3.7 – 1.9 pg/ml, p = 0.03), and gastric somatostatin levels were lower in the same group (1.3 – 0.2 ng/ml vs. 4.9 – 3.0 ng/ml, p = 0.01). In conclusion, gastric motility is altered in rats infected by a gastric spiral bacterium. This abnormality could be related to the concurrent abnormalities of gastrin and somatostatin secretion. }" "Increased Gastric Emptying of Liquids in Rats Is Induced by ""H. helmanii"" Type I Infection"

"P P 56 1322"P 56 1322**Gastric Emptying Rate of Solid Food in Relation to Body Mass Index: A Scintigraphic EvaluationA. Brogna, R. Ferrara, A.M. Bucceri,**

*F. Catalano, V. Leocata, G. Natoli, A. Blasi

Istituto di Medicina Interna ""A. Francaviglia"" University of Catania, Catania, ItalyIt's known that different physiologic conditions including body size can modify gastric emptying. Few studies in the literature have compared gastric emptying to the Body Max Index (BMI). We have evaluated gastric emptying rate of solid meal in volunteers of varying sizes to determine whether BMI and gastric emptying rate are correlated.Twelve healthy volunteers (males, mean age 42 – 12 (SD) yrs, age range 23-54 years) with different BMI (mean 26.6 – 4.2 (SD) kg/m^2, range 18.5–31.8 kg/m^2) were studied. All the subjects, after an overnight fast, ate a standard 750 kcal meal containing chicken liver prelabelled in vitro with 150 \'b5Ci ^{99m}Tc sulphur colloid. Immediately after the meal, the subject was asked to lie supine for radioscanning with two scintillators placed opposite one another and connected to a computerized ratemeter to evaluate gastric radioactivity decrement. Results were expressed as emptying index at 120 min (E.I.) calculated by means of the following formula: E.I. = [(100{ -}RRt)/At] times; 100, where RRt = % residual radioactivity at time t; At = area under the emptying curve at time t (= 120 min).Results are show in fig. They demonstrate an inverse linear relationship between gastric emptying rate and BMI.*Conclusion:*The variable of BMI must be taken in account when gastric emptying is evaluated.

"P P 56 1323"P 56 1323**Effects of Levosulpiride on Clinical Symptoms, Gastric Emptying and Orocaecal Transit Time in Functional Dyspepsia: A Randomised, Double-Blind Placebo-Controlled, Cross-Over Study**

*M.P. Brunori, P. Bovo, M. Marcori, S. Brunelli, L. Rigo, B. Vaona, M. Filippini, G. Talamini, V. Di Francesco, L. Frulloni, A. Gaudio, A. Moi, G. Cavallini

Gatroenterological Unit, University of Verona, ItalyFifty percent of patients with functional dyspepsia present abnormal gastric emptying [1]. Levosulpiride is an orthopamidic drug which stimulates gastrointestinal motility. The aim of the study was to assess the efficacy of levosulpiride in speeding up gastric emptying and orocaecal transit time and in relieving symptoms in patients with functional dyspepsia. The patients sample comprised 30 subjects (11 M, 19 F; mean age 37.63 – 12.21 years; range 22–65 years) suffering from functional dyspepsia. The patients were submitted to clinical assessment, blood-chemistry tests and instrumental investigations (US, EGDS, barium enema) to exclude the presence of organ disease and were then treated for two 3-week periods with levosulpiride (25 mg {\'b4} 3/day) and placebo (according to a double-blind cross-over design) with a 2-week wash-out period between the two treatments. Prior to therapy and after each course of treatment, orocaecal transit time was estimated (lactulose H_2 breath test) together with gastric emptying (ultrasonographical method), the latter after a standard balanced 700 cal meal. Subjective symptoms were assessed before and after treatment with scores from 0 to 3 for each symptom. Data were analyzed statistically by non-parametric multivariate analysis for repeated measures. *Results* 1) gastric emptying time was significantly reduced ($p < 0.00001$) after levosulpiride (236.6 – 38.7) as compared to both baseline (295.50 – 32.3) and post-placebo (298.50 – 30.0) levels; 2) orocaecal transit time was also reduced ($p < 0.007$) after levosulpiride (66.00 – 25.09) as compared to both baseline (88.00 – 38.54) and post-placebo (84.0 – 36.01) levels; 3) symptoms, considered as a whole, were better relieved by levosulpiride therapy (6.90 – 6.01)($p < 0.0001$) than by placebo (13.8 – 7.33) ($p < 0.0001$) as compared to baseline value (20.30 – 4.23). *Conclusions:* from both the clinical and instrumental points of view levosulpiride was found to be an effective drug in the treatment of functional dyspepsia.

"P P 56 1325"P 56 1325**Gastric Emptying Time and CLO-Test in Patients with NUD: Effect of Cisapride**

*V. Mahachai[1], T. Chaiwatanarat[2], P. Kullavanijaya[1], A. Sriratanabann[1], S. Anuras[3]

[1] GI Unit, Department of Medicine, Bumrungrad Hospital, Bangkok

[2] Department of Radiology, Bumrungrad Hospital, Bangkok

[3] Chulalongkorn University Hospital, Bumrungrad Hospital, BangkokThis study was designed to compare the gastric half emptying time (GET 1/2) in patients with non-ulcer dyspepsia (NUD) and healthy controls, and to study the effect of cisapride on GET-1/2 in NUD patients. All NUD patients had normal ultrasound and normal upper endoscopy. Gastric biopsy was taken from the antrum for CLO-test.All underwent a solid gastric emptying test using a Technetium-99 labeled egg meal. NUD patients received oral cisapride 10 mg tid ac for 2 weeks and had a repeated gastric emptying test after treatment. Symptoms were scored before and after cisapride treatment. In total 35 patients with NUD and 22 healthy controls were studied.The pre-treatment GET-1/2 in NUD patients was 90.92 – 28.47 min. This value was significantly different from that of healthy controls who had a mean GET-1/2 of 77.64 – 14.23 min ($p = 0.023$). CLO test was positive in 20/35 patients (57.1%). After 2 weeks of cisapride treatment, the GET-1/2 decreased significantly (90.92 – 28.47 min VS 73.59 – 21.63 min, $P < 0.0001$) in the NUD group. Significant symptom improvement was obtained similarly in the CLO positive and CLO negative NUD patients. The GET-1/2 after cisapride treatment was reduced to the same extent in both CLO positive and CLO negative patients.This study suggested that cisapride can improve dyspeptic symptoms and shorten GET-1/2 in NUD patients regardless of their CLO status. Delayed gastric emptying may be one of the permissive factors in the pathogenesis of NUD and may account for the symptomatology in this group of patients. "P P 56 1326"P 56 1326**The Effect of Phenytoin on Gastric Dysrhythmia in Diabetic PatientsS. Unal, Z. Ozturk, I. Dogan**

Gazi University School of Medicine, Department of Gastroenterology, Ankara, TurkeyPatients with diabetes frequently complain about gastrointestinal symptoms. Almost half of these patients have delayed gastric emptying. In EGG, the frequency of gastric dysrhythmia observed more frequently than normal population. It has been thought that at least in some diabetic patients gastric dysrhythmia might still be the probable causes of delayed gastric emptying.In this study, we examined 42 diabetic patients and 20 healthy controls. The diabetic patients consist of 33 female and 9 male, whereas the control group was 13 female and 7 male. The mean age was 52 – 12 for the diabetic patients and 34 – 12 for the controls. The average duration of diabetes was 7 – 5 years. EGG examinations were done after an overnight fasting period with cutaneous electrodes. The electrogastrograms were recorded for 30 minutes fasting period and 30 minutes postprandial period. Patients with abnormal EGG records were given 300 mg, 200 mg phenytoin P.O. at 7 p.m and 12 p.m., respectively. In the following morning EGG records were repeated.52 percent of diabetic patients had peripheral neuropathy, 26 percent had autonomic neuropathy, and 59 percent had upper gastrointestinal symptoms. While 15 diabetics patients had abnormal EGG records, in controls only 2 were abnormal ($p < 0.05$).Table 1: The effect of phenytoin on gastric dysrhythmia Before After p value phenytoin phenytoinPercentage of normal slow waves 49 – 13 70 – 11 < 0.001Tachygastria percent 33 – 13 19 – 6 < 0.001Percentage of bradygastria 17 – 11 10 – 7 < 0.05Power ratio (postprandial/fasting) 1.38 – 1.02 1.97 – 0.78 < 0.05In this study, it has been found that diabetics have more EGG abnormalities compared to normal subjects. Phenytoin reduces the gastric dysrhythmia in most of the patients. It is concluded that the therapeutic benefit of phenytoin is due to its effects on the activity of ectopic pacemaker foci in the antrum. Motility, specific: Stomach }" "The Effect of Phenytoin on Gastric Dysrhythmia in Diabetic Patients"

"P P 56 1327"P 56 1327**Solid Meal Gastric Emptying in Hypothyreosis — A Prospective Clinical Study**

*K. Jonderko, G. Jonderko, T. Golab, C. Marcisz

Dept. of Physiology, IOMEH Sosnowiec, IV. Chair and Dept. of Internal Medicine, SUSM Tychy, Poland*Objective.* The study aimed at the evaluation of the gastric emptying (GE) kinetics of a solid meal in hypothyreotic patients before and after a substitutive treatment with L-thyroxin. *Methods.* Twelve female hypothyreotics (aged 45.3 – 8.7 years, mean – SD) and a control group of 12 healthy women (aged 34.5 – 8.1 years) were examined. The GE of a ^{99m}Tc-labelled solid meal was measured with the use of a gamma camera in every patient before the treatment, and in 10 of them a repeat GE examination was performed after the restoration of euthyreosis; the median duration of the treatment was 5.5 mo (range 2.5 to 12 mo). *Results.* The mean gastric transit time (MTT_{90}) and the fraction of the test meal retained in the stomach after 90 min (F_{90}) were statistically significantly greater in untreated hypothyreotics than in healthy controls (MTT_{90}: 42.01 – 1.86 min patients vs 40.06 – 1.00 min controls, p = 0.0043; F_{90}: 64.3 – 15.4% patients vs 50.8 – 8.2% controls, p = 0.0173). In ten patients in whom a second GE measurement was taken after the achievement of euthyreosis, a slight increase of the GE was observed (MTT_{90}: 41.46 – 1.49 min before vs 41.04 – 1.81 min after the treatment, NS) which was then no longer statistically significantly different from that of the healthy controls. No relationship was found between the GE and the severity of clinical symptoms of hypothyroidism. GE remained, however, slowed in some patients despite the restoration of euthyreosis. *Conclusion.* We conclude that: (i) long-lasting hypothyreosis is accompanied by a slightly slowed GE of solids, and (ii) restoration of euthyreosis does not imply a parallel improvement of the hypothyroidism-associated delay in GE. "P P 56 1328"P 56 1328**Patterns of Solid Meal Gastric Emptying in Hyperthyreotic Patients-Effect of Pharmacological ManagementG. Jonderko,**

*K. Jonderko, T. Golab, C. Marcisz

IV. Chair and Dept. of Internal Medicine, SUSM Tychy, Poland

Dept. of Physiology, IOMEH Sosnowiec, Poland*Objective.* The study aimed at the evaluation of the kinetics of gastric emptying (GE) of a solid meal in hyperthyreotic patients during a pharmacological treatment with thiamazole until the moment of euthyreosis restoration. *Methods.* Fourteen female patients (33.4 – 2.6 y, mean – SE) with recently diagnosed hyperthyreosis took part in the study. Twelve age-matched healthy women (34.5 – 2.3 y) constituted a control group (C). Every patient underwent the GE examination before treatment (I). In 12 patients the GE was re-examined on the 3rd treatment week (II). After the achievement of euthyreosis, which happened after 4.5 mo (median; interquartile range 2.0 to 7.3 mo), a third GE measurement was taken in 13 patients (III). The GE of a ^{99m}Tc-labelled solid meal was measured with the use of a gamma camera. Time-activity curves form the gastric region of interest were used, after subjection to appropriate corrective procedures, to calculate the mean gastric transit time (MTT_{90}) and the fraction of the test meal retained in the stomach after 90 min (F_{90}). *Results.* Before the treatment and on the third week of management the GE of hyperthyreotics was not statistically significantly different from that of healthy controls (MTT_{90}: 39.44 – 0.30 min [I], 39.31 – 0.64 min [II] and 40.06 – 0.29 [C]; F_{90}: 46.6 – 1.9% [I], 47.9 – 3.7% [II] and 50.8 – 2.4% [C]). The restoration of euthyreosis was accompanied by a slight but statistically significant increase in the GE – $p < 0.05$ in the case of F_{90} vs the pre-treatment situation. Also the patients' GE was found then to be slightly but statistically significantly faster than in healthy controls (MTT_{90}: 38.72 – 0.39 min [III], and F_{90}: 42.2 – 2.3% [III] – $p < 0.05$ vs C for both parameters). *Conclusion.* We conclude that in hyperthyreotic women the GE of solids does not differ significantly from age-matched healthy female controls and remains unchanged during a pharmacological treatment. After achievement of euthyreosis a slightly but statistically significantly faster GE is observed in the patients when compared to healthy controls. Motility, specific: StomachMotility, general: Functional GI disorders }" "Patterns of Solid Meal Gastric Emptying in Hyperthyreotic Patients-Effect of Pharmacological Management"

"P P 56 1329"P 56 1329**Gastric Emptying of Fat Determines the Pattern of Postprandial Gallbladder Contraction in Humans**

*A. Kasicka-Jonderko, K. Jonderko, Z.K. Sliwinski, A. Nowak

Dept. of Gastroenterology, SUSM Katowice, Poland

Dept. of Physiology, IOMEH Sosnowiec, Poland*The purpose* of this study was to determine factor(s) accounting for the functional relationship between the gallbladder (GBE) and gastric (GE) emptying. *Methods.* Two nearly isocaloric but differing with regard to their fat content semiliquid meals were used. A low-fat meal (LFM, 0.94 kcal/ml, 500 ml, 10.5 g fat) was consumed by 19 healthy subjects (8 M and 11 F, aged 27.8 – 1.7 years) on 19 occasions. A high-fat (HFM, 1.08 kcal/ml, 250 ml, 21.3 g fat) was eaten by 12 healthy subjects (8 M and 4 F, aged 33.8 – 3.0 years) on 22 occasions. Gallbladder volume and antral cross-sectional area was measured ultrasonographically before and at 10-min intervals for one hour after meal ingestion. Data are means – SE. *Results.* The two meals evoked different patterns of GE and GBE ({'} Figure). At 60 min postprandially 154.7 – 17.0 kcal contained in 165 – 18 ml of the LFM left the stomach, whereas with HFM the corresponding values were 205.0 – 11.4 kcal in 190 – 11 ml. At that time, however, 3.5 – 0.4 g fat was evacuated from the stomach with LFM, as opposed to 16.2 – 0.9 g fat with HFM. Considering the fractional GBE as a dependent variable, whereas volume, energy, and fat emptied from the stomach as possible predictive factors, a forwardly prosecuted stepwise multiple linear regression revealed that only the GE of fat was a significant predictor of the postprandial GBE: multiple R = 0.8817, p = 0.00015. *Conclusion.* The gastric evacuation of fat appears to be a crucial factor determining the time-course of the GBE evoked by a semiliquid caloric meal.

"P P 56 1330"P 56 1330**An Experimental Stressor, Isometric Exercise, Affects the Intragastric Distribution of a Solid Meal in Humans**

*A. Kasicka-Jonderko, K. Jonderko, J. Kolodziejczak, S. Nowak, A. Nowak

Dept. of Gastroenterology, and Dept. of Nuclear Medicine, SUSM Katowice, Poland

Dept. of Physiology, IOMEH Sosnowiec, Poland*Aim.* We investigated the effect of physical stress by handgrip isometric exercise on human solid meal gastric emptying (GE). *Methods.* Twelve healthy subjects (7 M and 5 F, aged 26.2 – 1.5 [SE] years) participated in the study. On separate days, after ingestion of a 300 kcal solid test meal they performed isometric exercise by squeezing a handgrip dynamometer for five three-minute periods separated by seven-minute intervals, *or* rested on the control day. The gastric emptying of a ^{99m}Tc-Amberlite-labelled meal was continuously surveyed for 120 min postprandially by means of a gamma camera. Systolic (SBP) and diastolic (DBP) arterial blood pressure, heart rate (HR) and skin resistance (SR) were monitored as indices of the cardiovascular response to stress. Data are means – SE. *Results.* Isometric exercise brought about a strong sympathetic excitation: { D}SBP +35.7 – 2.0 mmHg (p ≪ 0.001); { D}DBP +29.5 – 2.2 mmHg (p ≪ 0.001); { D}HR +16.0 – 1.7 beats{\'d7}min{ ¯1} (p ≪ 0.001); { D}SR = { -}448 – 55 kohm (p ≪ 0.001) ({ D} = mean difference stressor minus control). In every subject the repeated handgrip exercise caused transient retrograde shifts of the radiolabelled solid meal from the antral into the fundal stomach part. This phenomenon resulted in short-term periods of delayed emptying of the proximal stomach (ANOVA: $p < 0.001$ vs control) and antral filling (ANOVA: $p < 0.005$ vs control). The total stomach emptying of solids remained, however, unaffected during and after the stress period, although shortly after the termination of the stress exposure a negligible trend towards an increased GE was observed. *Conclusion.* Isometric exercise evokes bouts of a retrograde movement of solid food from the distal into the proximal stomach without, however, any significant effect on the overall GE of solids. Motility, specific: StomachHormones and receptors: Brain gut axis }" "An Experimental Stressor, Isometric Exercise, Affects the Intragastric Distribution of a Solid Meal in Humans"

"P P 56 1331"P 56 1331**The Effect of Cisapride on Gastric Emptying in the Critically Ill Patient**

*D. Heyland, G. Tougas, D.J. Cook, G.H. Guyatt

McMaster University Medical Centre, Hamilton, Canada*Background:* Early administration of enteral nutrition to critically ill patients is associated with improved clinical outcome including reduced sepsis, improved wound healing, maintenance of intestinal mucosal integrity, and decreased mortality. In critically ill patients, gastric emptying is often markedly delayed and precludes enteral nutrition. The efficacy of prokinetic therapy in improving gastric emptying has not been demonstrated in critically ill patients. *Objective:* To evaluate the effects of cisapride, a gastrointestinal motility agent, on gastric emptying on critically ill patients. *Methods:* In a randomized, double-blind, placebo-controlled study, we recruited mechanically ventilated patients expected to remain the ICU for more than 48 hours. We enrolled 72 patients; male (61%), age 54.0 (+19.1), 47% were post-operative, 83% were receiving narcotics and the mean SAP Score was 9.5 ({ -}2.9). As acetaminophen is only absorbed in the small bowel, acetaminophen absorption rate can be used as an index of gastric emptying. 1.6 g of acetaminophen suspension was administered via a nasogastric tube into the stomach (day 1). Blood samples were drawn at t = 0, 30, 60, 90, 120, and 180 minutes for measurement of plasma acetaminophen levels determined by the enzymatic degradation method. We measured the maximum plasma concentration (C_{max}, umol/L), time to reach C_{max} (min.) and area under the plasma concentration-time curve t = 180 ($AUC_{180,}$ umol/min/L). The following morning (day 2), patients were randomized to receive either 20 mg of cisapride suspension or placebo and gastric emptying was repeated. *Results:* The difference (day 2 { -} day 1) in C_{max} was 49.1 umol/L in the cisapride group compared to 12.3 umol/L in the placebo group (p = 0.005). The time reach to reach C_{max} was also significantly shorter in the cisapride group ({ -}40.8 minutes vs. { -}4.2 minutes, p = 0.02). The difference in the area under the time-acetaminophen concentration curve was also greater in the cisapride group (5534 vs 2832, p = 0.09). *Conclusions:* Cisapride enhances gastric emptying in critically ill patients. Since intolerance to enteral feedings is associated with increased morbidity, improved gastric emptying with cisapride may improve mortality and morbidity in this patient population. Studies to specifically examine the effects of Cisapride on tolerance of enteral nutrition and infectious morbidity are needed. Supported by the Janssen Research Foundation. [3] Departments of Surgery and Anesthesiology, University of Washington, Seattle WA, USA

The Center for Bioengineering, University of Washington, Seattle WA, USA*Aims:* To investigate the accuracy and applicability of a magnetic position sensor system for acquisition of 3D ultrasound images for the purpose of determining gastric emptying rates and intragastric distribution of a meal. *Methods:* A system for position and orientation measurement based on magnetometry was interfaced to an ultrasound scanner with a 5–3 MHz phased array transducer. After calibration, in vitro accuracy was evaluated by scanning a porcine stomach. Thereafter, fourteen male volunteers, median age 35 years, were included and examined in the morning after ingestion of a 500 ml soup meal (20 kcal). One subject was scanned on 6 consecutive days. Scanning was performed fasting, and up to 35 min postcibally by conventional 2D scanning of the antrum and 3D ultrasound of the total stomach. Volume estimation and reconstruction of the stomach in 3 dimensions were performed after manual tracing on a Unix workstation. *Results:* This 3D system yielded a strong correlation (r = 0.997) between true and estimated volumes in vitro. The limits of agreement were { -}9.1: 70.1 ml in the volume range 1200–1900 ml. The mean error was 2.1 – 1.1% (SD) in vitro. The intersubject variability of the total gastric volumes ranged from 12.5% to 46.0%, less than for antral area variability. The average half emptying time in healthy subjects was 22.1 – 3.8 min. Intragastric distribution of the meal, expressed as Proximal/Distal volume, varied on average from 3.6 – 2.1 (5 min pc) to 2.7 – 1.9 (30 min pc).*Conclusions:* This 3D ultrasound system using magnetic scanhead tracking demonstrated high in vitro accuracy, calculated gastric emptying rates more precisely than 2D ultrasound, and enabled estimation of intragastric distribution of a soup meal in healthy subjects. Motility, specific: StomachMotility, general: Functional GI disordersRadiology and ultrasound: Diagnosis }" "Intragastric Distribution and Gastric Emptying Estimated by 3D-Ultrasonography"

"P P 56 1333"P 56 1333**Accommodation of the Proximal Stomach is Fat Dependent in Functional Dyspepsia**

*O.H. Gilja, T. Hausken, S. \'d8degaard, A. Berstad

Medical Department A, Haukeland Hospital, University of Bergen, Bergen, Norway*Aims:* Patients with functional dyspepsia seem to have impaired accommodation of the proximal stomach to a meal. The objective of this study was to examine whether the amount of fat in the soup influenced gastric accommodation in functional dyspepsia.*Methods:* 11 patients, 9 females and 2 males, median age 40 years (range 21–52 years), were scanned fasting in a sitting position after ingestion of 500 ml meat soup (Toro'). On two separate days, the patients randomly ingested either 2 or 17 g of bovine fat in the meal (20 vs. 170 kcal). An ultrasound scanner, CFM 750 Vingmed Sound, with a 3.25 MHz transducer was used to obtain images 10 min after a 4 min ingestion period. Two sonographic sections, a sagittal area and an oblique frontal diameter were applied on the proximal stomach. 3D ultrasound with a tilting device for acquisition was used to scan the distal stomach. Volumes of the gastric antrum were estimated on a Unix workstation after scanconversion and manual contour indication using software from Advanced Visual Systems'. All subjects were asked to score total symptoms (1–9) provoked by the meal. Statistical differences were analyzed using Wilcoxon signed ranks test.*Results:* The size (mean – SD) of the proximal stomach was larger after high fat compared with low fat content, both in the sagittal (22.1 – 3.4 cm^2 vs 15.5 – 4.4 cm^2, p = 0.01) and the frontal section (6.8 – 0.8 cm vs 6.0 – 0.8 cm, p = 0.01). Volumes of the antrum were 28.7 – 13.8 ml and 27.7 – 10.4 ml after high fat and low fat (p = 0.86, NS), respectively. Symptom score was 2.18 – 2.04 after high fat and 1.09 – 1.22 after low fat (p = 0.12, NS).*Conclusions:* In patients with functional dyspepsia, volumes of the antrum did not change significantly with increasing fat content of the meal whereas accommodation of the proximal stomach seemed to be dependent on the fat content. "P P 56 1334"P 56 1334**Effects of Medium-Chain and Long-Chain Triglycerides on Antroduodenal Motility**

*M. Verkijk, J. Vecht, H. Gielkens, I. Biemond, C. Lamers, A. Masclee

Dept. of Gastroenterology, University Hospital Leiden, The NetherlandsThe use of medium-chain triglycerides (MCT) as additional caloric source in diets is limited by the frequent occurrence of abdominal symptoms. Recently we have shown that MCT accelerates intestinal transit but little is known on the effect of MCT on gastrointestinal motility. Therefore, we have investigated the effects of both equimolaric and equicaloric amounts of MCT and long-chain triglycerides (LCT) on antroduodenal motility, duodenocecal transit time (DCTT; lactulose H_2 breath test) and CCK release (RIA).Eight healthy subjects (age 19–28 yr) were studied on 4 separate occasions, after spontaneous occurrence of duodenal phase III, in random order during continuous intraduodenal administration of: (a) saline (control), (b) MCT 15 mmol/h, 67 kcal/h (MCT-1), (c) MCT 30 mmol/h, 135 kcal/h (MCT-2) or (d) LCT 15 mmol/h, 135 kcal/h, each for 360 min. *Results:* Both doses of MCT resulted in a sign. faster reoccurrence of phase III (MCT-1, 75 – 7 min, $p < 0.05$; MCT-2, 58 – 13 min, $p < 0.05$) compared to saline (151 – 18 min). LCT, on the other hand, sign. ($p < 0.05$) delayed reoccurrence of phase III compared to saline (290 – 30 versus 151 – 18 min), and induced a fed motor pattern. MCT at both doses did not interrupt interdigestive motility. Migrating motor complex (MMC) cycle length was sign. ($p < 0.05$) shorter during MCT (MCT-1, 65 – 7 min; MCT-2, 53 – 6 min) compared to saline (127 – 14 min) resulting from a sign. ($p < 0.05$) shorter duration of phase II. Phase III amplitude and velocity were sign. ($p < 0.05$) reduced during MCT. Infusion of LCT did not affect DCTT (105 – 13 min) compared to saline (101 – 9 min), whereas DCTT was sign. ($p < 0.05$) accelerated during MCT (MCT-1 56 – 6 min and MCT-2 69 – 9 min). DCTT was positively correlated with MMC length ($r = 0.42$; $p = 0.05$). LCT but not MCT sign. ($p < 0.05$) increased plasma CCK levels.*Conclusions:* LCT induces a fed motor pattern, whereas MCT maintains interdigestive antroduodenal motility with shorter MMC cycle length resulting from shorter duration of phase II. MCT accelerates intestinal transit. The effect of MCT is independent of CCK. "P P 56 1336"P 56 1336**Interdigestive Antroduodenal Motility and Gastric Acid Secretion. Effect of Acid Inhibition**

*H.A.J. Gielkens, A. Nieuwenhuizen, I. Biemond, C.B.H.W. Lamers, A.A.M. Masclee

Dept. of Gastroenterology, University Hospital Leiden, The NetherlandsIn man interdigestive acid secretion and antroduodenal motility are closely related with cyclic variations in acid secretion synchronous with the various phases of the migrating motor complex (MMC). Duodenal acidification inhibits antral motility but little is known on the effect of acute acid inhibition on antroduodenal motility. We have simultaneously studied antroduodenal motility (perfusion manometry) and gastric acid secretion (continuous aspiration in 10 min portions using phenol red as recovery marker) in 9 healthy subjects (age 20–31 yr). Each subject was studied twice in random order during 1) saline i.v. (control) for 1–2 complete MMC cycles and 2) during acute acid inhibition with famotidine i.v. (bolus 20 mg, continuous infusion 4 mg/h) for 1–2 complete MMC cycles. Plasma gastrin and pancreatic polypeptide (PP) levels were determined (RIA).*Results:* In the control study acid output in phase III (2.1 – 0.3 mmol/10 min) and late phase II (1.7 – 0.2 mmol/l 10 min) was significantly ($p < 0.05$) increased over early phase II and phase I (1.2 – 0.2 and 1.2 – 0.2 mmol/l 10 min resp.). Famotidine increased gastric pH to > 6 within 30 min. After acid inhibition duration of MMC cycle during famotidine (106 – 8 min) was reduced but not significantly different from the control experiment (133 – 14 min). Phase distribution of the MMC cycle was not significantly different between famotidine (I, II and III: 12 – 3%, 83 – 2% and 5 – 1% resp.) and control (I, II and III: 14 – 3%, 82 – 3% and 4 – 1% resp.). Plasma PP levels fluctuated synchronous with phase I (25 – 3 pM), phase II (32 – 3 pM; $p < 0.05$) and phase III (40 – 3 pM; $p < 0.01$) independent of acid secretion. No cyclic alterations in serum gastrin levels were observed.*Conclusions:* Gastric acid secretion varies cyclically with interdigestive antroduodenal motility. Acute acid inhibition with famotidine i.v. does not significantly affect interdigestive antroduodenal motility and PP secretion. "P P 56 1337"P 56 1337**Glyceryl Trinitrate Improves Intragastric Meal Distribution and Prevents Meal-Induced Discomfort in Patients with Type I Diabetes Mellitus**

*K.A. Undeland, O.H. Gilja, T. Hausken, A. Berstad

Division of Gastroenterology, Medical Department A, N-5021 Haukeland University Hospital, Bergen, Norway*Purpose:* Impaired accommodation reflex of the proximal stomach is often seen in patients with diabetes. Nitrogen monoxide (NO) serves as a neurotransmitter in this reflex, and we hypothesised that glyceryl trinitrate (GTN), an exogenous donor of NO, could improve accommodation and intragastric meal distribution in patients with diabetes.*Methods:* A double blind, placebo-controlled, cross-over study was designed in twenty patients with type 1 diabetes (DM) and twenty healthy controls (HC). All received GTN or PLC in random order five minutes prior to a 500 ml soup meal. Two proximal sections, a sagital area (sA) and a frontal diameter (fD), and an antral area (aA) was outlined by ultrasound. Symptom score was assessed by visual analogue scales.*Results:* GTN had no significant effect on the sagital area (sA) or on the frontal diameter (fD). An estimated volume (eV) based on these measures (eV = sA {\'b4} fD) was neither significantly different with GTN compared to PLC. GTN decreased significantly (p = 0.05) antral area (aA) 5 min after soup in patients with diabetes (16.1 cm^2 – 4.3 with PLC vs. 13.5 cm^2 – 4.5 with GTN). This effect was consistent throughout the investigation period in DM. In HC, there was a similar tendency (p = 0.14) 5 min after soup (16.4 cm^2 – 6.6 vs. 13.2 cm^2 – 5.6). GTN had a significant (p = 0.04) effect on the intragastric meal distribution in DM, increasing eV/aA -ratio from 9.1 – 4.0 to 11.9 – 6.4. GTN also prevented meal-induced symptoms in patients with diabetes.*Conclusion:* GTN improves intragastric meal distribution and prevents postprandial symptoms in patients with type 1 diabetes mellitus. "P P 56 1338"P 56 1338**Relationship between Early Postprandial Symptoms and Transpyloric Flow**

*T. Hausken, K.A. Undeland, A. Berstad

Div. of Gastroenterology, Med. Dept., Haukeland University Hospital, Bergen Norway*Background:* Patients with functional dyspepsia (FD) exhibit increased sensitivity to gastric distension (mechanoreceptors) and to meals rich in fat (duodenal chemoreceptors).*Aim:* to relate initial transpyloric emptying and antral motility to early postprandial symptoms in FD using duplex sonography.*Methods:* Twelve patients with FD were investigated during 3 min of fasting, during 3 min of ingesting 500 ml of a meat soup and during the first 10 min postprandially.*Results:* Transpyloric forward flow commenced on average 52 sec and propulsive transpyloric flow (generated by propulsive antral contractions) 115 sec after start of drinking the soup. Initial nonpropulsive transpyloric flow (i.e., pendulating, transpyloric flow not generated by antral contractions) lasted 58 sec. Postprandial symptoms occurred in all patients and commenced on average 142 sec after start of ingestion. In all subjects symptoms appeared after commencement of transpyloric emptying. A negative correlation was found between intensity of fullness and time duration between start of emptying and start of symptoms. No correlation was found between antral distension and symptoms.*Conclusion:* The inverse relationship between symptom intensity and duration of the emptying period before symptoms suggests that meal related symptoms in FD patients are mainly due to gastric mechanoreceptors. "P P 56 1339"P 56 1339**Duodeno-Jejunal Postprandial Motility in Severe Chronic Idiopathic Dyspepsia: Comparison with Motor Patterns of Healthy Volunteers and Relationship with Results of Radionuclide Gastric Emptying**

*O. Lalaude, C. Maillot, G. Riachi, A. Zalar, F. Ducrot, P. Ducrott\'e9, P. Denis

GBPDN Hospital Charles Nicolle, 76031 ROUEN CedexOur aim was to describe the duodeno-jejunal postprandial motility in dyspeptic patients having an objective delay at radionuclide gastric emptying.*Methods:* Ten patients, 5 men and 5 women, (median age: 52 years; range 34–76), with daily symptoms were studied. Gastric emptying of solids was delayed in all patients: lag phase > 60 mn (N < 40) (n = 6), decreased evacuation slope (N > 0.25) (n = 6). Liquid emptying was also impaired in 6 cases with an half emptying time > 113 mn. A four port recording device registered duodenojejunal motility during three hours after a 750 kcal-meal (carbohydrates: 50%, lipids: 30%, proteins: 20%). The duodenal and jejunal areas under curves (AUC) were calculated by a validated software on the whole 3 hours and on each of the 6 half-hours of the postprandial period. Manometric results in dyspeptics were compared to those of 20 healthy volunteers, 10 men and 10 women, median age 30 years (range 21–46) studied in the same conditions.*Results:* a) In volunteers, postprandial motility was characterised, at each level of recording, by a maximal motor activity during the first half hour, followed by a significant decrease with time ($p < 0.003$). In every volunteer, jejunal post-prandial motor activity was always higher than the duodenal one ($p < 0.01$). b) The global overall AUC and the AUC on each of the successive half hours were not different between dyspeptics and volunteers. c) in all dyspeptic patients, duodenal and jejunal AUCs failed to decrease with time. d) Duodenal activity was greater than the jejunal one in 6 cases. d) Lag phase duration was correlated with the duodenal AUC in the first hour (r: 0.85; $p < 0.01$). No other correlation was found between duodenal or jejunal motor parameters and results of radionuclide gastric emptying for solids or liquids.*Conclusion:* In severe dyspepsia with a gastric emptying objectively delayed, the kinetics of the duodeno-jejunal postprandial motility was always different from that observed in volunteers. The correlation between lag phase and duodenal motor index suggests that duodenum could act as a brake in some dyspeptic patients. "P P 56 1340"P 56 1340**Gastric and Gallbladder Emptying after a Mixed Meal are not Coordinated in Liver Cirrhosis: An Ultrasound Monitoring**

*Monica Acalovschi, Dan L. Dumitrascu, Ildiko Csakany

3rd Medical Clinic, University of Medicine and Pharmacy, Cluj-Napoca, RomaniaAn impaired contractility has been suggested as a contributing factor to the increased incidence of gallstones in liver cirrhosis, but the few studies on gallbladder emptying in cirrhotics offered contradictory results. Ingestion of a meal triggers the physiological pathway of gallbladder emptying, therefore it seems very important to assess simultaneously the rates of gastric and gallbladder emptying in analyzing postprandial kinetics.Gastric and gallbladder emptying were measured using ultrasound techniques after a solid-liquid meal (14 g fat, 465 kcal) in 24 patients with liver cirrhosis and in 12 controls. None of the subjects had gallbladder disease. Sequential changes in cross-sectional area of the gastric antrum and in gallbladder volume were represented as a monoexponential process after the test meal. Cirrhotic patients were analyzed according to the severity of disease (Child classes). The presence of portal gastropathy was assessed by endoscopy. Differences between groups were analyzed using the two-tailed Student's t test for unpaired observations and the correlations by linear regression (Pearson's coefficient).We found all parameters of gastric emptying following the solid-liquid meal similar in patients and controls. On the contrary, gallbladder emptying was significantly diminished in cirrhotic patients: the area under curve was reduced in Child A ($p = 0.01$), Child B ($p = 0.04$) and Child C ($p = 0.014$) cirrhotics. No correlation was found between the parameters of gastric and gallbladder emptying. Gallbladder refilling began earlier in cirrhotics than in controls, before completion of gastric emptying. Our results indicate the lack of a quantitative coordination between gastric and gallbladder emptying in liver cirrhosis. They also support the hypothesis that diminished gallbladder contractility could contribute to the increased gallstone formation in liver cirrhosis. "P P 56 1341"P 56 1341**Effect of Intraduodenal Application of Acid and Lipids on Gastric Tone in Healthy Subjects**

*J.E. Dom\'ednguez-Mu\'f1oz, G. Manes, A. Leodolter, P. Malfertheiner

Department of Gastroenterology, University of Magdeburg, GermanyGastric emptying of fat leads to inhibition of antral motility and relaxation of the proximal stomach, which are likely mediated by neural duodenogastric reflexes. An acidic intraduodenal pH also induces an inhibition of the antral motility, but the effect on the tone of the proximal stomach is unknown. Aim of this study was to compare the relaxation of the proximal stomach after intraduodenal perfusion of different doses of a citric acid solution (pH = 2.2) and of a fat solution (Intralipid 20%) in healthy subjects. *Methods.* 6 healthy males, age 24–28 years, were studied. After an overnight fast a duodenal tube was placed through the nose with a side hole in duodenal bulb. A second tube with a 1200 ml balloon at the tip was placed in the proximal stomach and connected to a barostat. After a 30 min accomodation period, the balloon was inflated at a pressure of 1 mmHg above the minimal distending pressure of the stomach and volume was continuously recorded. A citric acid solution was infused into the duodenal bulb at rates of 1, 5 and 10 ml/min, each one for one minute. After each infusion the maximal volume of the proximal stomach and the slope (velocity of relaxation, ml/sec) from onset to maximal relaxation were recorded. Each following infusion was given after gastric volume had returned to basal value. The same procedure and the same infusion rates were repeated with Intralipid. Results are expressed as median. *Results.* The basal volume of the proximal stomach was 48 ml. A similar relaxation was obtained with both citric acid and lipids from the lowest infusion rate (gastric volume 139 ml after 1 ml citric acid and 182 ml after 1 ml intralipid, n.s.), and no further volumen increase was achieved with higher doses (max. gastric volume 167 ml after 10 ml citric acid and 187 ml after 10 ml intralipid; n.s. compared to values after 1 ml). The velocity of gastric relaxation (slope) was similar with both citric acid (2.9 ml/sec) and lipids (3.6 ml/sec). *Conclusions.* Intraduodenal acid and fat infusions exert a similar dosis-independent relaxation of the proximal stomach. This relaxation occurs at a similar velocity, which support a common reflex mechanism for acid and fat. "P P 56 1342"P 56 1342**Comparison of Radiologic and Isotopic Measurement of Gastric EmptyingA. Giguére,**

*P. Poitras, R. D\'e9ry, M. Picard, M. Boivin

Hospital Saint-Luc, University de Montr\'e9al, Montr\'e9al, CanadaScintigraphic measurement of isotopes labelled nutrients is currently the gold standard technique for the evaluation of gastric emptying function. However, its availability is often limited. Radiologic gastric emptying of radioopaque markers could constitute a cost effective and easily available procedure but it remains unknown to many practitioners. We conducted a 5 yr retrospective study with 46 patients suspected of gastroparesis and submitted to both radiologic and isotopic gastric emptying tests, to verify if the radiologic emptying correlated with the isotopic one, and if the former could be an alternative to evaluate gastric emptying in the clinical setting.*Methods:* the gastric emptying of a meal containing Tc-99 beef liver was measured in the nuclear medicine laboratory, and was considered as our reference standard. The radiologic test required patients to ingest 10 radioopaque markers (consisting of 5 mm pieces of a 12 Fr radioopaque feeding tube) swallowed with 240 ml of 7-UP and a bun. Abdominal X-Rays (PA) were obtained 2, 4 and 6 hrs later, and the number of residual markers in the stomach was counted at each time point.*Results:* a) significant relationship ($r = 0.66$; $p < 0.00001$) was found between the emptying time of isotopes and pellets. b) isotopic emptying was considered abnormal in 24/46 patients. In these patients with identified gastroparesis, the number of pellets remaining in the stomach after 6 hrs was significantly higher than in those with normal isotopic emptying (5.1 – 1 vs 2.2 – 0.6; $p < 0.01$). c) both tests correlated perfectly in 85% subjects: both tests were normal in 21/46 and abnormal in 15/46 patients. d) three patients showed normal pellets emptying but had a slight delay in isotopic transit (T&fract12; = 160, 160, 190 min; n = < 150 min). Seven patients with normal isotopic transit showed a delayed pellet emptying; 6 of these 7 patients were diabetics clinically suffering of gastroparesis.*Conclusion:* X-Ray determination of residual markers in the stomach 6 hrs after their ingestion seems to correlate with isotopic evaluation of the gastric emptying rate. In some circumstances, the radiologic test appeared even superior than the isotopic one to identify gastroparesis. The marker test is easy to realize in any clinical set up and appears to be a cost effective tool for the clinician. Clinical practice: Management strategyMotility, general: Functional GI disordersMotility, specific: Stomach }" "Comparison of Radiologic and Isotopic Measurement of Gastric Emptying"

"P P 56 1343"P 56 1343**Treatment of Diabetic Gastroparesis with CisaprideH. Hasche**

Diabetes Zentrum, Ambulant Praxis, D-97688 Bad Kissingen, GermanyStudies in gastroparesis mostly focus on gastric emptying in a limited patient (pt) sample. We evaluated the effects of cisapride (CIS) on symptoms and glucose control in pts with diabetic autonomic neuropathy.*Method.* Patients (pts) with a history of insulin-dependent diabetes mellitus {\'b3} 5 yrs, under medical control {\'b3} 3 months and with chronic abdominal symptoms, suggestive of delayed gastric emptying due to automic neuropathy, were eligible. They received CIS 10 mg qid. Patients were evaluated at start and after each month during a 3 month period. Several dyspeptic symptoms and hypoglycemia were scored as absent, mild, moderate, severe, very severe. HbA1c was also measured. Dose changes, daily insulin-intake and glucose control (unsatisfactory, satisfactory, good and very good) were documented.*Results.* 544 pts (55 – 13 yrs, 331 females, 174 with diabetic nephropathy, 294 with retinopathy and 316 with sensory neuropathy) participated. After 8 and 12 wks of treatment, 86% and 90% of pts had no or only mild symptoms. Before study, 65.2% of pts had no symptoms of hypoglycemia, 83% at end of the study. Only 4% still had mainly moderate symptoms of hypoglycemia. Glucose control was evaluated as good or very good in 31% of pts prior to study, 54% and 62% after 8 and 12 wks of treatment. After 12 weeks, the HbAc1-value indicated a better diabetic control in 386 (71%) of pts. CIS was well tolerated. Dose increase was not required, while a decrease occurred in a few pts only.*Conclusions.* These data support that CIS relieves dyspeptic symptoms and may have a beneficial effect on glucose control in diabetic neuropathy, indicating that the difficult diabetic control in these pts may be related to disordered gastric emptying. There was no evidence for tachyphylaxis over this 3-month study period. "P P 56 1345"P 56 1345**Identification of Gastric Contraction by Surface Electrogastrography**

*C.I. Sohn, P.L. Rhee, J. Kim, K.C. Koh, S.W. Paik, J.C. Rhee, W.T. Han[1], I.Y. Kim[1]

Division of Gastroenterology, Samsung Medical Center, Seoul, Korea

[1] Samsung Biomedical Research Institute, Seoul, Korea*Purpose:* The aim of this study is to identify gastric contraction by surface electrogastrography (EGG).*Method:* Simultaneous recording of antropyloroduodenal manometry and EGG was made in 10 functional dyspeptic patients during an hour fasting peroid. For EGG signal acquisition, high cutoff frequency was set 10 Hz and signal sampling frequency was 16 Hz.*Result:* During motor quiescence period, the EGG showed normal smooth sine wave form. On time domain frequency analysis, there was only single dominant frequency of three cycles per minute, namely first harmonic. During antral contraction, the slow wave showed configurational change resulting in a late peak on its wave form. On time domain frequency analysis, there was marked increase in second harmonic during contraction. When the power of second harmonic was compared to the manometric peaks, the increase in second harmonic was well matched with each group of gastric contractions.

Conclusion: Each group of gastric contractions could be identified by surface EGG. But 1:1 correlation between individual gastric contraction and EGG is not yet possible. "P P 56 1346"P 56 1346**Changes of Motility in the Stomach Transplant Implanted to the Small Intestine**

*T.S. Popova, T.Sh. Tamazashvili, N.S. Tropskaya, G.A. Platonova, A.E. Shestopalov

Sklifosovsky Institute for Emergency Medicine, Moscow, RussiaThe objective was to study the morphofunctional restructuring of the stomach tissue implanted to the small intestine.A tubular transplant on vascular pedicle was formed on the greater curvature of the stomach in 6 dogs. It was implanted into the initial portion of the small intestine. We studied the electrophysiologic parameters and the morphology of the stomach stump, the transplant, the adducting and abducting portions of the small intestine. We used the computer-assisted method of processing electric myogram data taken from implanted electrodes, impedancemetry, histologic and histochemical methods. Observation period was 1.5–3 years.The obtained results indicate that from the first hours of transplantation in the transplant, besides the basic spectrum maximum located in the frequency range typical for basal stomach motility rate (0.05–0.10 Hz), there were noted additional maxima in the range of jejunum frequencies (0.27–0.29 Hz) and ileum frequencies (0.20–0.23 Hz). It is necessary to mention that the power of the basic maximum in the transplant was 6 fold higher than in the stomach stump. Within the further observation we found the restoration of the adhesive activity in the transplant. The impedancegraphy findings confirmed the transplant contractions with the frequency of the stomach basal electric rate and the intestine basal electric rate.The dystrophic abnormalities found in the smooth muscular tissue were probably related with the adaptation of transplant muscular fibers to bowel peristalsis.

"P P 56 1347"P 56 1347**Simultaneous Validation of the Ultrasonographic Method and the Sulfasalazine Salivary Test for Gastric Emptying, Oro-Cecal and Duodeno-Cecal Transit Time Assessment — Comparison with the Isotopic Technique**

*A. Kodjo[1], F. Augry[2], S. Benhelhadj[3], O. Chassany[1], F. Bergmannj[1], C. Caulin[1]

[1] Therapeutics Research Unit, Lariboisiére hospital, 75010 Paris, France

[2] Department of Pharmacy and Scintigraphic Explorations, Lariboisiére hospital, 75010 Paris, France*Aims:* To validate echographic gastric emptying after ingestion of a dyspeptic test meal and sulfasalazine (SAZ) salivary test in order to determine oro-cecal (OCTT) and duodeno-cecal transit time (DCTT) in comparison with the isotopic technique. *Methods:* Twelve healthy male volunteers were enrolled. In *phase 1,* after fasting for twelve hours, each volunteer consumed a dyspeptic meal (1020 kcal) labelled with Indium 111-DTPA (11.1 MBq) and SAZ (2 gm). Gastric emptying time was assessed simultaneously by ultrasound and scintiscans. Salivary samples were collected from the 4th to the 14th hour and the first detection of sulfapyridine (SP) in saliva allowed the determination of OCTT. In *phase 2,* measurements of saliva appearance time were realized after administration of SAZ (2 gm) and Indium 111-DTPA (11.1 MBq) into the duodenum through a nasogastric tube. DCTT was assessed using the same method as OCTT. In both periods, scintiscans were taken until the visualization of the cecum. *Results:* The correlation between the two methods in the assessment of GE time was strong (110 – 22 min and 72 – 25 min; r = 0.70; p = 0.02). OCTT assessed by both methods was respectively 506 – 83 min and 276 – 56 min (r = 0.63; p = 0.07). The correlation between the two methods in the evaluation of DCTT was highly significant (232 – 74 min and 178 – 38 min; r = 083, p = 0.002). *Conclusion:* This study validates echographic gastric emptying measurement in dyspeptic conditions. SAZ salivary test is a simple, non invasive and validated method for the evaluation of intestinal transit time useful in clinical pharmacology studies. It's possible to study simultaneously gastric emptying time by ultrasound and OCTT by SAZ test. DCTT can be measured by the SAZ test but it requires nasogastric intubation. Motility, general: Functional GI disordersMotility, specific: StomachMotility, specific: Small bowel }" "Simultaneous Validation of the Ultrasonographic Method and the Sulfasalazine Salivary Test for Gastric Emptying, Oro-Cecal and Duodeno-Cecal Transit Time Assessment / Comparison with the Isotopic Tech"

[2] Istituto Superiore della Sanit\'e0, Rome, Italy

[3] Cattedra di Anatomia Patologica, Universit\'e0 \lquoteLa Sapienza\rquote, Rome, ItalyPolymerase chain reaction (PCR) has been recently proposed as a more reliable diagnostic tool for the identification of HP [1]. Aim of the present study was to compare diagnostic accuracy of this test in respect to rapid urease test (RT), histology (HI) and colture (CO).*Patients & Methods:* 43 pts (22 males and 21 females), with a mean age (\'b1 SD) of 50 yrs (\'b1 14), undergoing upper GI endoscopy for ulcer-like dyspepsia were enrolled. During endoscopy five antral biopsies were collected to evaluate HP infection which was assessed by RT (1 biopsy), HI (2 biopsies, Giemsa), CO (1 biopsy) and PCR for ureA gene (1 biopsy). Endoscope and biopsy forceps were disinfected with glutharaldheyde 2%, and specimens for each test were collected with different forceps. Moreover, a \lquotewash-out\rquote test (search of HP DNA by PCR in 10 ml of sterile saline solution collected after lavage of biopsy channel) was performed.*Results:* HP infection was detected in 35/43 pts (81%) by PCR, in 26/43 pts (60%) by RT, in 24/43 pts (56%) by HI and in 18/40 pts (45%) by CO. In three pts colture was not reliable for contamination of grown plates. No wash-out test was positive.*Conclusions:* PCR seems to be the most accurate method to detect HP infection in the present series. Higher accuracy of PCR seems to be particularly useful to assess the presence of HP in coccoid form, such as after antibiotic or antisecretory therapies, or in pts with low bacterial charge, such as dyspeptic pts.

"P P 57 1349"P 57 1349**Is *Helicobacter Pylori* Serology on Plasma Accurate?**

*P. Moayyedi, A. Catto[1], A.M. Carter[1], P.J. Grant[1], S. Smith, D.M. Chalmers, A.T.R. Axon

[1] Centre for Digestive Diseases and Academic Unit of Medicine, UK

General Infirmary at Leeds, UK*Introduction:* Serology is an important epidemiological research tool for investigating *H pylori.* Serology is conventionally performed on serum but in a retrospective survey that we wished to perform the only sample available was plasma. We aimed to validate a commercial *H pylori* serology kit (Shield Diagnostics) in plasma against a gold standard and against serum from the same patient. *Methods:* Patients attending the endoscopy unit were enrolled into the study and *H pylori* status was determined by histology, rapid urease test, culture and ^{13}C-urea breath test. Patients were defined as *H pylori* positive if two or more tests were positive and negative if all tests were negative. *H pylori* status was indeterminate if only one test gave a positive result. 10 ml of serum and plasma was obtained from each patient and anti-*H pylori* IgG was measured by ELISA with a value of > 10 IU/l defined as positive. *Results:* 96 patients were enrolled (mean age 47.7 – 14.4 years, 50 male), 42 were gold standard *H pylori* negative and 52 *H pylori* positive with 2 having indeterminate status. Serology on serum was 91% sensitive (5 false negatives) and 90% specific (4 false positives). Serology on plasma was 92% sensitive (4 false negatives) and 83% specific (7 false positives). Increasing the cut-off to > 13 IU/l increased specificity to 90% but reduced sensitivity to 85%. *Conclusions:* Serology on plasma is of similar accuracy to serum although there may be a small reduction in specificity at the manufacturers recommended cut-off point. Clinical practice: Quality assuranceOesophageal gastric duodenal disorders: Helicobacter Pylori }" "Is Helicobacter Pylori Serology on Plasma Accurate?"

"P P 57 1350"P 57 1350**B-Cell Clonality in Gastric Mucosa: The Significance of H. Pylori Infection**

*D. Sorrentino, G.F. Ferraccioli, S. DeVita, A. Labombarda, C. Avellini, C.A. Beltrami, M. Boiocchi, E. Bartoli

Departments of Internal Medicine and Pathology, University of Udine and 1st Division Experimental Oncology, CRO Aviano, ItalyData from our group (Gut, 1996 in press) indicate that gastric B-cell clonality is much more frequent than MALT (Mucosa Associated Lymphoid Tissue) lymphoma of which it is considered a precursor lesion. In addition, despite the reported association between MALT lymphoma and H. pylori infection the latter was not associated with B-cell clonality in several cases suggesting that other factors can play a role in its pathogenesis. Aims of the present study were to evaluate the behavior of clonality in patients with and without H. pylori infection after eradication. *Methods:* We followed for up to twenty-six months fourteen H. pylori positive and one H. pylori negative patients initially subjected to upper endoscopy and tested for B-cell clonality. H. pylori infection was treated by a standard regimen including omeprazole bid or tid plus amoxicillin bid or tid. In case of lack of eradication amoxicillin was substituted by clarithromicin. B-cell clonality was tested by VDJ-PCR using two protocols (Fr1 and Fr2) and running in parallel agarose and acrilamide gels, the latter known to increase the resolution of the technique. *Results:* The H. pylori negative patient, initially VDJ negative, became VDJ positive at the second biopsy (at 20 months). Of 11 H. pylori positive-VDJ positive patients nine were H. pylori eradicated: seven of these remained VDJ positive after a follow-up of 9–26 months while two of them became VDJ negative after 5 and 24 months. Of those who were not H. pylori eradicated one became VDJ negative after three months and one remained VDJ positive. Of three H. pylori positive/VDJ negative patients, two became VDJ positive 3 and 5 months after H. pylori was eradicated while one remained H. pylori positive and became VDJ positive after seven months. In three patients in whom VDJ positivity persisted the pattern of positivity changed from protocol Fr1 to Fr2 or vice versa. Finally, while a given sample displayed just one band in agarose gel, the same sample showed a few bands in acrilamide gel. *Conclusions:* B-cell proliferation detected in gastric mucosa of patients without clinical or histologic criteria of a pre-lymphomatous lesion is often oligoclonal and not truly monoclonal. Its prognostic value is unknown. As assessed by this follow-up study, B-cell clonality appears and disappears independently of H. pylori infection. Hence, other factors may play a role in the pathogenesis of B-cell clonality and by inference gastric MALT lymphoma. *M. Di Silvio[1], J. Larish[2], B. Vega[2], M. Dehesa[2], M. Dibildox[1], F. Amigo[3], L. Rodr\'edguez[2], I. Almaguer[1], J. Torres[2]

[1] Clinical Research Byk Gulden M\'e9xico

[3] TRI-MED Specialities, USA

[2] Centro M\'e9dico Nacional Siglo XXI IMSS, M\'e9xico*Objective:* The aim of this preliminary report is to compare the sensitivity and specificity, in an ongoing clinical trial, of ^{14}C urea breath test (UBT) versus rapid urease test (CLOtest), microbiology and histology, in order to evaluate H. pylori infection diagnosis in patients with florid duodenal ulcer.*Methods:* 36 patients (23 male) mean age 51 with no prior proton pump inhibitors or antibiotics intake 30 days before the study or history of gastric surgery were included. Fasted patients swallowed 1 gealtin capsule with 200 mg of sugar beads containing one microcurie of ^{14}C-labeled urea, after 15 minutes a breath sample was collected in a balloon, the isotope linked to scintillation fluid was quantified by beta-counter. At endoscopy several samples were taken from antrum and corpus and used for CLOtest, histology and microbiology which was performed in selective and non-selective media.*Results:* 34/36 (94%) patients with endoscopically demonstrated florid duodenal ulcer had positive CLOtest, positive in histology (Giemsa, H&E) and positive cultures for H. pylori. In this patients ^{14}C-UBT readings showed an average of 1768 DPM, max 4061 min 117, (positive cut-off value > 100 DPM). 2 patients with negative CLOtest, histology and culture showed also very low ^{14}C-UBT readings (6 and 4 DPM respectively). In this study ^{14}C-UBT, as a tool for gastric H. pylori infection diagnosis, had sensitivity and specificity of 100%*Conclusions:* Non-invasive ^{14}C-UBT is an excellent method for H. pylori infection diagnosis, easy to perform and timeless, with accuracy and reproducibility comparable to gold standard methods. "P P 57 1352"P 57 1352**Detection of Helicobacter Pylori in Post-Treatment Gastric Biopsy: Comparison between Classic Histology, CLO Test and H.P.-DNA PCRR. Pedrana[1], P. Locicero[1], M. Fay[2], A. Naves[2], M. Sylvestre Begnis[2], C. Banchio[3], H. Gramajo[3], F. Fay[3]**

[1] Centro de Gastroenterologia, Rosario, Argentina

[2] Instituto de Histopatologia, Rosario, Argentina

[3] Bios Rosario, Rosario, Argentina*Background/Aims:* a sensitive and specific methodology is necessary for detection of H.P. in gastric biopsy to evaluate post-treatment microorganism presence. This would allow to differentiate recrudescence from reinfections. The aim of this study was to compare the sensitivity of gastric biopsy, Clo test and H.P.-DNA PCR for the detection of H.P. in a group of recently treated patients (6–8 weeks after treatment).*Patients and Methods:* H.P.-DNA PCR was performed gastric biopsies from 50 treated patients (33 males and 17 females) (age: 48 – 12 years), in whom success of treatment was defined only by histological means and Clo test. Therapeutic schemes were as follows: Treatment 1: (11 patients) Amoxyciline 500 mg b.i.d. during plus Metronidazol 500 mg b.i.d. plus Dicidrato Bismuth Tripotasic 120 mg q.i.d. during 14 days. Treatment 2: (19 patients) Omeprazole 20 mg b.i.d. plus Zitromicine 250 mg b.i.d. during 3 days. Treatment 3: (20 patients) Amoxiciline 1 gr b.i.d. plus Lanzoprasole 20 mg/day. H.P. eradication was defined on histological grounds (gastric histology: 10% buffered formol fixation; paraffin inclusion; Giemsa and HE staining), Clo test (Delta West Pty. Ltd. Bentley, Australia) and by the absence of H.P.-DNA by PCR (amplification of a 296 bp of the species-specific antigen of H.P. and visualization of the amplified product in agarose gel with Ethidium Bromide and U.V. light), all of them performed within 6 to 8 weeks after the end of treatment.*Results:* Histology & Clo Test PCRPositive Negative Positive Negative0 50 6 441 out of 6 (16.7%) reinfected patients received treatment 1, 3 of them (50%) treatment 2 and the other 2 (33.3%) treatment 3.*Conclusions:* H.P.-DNA PCR is more sensitive than conventional accepted methods for assessing H.P. presence in the immediate post-treatment period, as it was able to detect a 12% false negatives by traditional methods. This would allow discriminate between residual replication and true reinfection of H.P. on a long term follow up basis of these patients. "P P 57 1353"P 57 1353**The Occurrence of IgG Antibodies to High Molecular Weight Proteins of H. Pylori Antigen among Duodenal Ulcer Patients and Practically Healthy Persons in LithuaniaT. Wadstrom[1], J. Miciuleviciene[2],**

*L. Kupcinskas, J. Kligiene, V. Petrenkiene

[1] Department of Medical Microbiology, University of Lund, Sweden

[2] Department of Microbiology, Kaunas Medical Academy, Kaunas, Lithuania

Department of Gastroenterology, Kaunas Medical Academy, Kaunas, Lithuania*Aim of the study* – to assess in duodenal ulcer (DU) patients and practically healthy persons the presence of high molecular weight (85 and 120 kDa) IgG antibodies to H. pylori (HP). *Material and Methods:* The seras of 22 consecutive patients with DU and 18 practically healthy medical students were analysed for IgG antibodies in ELISA and immunoblot using glycine extracted proteins of HP (NCTC 11637) as antigen. ELISA results were expressed as relative antibody activity (positive > = 35). Presence of high molecular weight IgG antibodies to HP by western blotting method were assessed semiquantatively. *Results:* In ELISA, IgG antibodies to HP were found in 18/22 DU and in 15/18 controls. In the sera of DU ulcer patients, antibodies to 120 kDa protein were expressed in 21/22 cases and to 85 kDa – in 18/22 samples. In control group sera reactivity to 120 kDa protein was found in 13/18 cases and to 85 kDa antigen in 12/18 samples. The frequency and expression of 120 kDa antigen in DU patients were significantly higher ($p < 0.001$ according to the { ?}^{2} test) in comparison with the control group. No statistically significant differences in frequency of 85 kDa antigen were revealed between the groups. *Conclusion:* Our pilot study showed high frequency of 120 kDa antigen among Lithuanian DU patients (95.6%) as well as the control group of practically healthy persons (73.2%). The prevalence of virulence factors of HP infection (especially CagA – cytotoxin-associated protein closely related to 120 kDa protein) could likely explain high peptic ulcer morbidity and complication rate as well as high gastric cancer rate in Lithuania. "P P 57 1355"P 57 1355**Plasma Nitrate/Nitrite Level is Higher in Patients with Peptic Ulcer Disease and Chronic Gastritis — The Increase is Independent of Helicobacter Pylori Status or Eradication**

*L. Pr\'f3nai, E. Szaleczky, H. Nakazawa[1], Zs. Tulassay

2nd Department of Medicine, Semmelweis Medical School, Budapest, Hungary

[1] Department of Physiology, Tokai University, School of Medicine, Isehara, JapanPlasma nitrate/nitrite level reflects the endogenous nitric oxide production in fasting human. Both elevated and unaltered nitric oxide synthase activity in the gastric mucosa, and in contrast, low nitrate/nitrite level in the stomach and in the plasma have been reported in patients with peptic ulcer disease. Helicobacter pylori (H. pylori) infection has been shown to induce nitric oxide synthesis in the gastric mucosa in vitro, but no data is available about the in vivo conditions.To answer the questions whether 1) nitric oxide synthesis is enhanced in peptic ulcer disease, 2) the increase is disease specific, and 3) whether it has any correlation with H. pylori infection; we measured plasma nitrate/nitrite levels in 50 patients (mean age 50 – 15 y.o.) with upper gastrointestinal symptoms. We also studied the effect of H. pylori eradication on plasma nitrate/nitrite levels in these patients. Blood was obtained from patients with upper gastrointestinal symptoms immediately after gastroscopy, and was repeated at 4 weeks after successful H. pylori eradication. Plasma nitrate/nitrite was measured by HPLC at 550 nm using a cadmium column for nitrate reduction.Plasma nitrate/nitrite level was significantly higher both in patients with peptic ulcer disease (87 – 48 \'b5M, n = 12) and chronic gastritis (47 – 18 \'b5M, n = 23), when compared with that in patients with reflux oesophagitis (33 – 5 \'b5M, n = 6) or dyspesia symptoms (28 – 3 \'b5M, n = 9). When compared with histology grading, plasma nitrate/nitrite level increased significantly as the severity of chronic gastritis progressed (grade I = 44 – 14 \'b5M, grade II = 49 – 21 \'b5M, grade III = 113 – 56 \'b5M). There was no difference in plasma nitrate/nitrite levels between H. pylori positive (n = 32) and negative (n = 18) patients (61 – 39 \'b5M vs. 42 – 18 \'b5M). Successful eradication of H. pylori did not alter the elevated plasma nitrate/nitrite levels (data not shown).Based on the elevated plasma nitrate/nitrite levels observed, nitric oxide synthase activity of gastric mucosa is enhanced in patients with peptic ulcer disease. This increase, however, is specific neither for peptic ulcer disease nor for H. pylori infection, since it can also be observed in patients with chronic gastritis and after the successful eradication of H. pylori. Oesophageal gastric duodenal disorders: Helicobacter PyloriOesophageal gastric duodenal disorders: GD disorders, acid pepticOesophageal gastric duodenal disorders: Secretion: mechanism, regulation }" "Plasma Nitrate/Nitrite Level is Higher in Patients with Peptic Ulcer Disease and Chronic Gastritis / The Increase is Independent of Helicobacter Pylori Status or Eradication"

"P P 57 1356"P 57 1356**Screening for IgG Antibodies Against Helicobacter PyloriB.F.M. Werdmuller, A.B.M.M. v/der Putten,**

*R.J.L.F. Loffeld

Department of Internal Medicine, Ziekenhuis De Heel Zaandam, The NetherlandsScreening for IgG antibodies against HP can be used for omitting endoscopy in selected cases. The present study was done in order to assess the best screening strategy. The population consisted of non selected consecutive patients referred for endoscopy from 3/1994 till 3/1995. A serum sample was taken. IgG antibodies against HP were detected using a home-made ELISA technique. During the study period 1527 patients underwent upper GI endoscopy. In 233 cases endoscopy was done because of follow-up or serum from the patient was not available. Hence 1293 serum samples were available. IgG antibodies were present in 622 patients (48%) (303 ♂ 319 ♀, mean age 57 years, range 17–87), the remainder, 671 (52%) (316 ♂, 355 ♀, mean age 52 years, range 13–84) was negative. The following abnormalities were present in the seropositive group: oesophagitis 10%, hiatal hernia 12%, oesophageal cancer 0.5%, Barrett 3.4%, varices 1.9%, candida 1.9%, gastritis 8.5%, GU 3.8%, gastric cancer 1.6%, DU 6.4%, and bulbitis 8.3%. And in the seronegative group: oesophagitis 15%, hiatal hernia 15.4%, oesophageal cancer 0.3%, Barrett 4.3%, varices 1%, candida 1.3%, gastritis 10.6%, GU 1.8%, gastric cancer 0.1%, DU 1.6%, and bulbitis 5.5%. The following abnormalities were present in the seropositives below the age of 45 years: oesophagitis 6.8%, hiatal hernia 8%, Barrett 1.3%, varices 1.3%, candida 0.65%, gastritis 6.8%, GU 0.6%, DU 14.5%, and bulbitis 6.8%. And in the seronegatives: oesophagitis 12%, hiatal hernia 6%, Barrett 1.7%, varices 0.4%, gastritis 7.3%, DU 2.6%, and bulbitis 4.7%. If screening would have been applied on the total group of seronegatives than 318 patient would undergo endoscopy and 353 (27.3%) endoscopies could have been saved. Omitting endoscopy in seronegative cases below the age of 45 years would result in 182 (14%) endoscopies saved. If this strategy again is applied on the total group of seropositives than 188 patients still would undergo endoscopy and 434 endoscopies (34%) would have been saved. Omitting endoscopy in seropositive cases below the age of 45 years would save 119 (9%) endoscopies. It is concluded that endoscopy can be savely omitted in seropositive cases. Endoscopy in seronegatives will reveal more reflux oesophagitis. In addition, in oesophagitis helicobacter infection needs treatment since long term acid suppressive therapy will increase the development of atrophic gastritis. After eradication therapy oesophagitis complaints are likely to return and endoscopy will be done. Many patients with functional dyspepsia will benefit from this therapy and the number of recurrent complaints will be low. This study indicates that omitting endoscopy in seropositive cases, regardless of age, reduces the workload more than omitting endoscopy in seronegative cases, 34% fewer endoscopies versus 27%. "P P 57 1357"P 57 1357**Detection of Helicobacter Pylori in Faeces by PCR Assay**

*M. Notarnicola, F. Russo, A. Cavallini, M. Bianco, G. Di Matteo, A. Di Leo

Lab. Biochemistry, Endoscopy Unit, IRCCS ""S. de Bellis"" Castellana G. (Ba) ItalyHelicobacter pylori (Hp) is the major cause of chronic gastritis and has been associated with gastric cancer [1]. There are some evidences for a faecal-oral transmission, even if few data are available about Hp detection in faeces. Recently, Hp genome has been detected by PCR in faeces from patients with gastritis [2]. Notwithstanding, faecal samples can easily give false-negative results because different chemicals present in faeces, such as polysaccharides, inhibit PCR [3]. *Aims* of our study were: 1) to remove the possible inhibitors present in faeces and 2) to detect by PCR the presence of Hp in faecal samples of symptomatic patients undergoing endoscopy in our Institute. *Patients and Methods:* Fifty consecutive patients (28 males, mean age 51.8 – 10.4, and 22 females, mean age 46 – 12.8) entered the study. Faecal samples were suspended in phosphate buffered saline pH 7.4. The mixture was filtered by polypropylene filter (mesh opening 149 \'b5m) in order to remove PCR inhibitors. DNA was extracted from faeces by Tri-Reagent (Mol. Res. Center Inc. Cincinnati, OH, USA), and subsequently amplified by the primers taken from urease gene A. PCR products were separated and identified by electrophoresis on 2% agarose gel. *Results:* Warthin Starry PCR Positive NegativeHp positive 34 30 4Hp negative 16 0 16Hp specific DNA was detected in 88% of faecal samples with a specificity of 100%. *Conclusions:* The present findings suggest a faecal oral route of Hp transmission. Nevertheless, an unequivocal pattern of Hp spread cannot be established. The presence of Hp DNA in our samples may be due to DNA from non viable or viable cells present in faeces. Finally, since Hp detection in faeces by PCR is a non-invasive method, it may represent a useful tool for the follow-up after eradicating therapy.

"P P 57 1362"P 57 1362**How Do Two Diagnostic Tests for *H. Pylori* at 1 Month Compare to Two ^{13}C-Urea Breath Tests (UBT) in Assessment of Eradication?P.G. Johnson[1], A.E. Duggan[2], C. Olson[3]**

[1] BSIA Ltd., U.K.

[2] Glaxo Wellcome R & D, U.K.

[3] Abbott Laboratories, Illinois, USA*Introduction:* To evaluate the eradication of *H. pylori* it has been suggested that either 2 diagnostic techniques might be used 1 month (m) post-treatment, or that UBT alone might be performed at both 1 and 3 m post-treatment. Data from 7 multinational studies conducted to the standards of Good Clinical and Laboratory Practice are presented for a series of time points.*Methods:* Patients who had an active DU and positive CLOtest™ pre-treatment, were evaluated post-treatment. *H. pylori* was assessed by UBT (excess 3.5 $^{13}CO_2$ per mil = positive) and at least 1 other test, [CLOtest, histology (Hx), or culture (Cx)], before and 1, 3, 6, or 12 m post-treatment, dependent on study. UBT, Hx and Cx (antral and corpus biopsies) were processed by central laboratories. *H. pylori* status assigned from the pooled result of UBT at 1 and either 3, 6 or 12 m was compared with the pooled result of two diagnostic tests at 1 m, and also the UBT alone at 1 m, in the same subset of patients.*Results:* UBT (1 m + 3 m) (1 m + 6 m) (1 m + 12 m) % *Hp* { -}ve % *Hp* { -}ve % *Hp* { -}ve (n = 277) (n = 477) (n = 69)Pooled UBT 59.9 50.3 49.3Two tests 1 m 62.1 54.7 50.7UBT alone 1 m 64.3 56.0 50.7*Conclusions:* 2 diagnostic tests at 1 m post-treatment or the pooled result from 2 consecutive breath tests provide satisfactory alternatives in the definitive assessment of *H. pylori* eradication. UBT alone at 1 m gives a slightly raised estimate of eradication, but on balance compares favourably for clinical practice by not requiring endoscopy whilst giving a rapid answer. Oesophageal gastric duodenal disorders: Helicobacter Pylori }" "How Do Two Diagnostic Tests for H. Pylori at 1 Month Compare to Two 13C-Urea Breath Tests (UBT) in Assessment of Eradication?"

"P P 57 1363"P 57 1363**Current Use of Helicobacter Serology for Pre-Endoscopy Screening in the UK**

*A.G. Lim, R.M. Martin, M. Montileone, A.C. Walker, S.R. Gould

Department of Medicine, Epsom General Hospital, Epsom, UK

Department of General Practice & Primary Care, St George's Hospital Medical School, London, UKConsiderable savings have been reported using Helicobacter pylori (HP) serology as a pre-endoscopy screening test for young dyspeptics although the extent of these savings and the efficacy of various clinical strategies have been disputed. We conducted a survey amongst UK hospital gastroenterologists and general practitioners with an interest in gastroenterology to establish current practice in the management of dyspeptics under the age of 45 years.Postal questionnaires were sent to 536 members of the British Society of Gastroenterology and 164 members of the Primary Care Society in Gastroenterology. The response rate was 66%.HP serology is currently used by 25% of general practitioners and 17% of gastroenterologists. Following screening, most general practitioners would eradicate infection prior to endoscopy (92.4%) whilst most gastroenterologists (74.5%) would endoscope patients before treatment. 70% of gastroenterologists would endoscope sero-positives but 30% would endoscope sero-negatives. Of those not currently using serology, 78% would use it as a pre-endoscopy test if it were available. 106 different drug regimens were used by respondents as first line HP treatment. 83.4% used triple therapy and the most popular combination was that of omeprazole, amoxycillin and metronidazole (38.2%). Following treatment 57% of respondents re-tested selected patients, 29% re-tested all patients and 14% never re-tested.Our survey shows that in the UK, HP serology is being used as a pre-endoscopy screening test for young dyspeptics by only a fifth of gastroenterologists. There was wide variation in strategies preferred by hospital gastroenterologists and by general practitioners. Trials comparing symptomatic outcome and economic consequences of different HP serology based clinical strategies are needed. Clinical practice: Management strategyOesophageal gastric duodenal disorders: Helicobacter Pylori }"

"P P 57 1364"P 57 1364**Helisal Rapid Whole Blood Test for the Diagnosis of Helicobacter Pylori**

*A.G. Lim, C. Walker, S.R. Gould

Dept of Medicine, Epsom General Hospital, Epsom, UKDiagnosis of *Helicobacter pylori* by histopathology, culture, urea breath tests or serology using enzyme linked immunosorbent assay (ELISA) are relatively time consuming. A test kit for diagnosing *H. pylori* using diluted whole blood has become commercially available (Helisal^{tm} – Cortecs Ltd). This test is easy to perform, requires no laboratory equipment. Our aim was to independently assess its diagnostic accuracy.Dyspeptic patients referred for investigation at our hospital were invited to participate. Patients who had received proton pump inhibitors over the preceding month or had previously received H. pylori eradication therapy were excluded. ^{13}C urea breath test was used as the gold standard for *H. pylori* status. All urea breath tests and rapid whole blood tests were performed by a single investigator.92 patients were recruited in this study (median age 52.5, range 10–72 years, 51 males. All rapid whole blood tests were completed within ten minutes. Of the 59 patients *H. pylori* positive by urea breath test, 4 were false negative by rapid whole blood test. Of the 33 patients *H. pylori* negative by urea breath test, 11 were false positive by rapid whole blood test. The sensitivity and specificity of the kits for *H. pylori* were 93% of 67% respectively.The Helisal rapid whole blood test was quick and easy to perform. In our hands, its sensitivity was good but its specificity was less impressive. Oesophageal gastric duodenal disorders: Helicobacter Pylori }" "Helisal Rapid Whole Blood Test for the Diagnosis of Helicobacter Pylori"

"P P 57 1365"P 57 1365**Intragastric Urease Activity in Helicobacter Pylori (H.p.) Infection after Urea Application**

*J.W. Dlugosz[1], A. Kemona[2], B. Cylwik[3]

[1] Gastroenterology, Department, Medical Academy, Bialystok, Poland

[2] Anatomopathology Department, Medical Academy, Bialystok, Poland

[3] Biochemical Diagnostics, Department, Medical Academy, Bialystok, Poland*The purpose* of the study was to evaluate whether intragastric ammonia production with exogenous urea as substrate by bacterial urease could be a criterion of severity H.p. infection and efficacy of therapy.*Methods.* In 31 patients (pts), (23 F, 19–68 yrs, and 8 M, 23–61 yrs) with peptic ulcer (6 pts) or gastritis (25 pts) and H.p. infection (in 14 severe), the ammonia output (mg/h) in basal (BAO) and pentagastrin (6 \'b5g/kg *s.c.*) stimulated gastric juice (MAO_1), was estimated. In 15 pts MAO_2 after repeated stimulation during *i.g.* infusion of urea solution (7.5 g/60 ml H_2O {\'b4} h{ˉ1}) was collected. This test was repeated after treatment with triple or bismuth salt therapy when indicated.*Results.* The ammonia output (A.O.) in MAO_2 before treatment was almost twice higher than in MAO_1 (20.9 – 12.5 *vs* 10.9 – 4.8, $p < 0.01$). After effective treatment (8/15 pts) it decreased by 40% in BAO, 57% in MAO_1 and 42% in MAO_2 ($p < 0.05$). Ineffective therapy (3/15 pts) did not affect the ammonia output significantly. The ratio of A.O. in MAO_2/BAO was markedly higher then in MAO_1/BAO and MAO_2/MAO_1 before treatment (3.86 – 2.99 *vs* 2.16 – 1.41; $p < 0.01$ and *vs* 1.93 – 0.93; $p < 0.01$). After effective therapy MAO_2/BAO decreased by 37% and MAO_2/MAO_1 by 30% ($p < 0.05$), what was not the case after ineffective therapy. MAO_1/BAO ratio of A.O. after single stimulation was also reduced (1.45 – 0.35 *vs* 2.98 – 2.47) after effective treatment ($p < 0.05$).*Conclusion.* The ammonia output in the pentagastrin stimulated gastric juice secretion could be simple and nonexpensive test of total gastric Helicobacter pylori infection and effectivity of therapy, especially when performed after application of exogenous substrate: urea for bacterial urease. Oesophageal gastric duodenal disorders: Helicobacter PyloriOesophageal gastric duodenal disorders: GD disorders, acid peptic }" "Intragastric Urease Activity in Helicobacter Pylori (H.p.) Infection after Urea Application"

"P P 57 1366"P 57 1366**Does a Second Biopsy Specimen Increase Clo-Test Accuracy for Helicobacter Pylori (HP) Detection after Eradication Treatment in Duodenal Ulcer (DU) Patients?**

*S. Michopoulos, M. Sotiropoulou[1], I. Vougadiotis, H. Bouzakis, I. Papaspyrou[1], N. Kralios

Gastroenterology Unit, ""Alexandra"" Univ. Hosp., Athens, Greece

[1] Pathology Unit, ""Alexandra"" Univ. Hosp., Athens, GreeceRapid urease test is considered as a reliable and inexpensive method for HP detection. Histology (HIS) is the reference method although misdiagnosis is possible when HP density is low. It is suggested that the positivity of CLO-test is related to the HP burden. Translocation of HP to the fundus after anti-secretory treatment has been reported. The *aim of our study* was to evaluate the diagnostic accuracy of CLO-test'-(Delta west Pty Ltd) in DU patients after HP eradication treatment, correlate CLO results with HP density and assess possible benefits by adding a fundic (F) or antral (A) biopsy specimen. *Patients and methods:* 123 patients (81 men), with DU had 2A + 2F biopsies for HIS [modified Giemsa, Warthin Starry] and immunohistochemical (IHC) [Rabbit anti HP antibodies DAKO: B 471] analysis, 4–6 weeks after the end of eradication therapy. All patients had a CLO-test with one A biopsy (CLO1). 63 patients had a second one (CLO2f) with one A and one F biopsy together while 60 patients had also a second one with two A biopsies together (CLO2a). *Stat:* t-test, x2-test, Bartholomew test. *Results:* There was no difference between CLO1 and CLO2f or CLO2a concerning the qualitative results. The time for the test to become positive was significantly shortened only when a second A biopsy was added (1.98 – 0.28 vs. 1.09 – 0.75 h) $p < 0.001$. CLO-test compared to HIS has 58% Se, 100% Sp, 100% ppv and 69% npv while compared to IHC has 77% Se, 100% Sp, 100% ppv and 86% npv. CLO positivity was strongly correlated to HP density ($p < 0.01$). *Conclusions:* 1) The specificity of CLO-test is excellent for detection of HP after eradication treatment for DU patients, while its sensitivity is mediocre compared to IHC (77%) and poor compared to histology (58%) 2) The addition of a second biopsy specimen either A or F in the CLO-test does not improve its diagnostic value and 3) The disagreement between IHC and HIS (15/123 patients) needs further evaluation in order to avoid HP overdiagnosis. Clinical practice: Management strategyClinical practice: Quality assuranceOesophageal gastric duodenal disorders: Helicobacter Pylori }" "Does a Second Biopsy Specimen Increase Clo-Test Accuracy for Helicobacter Pylori (HP) Detection after Eradication Treatment in Duodenal Ulcer (DU) Patients?"

"P P 57 1367"P 57 1367**13C-Urea Breath Test and the Density of Helicobacter Pylori in Gastric Mucosa — Study of the Patients with Functional Dyspepsia**

*J. Koskenpato, M. F\'e4rkkil\'e4

Helsinki University Central Hospital, Department of gastroenterology, Helsinki, FinlandThe studies of influence of *Helicobacter pylori* gastritis on symptoms of functional dyspepsia has produced inconclusive results. The 13C-urea breath test is a noninvasive method to detect the presence of *H. pylori* infection. The relationship between the results of 13C-UBT and the density of *H. pylori* in histologic samples is not established. The aims of our study were: 1. to analyse the relationship between the results of 13C-urea breath test and the density of *H. pylori* in histology and 2. to analyse the assosiation between the symptoms of functional dyspepsia and the density of *H. pylori* in gastric mucosa.*Material and methods:* 29 patients with functional dyspepsia were evaluated by gastroscopy and ultrasonography of upper abdomen. Every patient had a nonerosive *H. pylori* positive chronic gastritis without any other macroscopic abnormality. Biopsies from duodenum, antrum and corpus were taken for histological examination.- The scores of the density of *H. pylori* were graded on a scale ranging from 0 to 6 (antrum 0–3, corpus 0–3). The dyspepsia symptom scores (range 0 to 12) were recorded by a standardized questionnaire. All patients received the 13C-UBT and the 13C-enrichment was analyzed by isotope ratio mass spectrometry. Statistical analysis was made by using simple linear regression analysis.*Results:* The mean delta-value of 13C-UBT was 43.0 – 21.1 0/00, the mean dyspepsia score was 4.2 – 2.4 and the mean value of the density of *H. pylori* was 3.6 – 1.4. There was a statistically significant assosiation between the density of *H. pylori* in histological examination and the delta-value of 13C-UBT (p = 0.01, pearsonr. = 0.46). There was no association between the symptoms of functional dyspepsia and the delta-value of 13C-UBT (p = 0.55, pearsonr = { -}0.12)*Conclusions:* These data suggest that the delta-value of 13C-UBT is assosiated with the density of *H. pylori* in gastric mucosa. The severity of symptoms caused by functional dyspepsia are not assosiated with the density of *H. pylori* in gastric mucosa. "P P 57 1368"P 57 1368**Diagnostic Value of a Commercial IgG Enzyme-Linked Immunosorbent Assay (Elisa) Kit for *Helicobacter Pylori* Infection Diagnosis**

*C. Mart\'edn de Argila, D. Boixeda, N. Valdezate, S. Mir, I. Garc\'eda, J.P. Gisbert, R. Canton, A. Garc\'eda Plaza

Gastroenterology and Microbiology Departments, ""Ram\'f3n y Cajal"" Hospital, Madrid, SpainEnzyme-linked immunosorbent assays (ELISAs) are considered good non-invasive methods to diagnose *H. pylori* infection. The aim of this study was to evaluate the clinical usefulness of a commercial IgG *H. pylori* antibody test kit.*Methods:* A total of 400 patients attended at the Endoscopy Unit because of symptoms attributable to the upper gastrointestinal tract were studied. At endoscopy, multiple biopsies from gastric antrum and gastric body were obtained for histology and culture. *H. pylori* was diagnosed if culture was positive in at least one of the biopsy samples obtained. Ten milliliters of venous blood were collected at the time of endoscopy for serological assessment. Serum samples were analyzed for *H. pylori* by a quantitative commercial IgG ELISA, based on an acid glycine extract: Helico G, Porton, Cambridge, UK. The test was performed in duplicate according to the manufacturer's instructions and by the same person. Results were evaluated on the basis of different cut-off values.*Results:* In the study population, 89.8% of the patients were *H. pylori* positive (by culture). The serology results were as follows: Cut-off Sensitivity (%) Specificity (%) PPV (%) NPV (%) LR8 U/ml 98.3 53.7 94.9 78.6 2.110 U/ml 97.2 85.4 98.3 77.8 6.611 U/ml 94.7 85.4 98.3 64.8 6.4PPV = Positive predictive value; NPV = Negative predictive value; LR = Likelihood ratio.The area under the receiver operator characteristic (ROC) curve was 0.96.*Conclusions:* This study confirms the diagnostic efficiency of this IgG commercial ELISA in detecting *H. pylori* infection. According to the manufacturer, 10 U/ml is the most appropriate cut-off value. The competitive cost of this technique and the fact that it is non-invasve render this method an optimum tool to study *H. pylori* infection in large population groups. "P P 57 1369"P 57 1369**Measurement of Helicobacter Pylori Antibodies in Saliva: A Non Invasive in Comparison with 13C-UREA Breath Test and SerologyR. G[a]Valriberas, J.A. Correa Esta\'f1, C. Hermida, Y. Jimenez, J.M. Pajares G[a]**

Dept. of Gastroenterology, Hospital La Princesa, Madrid, Spain*Background & Aim:* Numerous serological Kits are available to provide cheaper, non invasive and more rapid diagnosis of the Helicobacter Pylori (Hp) infection. These study evaluated the accuracy of the determination of Ig G antibodies in saliva for detection of Hp status using 13C-Urea Breath Test (UBT) as gold standar.*Patients & Methods:* 24 patients (mean age 50, sex: 10 F, 14 M) presenting bleeding peptic ulcer endoscopically documented with two antral biopsies and rapid ureasa test (RTU) and 24 controls (mean age 23, sex: 4 F, 21 M) without peptic disease were studied. We realized to all the patients venous punction for serology tests (Helico-G), collection of saliva using OMNI-Sal collection device (SDS), and 13C-UBT. We exclude those patients in treatment with omeprazol, antibiotics or eradication therapy in the previous four weeks. The cut-off of salivary antibody was established between 0.8–1 U/ml and for serum Ig G titers in 10.*Results:* Cases 24 Controls 24Patients 15/24 3/24 6/24 6/24 8/24 1/24 7/24 2/24Saliva antibodies + { -} + + { -} + { -} +Serum serology + { -} + + { -} + + { -}UBT + { -} { -} + { -} { -} + { -}*In cases:* 6 patients were UBT negative, being positive both serologies. In the biopsies and RTU all except one, were negative for Hp infection. We review the results and we found that all these patients had taken antibiotics for urinary infection during the hospitalization. We repeat the UBT 3–4 weeks later and 4 were positive and 2 continue negative. The control group had false positives due to low sensibility, spontaneous eradication or urea-producers pathogens.*Conclusions:* The determination of specific Hp antibodies could be a valid method for determinate Hp infection in patients with peptic disease but isn't good for screening test. Oesophageal gastric duodenal disorders: Helicobacter Pylori }" "Measurement of Helicobacter Pylori Antibodies in Saliva: A Non Invasive in Comparison with 13C-UREA Breath Test and Serology"

"P P 57 1370"P 57 1370**^{14}C-Urea Breath Test in Detection of *Helicobacter Pylori*-Associated Gastric Diseases**

*W. Bielanski, J. Dobrzanska, A. Kaminska, J. Pytko-Polonczyk, S.J. Konturek, E. Sito

Inst. Physiol., Univ. Sch. Med., Krakow, Poland*Purpose:* High urease activity of *Helicobacter pylori* (Hp) is used to detect this bacterium by non-invasive urea breath test (UBT). We employed the microdose version of the test in which 37 kBq of ^{14}C urea is given orally in capsule. The objectives of the study were: 1. to evaluate a microdose (37 kBq) ^{14}C-urea enclosed in a quick dissolve capsule; 2. to assess whether the fasting period is required before the procedure of ^{14}C-UBT; 3. to determine whether breath test results are changed when they are mailed to a remote site for analysis; 4. to define the diagnostic ranges of ^{14}C-UBT for Hp-positive and Hp-negative patients.*Methods:* In the study we breath tested 239 consenting patients (18–75 yr old) without previous antibiotic or antiulcer therapy or gastric surgery. The breath samples were collected and analyzed before (at basal state) and at 10 min intervals after the ingestion of 37 kBq ^{14}C-urea by patients prior to their endoscopy. With the cut-off value > 100 DPM as positive, UBT results correlated highly significant with combined results of invasive gold standards i.e. CLO-test + histology score.*Results:* The breath test performed locally were almost identical with those read at remote laboratory. The data found for fasting and fed states of subjects agreed in 87%. When ^{14}C-urea was dissolved in water and confined for 5 min in the mouth (without swallowing), both 30 Hp positive and 30 HP negative patients with gastric UBT showed the presence of urease activity in the mouth.*Conclusions:* 1. ^{14}C-urea in quick dissolved capsule is a convenient, non-invasive test for detection of gastric Hp with accuracy and reproducibility equal to those of gold standards; 2. feeding does not affect the accuracy of the test; 3. the results can be analyzed within 10–15 min locally or at a remote site; 4. orally applied liquid ^{14}C-urea may lead to false positive results due to oral urease activity. Oesophageal gastric duodenal disorders: Helicobacter Pylori }" "14C-Urea Breath Test in Detection of Helicobacter Pylori-Associated Gastric Diseases"

"P P 57 1371"P 57 1371**Antibody Response to Helicobacter Pylori Antigens: Sensitivity and Specifity of IGG-ELISA and an H. Pylori Specific Immuno-Blot SystemU. Schmidt-Wittig, U. Platzer, G. Illies, M. Nilius, A. Hackelsberger, P. Malfertheiner**

Dept. Gastroenterology, Hepatology and Infect. Diseases Otto-von-Guericke-University Magdeburg, Germany*Background:* H. pylori infection is either detected by invasive means using the urease test (HUT), histology, culture or noninvasively by ^{13}C-urease breath test or serology. Antibody response may be determined either by ELISA or by immunoblot technique. Aim of our study was to investigate the sensitivity and specifity of a new immunoblot system in comparison to other methods.*Methods:* 66 patients with chronic gastritis (CG), 29 with gastric (GU) and 25 patients with duodenal (DU) ulcer were tested for presence of H. pylori infection by HUT, histology, IgG-ELISA (Biorad, Germany) and a new commercially available immunoblot system (BAG-Pylori-Blot, BAG Germany) based upon H. pylori specific antigens. For evaluation of IgG-ELISA and immunoblot 66 patients with positive and 43 patients with negative HUT and histology served as reference for sensitivity and specifity, respectively, as well as for positive (PPV) and negative (NPV) predicted value.*Results:* Both methods showed highest sensitivity in DU sera, while specifity was best in CG patients. In most of the calculated parameters immunoblot results exceed all those of IgG-ELISA. ELISA Sensitivity Specifity PPV NPVCG 77% 68% 70% 56%GU 76% 38% 76% 37.5%DU 94% 14% 74% 50% Blot Sensitivity Specifity PPV NPVCG 81% 68% 71% 58%GU 81% 38% 77% 43%DU 94% 28% 77% 66%*Conclusion:* Tested immunoblot-system represents a suitable alternative for IgG-ELISA with even higher sensitivity and specifity and implies the possibility of screening for specific antigens of infecting H. pylori strains in patients. "P P 57 1373"P 57 1373**Is There Any Correlation between ^{13}C-UREA Breath Test Values and Response to *H. Pylori* Eradication Therapy?**

*J.P. Gisbert, D. Boixeda, Mart\'edn C. de Argila, F. Bermejo, T. P\'e9rez, I. Jim\'e9nez[1], J.M. Pajares[1]

""Ram\'f3n y Cajal"" Hospitals, Madrid, Spain

[1] ""la Princesa"" Hospitals, Madrid, Spain*Purpose:* To study whether there is a correlation between urea breath test values prior to treatment and the response to *H. pylori* eradication therapy in patients with duodenal ulcer.*Methods:* Two-hundred and one patients with duodenal ulcer were retrospectively studied (mean age: 47 – 13 years; 69% males). Initially, an endoscopy with biopsy samples (H&E stain) taken from antrum and body and a ^{13}C-urea breath test (according to the European standard protocol, measuring ^{13}C difference: { d}$^{13}CO_2$) were performed. Both procedures were repeated one month after completing therapy: ""classic"" triple therapy (n = 29), omeprazole or lansoprazole plus amoxycillin (n = 58), and omeprazol plus two of the following antibiotics: amoxycillin, clarithromycin, metronidazole (n = 114).*Results:* Overall, eradication was achieved in 66% (n = 132). The corresponding rates for the therapy groups were: ""classic"" triple therapy: 64%; omeprazole or lansoprazole plus amoxycillin: 33%; omeprazol plus two antibiotics: 83%. Mean { d}$^{13}CO_2$ level was { -}31.5 – 23. There were no differences when comparing values of patients with therapy success (33 – 24) and failure (30 – 20). No differences were observed when considering therapies separately and comparing eradication rates depending upon breath test levels prior to therapy. Breath test values did not influence the eradication in the logistic regression model. Mean { d}$^{13}CO_2$ values after therapy in patients with eradication failure ran in parallel with initial values.*Conclusion:* No correlation was observed between urea breath test values before treatment and the response to *H. pylori* eradication therapy in patients with duodenal ulcer. Thus, we conclude that quantitation of this diagnostic method is not useful to predict the success or failure of eradication therapy.

"P P 57 1374"P 57 1374**Breath Test for the Diagnosis of *H. Pylori* Infection: Concordance with Histologic Methods and Correlation with Histologic Lesions of Gastric Mucosa**

*J.P. Gisbert, D. Boixeda, C. Redondo, Baleriola I. Alvarez, I. Jim\'e9nez[1], J.I. P\'e9rez Garc\'eda[1], J.M. Pajares[1]

""Ram\'f3n y Cajal"" Hospitals, Madrid, Spain

[1] ""la Princesa"" Hospitals, Madrid, Spain*Purpose:* To study the concordance between ^{13}C-urea breath test and histology in the diagnosis of *H. pylori* infection, and to evaluate whether there is a correlation between breath test values and histologic lesions of gastric mucosa.*Methods:* One-hundred and sixty-one patients with duodenal ulcer were prospectively studied. An endoscopy with biopsy samples (H&E stain) taken from antrum and body was performed, and a ^{13}C-urea breath test (according to the European standard protocol, measuring ^{13}C difference: { d}$^{13}CO_2$) was also performed at initial momment. Both procedures were repeated one month after completing therapy: ""classic"" triple therapy, omeprazole or lansoprazole plus one antibiotic, or omeprazol plus two antibiotics (amoxycillin, clarithromycin, metronidazole). Eradication was defined as the absence of *H. pylori* both by histologic and breath test methods.*Results:* At initial momment; 95.6% of patients (n = 153) were *H. pylori* positive by histologic methods, and 97.5% (n = 156) were positive by breath test (proportion of positive agreement = 0.98). Kappa for *H. pylori* diagnosis after therapy was 0.88 (EE: 0.08). A correlation between { d}$^{13}CO_2$ and histologic lesions at initial momment was observed, both at the antrum ($r = 0.23$; $p < 0.01$) and body ($r = 0.27$; $p < 0.01$). Similarly, a correlation after therapy in both gastric antrum (0.55; $p < 0.001$) and body (0.3; $p < 0.001$) was demonstrated. A significant difference was observed when comparing mean { d}$^{13}CO_2$ in patients with different degrees of histologic gastritis, both at initial momment (antrum: W Kruskal-Wallis = 9; $p = 0.05$; body: $W = 12$, $p < 0.05$) and after therapy (antrum: $W = 60$, $p < 0.001$; body: $W = 23$, $p < 0.001$).*Conclusion:* A high concordance was observe between ^{13}C- urea breath test and histology in the diagnosis of *H. pylori* infection. A correlation exists between breath test values and histologic lesions of gastric mucosa.
Oesophageal gastric duodenal disorders: Helicobacter PyloriOesophageal gastric duodenal disorders: GD disorders, acid peptic }" "Breath Test for the Diagnosis of H. Pylori Infection: Concordance with Histologic Methods and Correlation with Histologic Lesions of Gastric Mucosa"

"P P 57 1375"P 57 1375**Usefulness of the Combined Use of IgG and IgA ELISA Methods for Diagnosing *Helicobacter Pylori* Infection**

*C. Mart\'edn de Argila, D. Boixeda, R. Cant\'f3n, N. Mir, S. Valdezate, F. Bermejo, J.P. Gisbert, A.L. San Roman

Gastroenterology and Microbiology Departments, ""Ram\'f3n y Cajal"" Hospital, Madrid, Spain*Aim:* To determine the diagnostic value of the combined use of IgG and IgA ELISA methods to diagnose *H. pylori* infection.*Methods:* A total of 400 patients attended at the Endoscopy Unit because of symptoms attributable to the upper gastrointestinal tract were studied. At endoscopy, multiple biopsies from gastric antrum and gastric body were obtained for histology and culture. *H. pylori* was diagnosed if culture was positive in at least one of the biopsy samples obtained. Ten milliliters of venous blood were collected at the time of endoscopy for serological assessment. Serum samples were analyzed for *H. pylori* by a commercial IgA ELISA (G.A.P. Test IgA. Bio-Rad, Italy) and a commercial IgG ELISA (HelicoG, Porton, Cambridge, UK). The tests were performed in duplicate according to the manufacturer's instructions and by the same person. Two interpretations were possible: 1) Assumption 1: a serological result was considered positive for *H. pylori* when both methods (IgG and IgA) were positive, and negative when at least one of them was negative; 2) Assumption 2: a serological result was considered positive when at least one of the methods was positive, and negative when both methods were negative. Titres higher than 10 U/ml were considered positive (following manufacturer's recommendations) for both tests.*Results:* In the study population, 89.8% of the patients were *H. pylori* positive (by culture). The serology results were as follows: Cut-off IgG/IgA Sensitivity (%) Specificity (%) PPV (%) NPV (%) LR10/10 U/ml* 94.1 85.3 98.2 62.5 6.2610/10 U/ml** 99 80 97 94 4.95PPV = Positive predictive value; NPV = Negative predictive value; LR = Likelihood ratio; *Assumption 1; **Assumption 2.*Conclusions:* 1) The combined use of both serological methods provided more useful information compared with single IgG or IgA determinations. 2) The high specificity and PPV for assumption 1 render both determinations very useful when the clinician wishes to accurately know the ""true"" infection *H. pylori* status. 3) The extremely high sensitivity obtained with the assumption 2 renders this method very useful for screening large population groups. "P P 57 1377"P 57 1377**Blind Gastric Biopsy in the Diagnosis of Helicobacter Pylori Infection**

*H. Senturk[1], M. Akdogan[1], S. G\'f6ksel[2], A. Mert[1], S. Ozdemir[1], A. Sonsuz[1], P. Akin[1]

[1] Department of Internal Medicine, Istanbul, Turkey

[2] Department of Pathology of Cerrahpasa Medical Faculty of University of Istanbul, Istanbul, TurkeyGastric mucosal tissue is usually required for the diagnosis of helicobacter pylori (HP) infection. Serology, though a reliable method in initial diagnosis, is useless in assessing the response to the treatment. Breath test, on the other hand, is not widely available. We performed gastric mucosal biopsies through open ended 18 FR naso-gastric tube (NGT)s with Olympus FB-25 KR rotatable forcepses (Olympus, Japan) in 33 patients (19 female, 14 male, median age 38 ys; range 21–72) with dyspeptic symptoms. The average distance between the end of NGT and nasal insertion site was 50–55 cm. Four specimens obtained from each patient. Blind gastric biopsy (BGB) was repeated in 15 HP +ve patients one month after completion of treatment with 500 mg tid clarithromycin, 14 days, and omeprazole 20 mg bid, 28 days. Upper GI endoscopy was performed using a Fujinon FG7-CT2 panendoscope (Fujinon, Japan), immediately after BGB. The sites of biopsies were noted and four other specimens, two from corpus, and two from antrum, were obtained with the same type of forceps. Serological testing was performed from sera of 29/33 patients. All of the biopsies were evaluated by the same pathologist with hematoxylin-eosin staining in blinded fashion. 31/33 of initial biopsies obtained by endoscopic biopsy (EB) were +ve for HP. BGB was +ve in 30/31 of EB +ves. After treatment 13/15 (87%) were -ve for HP in both EB and BGB specimens and 2/15 (13%) were still +ve. All but one of the BGB specimens were from corpus. In 47/48 (98%), BGB were in accordance with EB. The only BGB sample with discordant result with EB was from distal esophagus, one of the first experiences. Serology was in accordance with biopsy results in all but one who was +ve by histology and -ve by serology. BGB was performed without anesthesia and tolerated well.We concluded that BGB is an easy, safe, reliable and cheap method in obtaining gastric mucosal tissue for HP evaluation. Its clinical value awaits further studies. "P P 58 1380"P 58 1380**Prescribing Patterns for Dyspepsia in Primary Care**

*K. Bodger, M.J. Daly, R.V. Heatley

Division of Medicine, St. James's University Hospital, Leeds, England

Department of Pharmacy, St. James's University Hospital, Leeds, England*Background* Expenditure on drugs for dyspepsia in primary care remains high, yet there are few published studies on the indications currently used by general practitioners (GPs) for prescribing different classes of drugs. We report a prospective observational study of prescribing patterns in our area.*Methods* GPs were recruited from 5 local multi-partner surgeries, representing a cross-section of doctors with respect to list size, fundholding status and prescribing expenditure. Each GP prospectively recorded details of all consultations for dyspepsia over a 4 month period.*Results* 257 consecutive consultations were recorded. Percentages of patients in specified dyspepsia sub-groups receiving each class of drug are summarised in the table: [Nil = No prescription, Ant = antacid, Mot = motility agent, H2A = H2- antagonist, PPI = proton pump inhibitor, HpE = *H. pylori* eradication] Subgroup N Nil Ant Mot H2A PPI HpENever investigated 144 9% 32% 8% 33% 16% 1%– new 59 8% 44% 5% 31% 12% 0%– consulted before 85 9% 24% 11% 35% 19% 2%– ulcer-like dyspepsia 22 18% 9% 0% 68% 5% 0%– reflux-like dyspepsia 50 8% 40% 2% 16% 30% 4%– non-specific dyspepsia 72 7% 35% 15% 33% 10% 0%Previously investigated 113 5% 9% 5% 35% 31% 14%– normal investigations 27 11% 19% 7% 37% 19% 7%– minor disease only 39 5% 10% 10% 33% 31% 10%– peptic ulcer disease 30 3% 3% 0% 43% 20% 30%– reflux oesophagitis 17 0% 0% 6% 18% 70% 6%*Conclusions* A wide range of agents were prescribed for dyspepsia, with considerable variation in drug choice for defined dyspepsia sub-groups. Management guidelines may help to reduce undue variation in practice, encourage more selective use of newer (more expensive) therapies, and thereby promote more cost-effective prescribing for dyspepsia in primary care.

"P P 58 1381"P 58 1381**Evaluation of Duodenogastric Reflux and Antral Motility by Color Doppler Sonography in Patients Underwent Cholecystectomy**

*J.R. Ladny, J. Laszkiewicz, J. Polak\'f3w, Z. Puchalski

Departments of General Surgery and Radiology, Medical University of Bialystok, Poland*Purpose:* to evaluate duodenogastric reflux, along with antral motility and gastric emptying of a liquid meal in patients underwent open and laparoscopic cholecystectomy.*Material and methods:* 53 patients (15 male and 38 female), aged 35–56 years, previously underwent open or laparoscopic cholecystectomy, underwent color Doppler sonography (CDS). Duodenogastric reflux, antral motility, and gastric emptying of 400 ml liquid meal were evaluated. As a control group served 23 asymptomatic healthy volunteers.*Results:* this approach was feasible in 51 (96.2%) of the 53 subjects studied. Duodenogastric reflux was demonstrated in 16 (59.3%) of the 27 patients underwent open cholecystectomy and in 22 (84.6%) of the 26 patients after laparoscopic procedures and only in 3 (13%) of the healthy volunteers. The frequency of the duodenogastric reflux and the reflux index were significantly increased in patients after laparoscopic cholecystectomy as compared with open cholecystectomy and asymptomatic volunteers groups. Gastric emptying and the motility index of antral contractions were significantly decreased in these patients.*Conclusions:* color Doppler sonography is useful for evaluating of gastroduodenal, especially in patients underwent laparoscopic cholecystectomy. These simple, noninvasive method can be used to understand the pathogenesis of such disorders. Motility, general: Functional GI disordersMotility, specific: StomachRadiology and ultrasound: Diagnosis }" "Evaluation of Duodenogastric Reflux and Antral Motility by Color Doppler Sonography in Patients Underwent Cholecystectomy"

"P P 58 1382"P 58 1382**Prognosis of Dyspepsia among Patients in General Practice. Dyspepsia Subgroups and Patient Characteristics**

*V. Meineche-Schmidt, T. J\'f8rgensen

Dept. of General Practice, The Panum Institute and Surgical Dept. K, Bispebjerg Hospital, University of Copenhagen, Denmark*Aim:* To assess the courses of different subgroups in dyspepsia.*Methods:* In 1991 to 1993 all patients consulting 93 general practitioners (GPs) because of dyspepsia (N = 7270) had a structured interview, covering 18 dyspepsia symptoms. The patients were classified in dysmotility-like (*dys*), reflux-like (*refl*) ulcer-like (*ulc*) or uncharacteristic (*unch*) dyspepsia. Patients with two or more presentations to the GP were classified as relapsing (*relap*) dyspepsia. A random sample of 300 patients with *dys, refl* and *ulc* and all patients with *unch* (n = 114) and *relap* (n = 212) were contacted after an average of 37 months (range: 17–53) through the GP. Both GPs and patients were asked to fill in a questionnaire. Information on consultation habits, upper endoscopy, dyspepsia symptoms and medication within the latest year were recorded. All death were recorded.*Results:* Among eligible patients, 98% of the doctors and 85% of the patients returned the questionnaires. Frequencies of various end-points according to the dyspepsia subgroups are shown in the table. End-point: Ulc % Refl % Dys % Unch % Relap %Symptoms disappeared 8 10 19 28 1Dyspepsia subgroup unchanged 46 32 35 27 -Further consultations 66 57 59 53 48Dyspepsia medication 65 53 33 23 63Upper endoscopy 10 7 4 1 3Patients with *ulc* dyspepsia had the highest frequencies of consultation, endoscopies, medication and unchanged symptoms, whereas patients with *unch* dyspepsia had the lowest frequencies. *Relap* dyspepsia seldom disappeared. Among the 67 deaths 24% were due to gastrointestinal disorders.*Conclusions:* A classification of dyspepsia patients in general practice reveals differences in course, consultations, investigations performed, and medication given. The classification could be a useful tool in decision making. Clinical practice: Management strategy }" "Prognosis of Dyspepsia among Patients in General Practice. [1] Primary Care Physicians, Stress and Dyspepsia Study Group, Portugal

[2] Pharmaceutical Physician, Medical Director Jansenn-Cilag Farmac\'eautica, PortugalStress factors and personality traits seem to influence the appearance and symptomatology of non ulcer dyspepsia and other related conditions. In order to assess the prevalence of economic, socio-demographic and stress factors in dyspeptic patients, as well as to determine whether an influence exists on the initial symptom score and the response to treatment with cisapride, an open multicentric study was carried out in a Portuguese population of dyspeptic patients.96 ambulatory patients with dyspeptic symptoms since at least four weeks were studied. Patients with history, symptoms or signs of organic underlying diseases were excluded. At selection upper gastrointestinal symptoms were assessed and patients were asked to complete a stress questionnaire giving details of socio-economic situation, health, living habits and stress factors according to the Holmes and Rahe scale. Patients were treated with cisapride 5 mg t.i.d. for 4 weeks and their symptoms were reassessed at the end of treatment.It was possible to establish a relationship between some stress factors and the severity of initial symptoms and their response to treatment. Independence at work, regularity of the meals, number of medical visits and non gastrointestinal symptoms were all correlated to the severity of the initial symptoms. The response to the treatment was good in the vast majority of patients ($p < 0.0001$) and also influenced by the independence at work, the regularity of meals and their smoking habits. The other 17 stress factors evaluated were not significantly correlated with the patient symptomatology either before or after treatment.In conclusion in this patient population only 4 out of 20 stress factors were correlated with dyspeptic symptoms and its treatment. This lack of correlation for the majority of stress factors is perhaps due to the number of patients and the big variability in this population and their response. Oesophageal gastric duodenal disorders: GD disorders, acid pepticClinical practice: PsychosomaticsClinical practice: Management strategy }" "Demographic, Socio-Economic and Stress Factors in Patients with Upper Gastrointestinal Symptoms (Dyspepsia) Who Seek Medical Help: Impact on the Therapeutic Response to Cisapride"

"P P 58 1384"P 58 1384**Symptom Profile of Dyspepsia in Latin America: A Multicentric Study**

*L.M. Bustoz Fern\'e1ndez[1], General Trial Coordinator, and Dyspepsia Study Group

[1] Instituto de Gastroenterologia Dr Bustos Fern\'e1ndez, 1428 Buenos Aires, ArgentinaDyspepsia is a broad symptom complex, overlapping with the irritable bowel syndrome (IBS). Studies often focus on epigastric pain. We studied the symptom profile in dyspeptic patients (pts) in Latin American populations and the response to cisapride (CIS).*Method: Phase 1:* 713 GP's, in coordination with local gastroentrologists, from Argentina, Bolivia, Paraguay, Uruguay and Venezuela enrolled 4020 pts with dyspepsia ({\'b3} 4 weeks). Pts were evaluated for demographic and disease characteristics, as well as symptoms, and classified into dysmotility-like (DL), ulcer-like (UL), reflux-like (RL) or non-specific (NS) dyspepsia. *Phase 2:* Pts were treated with CIS 10 mg t.i.d. for 4–8 weeks; pts with alarm symptoms, UL symptoms or history of ulcer/GORD, or receiving medication for GI symptoms or regular NSAIDs were excluded.*Results.* 3744 cases (47.8 – 15.3 (18–92) yrs, 38.7/61.3 M/F) were elegible for analysis: 47.3% had DL dyspepsia, 12.1% UL, 13.1% RL and 3.2% NS. Mixed types of dyspepsia were: 3.6% DL + UL, 12.2% DL + RL, 2.2% UL + RL and 6.5% DL + UL + RL. Concomitant disease was present in 50% of pts, history of previous ulcer and oesophagitis in 7.2% and 16% resp. Excessive use of alcohol, coffee or smoking was found in 20%, 53% and 28% resp. The most common symptoms were: postprandial fullness (in 83%), epigastric bloating (83%), belching (72%), postprandial nausea (66%), diffuse epigastric pain (64%), early satiety (62%), fat intolerance (58%) and heartburn (53%). Localized epigastric pain was present in 49%, nocturnal pain in 19%, periodic discomfort or pain in 46% and relief by meals or antacids in 32%. 55% had concomitant symptoms of IBS (37% in RL, 74% in the mixed group DL + UL + RL). Of the 2965 pts treated with CIS, 67% and 21.6% had excellent and good responses resp.; 6.7% experienced adverse events (leading to discontinuation of treatment in 23 pts only).*Conclusions.* DL symptoms prevail among the Latin American dyspeptic population. Overlap with IBS is very common. Pts (after exclusion of significant UL or alarm symptoms) respond well to CIS. Clinical practice: Epidemiology (non cancer)Clinical practice: Management strategyMotility, general: Functional GI disorders }" "Symptom Profile of Dyspepsia in Latin America: A Multicentric Study"

"P P 58 1385"P 58 1385**An International Survey Reveals Marked Differences between Countries in the Incidence, Diagnosis and Management of Upper Gastrointestinal (GI) Disease in Primary CareJ. Brun, S.A. Brunton, F. Carelli, H. Haslbauer, P. Heyse, H. Maurer, P. O'Connor, W. Peterz, K. R\'fcdy,**

*M.J. Whitaker

International Gastro Primary Care GroupThe International Gastro Primary Care Group (IGPCG) is a group of primary care physicians with representatives from different countries formed to improve the understanding and management of upper GI disease in primary care. This group conducted an international survey to examine differences between countries in the incidence and management of upper GI disease in primary care.A comprehensive questionnaire on upper GI disease was completed by 542 doctors from 11 countries. Key questions were asked concerning the number of patients with upper GI symptoms seen by doctors per week, the association of predominant symptoms with the diagnosis of upper GI disorders and the choices made regarding clinical investigations and drug therapy.The results revealed some interesting variations between countries in the incidence of upper GI disease. Of the doctors participating in the survey, 51% reported seeing 50 to 150 patients per week and 62% saw 11 to 25 patients with upper GI complaints. In Japan, 57% of responding doctors saw more than 300 patients per week and 62% detected 21 to 25 patients a week with upper GI symptoms. Although the high number of patients seen per week by doctors in Japan must increase detection rates of upper GI disease, the data does suggest a higher incidence of these disorders when compared to other countries in the survey. Sweden had the lowest incidence with 80% of GPs seeing 10 or less patients per week with upper GI symptoms. Clear differences were observed in the responses of doctors from different countries to H. pylori (Hp) eradication programs. In those patients testing positive for Hp, eradication was considered logical by over 50% of doctors in 4 countries and by under 50% of doctors in the remaining 7 countries. The percentage of doctors agreeing that patients with duodenal ulcer history need further investigation prior to Hp treatment, varied from 42% to 79%.In summary, this IGPCG international survey demonstrates the different approaches taken by the participating countries in the management of upper GI disorders and highlights the fact that any conclusions drawn from limited data (from one or a few countries) may not apply on a worldwide basis. Clinical practice: Management strategy }" "An International Survey Reveals Marked Differences between Countries in the Incidence, Diagnosis and Management of Upper Gastrointestinal (GI) Disease in Primary Care"

"P P 58 1386"P 58 1386**The Clinical Presentation of Peptic Ulcer Disease**

*R.J.L.F. Loffeld, B.F.M. Werdmuller, A.B.M.M. van der Putten

Department of Internal Medicine, Ziekenhuis De Heel Zaandam, The NetherlandsAccording to the literature the discriminative value of the classical ulcer symptoms is rather poor. A prospective study was done in order to assess the presentation of peptic ulcer. Consecutive patients undergoing upper GI endoscopy received a questionnaire consisting of 82 different questions, 23 questions were related to the upper abdomen. Eleven questions were scored on a linear scale, a symptom score was calculated (minimum score 2, maximum score 55). In addition the reason for doing the endoscopy, the duration of complaints, the medical history, smoking habits, alcohol use, and use of to anti-ulcer drugs were noted. Patients with a gastric (GU) or duodenal (DU) ulcer were included. Patients with concomitant abnormalities like gastric carcinoma or reflux oesophagitis were excluded. As a control group patients, in whom endoscopy did not reveal abnormalities were included. This group, for the sake of the study designated as functional dyspepsia (FD), was subdivided pending on whether their history was positive (FD+) or negative (FD{ -}) for peptic ulcer.GU was diagnosed in 43 patients (♂ 19, ♀ 24, mean age 67), DU in 60 (♂ 37, ♀ 27, mean age 50), FD+ in 94 (♂ 49, ♀ 45, mean age 52), and FD{ -} in 382 (♂ 148, ♀ 134, mean age 47). Patients with GU were significantly older ($p < 0.0001$) than the other groups; while FD{ -} patients were the youngest. DU was more often diagnosed in men, while FD{ -} was present more often in women. Patients with DU and FD+ were significantly more often treated with anti-ulcer drugs prior to endoscopy ($p < 0.001$). The symptom score was 14 in GU, 16.6 in DU, 19.5 in FD+, and 16.7 on FD{ -}. Patients with FD+ had significantly higher symptom score than the other groups. The mean number of complaints present was 8.1 in GU, 9.2 in DU, 9.8 in FD+, and 9.2 in FD{ -}. No statistical differences were present. If all ulcer patients (amalgamation of DU, GU and FD+) were compared with FD{ -} a prior history of complaints or peptic ulcer (sens 64%, spec 56%, ppv 44%, npv 74%); pain waning after a meal (sees 35%, spec 70%, ppv 51%, npv 70%); and smoking (sens 38%, spec 74%, ppv 44%, npv 69%) were the only features linked to peptic ulcer. On the other hand, post prandial pain (sens 31%, spec 58%, ppv 28%, npv 61%); food intolerance (sens 43%, spec 47%, ppv 31%, npv 60%); nausea (sens 49%, spec 38%, ppv 30%, npv 58%); and alcohol use (sens 39%, spec 51%, ppv 30%, npv 61%) have a negative prediction and plead more for the presence of FD.It can be concluded that the symptoms score in peptic ulcer disease is rather low, this cannot be explained by prior use of anti-ulcer agents. It is not possible to distinguish peptic ulcer patients from FD{ -} patients on basis of clinical presentation. Further investigations are inevitable. Whether serological testing for Helicobacter pylori in combination with a simple and reliable questionnaire can increase the prediction of outcome of endoscopy is yet to be studied.

"P P 58 1387"P 58 1387**Measurement of Quality of Life (QoL) with QPD32, a New Specific Questionnaire for Italian Peptic Patients (Pts)A. Olivieri,**

*F. Arpinelli, G. De Carli, F. Bamfi, L. Gandolfi[1], L. Norberto[1], F. Pacini[1], C. Surrenti[1], S.H. Irvine[2], G. Recchia, AIGO, SIED, SIGE

[1] Glaxo Wellcome S.p.A. Research and Development, Verona, Italy

[2] Italy

University of Plymouth, UKMeasurement of QoL is become important since therapies are not only aimed at an increase of quantity of life, but also at an improvement in its quality. Despite the number of Italian peptic pts and their social and economical importance, no specific QoL questionnaire was available up to 1994, when we developed a specific tool. It was validated in a multicentre trial on a 1774 pts sample. Validation reduced the 48 original items to 30, which increased to 32 after the inclusion of an item on the severity of pain and the Personality Inventory Scale, that allows us to detect differences in individual QoL due to psychological characteristics. The validated questionnaire was called QPD32.During 1995, QPD32 was administered to 2155 pts suffering from gastric or duodenal ulcer or reflux oesophagitis by 222 gastroenterologists and endoscopists of Italian scientific societies. Pts suffering from other acute and severe diseases or experiencing recent psychosocial trauma (loss of job, death of spouse etc) were excluded.Most of pts were male (62.6%), with a mean age of 49.2 y., suffering from duodenal ulcer (53.8%), oesophagitis (18.4%) gastric ulcer (10.6%), other upper gastrointestinal complaints (16.0%). The latter group was submitted to analysis because of its size, in spite of the protocol's violation. The mean total score of QPD32 was similar in pts who filled in the questionnaire before (61.25, sd 11.9), just after (60.0, sd 11.4) or few days after endoscopy (60.5, sd 11.2). Mean score in different diseases was like (range 59.8–60.2), and the score of each domains of QPD32 (pain, symptoms and physical) did not differ significantly among diagnoses.In conclusion, pts with different upper gastrointestinal diseases have the same perception of their illness; moreover, thanks to its specificity, our questionnaire could be administered indifferently before or after an upper digestive tract endoscopy. }" "Measurement of Quality of Life (QoL) with QPD32, a New Specific Questionnaire for Italian Peptic Patients (Pts)"

"P P 58 1388"P 58 1388**Role of Peptides in Hydrochloric Acid Secretion Regulation of Patients Sick of Duodenal Ulcer before and after Surgical Treatment**

*L.I. Vinnitsky, M.V. Poroykova

Research Center of Surgery of the A.M.S. of Russia, Moscow, RussiaThe acid creation regulation mechanisms in duodenal ulcer were studied. We determined contents of gastrin (G), somatostatin (S) and glucagon (Glu) of patients with hydrochloric acid hyposecretion and hypersecretion in case of duodenal ulcer (20 persons – 1a group and 25 persons – 1b group accordingly), in case of duodenal ulcer complicated by reflux esophagitis (6 persons – 2a group and 11 persons – 2b group accordingly) and in case of duodenal ulcer complicated by pylorostenosis (9 persons – 3a group and 7 persons – 3b group accordingly) before and after different surgical operation (in 3 weeks). 20 practically healthy persons were examined.Contents of G in all groups of patients (exclude 3b) exceeded the normal meanings. In hyposecretion groups G concentration before the operation was higher than in hypersecretion groups. After the operation G concentration in hyposecretion groups was the same, but in hypersecretion groups G concentration increased. Contents of S in all groups exceeded normal meanings. In groups 1 and 3 contents of S before the operation in case of hyposecretion was higher than in hypersecretion, and in group 2 vice versa. After the operation the contents of S in groups 1 and 2 was the same, in group 3a and 3b the contents of S in increased.Blood Glu level in all groups before the operation was less than normal meanings. In groups 2 and 3 in hyposecretion Glu concentration was less than in hypersecretion. After the operation content of glucagon in groups 1a, 1b, 2b and 3b was the same, in groups 2a and 3a content of Glu increased. In group 3a content of Glu increased up to normal meanings. Complex examination exposed compensating lowering G levels and prevailing of S and Glu contents in all groups of patients sick of duodenal ulcer with hypersecretion. The results of examination allow to assume that patients with duodenal ulcer have different status to receptor apparatus for G, S and Glu. "P P 58 1389"P 58 1389**Peptic Ulcer in Rural Residents with Abdominal Complaints**

*T. Litvinenko, P. Varmann, V. Bushina, N. Elshtein, E. Lond

Department of Gastroenterology, Institute of Experimental & Clinical Medicine, Tallinn, EstoniaThe aim of the present study was to evaluate the prevalence of peptic ulcer in rural residents with abdominal complaints.We interviewed 2304 subjects above 15 years of age, which was 74.6% of the population of a rural district of Estonia. The interview was based on a questionnaire compiled to screen out persons with abdominal complaints. All 854 subjects with abdominal complaints were offered upper endoscopy, 575 (67.3%, 374 female, 194 male) agreed to be investigated. Peptic ulcer disease was defined as an active peptic ulcer, a scar or a deformed doudenal bulb.Peptic ulcer was diagnosed in 71 cases (50 male, 21 female), the overall prevalence being 12.3%. The prevalence increased with age, reaching the peak in the 4th life decade in males and in the 5th life decade in females. Duodenal ulcer occurred 2.2 times more frequently than gastric ulcer. In 23 cases (32.4%) the diagnosis of the peptic ulcer was made for the first time.The prevalence of peptic ulcer in rural residents with abdominal complaints was 12.3%, the proportion of newly diagnosed cases being extremely high. "P P 58 1390"P 58 1390**Monthly Variations of Symptomatic Duodenal Ulcer Activity in Taiwan: a Comparison Between Subjects with and without Hemorrhage****Chung-Jyi Tsai**

Chi Mei Foundation Hospital, Yung Kang City, Tainan, TaiwanThe occurrence of peptic ulcer has geographic, temporal, socioeconomic and ethnic variations. Controversy exists regarding duodenal ulcer (DU) seasonality. We have observed that patients with DU may be divided into those whose ulcers repeatedly bleed as distinct from those whose ulcers repeatedly cause pain. It is still not known which or when DU patients would bleed. The purposes of the present study are, therefore, 1) to investigate the seasonal incidence of DU activity in a developed subtropical country, 2) to compare the seasonality of DU patients with pain and that of those with hemorrhage, and 3) to clarify the roles of sex and age factors play.*Methods:* All of the reports of endoscopic examination of the upper gastrointestinal tract performed from April 1, 1989 to March 31, 1995, were reviewed to identify patients with DU disease Active bleeding due to DU was confirmed when a definite bleeding site or visible vessel or a blood clot within an open crater in the mucosa of the duodenum was identified. Excluded were all patients who had any extrinsic factors that might influence the exacerbation of DU disease. In the same study period, hepatoma and colorectal adenocarcinoma were used as the control diagnoses. The 12 months of the year were divided according to the climate in Taiwan into four seasonal periods, viz. Dec.–Feb., Mar.–May, Jun.–Aug., Sep.–Nov. Statistical analysis with { ?}^{2} test, linear regression with Pearson correlation, and ANOVA with post hoc comparisons were used as appropriate.*Results:* During the years of the study, 10331 DUs were diagnosed. Among these, 2088 patients presented with hemorrhage, and 8243 patients with pain. The monthly distribution of total DU patients revealed a trend toward more occurrence from Nov. to Mar. ($p < 0.001$). In the patients with DU hemorrhage, the peak incidence was in the months from Nov. to Mar. ($p < 0.001$). There was significant seasonal variation ($p = 0.03$), the peak was in the winter (Dec. through Feb.). In the DU patients with pain, the peak months were from Dec. to Feb. ($p < 0.001$). Significant seasonal variation, peaked in winter, was also observed ($p = 0.04$). In both groups, the monthly and seasonal variations were unaffected by age or sex. There were no significant monthly variations of control diagnosis for hepatoma ($p = 0.94$) or colorectal adenocarcinoma ($p = 0.79$).*Conclusions:* Both groups of DU patients presenting with hemorrhage and those with pain demonstrated similar monthly and seasonal fluctuations, the incidence being significantly greater during the cold season. These data suggest that climatic changes may influence pain and hemorrhage in the DU patients, which brings important etiological and therapeutic implications.

"P P 58 1391"P 58 1391**Helicobacter Pylori Infection and Chronic Antral Gastritis in Patients with Non-Ulcer Dyspepsia**

*S. Grgov, M. Stefanovic, J. Dimitrijevic, P. Stamenkovic

Internal department, Health centre, Leskovac, YugoslaviaWe made a prospective study on 66 patients, averaged 46.6, with the symptoms of non-ulcer dyspepsia and histological findings of chronic superficial (21 or 31.8%) and atrophic (45 or 68.2%) antral gastritis. Helicobacter pylori (Hp) has been proved in bioptic sample of antral mucosa by urease test and histological check-up of preparations coloured with hematoxylin-eosin. Endoscopically, diffuse erythema was found in 31.2% of Hp positive patients and polycolority of antrum with bizzarre reddish-pale zones in 38.9%, but without statistically significant difference with regard to Hp negative patients ($p > 0.05$). Chronic mucous erosions were present in 87.5% Hp positive and 12.5% Hp negative patients, which is statistically significant difference ($p < 0.05$). Hp infection existed in 47.6% chronic superficial gastritis and 46.7% chronic atrophic antrum gastritis. In the group of active superficial gastritis there were 90.9% with Hp infection. The group with active atrophic gastritis comprised 87% of Hp positive and 13% Hp negative patients which is statistically significant difference ($p < 0.01$). At low degree of chronic gastritis atrophy Hp was positive in 46.7% of patients, at medium degree in 38.5% and in high degree of atrophic gastritis in 52.9%, but differences are not statistically significant with regard to Hp negative ($p > 0.05$). Intestinal metaplasia was found in 18 (40%) patients with atrophic gastritis, but without statistically significant difference between Hp positive and Hp negative patients ($p > 0.05$). Our research shows that endoscopically seen chronic mucous erosions of antrum in the majority of cases indicate Hp infection, which is an important factor of chronic antral gastritis activity. Although the presence of Hp infection doesn't correlate with the degree of gravity of chronic atrophic antral gastritis, it is one of the possible factors of the development of intestinal metaplasia and dysplasia as precancerous lesions. "P P 58 1392"P 58 1392**Colonization of Human Achloridric Stomach by Bifidobacteria**

*G. Brandi[1], S. Sarchielli[1], P. Mordenti[1], S. Tamberi[1], C. Calabrese[1], P. Mattarelli[2], B. Biavati[2], G. Biasco[1]

[1] Dipartimento di Medicina Interna e Gastroenterologia, Bologna University, Italy

[2] Istituto di Microbiologia Agraria e Tecnica, Bologna University, ItalyAim of the study was to ascertain whether and which populations of bifidobacteria are able to colonize the stomach of subjects with achloridria induced either by autoimmune athrophic gastritis (CAG), or by omeprazole (Ome) treatment (20 mg/day for 1 month) for reflux oesophagitis. The isolation of bifidobacteria was carried out on samples of gastric juice and homogenates of biopsies (4 for the antrum and 4 for the corpus) of 14 subjects (6 CAG: mean age 39 yrs; 8 Ome: mean age 48 yrs) by using BHA and TPY added with propionic acid. The mean pH value of the juice 7.3 in CAG subjects and 6.8 in Ome-treated ones. In order to assign the isolates to the genus *Bifidobacterium,* we took into consideration morphology, Gram staining, fermentation products and the presence of the fructose-6-phosphate phosphoketolase enzyme. Fifty-five strains of bifidobacteria isolated from 10 subjects over 14 examined have been grouped by cell protein electrophoresis. They were characterized through the following determinations: G-C% of DNA, fermations of 49 complex carbohydrates, DNA-DNA hybridization. Fifty-two strains can be subdivided in different groups which differ to the typical species of the oral cavity: *B. denticolens, B. inpinatum* (two new species recently isolated from human dental caries) and *B. dentium.* The remaining 3 strains (all from the same subject), which were recognized as a single group, do not hybridize with any species of the genus *Bifidobacterium* or with *Gardnerella vaginalis.* We were unable to isolate similar strains from the oral cavity of this subject. Our results suggest that the three strains belong to a new species (description in preparation). The achloridric stomach represents a suitable habitat for the colonization of bifidobacteria mainly belonging to the oral cavity rather than to the intestinal tracts. The probiotic potential of the isolates, demonstrable through clinical and nutritional studies, makes promising and desirable further experimentation in this area. "P P 58 1393"P 58 1393**Long Term Follow-Up of Fedotozine Treatment in a Cohort of Dyspeptics in Current Medical Practice****J. Salducci, J.-C. Grimaud, J.-L. Abitbol[1], C. de Meynard[1],**

*B. Fraitag[1]

Hospital Nord, 13015 Marseille, France

[1] Institut de Recherche Jouveinal, 94265 Fresnes, FranceThe efficacy of fedotozine (F) administered for 6 weeks had already been demonstrated in functional gastrointestinal disorders, both in functional dyspepsia [1] (FD) and irritable bowel syndrome [2] (IBS). However, the chronic course of these diseases can justify long-term treatment. *Methods.* During an open, prospective, uncontrolled, multicenter study in France, we evaluated the safety of prolonged administration of F (30 mg tid for one year) in dyspeptic outpatients seeking medical advice (diagnostic criteria of FD left to the investigator, concomitant treatments allowed). The course of symptoms and their impact on the quality of life (QoL) were secondary criteria. Safety was evaluated every 3 months by monitoring adverse events (AE), standard blood tests, ECG and EEG (2 subgroups). The overall therapeutic result was evaluated every 3 months and QoL every 6 months (SQLP questionnaire [3]). Statistical analysis was purely descriptive. *Results.* 165 centers (28% gastroenterologists, 72% general practitioners) treated 624 patients with FD, most often associated with IBS (64%) or gastro-oesophageal reflux (19%). The study was completed by 66% of patients. The mean duration of exposure to treatment was 296 days (range 1 to 483), corresponding to 506 patient years. AE were recorded in 246 patients and were potentially treatment-related in 178. The most frequent were constipation, abdominal pain, headache, and nausea (5.5 to 2.1%). There were 30 serious AE, of which 6 were potentially treatment-related and which mainly concerned the GI tract. Laboratory tests showed the absence of any abnormal trend or specific abnormality. ECG and EEG further demonstrated the safety of F. Improvement or resolution of symptoms according to the patient and the investigator was reported in 84 and 87% of cases respectively. Efficacy was maintained over time. Patients noted an improvement in QoL for health-related items (digestion, pain, state of health, general form, diet). *Conclusion.* This study carried out in a large number of patients (equivalent to 506 patients followed-up for 1 year) demonstrated the very good clinical, ECG/EEG, biochemical and haematological safety of F (30 mg tid) administered for a long period. Good efficacy results, stable over time, and improvement in QoL were further obtained.This research was funded by Institut de Recherche Jouveinal, Fresnes, France.

"P P 58 1394"P 58 1394**Efficacy of Fedotozine in Functional Dyspepsia: A Meta-Analysis of Individual Data from Randomized, Placebo-Controlled Studies**

*J.-L. Abitbol, B. Scherrer, C. de Meynard, G. M\'e9ric, B. Fraitag

Institut de Recherche Jouveinal, 94265 Fresnes, FranceA meta-analysis of the therapeutic efficacy of fedotozine (FZ) in functional dyspepsia was carried out on all the individual data from the phase IIb and III randomized, double-blind studies comparing a placebo group (PL) with a group receiving FZ 30 mg t.i.d. *Methods.* Since the study designs were identical (a one to two week run-in period followed by six weeks treatment in parallel groups), meta-analysis of 3 multicentre studies carried out in France and the UK was justified. Inclusion and evaluation criteria were similar for the 3 studies. Therapeutic efficacy was evaluated on the mean overall score of the intensity of the 5 dyspeptic symptoms assessed daily by the patient. The mean treatment effect (T) for the 6 weeks, the study effect (S), and the TxS interaction were tested by intent to treat ANCOVA with adjustment for the means at run-in. The difference between FZ and PL at each of the 6 treatment weeks was assessed by ANOVA. *Results.* 658 patients (FZ: 331, PL: 327; M: 39%, F: 61%) with a mean age (\'b1 SD) of 44 – 15 years were randomized in these 3 studies. The percentage of withdrawals was higher in the PL group (PL: 22.6%, FZ: 15.7%, $p < 0.05$). The effect of FZ on the overall dyspepsia intensity score was greater than that of PL ($p = 0.002$) with no significant difference in the magnitude of treatment effect between the studies (interaction TxS not significant), which justifies generalization of results. The PL overall score improved from 12% (week 1) to 29% (week 6) compared to run-in. The FZ overall score improved from 18% (week 1, $p = 0.036$ vs PL) to 36% (week 6, $p = 0.001$ vs PL). Moreover, the effect of FZ was significantly greater than that of PL for 4 dyspeptic symptoms out of 5: bloating/epigastric distension ($p < 0.01$), epigastric pain ($p < 0.01$), slow digestion ($p < 0.057$), and nausea/vomiting ($p < 0.05$), early satiety was NS. When meta-analysis was carried out on the 2 phase III studies alone, FZ was again more effective than PL and to a similar extent. There was no evidence of any effect due to patient characteristics (age, body mass index, sex) or to pre-inclusion gastroenterological or psychotropic treatments on the therapeutic effect of FZ. *Conclusion.* This meta-analysis allowed a comprehensive assessment of all available efficacy data from phase IIb and III studies. Fedotozine proved significantly more effective than placebo on both the overall dyspepsia intensity score and on 4 of the 5 dyspeptic symptoms. Motility, general: Functional GI disordersClinical practice: Management strategy }" "Efficacy of Fedotozine in Functional Dyspepsia: A Meta-Analysis of Individual Data from Randomized, Placebo-Controlled Studies"

"P P 58 1395"P 58 1395**Evaluation of the Quality of Life in Functional Gastrointestinal Disorders. Results of a 6-Month Study of Fedotozine Versus Usual TreatmentsJ.L. M\'e9rot,**

*J.-L. Abitbol[1], G. M\'e9ric[1], B. Fraitag[1], T. Poynard[2]

Benefit, 92632 Gennevilliers, France

[1] Institut de Recherche Jouveinal, 94265 Fresnes, France

[2] Hospital de la Salp\'eatriére, 75013 Paris, FranceThe objective of this general practice study was to evaluate the effects of functional gastrointestinal disorders on the quality of life (QoL) as well as changes in QoL during treatment. *Methods.* An open, prospective, randomized, six-month pharmacoeconomic study with 252 patients (irritable bowel syndrome: 74%; dyspepsia: 26%) compared fedotozine 30 mg per os tid. (n = 141, group F) with treatments usually prescribed by the investigator (n = 111, group T). The Functional Status Questionnaire was used to evaluate the 3 main dimensions of QoL: (i) physical, (ii) psychological, and (iii) social, as well as several sub-dimensions including overall satisfaction with general well being. The questionnaire was filled in by the patients at D0, D45, and D180. QoL scores vary in a range of 0 (worst QoL) to 100 (best QoL). *Results.* The reliability of the questionnaire was satisfactory with Cronbach { a} coefficients ranging from 0.69 to 0.88. At D0, scores were comparable between the two groups. The psychological dimension was the most altered (52.7 in the two groups), followed by the social dimension (74.6 F and 73.6 T), and the physical dimension (89.8 F; 90.0 T). Overall assessment of general well being was very perturbed at D0 (41.9 F and 49.4 T). Intragroup analysis showed a significant improvement at D45 and D180 for the two groups for the physical (*p* {\'a3} 0.05) and psychological (*p* {\'a3} 0.05) dimensions. The sub-dimensions social relations and general well being improved significantly at D45 and D180 only for group F (*p* {\'a3} 0.05 and *p* {\'a3} 0.001). Intergroup analysis showed that the improvement in the overall general well being score was significantly greater for group F at D45 (10.3 F versus 3.3 T; $p = 0.02$) as well as at D180 (24 F versus 5.8 T; $p = 0.03$). These results correspond to improvements compared to inclusion scores for F and T of 11% and 6% at D45, and 46% and 20% at D180, respectively. *Conclusion.* Functional gastrointestinal disorders affected the psychological and social dimensions of the QoL as well as the overall satisfaction of patients with their general well being. From D45 to D180 both fedotozine and the usual treatments had a beneficial effect on QoL. Only the fedotozine group showed significant improvement in general well being of the patient and from D45 to D180 the improvement was significantly greater in group F than in group T. "P P 58 1397"P 58 1397**Bilitec 2000 Study in Evaluation of Duodenogastric Biliary Reflux Following Conventional and Laparoscopic Cholecystectomy****R.M. Herman, T. Popiela,**

*W. Kawiorski, P. Walega

1st Dept. of General and GI Surgery, Collegium Medicum Jagiellonian University, Cracow, PolandSeveral clinical studies showed that episodes of the duodenogastric biliary reflux (DGR) increased following cholecystectomy.The *aim* of present study was to evaluate the incidence of gastric biliary reflux following conventional (CCh) and laparoscopic cholecystectomy (LCh).Twenty patients with cholelithiasis were ambulatory studied before and 3 months following cholecystectomy – 10 patients after CCh (Group I) and 10 after LCh (group II). Gastroduodenoscopy and 24-hour gastric spectrophotometry monitoring technique using Synectics BILITEC 2000 were performed in each patients. The results were computer analyzed using Gastrosoft, Synectics Medical program.*Results:* There were no symptoms of DGR during gastrofiberoscopy, not the increasing incidence of reflux (above 0.14%) episodes and its duration before surgery and all bilirubin concentration results ranged within the normal values.In the 1st group (following CCh) the presence of biliary reflux was noted during gastroscopy in 50% of patients versus 36% of patients following LCh. Significant increase of incidence of bilirubin reflux episodes was observed in 8 patients (80%) of 1st group and only 5 patients (50%) of 2nd group, during 24-hour Bilitec studies. *Conclusion:* The incidence of DGR and total exposure of gastric mucosa to biliary contents increased both following classical and laparoscopic cholecystectomy, but significantly higher after CCh. Motility, specific: Stomach }" "Bilitec 2000 Study in Evaluation of Duodenogastric Biliary Reflux Following Conventional and Laparoscopic Cholecystectomy"

"P P 58 1398"P 58 1398**Reflux Gastritis in Children with Giardiasis**

*P. Grigorescu-Sido, M. Grigorescu, I. Trif

1st Pediatric Clinic, ""Iuliu Hatieganu"" University of Medicine and Pharmacy, Cluj, Romania*The purpose of the study.* Considering that giardiasis, a frequent parasitic disease in children can generate pyloric incompetence with jejuno-duodeno-gastric reflux (JDGR) and that epigastralgia is a common symptom in school age children infested with lamblia, the authors have studied the role of JDGR as a possible factor generating gastritis in these children. *Patients and methods.* Two groups of patients were studied: group I (20 children) aged 7–17 years with giardiasis) and group II – controls (10 healthy children). The methods used included: a) tests for the support of the diagnosis of gastritis (barium meal and/or gastroscopy with gastric mucosa biopsy) in group I and b) detection of JGDR by the determination in the gastric aspirate of: total bile acids (spectrophotometry); sodium (flame photometry) and pH in both groups. *Results:* a) statistically significant increased levels of the bile acids in the gastric aspirate in children with parasitosis as compared with the controls: x&bar;$_{I}$ = 1.84 – 0.71 \'b5mol/l; x&bar;$_{II}$ = 0.42 – 0.4 \'b5mol/l; P < 0.001; b) a 90% incidence of the cases with high levels of bile acids in children with giardiasis; c) the presence in these children of endoscopic and histopathologic changes of the gastric mucosa, interpreted as reflux gastritis and d) the absence of statistical significance between the values of sodium and pH in the gastric aspirate in the two groups. Association of drugs regulating digestive motility with the etiologic treatment clearly improved the course of these cases. *Conclusion.* The study indicates the presence of reflux gastritis in 90% of the investigated children with giardiasis and recommends the determination of the bile acids in the gastric aspirate as a sensitive test for the detection of JDGR. Oesophageal gastric duodenal disorders: GD disorders, acid peptic }" "Reflux Gastritis in Children with Giardiasis"

Ist Medical Clinic & Histopathology Department, University of Bologna, Bologna, Italy*Purpose:* To assess the usability of the HC in the day by day practice.*Methods:* During a 3 months period, 113 patients with upper gastrointestinal symptoms (M/F 55/58; range 19–87; mean 49.7 yrs), underwent endoscopy. According to HC, 5 biopsies were obtained: antrum (A) = 2; corpus (C) = 2; angulus (AN) = 1. In addition 2 antral biopsies were taken for Helicobacter pylori (HP) culture and urease testing. The specimens were histologically assessed and scored according to the HC guidelines. Serum IgG to HP were assessed by a previously validated ELISA (sensitivity and specificity of 94%). 3/4 techniques testing positive gave H pylori status (gold standard).*Results:* A total of 68/113 (60%) patients were HP+ve (histology/urease test/culture/serology). The endoscopic findings were: macroscopically normal (n = 26; HP+ 50%), antral gastritis (n = 59, HP + 54%), erosive duodenitis (n = 12, HP + 67%), gastric ulcer (n = 5, HP + 80%) and duodenal ulcer (n = 11, HP + 100%). Sensitivity and specificity of samples taken compared to the gold standard were (%): A C AN A + AN A + C AN + CSensitivity 91 89 89 98 97 97Specificity 87 84 84 98 95 95The biopsies from the angulus revealed 15 cases of atrophy (moderate 1 and mild 14) that would otherwise not have been detected.*Conclusions:* 1. The combination of antral and angulus biopsies showed the highest rate of HP detection, 2. The additional biopsy specimen from the angulus added little to the diagnosis. However, in geographic areas with high prevalence of gastric carcinoma it may help detect early pre-neoplastic lesion. Oesophageal gastric duodenal disorders: Helicobacter Pylori }" "The Houston Classification (HC) of Gastritis Applied in the ""Real World"""

"P P 58 1400"P 58 1400**Nuclear Volume of Type I Gastric Intestinal MetaplasiaD. Mihailovic, B. Mladenovic, M. Ilic, V. Mihailovic**

Institute of Pathology, Medical Faculty, University of Nis, Serbia, YugoslaviaThe three-dimensional nuclear size may be viewed as a dynamic reflection of the metabolic state of the nucleus and as a physical correlate of its total content of biochemical constituents. Among these were histone and nonhistone proteins, inorganic materials, water, RNA and DNA.Metaplasia is a reversible change in which one adult cell type is replaced by another adult cell type. It has been postulated that intestinal metaplasia of gastric mucosa, characterized by incomplete differentiation and by sulphomucin secretion (type III intestinal metaplasia), is closely related to intestinal type gastric carcinoma, whereas other non-sulphomucin-secreting types (types I and II) are predominant in situations where the risk of cancer is relatively low (gastric cancer and chronic gastritis).The aim of this study was to estimate the mean volume-weighted nuclear volume of epithelial cells in type I intestinal metaplasia in various pathological states of gastric mucosa.*Material and Methods.* Endoscopic mucosal biopsies from gastric cancer (n = 25), gastric ulcer (n = 32), and chronic gastritis (n = 40) patients were analyzed. After standard fixation, embedding, sectioning, routine HE and AB-PAS (pH 1.0 and 2.5) staining, the mean point sampled nuclear intercept was estimated by the original test system and objective x100, at total magnification of x1200. To obtain the mean nuclear volume, the cubed nuclear intercept was multiplied by { p}/3. In each case a hundred epithelial cell nuclei were analyzed. For the statistical analysis Student's two tail t-test was used.*Results.* In type I intestinal metaplasia found in gastric carcinoma patients there is significantly greater nuclear volume (118.34 – 10.32 \'b5m^3) than in type I intestinal metaplasia in other pathological states of gastric mucosa (77.72 – 8.58 \'b5m^3).*Discussion.* The sampling of intercepts by points is a mathematical necessity to ensure an unbiased estimation. Our results suggest that nuclear volume may be used in early detection of precancerous states of gastric mucosa. }" "Nuclear Volume of Type I Gastric Intestinal Metaplasia"

"P P 58 1401"P 58 1401**A Flow Cytometric Study of Gastric Nuclear DNA Ploidy in Gastritis**

*S.M. Kamal, M.R. EI Wakil, M.A. Massoud, R. Fawzy

Departments of Clinical Tropical Medicine and Pathology, Faculty of Medicine, Ain Shams University, Cairo, Egypt*Purpose:* This study aimed to assess the gastric nuclear DNA ploidy pattern and correlate it with the clinicopathologic findings in gastritis.*Patients & Methods:* Forty patients (32 males and 8 females; mean age 42 – 5.8 yr) with endoscopic evidence of gastritis were enrolled in the study in addition to 20 patients not showing endoscopic evidence of gastritis as control group. Endoscopic assessment was done to every patient and at least two biopsies were taken from the site of lesion, close to each other, one for histopathological examination and Giemsa staining for Helicobacter pylori and the other biopsy for determination of DNA content (ploidy) and S phase fractions by Flowcytometry.*Results:* Whereas only diploid DNA histograms were found in control subjects, patients with gastritis showed diploid histograms in 34 (85%) cases while 6 (15%) specimen exhibited DNA aneuploidy. S phase fractions were higher in gastritis than control cases and showed significant direct correlation with age and duration of complains but not with activity of gastritis. All the six lesions showing DNA aneuploidy were antral lesions and were positive for Helicobacter pylori. Their histopathological examination revealed atrophic gastritis in the 6 cases with intestinal metaplasia in 4 (66.7%) of these cases and low grade dysplasia in 2 (33.3%).*Conclusion:* (1) This study suggests that determination of gastric nuclear DNA content (ploidy) may help to identify individuals with increased cancer risk as aneuploid histograms were found in non dysplastic mucosa. (2) Thus combination of endocopy, histology and flowcytometry can be integrated surveillance procedures for follow up of patients with gastritis for early detection of malignant transformation. [4] Department of Pathology, Medical School, Athens University, Athens, Greece*Objective:* To compare the accuracy of two different artificial neural networks (ANN), for the discrimination of benign and malignant gastric lesions using morphometric and textural data of the nucleus.*Study Design:* This study was carried out on 39 cancer cases, 34 cases of gastritis and 83 cases of ulcer. In each case 100 cells were measured from gastric smears stained by the Papanicolaou technique using a custom image analysis system. As a training set 30% of the cells were used and the remaining cells were used as a test set using two different neural net architectures: Back propagation (BP) and learning vector quantizer (LVQ).*Results:* The application of BP and LVQ established correct classification of more than 97% of the benign cells and more than 95% of the malignant cells, obtaining an overall accuracy of 97% at cellular level and 99.1% at patient level in both neural networks.*Conclusion:* This study indicates that the use of ANNs and image morphometry may offer useful information on the potential of malignancy of gastric cells and may improve the accuracy of cytological diagnosis. "P P 58 1404"P 58 1404**Do Dyspeptic Patients under the Age of 45 Need to be Investigated?**

*H. Kolk, H.-I. Maaroos

Department of Family Medicine, University of Tartu, Tartu, EstoniaAge under 45 years and negative non-invasive tests for detection of *Helicobacter pylori* (Hp) infection are the most often recommended criteria to avoid unnecessary endoscopy in dyspeptic patients without obvious clinical signs of organic diseases.*Aim:* To evaluate the diagnostic field of open access upper gastrointestinal endoscopy in relation to the age and Hp status of the patient.*Methods:* 135 consecutive dyspeptic patients aged 18 years and over referred for upper endoscopy by their GPs were included. Patients' Hp status was evaluated by histology (2 antral, 2 corpus, 2 duodenal biopsies). Gastritis was scored according to the Sydney classification.*Results:* Diagnostic category No (%) Sex Age Hp posit/ M/F < 45/{\'b3} 45 yrs Hp negatDuodenal ulcer 44 (33%) 30/14 34/10 41/3Gastric ulcer 10 (7%) 4/6 1/9 9/1Gastric carcinoma 1 (1%) 0/1 1/0 1/0Gastric erosions 21 (16%) 12/9 14/7 17/4Chronic gastritis 63 (47%) 42/21 39/24 61/2Other diseases 7 (5%) 3/4 4/3 6/1Normal findings 12 (9%) 7/5 12/0 0/12Total 135 63/72 88/47 112/23There is an overlap between duodenal ulcer and gastric erosions in 4 cases and between chronic gastritis and gastric erosions in 20 cases. The only case of gastric cancer was 36 years old female. Only 9% of all patients have normal endoscopic and histological findings.*Conclusions:* Among populations with high prevalence of Hp infection more than half of dyspeptic patients have clinically relevant disease at the age under 45 years. Presence of Hp infection is important predictor for organic disease. "P P 58 1406"P 58 1406**Gastric Duplications: Diagnosis and Management**

*Ch. Glaser, H.U. Baer, Ch. Maurer, V. Kuzinkovas, A. Gl\'e4ttli, M.W. B\'fcchler

[1] Department of Surgery, Zieglerspital, Inselspital, University of Bern, Switzerland

Department of Visceral and Transplantation Surgery, Inselspital, University of Bern, Switzerland*Purpose:* Intestinal duplications are a rare congenital disease. They appear in the whole gastrointestinal tract, especially in the ileum. In the literature 112 cases of gastric duplications are described, 80 of them in children. Here we describe two cases of gastric duplication cysts in adults. Diagnostic findings and surgical therapy are discussed.*Patients:* a:) A 23 year old patient had pain in the right upper abdomen, nausea, vomiting and attacks of fever. No pathological findings were described in endoscopy. CT-scan showed a fluid filled structure with obstruction of the duodenum. A duodenal duplication or choledochus cyst was discussed. b:) A 59 year old patient with pain in the left upper abdomen since one year was admitted to our department. She had no fever or vomiting, no weight loss. CT-scan and sonography presented a big cyst (14 {\'b4} 13.5 {\'b4} 9 cm) in the left upper abdomen close to the pancreas body, probably a pancreas pseudocyst. In ERCP were no pathological findings. Sonography was normal.*Methods:* Both patients had a diagnostic laparatomy. At the first patient a subtotal gastrectomy (Billroth I) was accomplished. For the second patient a tangential resection with a small wall of gastric mucosa was performed.*Results:* There were no perioperative problems. At the first patient an early dumping syndrome was successfully treated conservatively. The second patient had a good recovery without complications.*Conclusion:* Gastric duplications in adults are extremely rare. Diagnosis is often missed. Symptoms are unspecified pain in the upper abdomen, vomiting and fever. Some patients have weight loss. Complications are rare. Chronic infections and ruptures are described. For diagnosis, CT-scan with oral contrast should be preferred. Endoscopy is negative in most cases. Therapy is surgical. Local excisions with a small wall of gastric mucosa in most cases is sufficient. Sometimes, a subtotal gastrectomy is necessary.

*V. Nikolopoulou, K. Thomopoulos, E. Katsakoulis, B. Margaritis, K. Mimidis, A. Panagaris, C. Vagianos

Division of Gastroenterolgy and Department of Surgery, University Hospital, Patras, GreeceThis is a prospective study comparing the outcome between pharmaceutical and non pharmaceutical upper gastrointestinal bleeding (GI) due to benign peptic ulcer.*Methods:* A total of 907 patients were studied prospectively. They were suffering from acute upper GI bleeding due to endoscopically and histologically identified benigh peptic ulcer. The patients were divided in two groups. *Group A* included 506 patients who had received ulcerogenic drugs (either aspirin or NSAID's) and *Group B,* 401 patients with no history of drug consumption. The two groups were comparable in all clinical and endoscopic parameters which are known to influence prognosis: age, sex, history of previous GI bleeding, associated disease, shock on admission, endoscopic stigmata and location of ulcer, need for haemostasis, rebleeding, need for transfusion and duration of hospital stay.*Results:* Emergency surgical intervention for persistent or reccurent bleeding was required in 38 patients (7.5%) in Group A and in 42 (10.5%) in group B ($p = 0.148$). The overall mortality was 2.95% for Group A and 1.2% for group B. Endoscopic stigmata, median transfusion requirements, median duration of hospital stay, endoscopic haemostasis did not differ significantly. There were differences in sex distribution (more women than men), age, history of previous GI bleeding, associated disease, shock on admission ($p = 0.073$) and gastric ulcer ($p = 0.002$). Interestedly in Group A patients rebleeding rate was significantly less.*Conclusions:* Despite clinical presentasion pharmaceutical haemorrhage do not seem to differ in mortality, morbidity and hospital stay than non pharmaceutical. Endoscopy, general: GI bleedingEndoscopy, specific: Stomach, duodenum }" "Pharmaceutical Versus Non-Pharmaceutical Acute Upper Gastrointestinal Bleeding"

"P P 59 1408"P 59 1408***Helicobacter Pylori* Infection Increases the Risk of Peptic Ulcer Bleeding — A Case-Control StudyH. K\'f6hl, F. Leverkus, J. Labenz**

Elisabeth Hospital Essen, Germany*Purpose:* The study was designed to evaluate the role of *H. pylori* infection in the pathogenesis of peptic ulcer bleeding.*Methods:* 128 patients presenting with upper GI bleeding and 128 matched controls (age and gender) were studied prospectively. In all patients and controls a standardized questionnaire was performed. Patients were investigated endoscopically with assessment of *H. pylori* infection by a rapid urease test, culture and histology. In controls, the current *H. pylori* status was determined using a ^{13}C-urea breath test. Statistics included the Cochran-Mantel-Haenszel test and a conditional multiple logistic regression analysis (CMLR).*Results:* 72 patients had peptic ulcer bleeding (gastric ulcer (GU): n = 39; duodenal ulcer (DU): n = 33) and 56 patients bled from other sources. *H. pylori* infection was more frequently detected in ulcer patients than in controls (GU: OR 4.3 95%-CI 1.6–11.5, p = 0.005; DU: OR 3.3 95%-CI 1.1–9.4, p < 0.03), while the infection was not related to non-ulcer bleeding (OR 1.2 95%-CI 0.6–2.5, p = 0.59). NSAID use was associated with an increased risk of gastric ulcer bleeding (OR 4.5 95%-CI 1.1–18.2, p = 0.035). CMLR suggested that *H. pylori* infection is an independent risk factor for peptic ulcer bleeding (OR 3.3 95%-CI 1.5–7.0), p = 0.002). No interactions could be detected between the infection and NSAID use.*Conclusions: H. pylori* infection increases independently the risk of peptic ulcer bleeding. Thus, cure of the infection will lead to a decreased incidence of ulcer bleeding. However, it cannot be expected that curing *H. pylori* infection in NSAID users will substantially diminish the risk of ulcer complications. "P P 59 1410"P 59 1410**Clinical Investigation of Bleeding Peptic Ulcer in the Elderly**

*S. Noguchi[1], S. Tanabe[2], I. Kondoh, H. Imaizumi, M. Kida, W. Koizumi, Y. Yokoyama, T. Mitsuhashi, M. Ohida, K. Saigenji

[1] Department of Gastoroenterology, Sagamihara kyodou hospital, Sagamihara, Kanagawa, Japan

[2] Department of Internal Medicine, Kitasato University, Sagamihara, Kanagawa, Japan*Introduction:* The rapid increase in the elderly population of Japan has led to an increased number of elderly patients with bleeding peptic ulcer.*Objectives:* We compared the clinical characteristics of bleeding peptic ulcer in patients over 70 years of age or older in whom hemostasis was performed by heater probe treatment (elderly group) with those less than 70 in whom similar treatment was performed (younger group).*Methods:* Over a period of 9 years, 274 patients were enrolled, 48 in the elderly group and 226 in the younger group.*Results:* The incidence of concomitant disease was significantly higher in the elderly group (83.3%) than in the younger group (33.3%) ($p < 0.01$). The incidence of emergency surgery (younger group 5.8% vs. elderly group 6.3%) and the rate of mortality due to hemorrhage (2.2% vs. 2.1%, respectively) were similar in the two groups.*Conclusion:* Bleeding peptic ulcer in elderly patients was thus characterized by a high incidence of concurrent disease. Despite this, the results of the present study indicate that the rates of mortality and emergency surgery in elderly patients with bleeding peptic ulcer who undergo heater probe treatment are comparable to those in younger patients, provided that their general condition is monitored carefully and that endoscopic hemostatic procedures. "P P 59 1411"P 59 1411**Fifty Years of Upper Gastrointestinal Haemorrhage in NE Scotland**

*J. Masson, P. Bramley, G. McKnight, A. Fraser, N.A.G. Mowat

Gasrointestinal Unit, Aberdeen Royal Infirmary, Aberdeen, UKThe mortality associated with acute Upper Gastrointestinal Haemorrhage (UGIH) has not generally reflected the major improvements in patient care introduced over the past 50 years and this has been confirmed by the recent Royal College of Physicians' Audit with a mortality of 14%. The factors that influence the outcome of UGIH have been the subject of many studies, but no study has addressed the impact of changes in medical practice and demographic characteristics in a single community. There have been three whole-community studies over 5 decades which provide data on the management and outcome of upper gastrointestinal bleeding in NE Scotland and these studies provide an exceptional record of the changing patterns of UGIH in a single community.There has been an increase in age (in 1950 1.5% and 1990's 18.5% of patients admitted were over 80 years of age), the use of ulcerogenic drugs and co-morbid disease in patients presenting with UGIH. However, the incidence of UGIH has remained static (117,000 admissions per adult population per year) over the last 25 years and at present is similar to other recent large studies. Endoscopy has replaced barium meal as the investigation of choice and with the introduction of powerful anti-ulcer drugs semi-elective surgery for ulcer prevention has disappeared. The proportion of gastric ulcer, oesophagitis and mallory-weiss tear have increased, whereas the proportion of duodenal ulcer and undiagnosed patients has declined. These changes in the diagnostic mix may reflect more accurate diagnosis or a true change in the incidence of certain diagnoses. During the same period outcome was improved with surgical mortality falling from 25% to 8% and overall mortality from 13.7% to 3.9%.The factors determining outcome in UGIH are constantly changing and this review clearly demonstrates this within a single community. Despite an increasing aged population with it's associated co-morbid disease we have shown that by optimising patient care the mortality rate for UGIH can be reduced. *B. Annibale, M. Marignani, G. D'Ambra, F. Malagnino[1], G. Antonelli, M. Mecarocci[1], C. Bordi[2], G. Delle Fave

Dept. Gastroenterology, University ""La Sapienza"" Rome, Italy

[1] Dept. Hematology, University ""La Sapienza"" Rome, Italy

[2] Dept. Pathology Parma University, ItalyOxyntic mucosa trough acid and intrinsic factor secretions determines the availability for absorption of alimentary iron and vitamin B12 that are crucial in the haemoglobin synthesis. Furthermore duodenal mucosa is the main site for the absorption of reduced iron. The functional and structural integrity of gastric and duodenal mucosa is crucial since some diseases in which this integrity is lost, could result in anemia e.g. peptic ulcer disease (PUD), corporal atrophic gastritis (CAG), celiac disease (CD). Aim of study was to investigate in a consecutive anemic outpatients population referring to our Hematology Dept., the role played by gastric and duodenal mucosa integrity as possible cause of anemia. During a three-month period, 266 anemic consecutive outpatients (213 microcytic, 53 macro) were observed. Obvious blood loss causes, active gastrointestinal haemorrage, fecal occult blood positivity, and all haematological and GI malignancy constituted exclusion criteria for this study. 80 anemic patients (age 20–76; M 24, F 56) 36 macrocytic, 44 microcytic, without GI complaints, resulted eligible and were investigated with a screening procedure consisting in the sierological determinations of gastrin, IgG anti H pylori, antiendomysial IgA antibodies (EMA). Positivity of at least one of these determinations was further investigated with upper GI endoscopy with multiple antral (n = 2), fundic (n = 4) and duodenal (n = 2) biopsies. Patients negative to the screening also underwent gastroscopy. *Results* Gastrin was found increased in 35 pts, IgG Hp in 37 pts and EMA 16 pts. 6 patients refused further control. Endoscopy/histology Microcytic MacrocyticNormal 22 (29.7%) 14 8PUD Hp+ 6 (8.1%) 4 2CAG 21 (28.4%) 8 13 (pernicious anemia)Adult CD 12 (16.2%) 10 2Hp+ antral gastritis 13 (17.5%) 7 6*Conclusion:* This study in a consecutive asymptomatic anemic population enabled us to identify 39 out of 74 pts (52.7%) in whom upper GI diseases were the cause of anemia. The occurence of both types of anemia is similarly distributed in PUD and CAG. Only 29.7% of anemic screened patients had no alteration of gastric and duodenal mucosa. Evaluation of unexplained anemia in adults should include a thorough investigation of upper GI tract. [1] The Danish Epidemiology Science Centre, University of Aarhus, Denmark

[2] Department of Medicine V, Aarhus University Hospital, Aarhus, Denmark

[3] Department of Medicine M, Aalborg Hospital, Denmark*Background* – Recent clinical trials has established new indications for oral anticoagulation with warfarin; the efficacy was achieved with a low incidence of bleeding complications which may not be reproduced in clinical practice. Gastro-intestinal bleeding is the most frequent type of major bleeding and the objective of this study was to estimate the incidence of major gastro-intestinal bleeding requiring hospitalization among unselected outpatients treated with oral anticoagulants.*Design* – Through The Drug Prescription Register we identified a cohort of the 684 people commencing oral anticoagulant therapy in 1992 in the County of North Jutland. All discharge diagnoses for hospitalizations in this cohort from 1992 to October 1994 were reviewed for potentially bleeding complications followed by patient record review; death certificates were studied for deaths during follow-up.*Results* – The 684 patients represented 754 years at risk. There were 20 major gastro-intestinal bleeding events (2.7 per 100 treatment-years) in 19 patients of which none were fatal. Nearly all events were severe; requiring transfusion of two units of blood or more. Ten patients required four units of blood or more.*Conclusion* – The rates of major gastro-intestinal haemorrhages in this inception cohort was two to four times as high as in recent prospective trials and illustrates the continuous difficulties in translating the efficacy of oral anticoagulation in trials into effectiveness in clinical practice. Clinical practice: Epidemiology (non cancer)Clinical practice: Quality assuranceEndoscopy, general: GI bleeding }" "Incidence of Gastro-Intestinal Haemorrhagic Complications during Anticoagulant Therapy in a Danish Population-Based Cohort"

"P P 59 1416"P 59 1416**Upper Gastrointestinal Bleeding Today. A Prospective Analysis of 1350 CasesK. Thomopoulos,**

*V. Nikolopoulou, K. Mimidis, E. Katsakoulis, A. Panagaris, C. Vagianos

Department of Internal Medicine, Division of Gastroenterology and Department of Surgery, University Hospital, Patras, GreeceUpper gastrointestinal bleeding continous to be a serious and common clinical problem. In the last decades considerable improvement has been achieved concerning diagnostic and therapeutic approach to these patients. We present our data accumulated prospectively on 1350 patients admitted in our hospital over a 4 year period with upper gastrointestinal bleeding.During the last 4 years 1350 patients (14–96 years) admitted in our hospital with upper gastrointestinal bleeding (UGIB) or presented UGIB while were inpatient for any other reason. No exclusion have been made for age or comorbid disease. Emergency endoscopy was performed during the first 24 hours after admission or immediately after resuscitation in patients with massive bleeding. All patients have been managed by a team of gastroenterologists and surgeons in close cooperation. In all peptic ulcer, patients with active spurting or oozing bleeding, or a non bleeding visible vessel, endoscopic injection hemostasis with adrenaline diluted 1:10.000 in saline 0.9% (A/S) was performed during emergency endoscopy. Variceal bleeding was managed with octreotide, Sengstaken tube and emergency sclerotherapy.Peptic ulcer remains the main cause of UGIB (68.3%) following by gastroduodenal erosions (12.6%). We observed an increase in the incidence of peptic ulcer with a simultaneous decrease in the incidence of gastroduodenitis as a cause of UGIB in comparison to the previous decade. In patients with peptic ulcer the operation rate was 8.7%. Overall mortality was 2.5% and in patients with peptic ulcer as a cause of bleeding 2.2%. All patients who died had serious comorbid disease and 73.5% were over 65 years old.In conclusion peptic ulcer remains the main cause of upper gastrointestinal bleeding. Close cooperation between surgeons and gastroenterologists and endoscopic therapy has improved clinical outcome in patients with UGIB and reduced mortality. Endoscopy, general: GI bleeding }" "Upper Gastrointestinal Bleeding Today. A Prospective Analysis of 1350 Cases"

"P P 59 1417"P 59 1417**NSAID Utilization and Frequency of NSAID Induced Gastroduodenal BleedingA. Jelenkovic**

Department of Pharmacology and Toxicology, Faculty of Medicine, Nis, Serbia, YugoslaviaEstimation of frequency of adverse drug reactions (ADR) is usually based on drug utilization expressed in the number of packages, number of prescriptions, single drug units. But, differences in drugs formulations (tablets, capsules, suppositories, solutions), weight of the active substance in drug packages and weight of every single unit in the package are neglected. Because of that, estimation of drug utilization is not precise enough, comparisons of different studies can not be made, and therefore neither can estimations of ADR.An internationally accepted statistical unit for drug utilization which takes into account all the parameters mentioned above is a defined daily dose (DDD). It is by agreement established drug quantity most frequently used for most frequent indications.In this study utilization of NSAIDs prescribed to outpatients of the Nis region (320190 inhabitants) in 1995 expressed in DDDs and the number of DDDs leading to one hospitalized hematemesis and/or melena (HM) induced by NSAIDs are analyzed. The number of HM (endoscopically found gastric or/and bulbar lesions) is already known.The utilization of acetylsalicylic acid (ASA) was 409172.4 DDDs. One HM appeared on every 7868.7 DDDs or more (as there is no evidence of sold unprescribed drugs, they could not be taken into account). The DDD for orally (O) or rectally (R) applied ASA is 3000 mg, so appearance of one HM can not be expected below 23606.1 g of ASA taken.One HM can not be expected below 46679.9 DDDs of ibuprofen (O the DDD is 1200 mg), 189450.2 DDDs for diclofenac (O, parenterally-P, R the DDD is 100 mg) and for piroxicam (O, P, R the DDD is 20 mg) 160174 DDDs.Because of the said advantages, introduction of DDDs in ADR research can lead to easier and more precise estimation of ADR frequency. The DDDs are also a good tool for further investigations in the ADR field, including ADR in the digestive system, too. Clinical practice: Epidemiology (non cancer)Oesophageal gastric duodenal disorders: GD disorders, acid peptic }" "NSAID Utilization and Frequency of NSAID Induced Gastroduodenal Bleeding"

"P P 59 1423"P 59 1423**Sch\'f6nlein-Henoch Purpura in Adults (Gastrointestinal Manifestation and Endoscopy)J. Nov\'e1k**

Department of Gastroenterology, P\'e1ndy K\'e1lm\'e1n County Hospital, Gyula, HungaryDuring a 10 years period 62 adult patients were admitted with diagnosis of Sch\'f6nlein-Henoch purpura in our hospital. 25 female and 37 male patients ranging from 30 to 87 years (mean: 59.5 year) and presenting with cutaneous, joint, renal and particularly abdominal involvement were investigated retrospectively. During the course of the disease, all patients developed purpuric rash (100%), 14 (22.5%) patients had joint symptoms and renal involvement occurred in 12 (19.3%) patients. In this study, we discuss 15 (24%) patients with gastrointestinal symptoms appearing in Henoch's purpura. Analysis of the gastrointestinal clinical features revealed: abdominal pain 13 (86%), massive colorectal bleeding 3 (20%), occult blood loss 10 (66%) vomiting 6 (40%) and diarrhoea in 3 (20%) patients. Surgical consultation was obtained for 4 of the 15 patients and laparotomy was performed in 2 patients. All the patients underwent lower and upper endoscopic examination, in 3 cases the authors saw purpuric mucosal lesions in duodenum and in 8 patients were also found coin-like elevated lesions in colon, additionally, biopsy from colonic lesions showed leukocytoclastic vasculitis. It is concluded that endoscopy can be helpful in the diagnosis and treatment of Sch\'f6nlein-Henoch purpura, especially is in those without typical skin rash. Endoscopy, general: Instrumentation, diagnosisEndoscopy, general: GI bleeding }" "Schönlein-Henoch Purpura in Adults (Gastrointestinal Manifestation and Endoscopy)"

"P P 60 1432"P 60 1432**Clinical Uniformity of Inflammatory Bowel Disease at Presentation in the North and South of EuropeJ.E. Lennard-Jones,**

*S. Shivananda, EC-IBD study group

University Hospital Maastricht, The Netherlands*Background:* A prospective epidemiological survey conducted by The European Collaborative Study Group on IBD (EC-IBD) has assessed the incidence of non-specific inflammatory bowel disease (IBD) in the North and South of Europe. The protocol was also designed to study whether the clinical features of IBD are different in these two areas, because of genetic or environmental factors. Twenty European centres participated in the study, 8 were from the North and 12 from the South.*Methods:* All centres used uniform criteria of disease definition in ulcerative colitis (UC) and Crohn's disease (CD) and a common protocol for recording clinical and epidemiological data.*Findings:* Altogether 2201 patients with IBD aged 15 years or more were identified. Of the 1379 with UC 869 were from the North and 510 from the South. Of the 706 with CD, 477 were from the North and 229 form the South. An analysis of the diagnostic measures used in making the initial diagnosis of UC or CD in the North and South showed that every patient with colitis had an endoscopy and that a biopsy or operation specimen was available for pathological examination in most cases. For CD over 80% of cases had an X-ray and tissue was available for pathological examination in 87–92% of cases. There was no difference in the proportion of cases investigated by each means in the North and South of Europe, except that radiology was used a little more often in the South. The analysis of duration and nature of presenting symptoms and site and extent of disease showed no evidence that the initial clinical features of disease vary from Iceland in the North to mediterean countries in the South. *Conclusion:* This study provides evidence that modern methods of investigation of IBD are available both in the North and South of Europe, definitions of disease are uniform, clinical presentation of IBD is similar, and therapeutic management during the first year of disease follows a common pattern in most centres. Intestinal disorders: IBD diagnosis, monitoringIntestinal disorders: IBD, therapy }" "Clinical Uniformity of Inflammatory Bowel Disease at Presentation in the North and South of Europe"

"P P 60 1433"P 60 1433**Is Intestinal Permeability Really Increased in Patients with Inflammatory Bowel Disease?**

*B.J. Geerling, M.A. v. Nieuwenhoven, R.W. Stockbr\'fcgger, R.-J.M. Brummer

Dept. of Gastroenterology, university hospital Maastricht, The Netherlands*Introduction.* During the last years there is much interest in the intestinal permeability of patients with Inflammatory Bowel Disease (IBD) as this may play a role in the pathogenesis of IBD. However, methods used to measure the urinary sugar concentrations show lack of reproducibility and results are often conflicting. The aim of this study was to evaluate intestinal permeability in patients with IBD (Crohn's disease (CD) and ulcerative colitis (UC) versus controls, using a validated, newly developed analysis method.*Methods.* After an overnight fast, 27 patients with IBD (8 CD, 19 UC) at time of diagnosis (IBD-new), 23 patients with long-standing CD > 10 years, but during an inactive period (CD-long) and 39 controls, ingested a solution consisting of 10 gram lactulose (L) and 1 gram rhamnose (R) in 65 ml of water. Urine was collected for 5 hours and urine L and R excretion was measured using a validated, newly developed fluorescent detection HPLC [1]. Results are expressed as mean – SEM. Statistical analysis was performed by one-way ANOVA.*Results.* The L/R ratio for IBD patients (IBD-new: 0.01 – 0.002; CD-long: 0.02 – 0.006) was not significantly different compared to controls (0.01 – 0.002). However, the % recovery of R was significantly decreased for CD-long patients, compared to controls ($p < 0.001$). No significant correlations were observed between either disease activity indices (albumin, ESR, CRP or CDAI) and L/R ratio or disease activity indices and % recovery of the sugars.*Conclusions.* The L/R ratio was not increased in patients with IBD. The excretion of the monosacharide rhamnose was decreased for patients with long-standing CD. Whether this observation is related to malabsorption and reduced absorptive capacity of the small intestine of patients with long-standing CD remains to be established.

"P P 60 1434"P 60 1434**Decreased Trace Element Status in Patients with Inflammatory Bowel Disease**

*B.J. Geerling, R.-J.M. Brummer, R.W. Stockbr\'fcgger

Dept. of Gastroenterology, university hospital Maastricht, The Netherlands*Introduction.* Trace element deficiency is described in patients with Inflammatory Bowel Disease (IBD), mainly in active Crohn's disease (CD). Those trace elements, which are anti-oxidants, may play an important role in the pathophysiology of IBD as scavengers of free radicals. The aim of this study was to evaluate trace element status in various groups of IBD patients (CD and ulcerative colitis (UC)).*Methods.* In 27 IBD patients at time of diagnosis (IBD-new: 8 CD, 19 UC) and in 31 patients with long-standing, but recently inactive CD (> 10 years with one or several small bowel resections; CD-long) and in 15 controls, trace element status was assessed by serum values of selenium (Se), zinc (Zn), magnesium (Mg), copper (Cu) and whole blood gluthation peroxydase (GPx). Statistical analysis was performed by ANOVA.*Results.* Trace element values were not significantly decreased for IBD-new patients versus controls. However, compared to controls, Se, Mg, Zn, Cu, GPx of CD-long patients were significantly lower (86.5%, 90.4%, 93.8%, 76.7% and 82.7% of control values, respectively; $p < 0.05$). There were no correlations between trace element values and disease activity indices (albumin, ESR, CRP, CDAI or Truelove Witts index). We observed a significant correlation between Se and GPx in patients with IBD (IBD-new and CD-long: $r = 0.37$; $p < 0.05$), however, not in controls.*Conclusion.* Selenium requirement for GPx activity was met in controls, but not in patients with IBD. Patients with long-standing, but recently inactive CD, have significantly lower serum trace element values compared to controls. For IBD patients at time of diagnosis a similar, but not yet significant, trend was observed. This may indicate a poor anti-oxidant status with negative implications on the course of the disease. "P P 60 1435"P 60 1435**Serum Levels of Eosinophil Cationic Protein (ECP), ""Neurotoxin"" (EPX) and Myeloperoxidase (MPO) as Markers of Clinical Activity in Inflammatory Bowel Disease (IBD)**

*F. De Lazzari, A. D'Odorico, E.A. Galliani, E. Guido, P. Ravagnan, D. Faggian[1], R. D'Inc\'e0, G.C. Sturniolo, M. Plebani[1], F. Pozzato, R. Naccarato

Gastroenterology Dpt., University of Padua, Italy

[1] Medicine Laboratory Dpt., University of Padua, ItalyEosinophils may be the predominant cell type in the inflamed intestinal mucosa of IBD pts. Immunoallergic reactions have been postulated to be involved in the patogenesis of IBD. *Aim:* to evaluate if serum levels of protein released by eosinophils (ECP and EPX) and neutrophils (MPO) were related to clinical activity and/or allergic features in IBD pts. *Methods:* 104 consecutive out-patients affected by ulcerative colitis (UC: n. 60; mean age: 40 yrs; range: 17–74 yrs) or Crohn's disease (CD: n. 44; mean age 41 yrs; range 15–76 yrs) were included in the study. Pts on steroids or other immunosoppressive agents, were not included. Pts were submitted to prick-by-prick tests for food allergens (milk, apple pear, celery, parsley, onion, garlic, tomato, capsicum, walnut, peanut, banana, flour) and prick test for common inhalants (Dermatophagoides D.F, D.PT, Graminaceae, Candida Albicans, Compositae, Betulaceae, Parietaria). Serum ECP, EPX and MPO levels were tested by commercial kits (Pharmacia; Uppsala, Sweden). *Results:* 34% of pts have positive prick test irrespective of the type of disease. 55–70% of positive tests were found in pts in remission, but no statistically difference was found with disease clinical activity. Pts with positive allergic tests have ECP, EPX and MPO serum levels similar to those with negative prick tests (p: n.s.). MPO serum levels are related to clinical activity in IBD pts especially in UC pts ($P < 0.02$ t: 2.28). A significant correlation was found betweeen serum levels of ECP with MPO ($r = 0.537$; $p < 0.0001$) and EPX with MPO ($r = 0.517$; $p < 0.001$). *Conclusions:* MPO serum levels are related to clinical activity in IBD pts with a positive correlation with serum ECP and EPX levels. 34% of our pts had a positive reaction to food and/or inhalant allergens. These date indicate that PMN neutrophils might trigger eosinophils which contribute to tissue damage by releasing their active proteins. Intestinal disorders: IBD diagnosis, monitoring }" "Serum Levels of Eosinophil Cationic Protein (ECP), ""Neurotoxin"" (EPX) and Myeloperoxidase (MPO) as Markers of Clinical Activity in Inflammatory Bowel Disease (IBD)"

"P P 60 1436"P 60 1436**Humoral Immune Response to Human Stress (Heat Shock) Proteins in Inflammatory Bowel Disease****G. Pedersen, P.N. Schmidt, J. Hendel, T. Saermark,**

*J. Brynskov

Dept. Medical Gastroenterology C, Herlev University Hospital, DK-2730 Denmark*Purpose:* Human Stress Proteins (HSP) is a large group of intracellular proteins expressed when cells are exposed to different kinds of stress. They appear to have a cytoprotective function which diminish cellular damage. HSP's are believed to be involved in the pathogenesis of IBD, supported by the finding of enhanced mucosal expression of the stress proteins HSP 60 and HSP 70 in IBD. The level of autoantibodies to HSPs seems to be elevated in other autoimmune diseases. In this study the presence of circulating autoantibodies to HSP 60 and 70 was compared to the expression of mRNA for the proteins in colon mucosal biopsies from a series of IBD patients.*Methods:* Sera from IBD patients and controls were tested for autoantibodies by an ELISA based on HSP 60 and 70 from recombinant sources as the primary layers. Endoscopic colorectal biopsies were tested by PCR for the expression of HSP 60 and HSP 70 mRNA.*Results:* Autoantibodies against HSP 60 were found in all patients with IBD, and no difference was found in titre level between patients with IBD and healthy controls. Autoantibodies to HSP 70 were not found. Using PCR to detect expression of HSP 60 and 70 it was found that both were expressed in both healthy subjects and patients with IBD. The sequense specificity excluded bacterial expression as a false positive signal.*Conclusion:* It has been found previously that patients with Ulcerative Colitis have elevated levels of autoantibodies to HSP 70. This could not be reproduced although it was found that both healthy subjects and patients with IBD expressed HSP 70. This and the finding of circulating autoantibodies to HSP 60 suggest that the circulating antibody response to these two proteins is without importance in IBD. HSPs could still be involved in the pathogenesis of IBD acting as a local immunological mediator induced by inflammation. "P P 60 1437"P 60 1437**Hepatobiliary and Coexisting Pancreatic Duct Abnormalities in Patients with Inflammatory Bowel Disease**

*B. Heikius[1], S. Niemel\'e4[1], J. Lehtola[1], S. L\'e4hde[2], T. Karttunen[3]

[1] Dept. of Internal Medicine, University Hospital of Oulu, Finland

[2] Dept. of Diagnostic Radiology, University Hospital of Oulu, Finland

[3] Dept. of Pathology, University of Oulu, Finland*Background:* We performed a cross-sectional study to evaluate the prevalence of hepatobiliary disease in unselected patients with inflammatory bowel disease (IBD) and to estimate the frequency of coexisting cholangiographic and pancreatographic duct abnormalities and to correlate the findings with clinical, endoscopic and histologic variables.*Methods:* 237 IBD patients were screened for increased liver function tests. Further hepatobiliary evaluation consisted of transabdominal ultrasonography, endoscopic retrograde cholangio-pancreatography (ERCP) and a liver biopsy. In addition, we evaluated the ERCP findings in patients with abnormal pancreatic screening tests (pancreatic enzymes or PABA excretion).*Results:* Laboratory signs of hepatobiliary disease were found in 37 (16%) of our IBD patients. Those abnormal liver tests were more common in patients with Crohn's disease (CD) than in patients with ulcerative colitis (UC) (30.4% vs 11.2%, $p < 0.05$) and a similar trend was observed in the frequency of primary sclerosing cholangitis (PSC) in the respective groups of IBD patients. When combining ERCP findings with liver histology 26 (11% of the whole study group) patients with PSC were found, small duct disease included. In 23 (10% of the whole study group) patients definite cholangiographic changes consistent with PSC were found. In 11 (48%) of these there were coexisting pancreatic duct abnormalities. The prevalence of coexisting cholangiographic and pancreatographic duct changes in the whole study group was 4.6%.*Conclusion:* Hepatobiliary disease is at least equally common both in patients with UC and CD. Coexisting cholangiographic and pancreatographic duct abnormalities in patients with IBD are not occurring infrequently and they are considered extraintestinal manifestations of IBD.

"P P 60 1438"P 60 1438**Prevalence of ANCA and sANGA in Inflammatory Bowel Disease with Extra-Intestinal Manifestations**

*K. Koss, K. Adrych, A. Kryszewski

Gastroenterology Clinic, Medical University of Gdansk, PolandThe significance of anti-neutrophil cytoplasmic antibodies (ANCA) and other specific antibodies to neutrophil granules (sANGA) in ulcerative colitis (UC) and Crohn's Disease (CD) is unclear. We investigated the prevalence, antigen specificity and relative amounts of both ANCA and sANGA in sera of 45 UC patients. ten had extra-intestinal manifestations (EIM) such as arthritis, sacroilitis, ankylosing spondylitis, pericholangitis, sclerosing cholangitis, uveitis, conjunctivitis. All sera (plus 50 controls) were tested by indirect immunofluorescence for the prevalence of ANCA and by ELISA for antibodies (ab) against the following highly purified enzymes of human neutrophil granules: myeloperoxidase (MPO), elastase (E), cathepsin G (CG) from primary granules, lactoferrin (LF) from secondary granules and lysozyme (LY) derived from primary and secondary granules. ANCA were more common in UC patients with EIM (&)%) than in those without (30%). the prevalence of sANGA in UC patients with EIM (group A) and without EIM (group B) were:Group A: anti-MPO ab 60%, anti-E ab 80%, anti-CG ab 80%, anti-LF ab 70%, anti-LY ab 80%.Group B: anti-MPO ab 14%, anti-E ab 40%, anti-CG ab 38%, anti-LF ab 32%, anti-LY ab 49%.Titres of ANCA, anti-CG ab and anti-LF ab were significantly higher ($p < 0.05$) in group A. Venn diagrams shown limited overlap between presence of ANCA and antibodies in the sANGA group. Considerable overlap was however observed within the sANGA group. Both ANCA and sANGA occurred more frequently in UC patients with EIM suggesting they role in pathogenesis. Intestinal disorders: IBD, basicIntestinal disorders: IBD, etiology and geneticsIntestinal disorders: IBD diagnosis, monitoring }" "Prevalence of ANCA and sANGA in Inflammatory Bowel Disease with Extra-Intestinal Manifestations"

"P P 60 1439"P 60 1439**Test of Renal Function in Patients with IBD: Effects of 5-ASA Treatment**

*M. Luk\'e1s, M. Bortl\'edk, J. Kvasnicka, J. Fialov\'e1

IInd Medical Department Charles University, Prague, Czech RepublicIt has been shown that long term therapy of inflammatory bowel diseases (IBD) with 5-aminosalicylic acid (5-ASA) preparations is potentially nephrotoxic in susceptible patients (pts).*Aim of the study:* 1. to establish frequency of impairement of renal function in pts with IBD, 2. to compare the dosage of 5-ASA in patients with normal and impaired renal function, 3. to find correlation between markers of renal (tubular and glomerular) damage and degree of IBD activity.*Patients and methods:* We have evaluated the renal function in 41 pts with Crohn's Disease (CD) and Ulcerative Colitis (UC). Activity of IBD pts was estimated according clinical, endoscopical and laboratory findings. Mean dosage of 5-ASA was known in all pts during last 6 months. Renal function was assessed by: creatinine clearance, the urinary excretion for two markers of tubular toxicity ({ b}2-microglobulin, { a}1-microglobulin) and microalbuminuria. The urinary markers of tubular damage, microalbuminuria, renal function and mean dosage of 5-ASA was compared in pts with active and inactive IBD.*Results:* 1. Microalbuminuria did'nt correlate with activity of disease (12.5 mg/min in active group, 13.5 mg/min in inactive group $p > 0.7$), { a}1-microglobulinuria was significantly higher in pts with active disease (53.9 mg/l vs 11.6 mg/l, $p < 0.04$). 2. In pts with mean dosage of 5-ASA higher than 2 g/day was urinary excretion of { a}1-microglobulin significantly increased (43.7 mg/l vs. 8.6 mg/l, $p < 0.1$). 3. We didn't find significant difference of mean dosage of 5-ASA in patients with normal vs. pathological urinary of { b}2-microglobulin, { a}1-microglobulin and microalbumin.*Conclusions:* 1. According to the results of this study microalbuminuria isn't reliable marker of IBD activity. 2. We didn't find any correlation between the markers of tubular damage and mean dosage of 5-ASA. 3. It isn't clear, if higher urinary excretion of { a}1-mikroglobulin is consequence of disease activity or administration of 5-ASA. Intestinal disorders: IBD diagnosis, monitoringIntestinal disorders: IBD, therapy }" "Test of Renal Function in Patients with IBD: Effects of 5-ASA Treatment"

"P P 60 1440"P 60 1440**Acute Pancreatitis in Patients with Chronic Inflammatory Bowel Disease**

*H.H. Rasmussen, K. Fonager, H.T. S\'f8rensen, J. M\'f8ller-Petersen

Dept. of Med. Gastroenterology M, Aalborg Hospital, Dept. of Medicine V, and the Danish Epidemiology Science Center, Aarhus University Hospital, DenmarkSeveral case reports on co-existence of pancreatic dysfunction and chronic inflammatory bowel disease, especially Crohn's disease, have been published during the past few years. However, only few studies have estimated the risk of acute pancreatitis in patients with chronic inflammatory bowel disease.*Aim:* To estimate the risk of acute pancreatitis in patients with chronic inflammatory bowel disease in the Danish population.*Methods:* The study included all patients discharged from Danish hospitals with a diagnose of chronic inflammatory bowel disease and acute pancreatitis, registered in the Danish National Registry of Patients in the period from 1977 to 1992. Age- and sex specific incidence discharge rates for acute pancreatitis in patients with chronic inflammatory bowel disease and the background population were calculated. The expected numbers of acute pancreatitis were calculated and divided into groups according to sex, age and calendar-time in three age-groups.*Results:* Overall, 2 patients were discharged and followed for 93774 person-years yielding an average follow-up of 7.7 years for Crohn's disease and 8.6 years for ulcerative colitis. The incidence discharge rate ratio (IRR) for acute pancreatitis was increased in both patients with Crohn's disease (IRR = 3.0, 95% CL: 2.0–4.3) and in patients with ulcerative colitis (IRR = 1.5, 95% CL: 1.1–2.0), especially in the age-group from 15–64 years. No patients < 15 years had acute pancreatitis.*Conclusion:* Patients with chronic inflammatory bowel disease are at an increased risk for acute pancreatitis. Pancreas: Pancreatitis, acuteIntestinal disorders: IBD, basicClinical practice: Epidemiology (non cancer) }" "Acute Pancreatitis in Patients with Chronic Inflammatory Bowel Disease"

"P P 60 1441"P 60 1441**HLA Class II DRB1*0301 or DRB3*0301 Gene Involvement in Genetic Susceptibility to Inflammatory Bowel Disease (IBD)?D. Heresbach, M. Alizadeh, M. Pagenault, J.F. Colombel, F. Quillivic, P.M. Danze, A. Gauthier, M. Gosselin, B. Genetet, A. Cortot, G. Semana, J.F. Bretagne**

Department of Gastroenterology and University Laboratory of Immunology, 59000 Lille & 35033 RennesRecent european studies of HLA class II genes involvement in IBD genetic susceptibility have shown a negative association of HLA DRB1*0301 with IBD as well as with Crohn's disease (CD) than with ulcerative colitis (UC). HLA DRB1*03 allele and DRB1*11, 12, 13 and 14 alleles are associated with an allele HLA DRB3 polymorphic locus (at least 4 alleles described). Recently a north american study have showed an increased risk of CD in individuals who inherit HLA DRB3*0301 allele. *The aim* of the present study was to analyze the relationship between HLA DRB1 and DRB3 locus in the susceptibility to IBD.*Patients and methods:* One hundred thirty one UC and 157 CD patients were included in this study and compared with 200 ethnically matched controls. HLA DRB1 and DRB3 class II alleles were determined by PCR-SSO and if necessary by Reverse Dot Blot(Innolipa, kits from Innogenetics').*Results:* DRB1*0301 and DRB3*01, 02, 03 allelic distribution was analysed in patients groups and controls. A decrease frequency of DRB1*0301 allele was observed in patients (respectively 4% and 7% in UC and CD) versus 15% in controls ($p < 0.001$). Considering the DRB3 locus, a non significant increase frequency of DRB3*03 allele characterize CD patients (8.6% versus 4.0% in UC and 4.5% in controls). Finally, the analysis of DRB3 alleles subtypes (165, 113 and 86 DRB3 alleles in controls, CD and UC respectively) shows that the DRB3*03 allele is more represented in CD patients (23.8% vs 10.9% in controls and 12.8% in UC).*Conclusion:* The DRB3 locus is not involved in the protective effect confered by the MHC class II DRB1*0301 allele. We cannot confirm the strongly association of HLA DRB3*0301 allele with CD in an european population of CD patients. Intestinal disorders: IBD, etiology and genetics }" "HLA Class II DRB1*0301 or DRB3*0301 Gene Involvement in Genetic Susceptibility to Inflammatory Bowel Disease (IBD)?"

"P P 60 1442"P 60 1442**Ultrasound Bone (US) Densitometry in Patients with Inflammatory Bowel Disease (IBD) — A Comparison with Conventional Double X-Ray Densitometry (DXA)M. Dinca, W. Fries, G. Luisetto[1], F. Peccolo[1], F. Bottega[1], A. Martin**

Gastroenterologia, Universit\'e0 di Padova; Italy

[1] Ist. di Semeiotica, Universit\'e0 di Padova; ItalyPatients with IBD are frequently found to have osteoporosis. Bone densitometric measurements are routinely carried out with instruments employing X-rays or radionuclides as energy-sources which imply exposure to radiation. Thus repeated measurements within a short period of time may be harmful. US measurements on the other hand are easy to perform and do not have such side effects. *Aim:* of the study was to compare the new methodology of US of the os calcis with the conventional DXA of the lumbar spine. *Methods:* Bone mineral density (BMD) was measured in 36 IBD patients considered at risk for osteoporosis due to persistent disease activity and/or prolonged steroid intake (24 with Crohn's disease and 12 with ulcerative colitis (aged 24 to 65 years). We performed DXA at the lumbar spine and US of the left os calcis, both examinations within the same day. DXA measurements were expressed as g/cm^2, US measurements as speed of sound (SOS; m/sec), considered to represent density and elasticity, and attenuation of US (BUA: dB/MHz) indicating bone density and trabecular structure. *Results:* in our hands short term precision of DXA was 0.8%, that of US 1.1% for BUA and 1.8% for SOS. DXA and SOS values are closely correlated ($r^2 = 0.669$, $p < 0.00001$), whereas BUA showed a weaker but still significant correlation with DXA-values ($r^2 = 0.414$, $p < 0.01$). *Comments:* 1) Both indices, SOS and BUA, correlate with measurements obtained by conventional DXA of the lumbar spine; 2) US densitometric measurements have an acceptable reproducibility; 3) in IBD patients US may contribute to detect short-term variations due to disease activity, bed rest, or treatment influences (steroids or cyclosporin) and, thus, give new insights in pathophysiology of IBD-associated bone disease. Intestinal disorders: IBD diagnosis, monitoring }" "Ultrasound Bone (US) Densitometry in Patients with Inflammatory Bowel Disease (IBD) / A Comparison with Conventional Double X-Ray Densitometry (DXA)"

[1] Helsinki University Central Hospital, Dpt of Internal Medicine, Haartmaninkatu 4, 00290 Helsinki

[2] Helsinki University Central Hospital

[3] Maria Hospital, HelsinkiIn order to evaluate the extent of the genetic component underlying inflammatory bowel disease (IBD) 880 Finnish subjects suffering from ulcerative colitis (UC) or Crohn's disease (CD) were asked to complete a questionnaire addressing to the occurrence of IBD in their first-degree relatives. The questionnaire was completed by 570 patients (65%), of whom 554 individuals (276 men and 278 women) were unrelated.UC was present in 290 (52%) and CD in 226 (41%) subjects; in 38 subjects (7%) the exact nature of the disease was indeterminate. 13 (5.7%) CD patients and 21 (7.2%) of those with UC had at least one sibling with IBD. Five subjects with CD (2.2%) and 12 (4.1%) with CU had a parent suffering from IBD. Five (2.2%) CD patients and 7 (2.4%) UC patients had at least one affected child. There was a tendency towards genetic anticipation (earlier onset of IBD in successive generations) in both UC and CD. Thus in four families with CD the mean difference between ages at diagnosis in the first and second generation was 20 years and in five UC families 17 years.In conclusion, at least one affected first-degree relative was detected in 13.1% of UC patients and in 10.2% of CD patients. Intestinal disorders: IBD, basic }" "Familial Prevalence of Inflammatory Bowel Disease in Relatives of Finnish Patients with Crohn's Disease or Ulcerative Colitis"

"P P 60 1444"P 60 1444**Thrombophilia in Inflammatory Bowel Disease**

*A.G. Lim, L. Jones, S.R. Gould

Department of Medicine, Epsom General Hospital, Epsom, UKThrombo-embolic complications are important in inflammatory bowel disease (IBD). Thrombophilia may contribute to this thrombotic tendency. It is unclear whether patients with IBD and a previous history of thrombo-embolic complications form a specific subgroup. The aim of our study was to determine the frequency of a range of thrombophilic abnormalities in patients with IBD and in the subgroup of patients who have also suffered from thrombo-embolic problems.Serum levels of antithrombin III, protein C, protein S and lupus anticoagulant and the presence or absence of activated protein C resistance was assessed as a thrombophilia screen. All tests were performed in the absence of anticoagulant therapy.18 patients were studied. 11 had IBD alone (age range 27–78, 5 male) and 7 had BD and previous thrombo-embolic complications (age range 22–76, 3 male). Thrombo-embolic problems included 5 deep vein thromboses, 2 pulmonary emboli and 1 axillary vein thrombosis. The ratio of ulcerative colitis to Crohn's disease and active to inactive patients in the two groups were similar. Of those with IBD alone, thrombophilic abnormalities were detected in 6/11 patients. one patient had both antithrombin III and protein S deficiency, one had had both antithrombin III deficiency and lupus anticoagulant and one had activated protein C resistance. Borderline abnormalities in protein S deficiency and lupus anticoagulant were detected in three other patients. Of those with IBD and previous thrombo-embolic problems, one had activated protein C resistance, one had antithrombin III deficiency, one had protein C deficiency and one was borderline positive for lupus anticoagulant.In summary, the incidence of heterogeneous thrombophilic abnormalities is high (approx 60%) in IBD. Patients who have suffered from thrombo-embolic complications are not more likely to have thrombophilia. IBD patients requiring bedrest in hospital may need low dose heparin prophylaxis. Those with documented thrombophilia may need longterm anticoagulation. Intestinal disorders: IBD, basic }"

"P P 60 1445"P 60 1445**Adhesive *E Coli* in Inflammatory Bowel Disease**

*B.J. Rembacken, J. Rothwell, A.M. Snelling[1], E. Ellis[1], L.C.F. Hibbert-Rogers[1], A.T.R. Axon, P.M. Hawkey[1]

Centre for Digestive Diseases, The General Infirmary, Leeds, UK

[1] Dept of Microbiology, The General Infirmary, Leeds, UK*Escherichia coli (E. coli)* have been implicated in the aetiology of inflammatory bowel disease (IBD) as patients with active ulcerative colitis (UC) are more likely to carry strains adhesive to buccal epithelial cells. No previous study has investigated the coliform flora in patients with IBD and healthy controls over a prolonged period.Four faecal samples were collected over a 12 months period from 13 patients with UC, 8 with CD and 12 healthy volunteers. 10 *E. coli* colonies were isolated from each sample and typed by REP-PCR. The adhesiveness of each *E. coli* subtype was assessed by the buccal epithelial adhesive assay. Our adhesive standard *E. coli* strain (E851) had a mean buccal epithelial adhesive index (BECAI) of 15% and the non-adhesive standard (SC13), a mean of 0. The Mann-Whitney, Fisher's exact and Kruskal-Wallis tests were used in the analysis.Patients with IBD carried significantly more adhesive *E. coli* than healthy controls (UC; median BECAI 6, P = 0.007, CD median 8, P = 0.03, Controls median 0). This association did not change over time as more healthy controls carried non-adhesive *E. coli* (BECAI < 5) at most of the four collection times than patients with UC (9/12 and 2/12 respectively, P = 0.08). There was an association between adhesiveness and site of disease as patients with proctitis and extensive colitis were more likely to carry adhesive strains than patients with left colonic or small bowel disease (p = 0.02). Eight percent of *E. coli* strains followed for one year changed adhesiveness without changing REP-PCR pattern suggesting that the gene for adhesiveness is situated on a plasmid.In conclusion, we can confirm that not only patients with UC but also those with CD are more likely to harbour adhesive *E. coli* than healthy volunteers. The carriage of adhesive *E. coli* may be more related to site of inflammation than type of IBD. }" "Adhesive E Coli in Inflammatory Bowel Disease"

"P P 60 1446"P 60 1446**Immunoquantitation of a Novel Endothelial Cell-Specific Surface Antigen in Inflammatory Bowel Disease**

*N. L\'fcgering, T. Kucharzik, R. Stoll, W. Domschke

Department of Medicine B, University of M\'fcnster, M\'fcnster, GermanyThe aim of the present study was to investigate in detail the immunohistochemical properties of the two endothelial specific markers 1F10 (continuous endothelia) and MS-1 (discontinuous endothelia) in bowel tissues of patients suffering from chronic inflammatory bowel disease (IBD).Immunohistochemical techniques were employed to study the morphology and phenotypic expression of these two proteins in routinely processed bowel tissues from 27 patients with Crohn's disease (CD), 18 patients with ulcerative colitis (UC), and from 20 normal controls.All patients with IBD and controls showed a low to moderate 1F10 immunohistochemical staining restricted to the lamina propria and submucosa. In contrast to UC patients and healthy controls, 1F10 immunoreactivity was strongly *de novo* expressed in the muscularis propria of the small and large bowel in CD patients regardless of the histological severity of the inflammatory process. Neither in Crohn's disease nor in ulcerative colitis we observed immunoreactivity for MS-1 on endothelia surfaces.From this we conclude that endothelia in patients with IBD do not undergo metaplasia. The high immunoreactivity of 1F10 antigen in the muscularis propria in CD indicates a state of topical immunological activation and may be important in the maintenance of chronic inflammation by facilitating leukocyte migration into sites of Crohn's disease involvement. Further studies of the factors controlling endothelial cell differentiation in the bowel of CD patients may help to explain the features observed in this study. Intestinal disorders: IBD, basicImmunology and microbiology: Inflammation }" "Immunoquantitation of a Novel Endothelial Cell-Specific Surface Antigen in Inflammatory Bowel Disease"

"P P 60 1447"P 60 1447**Prothrombotic State in Inflammatory Bowel Disease (IBD)****G. Ciancio[1], B. Mallardi[1], G. Macri'[1], E. Surrenti[1], M.T. Passaleva[1], E. Chiarantini[2], R. Abate[2], G. Salvadori[1], C. Surrenti[1]**

Gastroenterology Unit, Istitute of Internal Medicine and Cardiology, University of Florence, Florence, ItalyPatients with Crohn's disease (CD) and Ulcerative Colitis (UC) show an increased risk of thromboembolic events. *Aims* were to investigate parameters of hemostatic function and the positivity of antiphospholipid antibodies (aPL) in IBD patients. *Patients and methods:* 22 consecutive patients affected by UC (13 M., 9 F; mean age 43.50) and 12 affected by CD (5 M, 7 F; mean age 49.59) were studied and compared with 20 healthy control subjects. In CU patients the disease activity was evaluated by Rachmilewitz index and in CD patients by Crohn's disease activity index (CDAI). In all patients platelet count (PLT), PT, aPTT, Fibrinogen (FBG), antithrombin (AT), protein C (PC), Protein S (PS), factor XIII (FXIII), plasminogen activator inhibitor (PAI), spontaneous platelet aggregation in platelet-rich plasma (PRP-SPA) and in whole blood (WS-SPA) and aPL were evaluated. The parameters of hemostatic function were analyzed by analysis of variance and the frequency of aPL by Fisher exact test. *Results:* In both UC and CD patients PLT, FBG were significantly increased ($p < 0.05$), FXIII was significantly decreased ($p < 0.05$) compared with controls. CU patients showed a higher aPL positivity ($p < 0.05$) than CD patients in comparison to control group. The increase of PLT and FBG was related to the activity of disease; on the other hand the decrease of FXIII and the positivity of aPL was not related to the disease activity or to the site of lesions. In IBD patients, PAI, PRP-SPA, WS-SPA, PC, PS and AT didn't show a significant difference vs. the control group. For what concernes hemostatic parameters were not statistically significant differences in UC and CD. *Conclusion:* Our data suggest that 1) In both UC and CD patients, the only alteration of hemostatic function was a decrease of FXIII levels. 2) In all patients there was no significant relationship between hemostatic parameters and disease activity. 3) aPL were significantly increased in UC in comparison with CD. }" "Prothrombotic State in Inflammatory Bowel Disease (IBD)"

"P P 60 1448"P 60 1448**ANCA in Ulcerative Colitis (UC): Comparison between ANCA + and ANCA { -} Patients and Longitudinal Follow Up**

*E. Louis, S. Demoulin, A. Lamproye, D. Franchimont, J. Salmon, P. Mahieu, J. Belaiche

Departments of Gastroenterology and Immunology, CHU Sart Tilman, 4000 Liége, BelgiumPositivity for ANCA has been described in about 65% patients with UC. The significance of this positivity is still unknown. The aim of our study was first to compare ANCA + and ANCA { -} UC patients on the basis of clinical characteristics and second to follow longitudinally the patients to assess the reproductibility of the results over time. *Patients and methods:* Forty seven consecutive UC patients, with ANCA determination, were included in the study. ANCA positivity was determined using an immunohistochemical method. *Results:* There were 24 ANCA { -} and 23 ANCA + patients. There was no significant difference between these 2 groups in duration of the disease or in smoking. The comparison between these 2 groups showed no significant difference in location and evolutivity (assessed by need for surgery and immuno-suppressive treatment) of the disease. The frequency of extraintestinal manifestations was however significantly higher in the ANCA + group (35% – including 8.5% of sclerosing cholangitis- vs 8%; $p < 0.05$). Twenty out of the 47 patients had several successive tests for ANCA. Five of them showed a change in their ANCA status. These changes were not consistently associated with a modification in location, systemic manifestation, activity or treatment of the disease. *In conclusion,* 1) The ANCA status may determine subgroups of the disease with different risk of systemic manifestations 2) some patients (25%) had a change in ANCA status over time, but this was not associated with any clinical feature. Intestinal disorders: IBD, etiology and geneticsIntestinal disorders: IBD diagnosis, monitoring }" "ANCA in Ulcerative Colitis (UC): Comparison between ANCA + and ANCA – Patients and Longitudinal Follow Up"

"P P 60 1449"P 60 1449**IgM Specific Anti-Measles Antibodies in Patients with Inflammatory Bowel Disease (IBD)**

*C. Goumas, A. Georgouli[1], C. Nasopoulos, A. Zacharopoulos, D. Soutos, P. Golemati[1], D. Katsaros

Gastroenterology Dept, Red Cross Hospital, Athens, Greece

[1] Microbiology Lab., ""Saint Sabbas"" Hospital, Athens, GreeceIgM specific anti-measles antibodies were found significantly increased in patients with IBD, especially in Crohn's disease (CD). A persistent measles infection has been implicated in the pathogenesis of Crohn's disease, via a chronic granulomatus vasculitis process, but data from other studies are not consistent with this hypothesis.*The aim* of this prospective study was to assess a possible causal relationship between measles infection and IBD, by titrating serum IgM specific anti-measles antibodies in patients with exacerbated IBD.*Materials-Methods:* Sixty nine (69) patients (40 males and 29 females, mean age 48.7 years) with exacerbated IBD were included in this study. Forty four (44) patients suffered from ulcerative colitis (UC) and 25 from Crohn's disease. The diagnosis of the exacerbated IBD had been established by endoscopy, X-ray, histology and determination of UCAI (> 20) and CDAI (> 150). The control group comprised of 60 healthy blood donors. Sera of all patients and controls were examined for the presence of IgM and IgG specific anti-measles antibodies. The indirect immunofluorescent method was used for antibody detection. Titers of IgM antibodies in excess of 1:80 were considered indicative of persistent measles infection.*Results:* High IgM antibody titers (> 1:80) were detected in none of our patients and controls. IgG antibodies in titer greater than 1:80 were detected in 81.8% (36/44) of UC, 88.0% (22/25) of CD patients and 85.0% (51/60) of controls (p > 0.10; NS).*Conclusion:* High titers of IgM specific anti-measles antibodies were not detected in patients with exacerbated UC or CD. A causal relationship between persistent measles infection and IBD is not likely. Intestinal disorders: IBD, etiology and geneticsImmunology and microbiology: GI infections in adults }"

"P P 60 1450"P 60 1450**Faecal Calprotectin Concentration as a Marker of Disease Activity in Inflammatory Bowel Disease**

*S.K. Bunn, A. Sim, D.E. Goudie, P. Clohessy, W.M. Bisset, B.E. Golden

Department of Child Health, University of Aberdeen, United KingdomA non-invasive test to quantify bowel inflammation is greatly needed in the management of Inflammatory Bowel Disease (IBD). Calprotectin is an abundant neutrophil protein, which is very stable in faeces and is significantly increased in adults with IBD [1]. The aim of this study was to investigate whether faecal calprotectin is raised in children with IBD and to determine its usefulness as a marker of disease activity.Faecal calprotectin was estimated in 45 spot samples of faeces, collected from 29 children receiving treatment for IBD, (5.0 to 15.2 years) and was compared to a group of 25 children and 31 adult controls. The level of disease activity was scored by the clinician who was blind to the calprotectin results. Faecal calprotectin concentration was determined by an ELISA. The data was expressed as mean – SD, the disease groups were compared using an unpaired T test.In children with Ulcerative Colitis (8992 – 5591 ug/l, $p = 0.001$) and Crohn's disease (10499 – 6746 ug/l, $p < 0.001$) the stool calprotectin concentration was significantly increased over control range (3056 – 2303 ug/L). The mean faecal calprotectin level rose significantly with increasing severity of disease ($p = 0.027$). In children felt clinically to be in remission, 40% with ulcerative colitis (UC) and 58% with Crohn's disease had stool calprotectin concentrations > 95th centile of the control range.Additionally, one newly presented child with UC had eight spot stool samples collected longitudinally. His faecal calprotectin concentration decreased from 500,000 ug/L before treatment to 6846 ug/L when clinically in remission two months later (within control range).The elevated faecal calprotectin in patients with IBD is likely to reflect the severity of disease activity and indicates that many children have active disease even when free of symptoms. Although further investigation is required, these preliminary studies illustrate the potential of this test for the screening and monitoring of IBD.

"P P 60 1451"P 60 1451**Antineutrophil Cytoplasmic Antibodies in Estonian Patients with Inflammatory Bowel Disease**

*K. Kull, R. Salupere, R. Uibo, V. Salupere

Department of Internal Medicine, University of Tartu, Estonia

Department of Immunology, University of Tartu, EstoniaAntineutrophil cytoplasmic antibodies (ANCA), originally found to be associated with vasculitis, have been reported to be present in inflammatory bowel disease (IBD). The ANCA staining pattern in IBD is most often perinuclear (p-ANCA). The presence of ANCA might prove the evidence of possible involvement of autoimmune mechanisms. However, the antigen to which those antibodies are reactive is not yet known.The aim of the study was to determine the prevalence and pattern of ANCA in patients with inflammatory bowel disease in Estonia. Enzume-linked immunosorbent assay (ELISA), using myeloperoxidase, proteinase-3 and lactoferrin as antigens, was performed to characterize the antigen specificity.64 sera of the patients with ulcerative colitis (UC), 16 with Crohn's disease (CD), 23 with irritable bowel syndrome and 87 healthy persons have been studied. Sera were analyzed for the presence of ANCA by the indirect immunofluorescence on ethanol-fixed neutrophils using fluorescin labelled anti-IgG. ELISA for specific ANCA was performed using antigens mentioned.ANCA were detected in 31/64 (48%) patients with UC, 3/16 (19%) patients with CD and 4/110 (4%) in controls. The immunofluorescence staining were mostly perinuclear (p-ANCA), but at the same time, ANCA with cytoplasmic pattern (c-ANCA) were also revealed. There was no correlation between ANCA and the duration or extent of the ulcerative colitis and Crohn's disease. In ELISA with purified proteinase-3, lactoferrin and myeloperoxidase only a few sera elicited binding above the normal range.Although, the prevalence of UC and CD in Estonia is much lower than in Scandinavia and Northern Europe, there seem to be no differences in immunological features. ANCA occur significantly more often in ulcerative colitis than in Crohn's disease. The ANCA pattern is predominantly perinuclear. The antigenic target for ANCA needs to be determined in further studies. "P P 60 1452"P 60 1452**Epidemiology of Inflammatory Bowel Disease (IBD) in the Province of Liege: Study of Subjects Older Than 60 YearsO. Plomteux,**

*D. Franchimont, E. Louis, P. Latour, J. Belaiche

CHU of LiégeIBD unusually may occur in subjects older than 60 years. The aim of this work was first to determine the incidence of Crohn's disease (CD) and ulcerative colitis (UC) in a population older than 60 years (group 1), and second, to compare their clinical features to the ones in a population younger than 60 (group 2), with IBD occuring during the same period. *Patients and methods:* Prospective study of the new IBD cases occuring in the province of Liége between 1/6/93 and 31/5/94. Incidence in groups 1 and 2 were calculated from the whole population for the considered age. Statiscal analysis: Chi2 test *Results:* 104 new cases of IBD were recorded during the study. In group 1, there were 25 new cases (24%), including 10 CD (40%), 11 UC (44%) and 4 undetermined colitis (18%). In group 2, there were 79 (76%) new cases, including 46 CD (58%), 25 UC (32%), and 8 undetermined colitis (10%). In group 1, mean age at onset was 67 years for CD and 67.5 for UC. The incidences were 4.5 and 5 over 10^5 for CD and UC respectively. This was different from group 2, where the incidence of CD was significantly higher than the one of UC: 5.8 and 3.2 over 10^5 respectively ($p < 0.02$). Sex ratio (F/H) was 1.7 and 1.5 for CD, and 0.6 and 1.2 for UC, in group 1 and 2 respectively. There was no significant difference in the clinical features (symptoms, location, systemic manifestations) at onset for both diseases. *In conclusion,* In the province of Liége, 1) the incidence of IBD is as high after 60 years of age as in youger subjects; 2) these 2 groups do not have different clinical features at onset. Clinical practice: Epidemiology (non cancer)Intestinal disorders: IBD, etiology and genetics }" "Epidemiology of Inflammatory Bowel Disease (IBD) in the Province of Liege: Study of Subjects Older Than 60 Years"

"P P 60 1453"P 60 1453**Value of Pathological Examination of the Colectomy Specimen to Predict the Outcome of Patients with IBD Limited to the Colon**

*M. L\'e9mann, A. S\'e9n\'e9joux, A. Lavergne, P. Valleur, E. Sarfati, A. Galian, P. Bertheau, J.C. Rambaud, R. Modigliani

St-Louis and St-Lazare Hospitals, Paris, FranceIn patients (pts) with IBD limited to the colon who need colectomy, distinction between Crohn's disease (CD) and ulcerative colitis (UC) may be of great importance before deciding the restorative procedure, especially ileo-anal anastomosis. Our aim was to study whether gross and microscopic findings on the colectomy specimen may predict the final outcome of the disease.*Methods.* From 1978 to 1993, 147 pts with IBD had total colectomy in our hospitals. Pts with extracolonic involvement before surgery were excluded (n = 46). The remaining 101 pts were followed after operation for a median of 5.3 yrs (3 mo to 15 yr). Pathological reports of colectomy specimens were reviewed and 12 histological criteria were analyzed in order to classify the pts as CD (when typical granuloma was found), probable CD, probable UC or indeterminate colitis (IC). Final diagnosis CD was based on the occurrence of extracolonic involvement (small bowel or anus) during the post-operative follow-up.*Results.* 22 out of the 101 pts were definitely classified as CD because of the occurrence of typical small bowel involvement (n = 8), anal lesions (n = 8), or both (n = 6). Extracolonic CD involvement occurred more frequently in pts with granuloma (7/10) compared with the other pts (15/91; $P < 0.001$); in contrast, the risk of extracolonic involvement was not significantly different between pts classified as probable CD (9/43), probable UC (3/33) and IC (3/15). Among the 12 histological criteria, only 2 were found, using a multivariate analysis (Cox model), to be significantly associated with a higher risk of extracolonic CD involvement: granuloma (RR = 4) and focal inflammation with intervals of normal mucosa (RR = 1.8).*Conclusion.* In pts without granuloma, the occurrence of extracolonic CD involvement after surgery is poorly predicted by the pathological examination of the colectomy specimen.

"P P 60 1454"P 60 1454**Phosphoprotein Patterns of Intestinal Mucosa in Chronic Inflammatory Bowel DiseasesB. Schnabl,**

*C. Heilmann, C. Spamer

Dept. of Gastroenterology, Medical Centre, University of Freiburg, D-79106 Freiburg, GermanyProtein phosphorylations/dephosphorylations play a fundamental and almost universal role in the regulation of cellular functions. Consequently, defective protein phosphorylation/dephosphorylation can give rise to a variety of disease states. This aspect has not yet been investigated in chronic inflammatory bowel diseases (IBD). Here we demonstrate and compare phosphoprotein patterns in normal and chronically inflamed intestinal mucosa of patients with ulcerative colitis (UC) or Crohn's disease (CD). *Methods:* Samples of colonic mucosa were obtained by endoscopic forceps biopsy from patients with normal mucosa (n = 11), UC (n = 9) or CD (n = 9). Homogenized tissue was incubated with [{ t}-^{32}P]ATP under conditions allowing for endogenous Mg-dependent protein phosphorylation. Endogenous phosphatases were inhibited with microcystin-LR. Following second dimensional electrophoresis (SDE, isoelectric focusing followed by SDS-PAGE) phosphoprotein patterns were analysed with a PDI-Scanner or with PD QUEST image master software, following auto-radiography. *Results:* A total of 45 – 8 distinct phosphoproteins were detected in normal mucosa as compared to 42 – 5 in UC and 36 – 3 in CD. UC and CD mucosa differed in 35 and 28 phosphoproteins, respectively, from normal mucosa. Importantly, UC and CD mucosa differed in 35 phosphoproteins. Major differences were detected in phosphoproteins in the range of 120 to 70 kDa and 32.5 to 23 kDa at isoelectric points between pH 5.4 to 7.9. The nature and function of the various phosphoproteins and related protein kinases is unclear at present. *Conclusions:* The incubation of intestinal mucosa with [{ t}-^{32}P]ATP resulted in endogenous phosphorylation of numerous proteins that could be detected in characteristic and reproducible patterns by second dimensional electrophoresis. The phosphoprotein patterns of normal, UC and CD mucosa exhibited extensive and characteristic differences, potentially providing a new diagnostic tool in the distinction of IBD. The potential role of impaired protein phosphorylation/dephosphorylation in the etiopathogenesis of IBD merits further investigations. *M. Flamenbaum[1], M. Z\'e9nut[1], P. Fabre[1], B. Aublet-Cuvelier[2], J.L. Larpent[1], Le Groupe EPIMICI[1], A. Abergel[1], M. Dapoigny[1], G. Bommelaer[1]

[1] Services d'h\'e9pato-gastroent\'e9rologie, H\'f4tel-Dieu, 63000 Clermont-Ferrand, France

[2] Services d'\'e9pid\'e9miologie, H\'f4tel-Dieu, 63000 Clermont-Ferrand, France*Background:* The aim of this prospective epidemiologic study was to investigate the incidence of Crohn's disease (CD) and ulcerative colitis (UC) in this county, using the same methodology as the Nord-Pas de Calais region and to determinate whether a North-South gradient of IBD in France is real.*Methods:* From 01/01/93 to 31/12/94, each Gastroenterologist collected patients consulting for the first time with clinical symptoms compatible with IBD. Data were reported on a questionnaire by an interviewer practitioner. The final diagnosis of CD, UC was made in a blind manner by two expert Gastroenterologists and recorded as definite, probable, or possible diagnosis.*Results:* 197 new cases were identified: 135 (68.5%) IBD with 100 (74.1%) CD, 31 (23.0%) UC, 4 (2.9%) unclassifiable chronic colitis and 51 (25.9%) acute colitis; 11 (5.6%) cases were unclassified. The annual incidence rate per 10^5 was 8.35 for CD (9.6 for men and 7.1 for women) and 2.5 for UC (2.4 and 2.7). The highest age-specific incidence rate for CD was between 40–49 ans (15.3) and for UC between 80–89 ans (6.8). The sex-ratio F/M was 0.8 for CD and 1.2 for UC. The mean age at the time of diagnosis was 42.3 years for CD and 46.4 years for UC. The incidences rates for CD and UC, definite and probable, are respectively 4.8 and 2.5 in the North and 6.6 and 2.3 in this county.*Conclusions:* 1) These preliminary findings revealed a high incidence of IBD in this county, and close to the highest incidences in the world for CD. 2) The incidence rate in France for UC is lower than CD, contrary to the other countries of Northern Europe. 3) This study doesn't show any North-South gradient for CD. Clinical practice: Epidemiology (non cancer)Intestinal disorders: IBD, basic }" "Incidence of Inflammatory Bowel Disease (IBD) in the Puy-De-Dome Department of France in 1993-94"

"P P 60 1456"P 60 1456**Prevalence of Helicobacter Pylori (H.p.) Infection in Inflammatory Bowell Disease (I.B.D.) — A Controlled StudyL.S. Sousa,**

*A.M. Santos, T.C. Macedo, A.S. Pinto, A.C. Sousa, J. Reis, M.G. Quina

Clinica Universit\'e1ria de Medicina Interna e Gastrenterologia, Hospital de Pulido Valente, Lisboa, Portugal*Objectives* To evaluate H.p. prevalence in patients with IBD submitted to several therapeutical regimens. *Material and Methods* 60 patients were studied prospectively. 30 with Crohn's disease (CD), median age – SD (38.46 – 14.63); 30 with Ulcerative Colitis (UC), median age – SD (43.13 – 13.19). Results were compared to those obtained in 60 healthy volunteers (control group – CG). These groups were matched by age. H.p. status was evaluated as follows: 1) Urea – ^{13}C Breath Test (n = 53 patients + 60 volunteers from CG); 2) Urease and Histology of antral biopsies from gastric mucosa in dispeptic patients (n = 11). Statistic analysis was carried out by $\{ ?\}^2$ and Kruskal-Wallis tests. *Results* Prevalence of H.p. was as follows: IBD group = 56.6% (CD = 50% and UC = 63.3%) and CG = 62% (no difference between groups). Duration, extension, clinical activity or drug therapy (Metronidazol, Sulphasalazine, Mesalazine, Steroids and Azathioprine) were not correlated to H.p. status in the IBD group. When comparing H.p. status between operated (n = 22) and non-operated patients, a significant decrease in the prevalence of H.p. was verified in operated patients (31.8%) p = 0.003. *Conclusions* 1) Prevalence of H.p. infection was similar in IBD sub-groups and also between these and CG. 2) A significant decrease was shown in patients with previous surgery. These patients were submitted to intensive drug treatment (several antimicrobial agents) and had medical intractability. 3) In the IBD group no other factors were detected that may influence H.p. status. [3] Sez. Distaccata IST-CSPO, Firenze

[4] Ist. Anat. Patologica, Univ. di Firenze, Az. Osp. CAREGGI, FirenzeA population-based study identified all the patients with a diagnosis of ulcerative colitis (UC) or Crohn's disease (CD) resident in the Florence area in the period 1978–1992. Overall, 920 patients were included in the follow-up since the date of diagnosis, January 1st 1978 (for cases diagnosed before the start of the study) or the date of migration into the area until death or end of study period (January 1st 1996). Approximately 9,000 person-years were available for observation, with a median follow-up of 9.7 years. A linkage with local town offices and the Regional Mortality Registry allowed the identification of 64 deaths and the retrieval of individual death certificates. Expected deaths were estimated on the basis of 5-year age group, gender and calendar year specific mortality rates of the general population in order to calculate Standardized Mortality Ratios (SMR) for overall mortality and selected groups of causes. Specific cancer sites were also considered; 95% confidence intervals (CI) were calculated assuming a Poisson distribution. General mortality was significantly lower than expected in UC (SMR 0.7; 95% CI: 0.5–0.9), due to a reduced number of cardio-vascular deaths. Smoke-related causes of death were also reduced in UC, in particular cancers of the respiratory tract (which tended to be increased among CD patients). Overall, there was only a limited evidence of an increased mortality for colorectal cancer (significant for rectal cancer in UC patients: SMR 5.0; 95% CI 1.0–14.6). A non significant excess of emolymphopoietic malignancies was observed Deaths due to non malignant gastrointestinal causes were increased among CD patients (SMR 3.9; 95% CI 1.1–10.0), but not in UC. These preliminary results suggest a specific mortality pattern for italian IBD patients. Clinical practice: Epidemiology (non cancer)Intestinal disorders: IBD, basicOncology, specific: Colon, rectum }" "General and Cancer Specific Mortality in the Follow-Up of a Cohort of IBD Patients in Florence"

"P P 60 1458"P 60 1458**The Polymorphism of Motilin Gene Differentiates Genetic Subgroups of Patients with IBD**

*V. Annese, G. Lombardi, A. Piepoli, F. Perri, L. Bisceglia, P. Gasparini, A. Andriulli

Gastroenterology and Human Molecular Genetic, e ""CSS"", I.R.C.C.S. Hospital, San Giovanni Rotondo, ItalySeveral lines of evidence suggest the importance of genetic factors, such as the HLA class II genes, in the susceptibility of ulcerative colitis (UC) and Crohn's disease (CD). We have recently defined the subchromosomal localisation of the motilin gene very close to the HLA-DQ{ a} locus (Hum Genet 1994; 94: 671). *Aim* of the study was to investigate DNA polymorphisms of the motilin gene in a population of inflammatory bowel disease patients. *Methods:* 88 patients with firm diagnosis of UC (49) and CD (39) were studied. Control values were obtained by 60 unrelated blood donors. Anti-neutrophil cytoplasmatic antibodies (ANCA) were identified by indirect immunofluorescence (perinuclear pattern). PCR of the second exon of motilin gene was performed to study the different alleles (1 and 2) frequency of motilin gene. *Results:* are summarised in the table. Patients with CD had a significant increase of the allele 2 frequency ($p < 0.03$ – { ?}^{2}). After stratifying patients according to their ANCA reactivity, ANCA-negative CD patients did not differ from healthy subjects, while ANCA-positive subjects had a striking increase of allele 2 frequency ($p < 0.02$). N. Allele 1 Allele 2 pControls 60 42% 58%UC 49 30% 70% n.sCD (total) 39 27% 73% < 0.03CD ANCA+ve 6 8.3% 91.7% < 0.02*Conclusions:* These results provide further evidence for genetic heterogeneity in patients with CD. It is also intriguing to hypothesize that the polymorphism of the motilin peptide produced by the nucleotide change might explain some of the intestinal motor abnormalities we found in CD patients (Gastroenterology 1993; 104: A470). "P P 60 1460"P 60 1460**The Presence of ANCA Identifies Only a Weak Clinical Heterogeneity in Patients with IBD**

*V. Annese, G. Lombardi, G. Piepoli, F. Perri, N. Caruso, A. Andriulli

Gastroenterology, ""CSS"", IRCCS Hospital S. Giovanni R., ItalyAntineutrophil cytoplasmatic antibodies (ANCA) have been suggested as a potential marker of genetic heterogeneity in IBD. However, their relation to different clinical features of ulcerative colitis (UC) and Crohn's disease (CD) is unclear. *Aim:* To investigate a possible relation between ANCA reactivity and clinical characteristics of the patients. *Methods:* 237 UC (mean age 42 yrs, 147 male) and 94 CD patients (mean age 35 yrs, 53 male) were studied. The determination of ANCA reactivity was performed by indirect immuno-fluorescence also in 169 consecutive unrelated blood donors. Patients were characterized by clinical features: gender, age at onset, disease location and severity (Truelove-Witts and CDAI scores) need for surgery, pouchitis, extra-intestinal manifestations, clinical course (remission or frequent relapses [{\'b3} 2/year]), therapy (need of steroids, need for immunosuppression). *Results:* ANCA positivity was infrequent in our patients being found only in 66 (28%) UC and 8 (8.5%) CD respectively. ANCA were found also in 2 (1.2%) blood donors. After stratifying patients according to their ANCA reactivity, the majority of clinical features were equally distributed between the two groups. ANCA reactivity was significantly more frequent only in UC patients using steroids (34% vs 19%; p = 0.019) and in CD patients with colonic localisation (26% vs 1.5%; p = 0.009). Moreover, a slight decrease of incidence was present in UC patients in remission (21% vs 46%: p = 0.047). However, ANCA positivity had only a 32% accuracy in differentiating UC from CD colitis, and a 51% accuracy in predicting UC patients with steroids need. *Conclusions:* ANCA may well represent a marker of genetic heterogeneity. However, on clinical ground, the correlation with clinical features is rather weak with a poor accuracy and a low negative predictive value. Intestinal disorders: IBD, etiology and geneticsIntestinal disorders: IBD diagnosis, monitoring }" "The Presence of ANCA Identifies Only a Weak Clinical Heterogeneity in Patients with IBD"

"P P 60 1461"P 60 1461**Antioxidant Enzymatic Systems in Inflammatory Bowel Disease**

*E. Monteiro, S. Ribeiro, M. Palmeira, Pedro A. Oliveira, M. Bicho

Department of Medicine II, Gastro, and Department of Genetics, Sta. Maria University Hospital and Faculty of Medicine, Lisbon, Portugal*Introduction:* The transmembrane redox enzymatic system has three main functions: growth control, reducing transferrin iron III and antioxidant actions through the recyclization of ascorbic acid, vitamine E and ubiquinone, and lipid hydroperoxide (HPR) inactivation. Oxygen free radicals have probably a role in either producing or amplifying the inflammatory response in Inflammatory Bowel Disease (IBD). *Aim of Study:* Activities of several enzymatic parameters of oxidative stress were measured in erythrocyte namely transmembrane reductase (RTM), methemoglobin reductase (RMetHb), and acid phosphatase (ACP1) and in plasma the epinephrine oxidasic activity (EO) in order to find out any difference between controls and IBD patients, ulcerative colites (UC) or Crohn's Disease (CD)), between male and female patients and state of disease. *Material and Methods:* 37 patients with IBD were studied, 16 male and 21 female, 18 with UC and 19 with CD. Age range between 17 and 72 years. A control group of 36 for RTM, 174 for RMetHb and 55 for ACP1 and 25 for EO, age and sex matched was used as comparison. Diagnosis of UC and CD was based on clinical, radiological, endoscopic and histological grounds. The activity of the RTM was assayed by the technique of Orringer and Roer modified by us; it is expressed in mmol/l cell/hour of ferricyanide reduced by intact erythrocyte. Other enzymatic systems were measured by standard spectrophotometric methods. The statistical analysis was done by parametric methods. *Results:* Patients with IBD showed RTM activity 4.625 – 2.079 while the controls showed 6.013 – 3.622 (difference statistical significant: $p < 0.05$). No difference was found in men, while in female the mean values of 4.417 – 2.183 was statistically significant compared with female controls (7.145 – 4.510/< 0.05). A non statisticaly significant difference was found neither between UC and CD patients, nor between the active or quiescent phases of the disease. Both RMetHb and ACP1 were statistically significant when compared with controls (17.62 – 4.87 in IBD patients vs 13.87 – 7.165 in controls p {\'a3} 0.05), (99.94 – 41.83 in IBD patients vs 307.2 – 154.7 in controls p {\'a3} 0.001), respectively. No statistically significant difference was found in EO. *Conclusions:* The results suggest an increased production of oxygen free radicals which can induce tissue injury. Intestinal disorders: IBD, etiology and geneticsIntestinal disorders: IBD, basic }"

"P P 60 1462"P 60 1462**Antiendotelial Cell Antibodies in IBD: A Marker of Vascular Injury?**

*C. Papi, V. Pittoni[1], G. Valesini[1], A. Ciaco, M. Bianchi, L. Capurso

Dpt Malattie Digestive & Nutrizionali Osp S Filippo Neri, Roma, Italy

[1] Clinica Medica I, Policlinico Umberto I, Roma, ItalyMesenteric vasculitis has been reported as a possible pathogenic mechanism in Crohn's disease (CD) [1]. Moreover it is well known that vascular endotelium plays an active role in inflammatory and immune processes through expression of endothelial adhesion molecules and of class I and II HLA molecules, cytokine production and expression of procoagulant activity. Antiendothelial cells antibodies (AECA) have been detected in various autoimmune vasculitides and there is some evidence that these antibodies can mediate endotelial injury and correlate with disease activity [2]. Recently AECA have been detected inflammatory bowel disease (IBD) [3] but their clinical significance is still unknown. Aim of the present study was to assess the prevalence of AECA in IBD as compared to normal controls.Sera of 70 patients with IBD (47 UC; 23 CD) and 40 normal controls were tested for AECA by ELISA on unfixed human umbilical vein endothelial cells.Sera positive for AECA were found in 20/70 (28.5%) IBD patients and in 3/40 (7.5%) controls ($p < 0.01$). No staistical difference have been observed in the prevalence of AECA in UC (13/47; 27.3%) as compared to CD (7/23; 30.4%).

The presence of AECA showed no correlation with age, sex disease duration, disease extent and disease activity. However a higher prevalence of AECA was observed in UC patients treated with steroids as compared to patients treated with 5-ASA alone (54% vs 18%; $p < 0.05$).The presence of AECA in about 30% of IBD patients suggests that endothelial damage can have a pathogenic role and provides further evidence of disturbed immunity in IBD. The higher prevalence of AECA in UC patients treated with steroids may reflect an association with a more severe disease requiring steroid treatment. This observation needs to be confirmed by prospective studies.

"P P 60 1463"P 60 1463**Leukergy in Inflammatory Bowel Disease; A Test in the Assessment of Disease Activity**

*F. Hamsioglu, A. Dobrucali, N. Bagatur, A. \'c7elik, M. Tuncer, K. Bal, H. Uzunismail, I. Yurdakul, E. Oktay

Gastroenterology Section, Internal Medicine Cerrahpasa Medical Faculty, University of Istanbul, Istanbul-TurkeyAssessment of disease activity is very important in the management and follow-up of the patients with inflammatory bowel disease (IBD). In spite of many efforts relying on clinical and labarotory parameters, there is still a lack of an inexpensive, rapid and convenient method in the evaluation of the IBD severity. In this study we evaluated leukergy phenomenon manifested as an aggragation of leucocytes in citrated whole blood in the assessment of the IBD activity. We studied 8 Crohn and 17 Ulcerative Colitis (UC) patients in various disease activities, Crohn Disease Activity Index (CDAI) described by Pam van Hees, and Ulcerative Colitis Activity Index (UCAI) described by Mitsuru Seo were used. We performed endoscopy, ESR, CRP and albumin measurements, whole blood count and leukergy to each patient. As a control group we used 30 age and sex matched healty volunteers with no evidence of any inflammation. In all the IBD patients leukergy values were significantly elevated. The mean leukergy value in control group was 3.33 + 2.6, in UC 20.58 + 5.49, and in Crohon 19.51 + 5.11. Moreover the leukergy test could effectively discriminate between various grades of disease activity. Using correlation analysis we found out that leukergy was the most accurate test in differentiation between various inflammatory states of IBD. Leukergy v UCAI r = 0.89 p < 0.0001, CRP v UCAI r = 0.264 P = 0.305, ESH v UCAI r = 0.5691 p = 0.017, Endoscopy v UCAI r = 0.6804 p = 0.003, Histology v UCAI r = 0.6804 p = 0.003, Leukergy v CDAI r = 0.7857 p = 0.021, CRP v CDAI r = 0.4286 p = 0.289. ESH v CDAI r = 0.0714 p = 0.867. This study has shown that the leukergy this very rapid and economical test is the best indicator in the assessment of the IBD activity. It is obviously superior to other acute phase reactants, and It is even more accurate than endoscopy score defined by Baron and histology scores defined by Truelove. Intestinal disorders: IBD diagnosis, monitoring }" "Leukergy in Inflammatory Bowel Disease; A Test in the Assessment of Disease Activity"

"P P 60 1464"P 60 1464**Inflammatory Bowel Disease in People of Afro-Caribbean Descent**

*N.I. McNeil, LONDON IBD Forum

Ealing Hospital, Southall, UKInflammatory bowel disease had been considered uncommon in immigrant populations in the UK, until studies in Leicester found a high incidence of ulcerative colitis in people of Indian origin. Early studies in Afro-Caribbean immigrants described Crohn's disease only.A postal questionnaire to all doctors registered with the London IBD Forum asked for details of patients of Afro-Caribbean origin having inflammatory bowel disease.Twenty one patients were identified, 13 being female. Eleven patients were born between 1960 and 1969, and 14 out of 18 born in the United Kingdom. Thirteen patients were aged under 30 at the time of diagnosis. Twelve patients had ulcerative colitis (6 total) with only 6 having Crohn's disease. 2 cases were classified as indeterminate colitis.This survey has established that in people of Afro-Caribbean origin: ulcerative colitis is more common than Crohn's Disease. The majority of patients were born in the UK and the disease started at an early age. Immigrants from the Indian subcontinent also have ulcerative colitis more frequently than Crohn's Disease. However inflammatory bowel disease is mostly diagnosed in the immigrant generation with a mean interval of 11 years after arrival in the UK.This survey has demonstrated differences in the occurrence of inflammatory bowel disease that may encourage research into environmental factors in their aetiology. Intestinal disorders: IBD, etiology and geneticsClinical practice: Epidemiology (non cancer) }" "Inflammatory Bowel Disease in People of Afro-Caribbean Descent"

"P P 60 1465"P 60 1465**Quality of Life and Physical Functioning are Different in Crohn's Disease and Ulcerative ColitisL. Neumann, L.R. Odes,**

*H.S. Odes, D. Buskila

Departments of Epidemiology and Gastroenterology and Rheumatic Diseases Unit, Soroka Medical Center and Ben Gurion University, Beer Sheva, IsraelCrohn's Disease (CD) and Ulcerative Colitis (UC) are chronic, debilitating diseases; controversy surrounds their impact on patients' functioning. The aim of this study was to assess and compare the Quality of Life (QOL) and the Physical Functioning of patients with CD and UC.*Methods:* Patients with CD and UC attending consecutively at the Gastroenterology Out-Patient Clinic were evaluated using the Flanagan-Burckhardt 16-item QOL questionnaire (a 7-point scale, where 1 = highly dissatisfied and 7 = highly satisfied) and the Burckhardt 10-item Fibromyalgia Impact Questionnaire (FIQ, a 4-point scale, where 0 = best and 3 = worst functioning). Data were calculated as mean – SD.*Results:* The response rate was 98%. There were 41 CD and 72 UC patients; their ages (43.8 – 14.5, 41.8 – 16.0 yr.), M/F ratio (0.64, 0.89), educational status, percentage working (46%, 47%), mean disease duration (6.8 – 5.3, 8.8 – 8.5 yr.), disease activity indices, and drug treatments were comparable. The QOL of CD patients (5.9 – 1.0) was significantly worse than UC patients (6.3 – 0.6, $p < 0.01$). Specifically, CD patients were less satisfied with relationships with relatives ($p < 0.025$), relationship with spouse ($p < 0.001$), active recreation ($p < 0.025$) and independence ($p < 0.001$). The QOL of 20 CD patients who had undergone surgery (6.0 – 0.9) was not different from 21 CD patients who had not had surgery (5.7 – 1.1). Physical Functioning was worse in CD (0.8 – 0.8) than UC patients (0.4 – 0.6, $p < 0.005$). In particular, the items on physical functioning ($p < 0.005$), ability to do the job ($p < 0.01$) and fatigue ($p < 0.002$) were worse in CD.*Conclusions:* While QOL and Physical Functioning are impaired in both CD and UC, the deficit is appreciably greater in CD patients. This difference cannot be attributed to the demographic or clinical characteristics which were similar in CD and UC. Greater recognition of these impairments will alter the clinical approach to these patients. Intestinal disorders: IBD diagnosis, monitoring }" "Quality of Life and Physical Functioning are Different in Crohn's Disease and Ulcerative Colitis"

"P P 60 1466"P 60 1466**Computerized Clinical Guidelines in Inflammatory Bowel Disease (IBD)E. Ricci,**

*G. Rocca, V. Giura, M. Ribotto, R. Sostegni, M. Astegiano, S. Greco, M.T. Fiorentini, M. Rizzetto, A. Pera

Dipartimento di Gastroenterologia, Ospedale Molinette, Torino, Italia*Purpose* HOLMES is an hybrid artificial intelligence system that integrates three software tools: a) an Expert System b) an Hypertext c) Computer based training. The aims of this Windows 95 based environment are: 1) Interactive teaching and training of practical strategies in IBD related problems for students or practicing physicians 2) Patient specific clinical guidelines for medical decision support in the diagnosis and treatment of suspected IBD 3) Assisted compilation of accurate Computerized Clinical Patient Record 4) Computer guided collection of relevant data in a specific data base.*Software* The medical knowledge of the system is based on the practical experience of gastroenterologist collected by the Delphi's method in a national survey, epidemiological data and a systematic review of the medical literature (1980–1996). The knowledge base consists of production rules compiled in an expert system language developed in C and based on the Rete algorithm. The hypertext is highly integrated with the expert system and can explain the reason for each question and the line of reasoning followed in suggesting or confirming a diagnosis or treatment hypothesis. Patient data activate specific modular agents of the knowledge base and the conclusion of the rules fired suggest the best clinical decision or diagnostic hypothesis. In the first stage, data from medical interview, physical examination and simple laboratory tests are used to decide if the criteria for the hypothesis of IBD are satisfied and the differential diagnosis among ulcerative colitis, Crohn's disease and indeterminate colitis is calculated by the OMGE score. Parallel processing of the same data is used for ongoing differential diagnosis and for the calculation of all the important validated severity scores. Treatment guidelines for Crohn's disease are based on the clinical pattern, global evaluation of the patient and severity scores. Treatment of ulcerative colitis is based on severity scores and extension of the disease. In 50 patients affected by IBD the diagnostic accuracy of the program compared with the independent diagnosis made by expert clinicians and confirmed by 2 year follow up was 94% In 3 cases the correct diagnosis was suggested in the diagnostic list but not as the most probable. This promising preliminary results are being verified in a prospective multicentre study with different case-mix and differential diagnosis contexts. Intestinal disorders: IBD diagnosis, monitoring }" "Computerized Clinical Guidelines in Inflammatory Bowel Disease (IBD)"

"P P 60 1467"P 60 1467**Which Factors Determine Bone Mineral Density in Inflammatory Bowel Disease?**

*S. Ghosh, S.J. Cowen, W.J. Hannan, A. Ferguson

Gastrointestinal Unit, Department of Medicine, University of Edinburgh, Western General Hospital, Edinburgh EH4 2XU, Scotland*Background:* Though low bone mineral density (BMD) is well recognised in inflammatory bowel disease (IBD), the relative roles of corticosteroids and systemic effect of inflammation are not well understood. *Patients and methods:* Three groups of IBD patients were studied. (1) Newly diagnosed patients – who had not received any treatment (15 Crohn's disease (CD), 12 ulcerative colitis (UC)); (2) Patients with intermediate duration of disease (median 3 years) – 14 CD patients (median 3.2 gm corticosteroids) and 10 UC patients (median 2.8 gm corticosteroids); (3) Patients with longstanding disease (median 8 years for CD and 7 years for UC) – 28 CD patients (median 9.5 gm corticosteroids) and 26 UC patients (median 8.6 gm corticosteroids). Lumbar 1–4 and forearm BMD was measured by dual energy X-ray absorptiometry. Records were kept of their smoking status, alcohol intake, bone fracture history, menstrual history, and experience of oral contraceptive pill and hormone replacement therapy. Body mass index was measured, Crohn's disease activity index and Powell-Tuck index (for UC) calculated, and their physical activities graded. *Results:* Both newly diagnosed and intermediate duration patients with CD had a significantly lower lumbar and forearm BMD Z-scores compared with patients with UC. However, in longstanding disease, both CD and UC patients were equally osteopenic. In UC, duration of disease (r = { -}0.78) and cumulative steroid dose (r = { -}0.66) were significantly correlated with BMD Z-scores. In CD however, low BMD Z-scores were not related to CDAI scores at the time of measurement. Biochemical parameters of bone metabolism were normal in all but one patient with CD. Multivariate analysis identified cumulative steroid dose as the variable associated with osteopenia in both CD and UC, with the duration of disease being an additional variable in CD. *Conclusion:* Osteopenia is a feature of newly diagnosed patients with CD, but not UC. With longstanding disease, the role of corticosteroids become more important, and it is the sole cause of osteopenia in UC. "P P 60 1468"P 60 1468**Postprandial Splanchnic Hemodynamics as an Activity Index in Inflammatory Bowel Disease (IBD)**

*D. Ludwig, S. Wiener, G. Jantschek[1], E.F. Stange

Dept of Medicine I, University of L\'fcbeck, Germany

[1] Dept of Medicine II, University of L\'fcbeck, GermanyIncreased splanchnic flow has been shown in IBD by different methods, including Doppler flowmetry. The aim of the present study was the assessment of changes in the overall splanchnic circulation under baseline and stimulated conditions.Nineteen patients with ulcerative colitis (UC, mean age 37 (17–80) yrs.), 20 with Crohn's disease (CD, mean age 30 (20–40) yrs.) and 13 healthy controls (mean age 27 (23–28) yrs.) were evaluated by Doppler US. Mean flow (Vm) and the cross-sectional area of the superior mesenteric artery (SMA), inferior mesenteric artery (IMA) and portal vein (PV) were measured before and 30 minutes after a standardized meal (Fresubin liqu. 5 ml/kgbw). Flow measurements and the derived resistive index were analyzed with regard to clinical and endoscopic criteria of disease activity.Compared to controls baseline Vm of the SMA and IMA was significantly increased in active CD (SMA 67.8%, IMA 100.7%; $p < 0.001$), UC (SMA 28.7%, IMA 353%; $p < 0.01$) and inactive CD (SMA 35.7%, IMA 73.3%; $p < 0.05$). The closest relation to disease activity was observed in CD with ileocoecal involvement ($p < 0.001$) but in pancolitis ulcerosa for IMA flow ($p < 0.005$). In active UC postprandial flow increase was maximal in SMA ($p < 0.001$), but in active CD in IMA ($p < 0.01$). Mean portal flow was not different to controls at baseline conditions, but the postprandial flow increase was significantly higher in active UC ($p < 0.05$) and active ($p < 0.01$) and inactive CD ($p < 0.05$).Postprandial hyperemia is superior to basal flow in the differentiation of active versus inactive CD as well as UC. Intestinal disorders: IBD diagnosis, monitoringIntestinal disorders: Splanchnic circulation, ischemiaRadiology and ultrasound: Diagnosis }" "Postprandial Splanchnic Hemodynamics as an Activity Index in Inflammatory Bowel Disease (IBD)"

"P P 60 1469"P 60 1469**Doppler Ultrasonography Assessment in Inflammatory Bowel Disease (IBD)E. Rolfo[1], S. Grosso, M. Bruno,**

*C. Sategna-Guidetti

Cattedra di Gastroenterologia, Universita' di Torino, Torino, Italy

[1] D.E.A. Medicina, Azienda Ospedaliera S. Giovanni Battista, Torino, Italy*Aim.* to evaluate haemodynamic changes in the Superior Mesenteric Artery (SMA) by means of Echo-doppler ultrasonography in IBD patients.*Patients and Methods.* 32 patients (19 M, 13 F; aged 18–78 years) affected by Crohn's disease (CD) entered the study, of these 19 had active disease with CDAI > 150. 14 patients (8 M, 6 F; aged 21–61 years) were affected by ulcerative colitis (UC). The control group consisted of 14 healthy volunteers (7 M, 7 F; aged 20–73 years) without vascular or inflammatory diseases which could influence splancnic blood flow. Echo-doppler was performed with the patient in supine position after an overnight fast, using an ultrasound equipment with anular phased probe 2.75 Mhz. In each subject we considered the following variables of the SMA: Peak Systolic Velocity (PSV), End Diastolic Velocity (EDV), Resistance Index (RI) calculated as PSV-EDV/PSV. Statistics: results were expressed as mean values and Standard Deviation (SD) and statistical analysis was performed by means of One Way analysis of Variance (ANOVA). Significance was defined as $p < 0.05$.*Results:* PSV (m/s) EDV (m/s) RIC D 1.18 (SD 0.6) 0.3 (SD 0.21) 0.77 (SD 0.1)U C 1.2 (SD 0.35) 0.2 (SD 0.12) 0.84 (SD 0.06)Controls 1.14 (SD 0.2) 0.15 (SD 0.003) 0.86 (SD 0.0002)p > 0.8 0.0226 0.0033*Conclusions:* in Crohn's disease and in ulcerative colitis there is a blood flow increase, probably due to dilatation and congestion of mucosal and submucosal vessels. "P P 60 1470"P 60 1470**Energy Expenditure and Body Composition in Inflammatory Bowel Disease**

*E. Capristo, G. Mingrone, G. Benedetti, A.V. Greco, G. Gasbarrini

Cattedra di Medicina Interna II, Universita' Cattolica del Sacro Cuore, Rome, ItalyWeight loss is a dominant feature in patients with Crohn's disease (CD), while few data at this regard are reported in ulcerative colitis (UC) patients. Aim of the study was to compare body composition, using both direct (bioimpedance) and indirect (anthropometry) methods and resting energy expenditure (REE), measured by indirect calorimetry, in 32 patients with biopsy-proven inflammatory bowel disease (IBD) (18 CD and in 14 UC) in clinical remission (CDAI < 120). The patients did not undergone steroid therapy nor receive parenteral nutrition. Twenty healthy volunteers, matched for sex, age and height were used as a control group. The average weight of CD was significantly lower than that of both controls (mean – SD: 58.1 – 8.17 kg vs 67.2 – 6.51 kg; p < 0.001) and UC (58.1 – 8.17 kg vs 70.2 – 12.1 kg; p < 0.001). Fat free mass was not different between the three groups examined, while fat mass content was significantly lower in CD than both UC and controls (respectively 12.5 – 2.69 vs 16.9 – 7.53 kg; P < 0.05 and vs 17.5 – 4.01 kg; p < 0.001). No difference was found in energy expenditure, both predicted by Harris-Benedict equations and measured by indirect calorimetry among the three groups, while normalizing the REE by body weight, a significantly higher value was found in CD with respect to UC (26.6 – 2.73 vs 24.2 – 2.63 kcal/kg/day; p < 0.05) and to controls (26.6 – 2.73 vs 23.7 – 1.29 kcal/kg/day; p < 0.001). The non protein respiratory quotient was significantly lower in CD compared to UC and controls (0.79 – 0.03 vs 0.83 – 0.02; p < 0.05 and vs 0.86 – 0.04; p < 0.001). In conclusion, CD and UC are substantially different. In fact, CD subjects showed a poor conservation of fat mass coupled with an enhanced utilization of lipids and a high energy expenditure per kg of body weight. These data must be considered in the nutritional management of these patients and as a contribution to lipid tissue wasting in CD. Intestinal disorders: IBD diagnosis, monitoringIntestinal disorders: IBD, therapyNutrition: Metabolism }" "Energy Expenditure and Body Composition in Inflammatory Bowel Disease"

"P P 60 1471"P 60 1471**Cyclosporin in Patients with Inflammatory Bowel Disease**

*T. Naftali, B. Novis, I. Pomerantz, G. Leichtman, Y. Maor, R. Shapira, M. Moskovitz, B. Avidan, Y. Avni, Y. Bujanover

Departments of Gastroenterology Meir, Schnieder, Ichilov, Sheba and Wolfson, Israel*Aim:* to review the experience with cyclosporin in cases of severe inflammatory bowel disease IBD in 5 hospitals in central Israel.*Methods:* Files of all patients treated with cyclosporin for IBD were reviewed. Status of disease was measured by disease activity index (DAI) that gave a maximal score of 21 (NEJM, 1994: 330: 1841–5). End points were operation, relapse or sustained remission for at least 6 months.*Results:* data on 28 patients was available. 15 were females and 13 males, average age was 24.8 (range: 11–48) Two had Crohn's disease and 26 Ulcerative Colitis. Average duration of disease was 37 months, (range: one to 180 months). All patients had an acute severe exacerbation of their disease that did not respond to IV. steroid therapy. Average duration of treatment with cyclosporin IV was 12.7 days (range 9 to 28 days). Average DAI was 14.6 before treatment (range 9 to 21), but dropped to 3.8 after first two weeks of treatment (only 2 patients had an index of more than 10). Complications included 6 cases of hirsutism, one case of allergy, one of pneumonia one of hypertension and one of hemolysis. In no case was treatment stopped because of complications. Despite the good initial response, 8 patients needed a total colectomy within 6 months from the start of cyclosporin, and 6 patients after 6 months, One patient with CD had a good initial response but relapsed after 18 months. In 1 patient treatment was stopped because of non compliance and one was lost to follow up. 11 patients maintained remission for an average of 14 months (range: 7 to 32 months)*Conclusion:* cyclosporin is an effective and safe treatment for induction of remission in acute IBD. In about 50% of patients, long term remission is maintained and they do not need an operation. }" "Cyclosporin in Patients with Inflammatory Bowel Disease"

"P P 60 1472"P 60 1472**Effect of Sacharomyces Boulardii on cAMP Dependent Cl{ -} Secretion in T84 Cells**

*D. Czerucka, P. Rampal

Laboratoire de Gastroenterologie, Facult\'e9 de M\'e9decine, Nice, FranceThe massive secretory diarrhea observed in cholera pathogenesis results from the modification of cAMP regulated Cl{ -} secretion in cryptic cells by cholera toxin (CT) and by mediators (PGE_2, VIP) which are released from subepithelial cells. *Saccharomyces boulardii* (S. boulardii) has been shown to inhibit the CT-induced secretion in rat jejunum. We have identified in the conditioned medium of S. boulardii (Sb-CM), a 120 kD protein which reduces CT and FSK-induced cAMP in intestinal cells. *Aim:* The current study was performed to evaluate the effect of Sb-CM on cAMP mediated Cl{ -} secretion in T84 cells.*Methods:* Secretagogues activation of Cl{ -} secretion was assessed by monitoring the rate of ^{125}I efflux (r.min{ -1}) and the stimulation of cAMP (pmol/min/mg) synthesis by RIA. *Results:* The rate of ^{125}I efflux and cAMP content were determined 2 minutes after addition of PGE_2, VIP or FSK to control monolayers (0 min) or to monolayers exposed for 30, 60 or 90 min to Sb-CM prior the secretagogues addition. The results reported in this table show that these parameters are significantly modified in cells exposed 60 and 90 min to Sb-CM. (Data show mean – SEM, n = 7, * $p < 0.05$) 0 min 30 min 60 min 90 minPGE_2 cAMP 28.9 – 1.4 22.1 – 3.5 14.3 – 1.8* 11 – 1.4*(0.2 \'b5M) r.min{ -1} 0.71 – 0.03 N.D. 0.49 – 0.04* 0.47 – 0.04*VIP cAMP 193 – 25.2 147.5 – 32.5 139 – 8* 112 – 14.5*(1 \'b5M) r.min{ -1} 0.59 – 0.03 0.48 – 0.03 0.42 – 0.04* 0.35 – 0.04*FSK cAMP 48.1 – 2.72 40.2 – 4 34 – 2.3* 26.2 – 2.9*(1 \'b5M) r.min{ -1} 0.49 – 0.04 0.39 – 0.02 0.36 – 0.03* 0.31 – 0.01*Experiments performed with CT, show that the stimulation of cAMP and ^{125}I efflux occurs 45 min after toxin addition to the incubation medium. In cells exposed 60 min to CT and Sb-CM, CT-stimulated cAMP is reduced by 50% (2.84 – 0.34 vs 5.41 – 0.59 in toxin treated cells) and the CT-induced ^{125}I efflux rates the basal level (0.11 – 0.01 vs 0.34 – 0.09 in toxin treated cells). We determined by LDH leakage assays, that T84 cells viability was not affected by Sb-CM.*Conclusions: In vitro,* Sb-CM counteracts the stimulation of cAMP synthesis and related chloride secretion induced by CT and others cAMP mediated secretagogues in T84 cells. These data contribute to the explanation of the benefical effects of the yeast therapy in certain intestinal disorders. "P P 60 1473"P 60 1473**Olsalazine versus Sulphalazine Concerning Sperm Motility, Sperm Count and Sperm Morphology in Patients with Inflammatory Bowel Disease**

*U. Sj\'f6qvist, R. L\'f6fberg, T. Hillensj\'f6, P. Sj\'f6blom, B. Rosenlund

Department of Gastroenterology and Hepatology and Department of Obstetrics and Gynecology, Karolinska Institute, Huddinge University Hospital, Stockholm, Sweden*Background:* Sulphalazine is a well established drug in the treatment of inflammatory bowel disease (IBD), e.g ulcerative colitis and Crohn's disease in the colon. However, in approximately 10–20% of the patients side-effects occur. The most common are allergy, headache and more seldom severe side-effects such as agranulocytosis and hepatitis. A well known side-effect is reversible oligospermia which can cause infertility. Almost all of the adverse reactions can be attributable to the sulphapyridine moiety of the drug. New 5-ASA compounds such as olsalazine does not contain sulphapyridine. Olsalazine consists of two salicylate radicals linked by a diazo bond. Previous case reports in patients allergic to sulphalazine have shown an improved sperm count and sperm quality when given olsalazine (J. Scherpenisse et al, Hetzel et al).*Aim:* To characterize the changes in sperm quality in patients initially treated with sulphalazine, and then switched to treatment with olsalazine.*Methods:* Nine patients, 20–40 years of age, with colonic IBD in remission having received long-term maintenance treatment with sulphalazine, 1 g b.i.d or t.i.d, were offered to participate in the study. The first sperm sample was obtained during sulphalazine treatment. The patients were then switched to olsalazine in an average dose of 500 mg b.i.d. After approximately 4 weeks of olsalazine treatment a second sample was obtained with a third sample after three months. Sperm variables were analysed by CASA, and morphology evaluated using strict criteria.*Results:* A statistical improvement of the sperm quality could be seen between the two samples. Motility was significantly ($p < 0.05$) improved from 32% to 57% ($p < 0.05$). A tendency to improved sperm count and morphology was observed already in the second sample. One patient had azoospermia unrelated to sulphalazine.*Conclusions:* The improvement in sperm motility during treatment with olsalazine suggests that the sulphapyridine or its metabolites are responsible for the seminal toxicity and infertility in patients treated with sulphalazine. The impairment of sperm production seems to be reversible in most cases.

"P P 60 1474"P 60 1474**The Effect of Rectal Prednisolone on Markers of Bone Turnover in Inflammatory Bowel Disease**

*R.J. Robinson, S.J. Iqbal, R.P. Whitaker, K. Abrams, J.F. Mayberry

Gastrointestinal Research Unit, Leicester General Hospital, Gwendolen Road, Leicester, U.K.Very little is known about the effect of rectal steroids on bone metabolism in inflammatory bowel disease. The aim of this study was to determine the effects of rectally administered prednisolone metasulphobenzate on bone turnover in patients with distal colitis.*Methods:* Study design: A longitudinal study comparing biochemical markers of bone turnover before, during and after two weeks of prednisolone metasulphobenzoate (Predfoam, Pharmax) 20 mg twice daily. Patients: Ten patients with active distal colitis were recruited to the study. Oral steroids within previous 8 weeks, rectal steroids within 4 weeks, and disease beyond the sigmoid colon were exclusion criteria. Biochemical analyses were performed on samples obtained before treatment, after 7 and 14 days of treatment and 1 week after cessation. Bone formation markers measured were serum osteocalcin (BGP), procollagen carboxy-terminal propeptide (PICP, ng/ml)) and bone specific alkaline phosphatase (BALP). Urinary deoxypyridinoline (dPyr) corrected for creatinine was measured to assess bone resorption.*Results:* Bone turnover markers are presented as mean (SD) in the table. Pre-steroids 7 days 14 days Post-steroidsBGP (ng/ml) 7.57 (1.8) 6.99 (2.7) 7.01 (1.8) 7.4 (2.3)BALP (U/L) 20.14 (6.5) 20.31 (6.6) 19.0 (6.6) 18.69 (6.9)*PICP (ng/ml) 96.0 (27.2) 95.0 (35.7) 114.0 (40.5) 113.6 (28.0)dPyr (NMOL/L) 6.03 (2.3) 5.28 (1.58) 5.38 (2.26) 9.44 (10.4)*BALP fell significantly after 14 days (Difference in means = 1.14 (1.33) 95% C.I. 0.12 to 2.17, p = 0.03) and was still low 1 week after cessation (Difference in means = 1.46 (1.17), 95% C.I. 0.56 to 2.36 p = 0.006). There was a non significant fall in osteocalcin and no significant change in the other bone turnover markers.*Conclusion:* Alkaline phosphatase and osteocalcin fell during treatment with rectal prednisolone. This suggests an impairment of bone formation which if sustained could lead to osteoporosis. Further study of the effects of rectal steroids on bone metabolism is warranted. "P P 60 1475"P 60 1475**Lupus-Like Syndrome Caused by the Use of 5-Aminosalicylic Acid in Patients with Inflammatory Bowel Disease**

*F.M. Habal, A. Kirkpatrick

The Toronto Hospital, University of Toronto, Toronto, Ontario, CanadaThe newer 5-aminosalycilic acid (5-ASA) preparations used to treat inflammatory bowel diseases (IBD) are reported to have fewer side effects than the Sulfasalazine, a combination of 5-ASA and sulfapyridine. Four patients with IBD, 2 with Crohn's colitis and two with ulcerative colitis developed antinuclear factor antibody positive migratory arthralgia with acute inflammation following the institution of 5-ASA at a dosage of 2 gm–4 gm daily. The arthralgia was asymmetric involving small and large joints. None of these had extraintestinal manifestation prior to the introduction of the drug. All four patients went into remission while the arthropathy began. Despite the use of nonsteroidal anti-inflammatory medications and steroids, the patients continued to suffer from the arthritis. Within 2–6 weeks following the discontinuation of the 5-ASA all their symptoms cleared and the ANA serology became negative. Over a follow-up period of 1–3 years none of the patients developed further arthropathy and remained seronegative. The patients had only minimal gastrointestinal symptoms without further therapy. Test Patient profilePre/Post 1 2 3 4ANA 1:320/0 1:320/0 1:640/0 1:640/0Anti-DNA *(Crithidia)* +/{ -} +/{ -} +/{ -} +/{ -}Anti-DNA (Farr) { -}/{ -} +/{ -} { -}/{ -} +/{ -}ESR (mm/h) 35/16 25/22 48/22 42/40We recommend that patients treated with 5-ASA compounds experiencing acute inflammatory symptoms or clinical deterioration not related to their gastrointestinal disease be screened to rule out a lupus-like reaction. "P P 60 1476"P 60 1476**I.O.I.B.D. Questionnaire on the Clinical Use of Azathioprine, 6-Mercaptopurine, Cyclosporine-A and Methotrexate in the Treatment of I.B.D.**

*S.G.M. Meuwissen, K. Ewe, M.A. Gassull, K. Geboes, D. Jewell, F. Pallone, D. Rachmilewitz, J. Rask-Madsen, R.H. Riddell

PO Box 7057, 1081 HV Amsterdam, the Netherlands*Purpose and Methods:* A questionnaire was mailed on behalf of the I.O.I.B.D. (International Organisation of Inflammatory Bowel Disease) to 300 gastroenterologists, living in the USA/Canada (US/C) (n = 76) and Europe (Eu) (n = 224) (12 countries), to obtain information on the clinical experience of azathioprine (AZA), 6-Mercaptopurine (6-MP), Cyclosporine-A (CSA) and Methotrexate (MTX) in the treatment of patients with I.B.D.. 168/298 (56.4%) of the respondents worked in Univers. Hospitals (UniH) and 58/298 (19.5%) in Gen. Hospitals (GenH). 65% had > 10 y. experience in GI. *Results:* Personal experience existed with AZA (88.4%), 6-MP (33.3%), CSA-A (48.7%) and MTX (36.3%). AZA was prescribed more frequently in Eu (92.6%) than in US/C (74.2%) (p = 0.0002), 6-MP less frequently in the Eu than in the US/C respondents (23.8 and 53.3% resp., p < 0.0001). 69.7% of the respondents always prescribed AZA together with steroids to CD patients, in 62.4% for periods longer than 24 mo. 77.9% had experience with AZA in UC., Eu > US/C (p < 0.0001). AZA had been prescribed by 69 respondents in pregnant patients, without apparent toxicity and acute pancreatitis was seen after AZA by 56.7% respondents; 25 malignancies were mentioned (lymphoma 6{\'b4}, leukemia 3{\'b4}, colon 3{\'b4} and renal carcinoma 4{\'b4}, others 9{\'b4}.). CSA-A had been prescribed in acute UC by 140/291 respondents (63.9% treated < 5 patients per centre, 36.1% 6- > 20 cases) (US/C 45.1%, Eu 49.1%, n.s.). CSA-A results were considered good in 29.5%, acceptable but with recurrences in 58.6% and poor in 14.3%. MTX was prescribed in US/C by 47.8% of the respondents, and by 33.9% in Eu (p = 0.478). Several significant differences were observed between the prescription behaviour of respondents working at UniH and GenH, in relation to participation in clinical trials.*Conclusion:* considerable experience exists in the use of immunosuppressive therapy in IBD, both in US/C and Eu, however differences exist in the choice of immunosuppressives. UniH participate more frequently in clinical trials. The study results may contribute to a better insight in the use of immunosuppressive agents in I.B.D. by a large group of experienced gastroenterologists.

"P P 60 1477"P 60 1477**Ferric Maltol Corrects Chronic Iron Deficiency Anaemia in Ferrous Sulphate Intolerant Patients with Inflammatory Bowel Disease**

*R.S.J. Harvey, L.A. Doig, R.P.H. Thompson, J.J. Powell

Gastrointestinal Laboratory, The Rayne Institute, St Thomas' Hospital, London, SE1 7EH, UKIron deficiency anaemia may occur in inflammatory bowel disease (IBD) but use of oral iron therapy is limited by poor absorption and gastrointestinal side effects. Hence, ferrous sulphate intolerance is common in IBD leading to chronic mild anaemia or necessitating parenteral iron. Ferric maltol is a novel iron compound in which ferric (Fe^{3+}) iron is chelated by the sugar derivative maltol. This complex has low side effects and high bioavailability compared to iron salts and we now report its efficacy in ferrous sulphate intolerant patients with IBD.Eleven patients with IBD (8 Crohn's) and iron deficiency anaemia (ferritin < 15 + haemoglobin < 12 F or 13 M) were recruited. All had documented intolerance to ferrous sulphate precluding its use. Ferric maltol was given b.d. (2 {\'b4} 30 mg of elemental iron) for three months. At baseline, ten symptoms were assessed and each graded from 0 (none)–3 (serious). During treatment, patients similarly recorded their third week of each month symptoms in a diary, and these are presented as the mean daily symptom score per patient (MDSS). Haemoglobin and ferritin levels were measured monthly.All patients fully tolerated ferric maltol. Completed data was obtained for 9/11 patients and all corrected their anaemia. (n = 9) Pre- Treatment Treatment Treatment treatment Month 1 Month 2 Month 3Haemoglobin(mean – SD) g/l 10.9 – 1.8 11.9 – 1.6 12.7 – 1.4 13.4 – 1.0Ferritin(mean – SD) \'b5g/l 7.4 – 3.8 14.0 – 7.3 15.0 – 6.2 21.8 – 8.7MDSS (\'b1 SD) 2.44 – 2.65 2.0 – 1.62 0.76 – 0.49 0.57 – 0.72Despite documented ferrous sulphate interolerance causing chronic anaemia in all patients, there was complete tolerance to ferric maltol and correction of anaemia. A double blind multi-centre trial is in progress. "P P 60 1478"P 60 1478**5-ASA Enemas Increase Mucosal Availability of Mesalamine up to Splenic Flexure**

*G. Frieri, G. Palumbo[1], M.T. Pimpo, A. Viscido, L. Onori[2], G. Latella, G.C. Pantaleoni[1], R. Caprilli

Gastroenterology, University of L'Aquila, L'Aquila, Italy

[1] Pharmacology, University of L'Aquila, L'Aquila, Italy

[2] Clinical Methodology Units, University of L'Aquila, L'Aquila, Italy*Introduction* Pharmacological effects of 5-ASA in ulcerative colitis (UC) is mainly due to its mucosal concentration. 5-ASA is often given by enema to treat left-sided UC, but no data exist either on mesalamine mucosal concentration or the extent of treated mucosa during chronic topical treatment.*Aim* This study was carried out to measure mucosal concentration of 5-ASA in patients with UC treated with both topical and oral 5-ASA (double treatment) compared to patients treated with oral 5-ASA alone (control).*Materials and methods* Sixteen patients with mild to moderate UC limited to the left colon were randomized to receive 2.4 gr. of oral mesalazine (9 patients) or 2.4 oral plus 4 gr. topical mesalazine (7 patients). After two weeks, two endoscopic biopsies were taken in the rectum (inflamed mucosa) and two biopsies at the splenic flexure (normal mucosa). The specimens were weighted, immediately frozen in liquid nitrogen and stored at { -}80\'b0C for later assay. HPLC method was used to determine 5-ASA and Acetyl 5-ASA concentrations (ng/mg) in tissue homogenates. The Wilcoxon's rank test was used for statistical analysis. Data are expressed as median.*Results* Mucosal 5-ASA of both rectal and proximal tracts was significantly higher in double treatment group than in controls. Median values of rectal mucosa were 51.5 and 1.6 ng/mg in double treatment group and in controls respectively ($p < 0.001$). Median values of proximal mucosa were 65.6 and 17.6 ng/mg in double treatment group and in controls respectively ($p < 0.02$). No differences were observed in Acetyl 5-ASA concentration.*Conclusion* Topical treatment significantly increased mucosal 5-ASA concentration at least up to splenic flexure. This finding supports the rationale to treat left-sided UC with 5-ASA enemas and explain the good results obtained in clinical trials in which this treatment was tested. Intestinal disorders: IBD, therapy }" "5-ASA Enemas Increase Mucosal Availability of Mesalamine up to Splenic Flexure"

"P P 60 1479"P 60 1479**Colitis, Non-Steroidal Anti-Inflammatory Drugs (NSAID'S) & Salicylates — A Strong Association**

*M.H. Gleeson, J.V. Hardman, C. Clinton

The General Hospital, Jersey, Channel Islands, UKA prospective study of 62 consecutive new cases of colitis from November 1993 to May 1996 revealed 45 patients who had been taking NSAID's or salicylates. Mean age of patients with NSAID-associated colitis was 40.5 years (range 20–77) and of the others (idiopathic colitis) was 49.9 (range 23–90).No patients had a previous history of colitis and diagnosis was always established by colonoscopy. Patients with NSAID-associated colitis had either distal disease identical in endoscopic appearances to ulcerative colitis (59%), or proximal disease with rectal sparing and discontinuous disease, similar to Crohn's colitis.Crypt abscesses, ulceration and a mixed inflammatory infiltrate were seen but no granulomatas. All patients received standard treatment for inflammatory bowel disease, and 8 (47.1%) of the NSAID group required systemic steroids compared to 18 (40.0%) of the idiopathic group and 15 patients with NSAID-associated colitis have relapsed without further exposure to NSAID's or salicylates and appear to be developing a chronic colitis.A drug history was obtained from a control group of 513 attenders at a minor injuries clinic. The age range of this series was 18–90 (mean 38) years. 38 (7%) were taking NSAID's or salicylates. This compares to 45 (75%) of 62 patients taking NSAID's or salicylates in the colitis group. This gives an odds ratio of 33.1 significantly supporting a causal association between these agents and colitis. They appear to be an important aetiological trigger factor in inflammatory bowel disease.

[1] Department of Immunology, University Hospital, Amiens, France

[2] Department of Gastroenterology, University Hospital, Amiens, France

[3] Department of Hematology, University Hospital, Amiens, FranceActivation of procoagulant factors and inhibition of fibrinolysis may be involved in the pathogenesis of inflammatory bowel diseases. It has been suggested that heparin, acting by its anticoagulant and/or immuno modulatory properties, may be useful in the treatment of inflammatory bowel diseases. *Aim:* To evaluate the effects of heparin on marker of coagulation (F1 + 2), fibrin degradation products (FbDP) and cytokines (IL6, TNF{ a}) serum levels during the treatment of patients with Crohn's disease (CD) or ulcerative colitis (UC). *Methods:* 12 patients (8 CD, 4 UC, age 19–43 yrs) with clinically active disease were included. 4 patients had chronically active CD treated by prednisolone 20–40 mg/d unchanged in the 3-weeks period before and during the study. All patients received heparin either IV (3000 UI/4 hrs), or SC (2500 UI/10 kg bid) for 1 week. F1 + 2, FbDP, IL6 and TNF{ a} blood levels were determined before and after 1-week heparin treatment. *Results:* significant clinical improvement was observed after 1-week heparin therapy in 7/8 patients with CD and 2/4 patients with UC. Normal day 0 day 7 PF1 + 2 nmol/l < 1.1 2 1.5 NSmean (95% CI) (1–3) (0.6–2.5)FbDP ng/ml < 450 617 405 NSmean (95% CI) (159–1075) (134–676)CRP mg/l < 5 79 36 P < 0.02mean (95% CI) (38–120) (15–56)IL6 pg/ml 3–8.5 74.3 42.0 P < 0.02mean (95% CI) (41.7–106.9) (26.6–57.3)TNF{ a} pg/ml 3–20 40.8 27.9 NSmean (95% CI) (22.8–58.9) (22.9–33.9)*Conclusions:* These results suggest that effects of heparin are more likely related to its immunodulatory than its anticoagulant properties. *M. Besnard[1], K. Benali[2], P. Th\'e9rond[3], A. Munck[1], C. Faure[1], J. Navarro[1], J.P. C\'e9zard[1]

[1] Pediatric Gastroenterology

[2] Biostatistics

[3] Biochemistry, Hospital Robert Debr\'e9, ParisIn order to assess the activity of CD in children, clinical and/or biological scores (Harvey-Bradshaw [HB], Pediatric Crohn Disease Activity Index [PCDAI]) have been defined. Biologic data included hematocrit (HT), erythrocyte sedimentation rate (ESR) and albumin (ALB). Recent laboratory parameters have been shown to be well correlated with CD inflammation in adults: C reactive protein (CRP), orosomucoid (ORO) and haptoglobin (HAP), but pediatric data are scarce.*Population:* 34 children (17 M, 17 F) treated for CD, mean age of 15 years. Follow-up: 21 months (Feb 92–Nov 93), mean interval between 2 measurements of 24 days.*Results:* On the 127 blood samples, the univariate study shows a highly significant difference of the three parameters between the acute (A) (PCDAI > 30, HB > 6) and the quiescent (Q) status of CD. We observed an excellent reproductibility of the 2 scores (correlation coefficient = 0.98). Variable A Q P (p < 0.01) Sen Spe PPV NPV (%) (%) (%) (%)HT 32.9 – 1.4 36 – 0.4 0.01 17 89 20 87VS 43 – 6.5 25.8 – 1.7 0.004 94 23 16 96ALB 29.9 – 1.5 35.6 – 0.6 0.004 29 95 50 89CRP 18.45 – 8.3 7.55 – 0.6 0.0005 58 70 23 91ORO 1.66 – 0.17 1.1 – 0.03 < 0.0001 94 16 14 94HAP 3.85 – 0.53 2.64 – 0.1 0.002 94 15 14 94Statistical diagnostic tests shows that sensibility (Sen) of ORO and of HAP is high (94%) as much as ESR, but their specificity (Spe) is low (15–23%). CRP seems to be the more specific biologic parameter (70%) but is not sensible (58%). However, NPV of these 3 acute phase proteins is very high (NPV {\'b3} 87%) but their PPV is still poor (VPP {\'a3} 50%). In multivariate study, CRP remains the best indicator of CD activity (OR 4.55; CI 1–20).These results suggest that no single laboratory test appears an adequate reflect of CD activity in childhood. Their increase is well correlated to CD activity index, mainly CRP. Their normality has a strong negative predictive value. Their poor PPV may reflect the weak correlation between clinical and endoscopic scores of CD activity. Intestinal disorders: IBD diagnosis, monitoringImmunology and microbiology: Inflammation }" "Acute Phase Reactants in Pediatric Crohn's Disease (CD): Interest and Predictive Values"

"P P 61 1482"P 61 1482**Thrombotic Risk Markers in Inflammatory Bowel Disease (IBD) in Children**

*M. Besnard[1], M.F. Hurtaud-Roux[2], Z. El Mountassir[2], K. Benali[3], A. Munck[1], N. Schlegel[2], J. Navarro[1], J.P. C\'e9zard[1]

[1] Pediatric Gastroenterology

[2] Biological Hematology

[3] Biostatistics, Hospital Robert Debr\'e9, ParisSevere thromboembolic events (TEE) are not uncommon in IBD. Their incidence ranges from 1 to 39%, occurring mainly during severe episodes with extensive colic lesions and after surgery. In adults, these TEE have been found to be associated with coagulation/fibrinolysis anomalies, probably related to intestinal vasculitis and increased cytokine production.*Aim of the study:* assessment of the thrombotic risk in children IBD in order to recommend a preventive treatment*Patients and methods:* 34 children (139 samples) with IBD (Crohn disease (n = 29), undetermined colitis (n = 5)) were clinically assessed by the Pediatric Crohn disease Activity Index (PCDAI) (flare-up defined by a PCDAI > 30). The thrombotic risk has been assessed by platelet numeration, dosage of main coagulation factors (I, II, VII + X, V, VIII, von Willebrandt factor (vWF)) and inhibitors (antithrombin, proteins C and S), fibrinolytic activity (tissue-plasminogen activator (t-PA) and its main inhibitor, PAI-1), markers of coagulation activation (D-Dimers, thrombin-antithrombin complexes) and endothelial markers (thrombomodulin (TM) in addition to vWF and t-PA).*Results:* In univariate analysis comparing active and quiescent disease, it has been found a significant increase of platelets (p = 0.005), fibrinogen (p = 0.00001), D-dimers (p = 0.01) and factors V (p = 0.005), VIII (p = 0.003) and vWF (p = 0.0002). Coagulation inhibitors, fibrinolytic system components and TM remained unmodified. In multivariate study, vWF and fibrinogen were significantly increased in active disease, with OR values of 21.2 (CI = 3.2–141) and 21.9 (CI = 1.84–262) respectively.In summary, during active IBD in children a hypercoagulable state with coagulation activation, able to induce TEE, has been observed, associated with anomalies of one marker of endothelial lesions (vWF). A preventive anticoagulation should be proposed in high-risk relapses of IBD in children in order to reduce the thrombotic risk (which can be fatal), and perhaps have a therapeutic effect on the intestinal vasculitis. Intestinal disorders: IBD diagnosis, monitoring }" "Thrombotic Risk Markers in Inflammatory Bowel Disease (IBD) in Children"

"P P 61 1483"P 61 1483**Crohn's Disease in Children 8 Years Old and Younger**

*H. Piloquet, D. Martin, O. Goulet, V. Colomb, B. Cuenod, R. Salomon, J. Schmitz, C. Ricour

Service de Gastroent\'e9rologie et Nutrition P\'e9diatrique, Hospital Necker Enfants Malades, 149, rue de Sévres, Paris, FranceDiagnosis of Crohn's disease (CD) before 8 years in rare. Few studies interested about this population. The purpose of this report was to examine the presentation, course and outcome of CD in children < 8 years old and to compare them with a group of older children.*Population:* We studied retrospectively 61 children in whom diagnosis of CD was made. Patients were categorized as the age at onset of disease in two groups. First one (G1) included 16 children < 8 years old at date of onset of disease (11 boys, 5 girls); group 2 (G2) (control group) included 45 children whose disease had been diagnosed after 8 years (26 boys, 19 girls).*Methods:* To compare them, records as diagnosis delay, clinical features, topography of lesions, recurrences and long term prognosis were reviewed. Statistical analysis was made with the Student's t test and Chi 2 test.*Results:* the difference of mean diagnosis delay between G1 and G2 was significative (respectively 22 months versus 12 months, $p < 0.05$). Anorectals lesions, bloody stools and anal fissures were more frequent in the G1 ($p < 0.05$). Ileocolic or colic localisations represented 94% of children of G1 et 62% of G2 ($p < 0.05$). Parenteral nutrition (PN) was longer in G1 than in G2 (42 months versus 12 months, $p < 0.001$). Surgical colic or ileocolic resections were more frequently necessary in G1 (84%) than in G2 (45%) ($p < 0.01$). Ileostomy was done in 54% of patients in G1 versus 21% in G2 ($p < 0.02$). Sequels as enterostomy were more frequent in the G1 (44%) than in the G2 (11%) ($p < 0.01$). The definitive height was under { -}0.5 SD (Standard Deviation) in 50% of the patients and under { -}1.5 SD in 15% of the patients. There was no significative difference between the 2 groups.*Conclusion:* in the childhood CD, the onset of the disease before 8 year's old is a index of severity. Colic localisation was more frequent. Aggressive medical (PN) and surgical therapeutics (large resections) were often necessary to control the illness. The sequels were more frequent than in children who began after 8 years (enterostomy). Thanks to that aggressive treatments, the height was similar in the 2 groups. }" "Crohn's Disease in Children 8 Years Old and Younger"

"P P 61 1484"P 61 1484**Congenital Secretory Diarrhea Associated with Choanal Atresia in Two Unrelated Children**

*Y. Finkel, E. Beijer, U. Myrdal, B. Bj\'f6rnestam

Dept. of Woman and Child Health, Karolinska Institutet, Stockholm, SwedenIntractable diarrhea in infancy due to specific syndromes such as congenital microvillus atrophy, autoimmune enteropathy, chloridorrhea and defective jejunal brush-border Na/H exchange have been described. We report 2 cases of congenital diarrhea in association with choanal atresia in unrelated children and propose that this may constitute a new syndrome. *Case 1.* A newborn fullterm boy was referred to ICU for respiratory care due to bilateral choanal atresia. At 2 weeks age he developed severe watery diarrhea and became hyponatremic. The diarrhea persisted in spite of cesssation of oral intake and has persisted until present age 20 months. Stool sodium was 125 mmol/l, stool osmotic gap < 50. Histological and electrone microscopy (EM) examination of small bowel biopsy (A Phillips, London), autoantibodies against gut-epithelium (R. Marakian London), gastrointestinal peptides, tests for inborn erros of metabolism, chromosome analysis, EM of nasal cilia, xylose challenge were all normal. By performing an ileostomy at 15 months of age we demonstrated an ileal output of 100–120 ml/kg/d but no secretion from the large intestine. He is maintained on TPN, linear growth and psychomotor development is normal. *Case 2.* A fullterm girl was admitted to ICU at 2 weeks of age for dehydration and hyponatremia with seizures due to severe watery diarrhea. The diarrhea has since persisted., in spite of no oral intake. Stool sodium 110 mmol/l, fecal osmotic gap < 50, histological examination of small and large bowel and biopsies, EM of small bowel biopsy, gastrointestinal peptides, metabolic tests, chromosome analysis, autoantobodies against gut-epithelium were all normal. At 2 months of age unilateral choanalatresia was demonstrated by CT scan. She also has a congenital defect in factor V causing severe coagulopathy and requires i.v. warfarin for maintaining vascular access for TPN. Her linear growth and psychomotor development is normal, she is on full TPN with minimal enteral feeding. Further studies to elucidate this proposed syndrome are warranted. Intestinal disorders, absorption: Pathophysiology of diarrheaIntestinal disorders, absorption: Malabsorption syndromes }" "Congenital Secretory Diarrhea Associated with Choanal Atresia in Two Unrelated Children"

"P P 61 1485"P 61 1485**High Prevalence of Positive Antibody Response Against Gliadin in Children and Parents of Children with Coeliac Disease**

*S. Belmer, Y. Lebedin

Russian Media University, Moscow, Dept. of PediatricsCoeliac disease is a gluten intolerance with malabsorption syndrome, based on any genetic disorders.Serum IgA and IgG antibodies to alpha (AGA) or crude (CGA) gliadin by commercial EIAs (Labodia and Pharmacia, respectively) were measured in children with biopsy-proven coeliac disease and their first-degree relatives.Among 18 full family records (AGA test), at least one of the parents was positive in 6 cases; both of the parents – in 10 cases. AGA test reveals more positive relatives than CGA EIA. False-negative results for CGA were obtained in 43% against IgA AGA and 50% against IgG AGA. None of AGA positive adults showed clinical symptoms of coeliac disease. The gluten-free diet influenced to level of antibodies. All patients with untreated coeliac disease expressed serum IgA and IgG antibodies to bovine serum albumin (BSA) and only 1/5 of these expressed serum IgA and IgG antibodies to ovalbumin (OVA). In cases of treated coeliac disease the level of antibodies to BSA decreased and antibodies to OVA on the contrary increased. The first-degree relatives expressed low level of mentioned antibodies and unimportant differences with non-coeliac patients and their parents. *Conclusions.* The positivity for anti-gliadin (especially alpha-gliadin) antibodies in healthy parents could represent a risk factor of development of full scale coeliac disease in children and, probably, represent the genetic predisposition of immune system to abnormal response on gliadin but not to gut affection. The limitation of bovine products and eggs in coeliac patient's diet should be discussed. Intestinal disorders, absorption: Malabsorption syndromesIntestinal disorders, absorption: Gluten enteropathyIntestinal disorders, absorption: Malabsorption: children }" "High Prevalence of Positive Antibody Response Against Gliadin in Children and Parents of Children with Coeliac Disease"

"P P 61 1486"P 61 1486**Mediators of Inflammation in Children with Inflammatory Bowel Disease**

*S. Nousia-Arvanitakis, M. Hatzistilianou-Sidiropoulou, C. Agguridaki, V. Tsavdaridou, M. Xefteri, A. Galli

4th and 2nd Depts of Paediatrics and Serology Laboratory, Aristotle University of Thessaloniki, Thessaloniki, GreeceInflammatory bowel disease in children remains the most challenging problem in gastroenterology. Crohn's disease and ulcerative colitis are characterised by an activation of intestinal mononuclear cells and T-cells within the inflammed lesions. The aim of the present study is to determine whether circulating inflammatory mediators, such as interleukins and adhesion molecules, represent useful markers of immune activation in vivo and to characterise their respective roles in monitoring disease activity. Serum concentrations of IL-2, IL-6, IL-8, IL-10, sIL-2R, sICAM-1 and sVCAM-1 were measured in 18 patients with inflammatory bowel disease, 8 with Crohn's disease (CD), 10 with ulcerative colitis (UC) and in 25 healthy subjects (control group, CG). The mean values and standard errors are shown in the table. Inflammatory CD UC CGmediators n = 8 n = 10 n = 25IL-2 (pg/ml) 108 – 12 80 – 24 15 – 3IL-6 (pg/ml) 49 – 5 39 – 4 9 – 2IL-8 (pg/ml) 245 – 39 198 – 24 23 – 9IL-10 (pg/ml) 167 – 25 138 – 28 41 – 7sIL-2R (IU/ml) 5518 – 415 3778 – 790 984 – 85sICAM-1 (IU/ml) 1632 – 116 852 – 34 254 – 18sVCAM-1 (IU/ml) 2086 – 153 1459 + 127 576 – 27*Conclusions:* All the inflammatory mediators are significantly increased in patients with CD and UC as compared to the control group. Pro-inflammatory mediators (IL-6, IL-8, IL-10) are elevated in the serum of patients with active disease, suggesting that they act as naturally occurring initiators in the acute inflammatory process. Increased IL-2 and sIL-2R levels reflect T-cell activation. Increased circulating sICAM-1 and sVCAM-1 levels may reflect increased adhesiveness and signal transmission across cells, probably as a result of shedding of the parent molecule during local cellular immunoresponses in vivo. The measurements of all these mediators may be useful adjuncts to clinical assessment and to routine laboratory testing in pediatric patients with CD and UC. "P P 61 1487"P 61 1487**Carbohydrate Intolerance after Gastroenteritis — A Disappearing Problem also in Polish Children?**

*H. Szajewska, M. Kantecki, J. Antoniewicz, P. Albrecht

Dept of Pediatric Gastroenterology & Nutrition, Warsaw University Medical School, Poland*Background:* Frequency of carbohydrate intolerance after acute gastroenteritis, and its importance, varies widely from centre to centre. In Western Europe its frequency decreased from 50–70% in 1970's to 0–5% in 1990's. The change from high-solute to low-solute, less sensitising modern adapted formula is considered to be a key factor.*Aim:* to investigate the incidence of carbohydrate intolerance after acute gastroenteritis in Polish children.*Method:* 125 consecutive children less than 3 years of age who were admitted to our hospital with acute gastroenteritis (defined as acute onset of watery or extremely loos stools with or without vomiting for no more than one but less than five days) were entered into the study. Standard treatment – ORS for 4–12 hours followed by refeeding with the usual diet – was given. Carbohydrate intolerance (diagnostic criteria: > 0.5% reducing substances and stool pH < 5.5) was assessed.*Results:* carbohydrate intolerance was diagnosed in 16 of the 125 [12.8%] of the children: lactose intolerance was present in 12 [9.6%] patients; glucose polymer intolerance in 3 [2.4%] and monosaccharide intolerance in 1 [0.8%]. 75% of the children (12 out of 16) with carbohydrate intolerance were under 12 months. The most important predisposing factor was rotavirus. In all cases the carbohydrate intolerance was transient resolving by five days.*Conclusions:* The study confirms the observation from Western Europe that carbohydrate intolerance after acute gastroenteritis is infrequent event also in Polish children though its incidence is higher compared with other countries. Restriction of lactose containing foods (use of lactose free formula) for the vast majority of children with gastroenteritis does not appear to be justified. Immunology and microbiology: GI infection, children }" "Carbohydrate Intolerance after Gastroenteritis / A Disappearing Problem also in Polish Children?"

"P P 61 1488"P 61 1488**Cyclosporin Induced Remission for Children Suffering from Ulcerative Colitis**

*R. Shapiro[1], T. Naftali[2], I. Zahavi[1], Y. Rosenbach[1], A. Hirsch, Y. Bujanover[3], G. Dinari[1]

[1] Division of Pediatric Gastroenterology and Nutrition, Schneider Children's Medical Center of Israel, Israel

[2] Division of Pediatric Gastroenterology and Nutrition, Meir Hospital, Israel

[3] Division of Pediatric Gastroenterology and Nutrition, Dana Medical Center, IsraelCyclosporin has been used successfully in adults suffering from fulminant refractory ulcerative colitis (UC), by avoiding immediate surgery in 75% and inducing long term remission in 55% of patients.Over the last five years we studied the effectiveness of cyclosporin in 12 children aged 10–17 years (mean 14.25 years). They were admitted to the hospital for fulminant refractory UC.. Treatment was begun with intravenous cyclosporin 4–8 mg/kg/24 h, aiming at blood trough level of 150–250 ng/ml. Oral cyclosporin therapy was begun after remission was achieved, usually within 2 weeks.*Results:* Clinical improvement was noticed in all the patients but one (91.7%) within 3—10 days. Five patients are in remission, 14–34 months after cyclosporin treatment for 6—8 months. Another patient is in remission 2 months after initiation of therapy. Four patients had an exacerbation of the disease while on cyclosporin treatment. Remission lasted 8.7 weeks on the average, with a range of 2–24 weeks. Another patient had an exacerbation one year after cessation of a six month cyclosporin course. All of these 5 patients subsequently underwent surgery.*Conclusions:* Cyclosporin is effective in achieving clinical remission in 91.7% of children suffering from UC, Although surgery may only be delayed in about 50% of the cases, it can be done under non emergent conditions. Intestinal disorders: IBD, therapy }" "Cyclosporin Induced Remission for Children Suffering from Ulcerative Colitis"

"P P 61 1490"P 61 1490**Comparison of Absorbtion of Macronutrients from a Defined Semi-Elemental Diet Containing Medium and Long Chain Triglycerides (MCT and LCT) in Children with Persistent Diarrhoea (PD)**

*P.K. Bardhan, N.H. Alam, M.A. Wahed, S.M. Akramuzzaman, D. Mahalanabis, K. Gyr

International Centre for Diarrhoeal Disease Research, Bangladesh

Dept. of Gastroenterology, Basle University, SwitzerlandPersistent diarrhoea (an episode of diarrhoea continuing for > 2 weeks) in children is associated with malabsorbtion (particularly of fat), malnutrition, and a high mortality rate. This study compares macronutrient absorbtion in children with PD treated with a diet containing either coconut oil (relatively rich in MCTs) or soybean oil as the source of dietary fat.*Methods:* Seventy male patients aged 3–12 months with PD were randomly assigned to one of the two dietary groups. The study diets contained minced chicken meat, glucose, and either coconut oil or soybean oil. A 72 hours balance study was started after a 24-hr prebalance. Aliquots from 72-hr homogenized stool, vomitus, urine, study diets and breast milk samples were preserved at { -}70\'b0C until analysed. The coefficients of absorption of fat, protein and carbohydrate were calculated as percentages, and the results are expressed as mean – SEM.*Results:* Thirty three and 37 patients received diet 1 (coconut oil-based) and diet 2 (soybean oil-based) respectively. The patients belonging to the two groups were comparable in age, body wt., nutritional status, duration of diarrhea, and socioeconomic status. The coefficients of absorbtion of the macronutrients are: Diet 1 Diet 2 pFat 60.4 – 4.8 61.0 – 4.0 0.924Protein 32.3 – 3.6 34.3 – 3.0 0.666Carbohydrate 64.4 – 4.8 62.7 – 5.5 0.813There were no significant difference between the two groups on stool output, nutrient intake or subsequent clinical course.*Conclusion:* There is significant malabsorbtion of macronutrients, particularly fat, in children suffering from PD, and dietary substitution of LCT containing dietary fat (soybean oil) by MCT-rich coconut oil has no effect upon macronutrient absorbtion. Intestinal disorders, absorption: Malabsorption: childrenNutrition: Nutrition: children }" "Comparison of Absorbtion of Macronutrients from a Defined Semi-Elemental Diet Containing Medium and Long Chain Triglycerides (MCT and LCT) in Children with Persistent Diarrhoea (PD)"

"P P 61 1491"P 61 1491**The Frequency of Surgery in Children with Crohn's Disease****Gabriella Palmer[1], Andreas Henschen[2], Rutger Bennet[2],**

*Yigael Finkel[2]

[1] Dept of Pediatric Surgery, Karolinska/S.t G\'f6ran's Children's Hospital, Stockholm, Sweden

[2] Dept of Pediatrics, Karolinska/S.t G\'f6ran's Children's Hospital, Stockholm, SwedenThe treatment of children with IBD in our hospital has changed during the last 15 years. New medical and nutritional therapies have been introduced, and a closer cooperation between the paediatric and paediatric surgery units has been established. This retrospective study has focused on the frequency of surgical procedures on patients with Crohn's disease from diagnosis in childhood to adulthood.*Subjects:* During 1980-1992 117 children with IBD were diagnosed and followed for 3–15 years. 52 had Crohn's disease, 44 ulcerative colitis, 21 indetermined colitis. 23 of the patients with Crohn's disease were referred to internal medicine/surgical departments at 18 years of age.*Results:* 52 patients with Crohn's disease were diagnosed at a mean age of 11.9 years. 35 underwent surgery at one or more occasions in our departments before the age of 18 years. After 2.5 years of disease duration 50% of the children had undergone therapeutic surgery, the main indications being growth failure and/or retarded puberty in spite of intensive medical and nutritional therapy. In the first surgical event the majority of operated children (17/35) underwent an ileoceacal resection, anal fistula operations was performed in 8/35 and other resections of ileum and/or colon were performed in 7/35. 2 children underwent explorative laparotomy. Elective operations preceeded by nutritional therapy were predominant and only two emergency operations were carried out. 5/23 referred to other departments were operated after the age of 18.*Conclusion:* Surgical treatment remains important in the therapy of Crohn's disease in children in spite of new therapeutic modalities. Close cooperation between paediatricians and paediatric surgeons improves the right timing of the procedures. }" "The Frequency of Surgery in Children with Crohn's Disease"

"P P 61 1492"P 61 1492**Screening for Coeliac Disease in Autoimmune Thyroid Disease****M. Bruno, S. Predebon, A. Carlino, E. Mazza, C. Brossa, S. Grosso,**

*C. Sategna-Guidetti

Dipartimento di Medicina Interna. Universita' di Torino, ItalyAn increased frequency of thyroid abnormalities has been reported in patients with coeliac disease (CD), while the occurrence of CD among patients with autoimmune thyroid disease (ATD) is still poorly documented. *Aim:* To evaluate CD prevalence in an adult population with ATD. *Method:* The study was entered by 103 patients (18 males, 85 females) with either Hashimoto's thyroiditis or Graves' disease, none of whom taking steroids nor medications able to interfere with immunological response, nor with selective IgA deficiency. The serological screening was performed by means of IgA antiendomysium antibodies (EmA) appraised by indirect immunofluorescence on commercial slides of monkey oesophagus. Statistical analysis was performed by calculating the 95% confidence intervals of the standardised ratio (observed number/expected number of CD patients); the ratio was considered as significant ($p < 0.05$) if the confidence interval did not contain 1.00. *Results:* EmA positivity was found in 3 out of 103 patients (2.91%). All 3 underwent intestinal biopsy that showed in all total or subtotal villous atrophy. None of these subjects had overt clinical signs of malabsorption nor impaired nutritional indexes. Considering that CD prevalence is close to 1:300, the expected number of CD patients would have been 0.34 (Standardised Ratio = 8.82 with confidence intervals from 1.8 to 25.78) [$p < 0.05$].*Conclusions:* Prevalence of CD among ATD patients is significantly higher than in the general population, probably because of a genetic link through same HLA aplotypes. We consider worthwhile the screening of ATD patients for silent CD. Intestinal disorders, absorption: Gluten enteropathy }"

"P P 61 1493"P 61 1493**Postheparin Plasma DAO Activity and Xylose Absorption Test-Correlationes with Jejunal Biopsy in Children with Protracted DiarrhoeaE. Toporowska-Kowalska, K. Wasowska-Kr\'f3likowska, W. Fogel, W. Kozlowski**

Medical University, Polish Academy of Science, Military Academy of Medicine, Lodz, PolandThe aim of the present paper was to attempt to answer the question, whether postheparin plasma DAO activity test may be an indirect non-invasive exponent of the morphological findings of small intestinal mucosa in children with protracted diarrhoea (pd) and its comparrision with xylose absorption test. DAO is an enzym which main sourse is the alimentary tract where the highest DAO's activity is observed in mature entrocytes. The study was carried out in a group of 45 children with pd. In all the children with pd jejunal biopses, xylose absorption test and DAO test were performed. The applicability of both tests was assessed by determining thier correlation with the degree of jejunal villous atrophy. Only a weak negative correlation of xylose absorption test with the degree of jejunal villous atrophy was observed in of children below 2 years of age (r = { -}36; p < 0.1). The percentage of consistent findings was only 36%. Analogous statistical analysis carried out for the DAO test demonstrated that as the atrophic changes in small intestinal villi progress, postheparin plasma DAO activity activly values, coresponding to the particular degrees of jejunal villous atrophy as well as those obtained for control group demonstrated statistically significant differences (0.60 vs 1.12 vs 1.62 vs 2.43 pmol/min/mg protein;)*Conclusiones:* 1/postheparin plasma diamine oxidase activity test (DAO test) allows for the differentiation of patients with normal and damaged jejunal mucosa barier; 2/DAO test is correlated with the degree of jejunal villous atrophy and other morphological indices of mucous membrane damage; 3/DAO test- unlike the xylose absorption test- is corelated with the degree of jejunal villous atrophy; independently of the age of children with protracted diarrhoea and stage of the diagnostic process. Intestinal disorders, absorption: Malabsorption syndromes }" "Postheparin Plasma DAO Activity and Xylose Absorption Test-Correlationes with Jejunal Biopsy in Children with Protracted Diarrhoea"

"P P 62 1494"P 62 1494**Beneficial Effects of DA-9601, Extract of *Artemisia Asiatica,* in TNB-Induced Experimental Colitis in the Rat**

*K.B. Hahm, B.O. Ahn, T.Y. Oh, W.B. Kim, J. Yang, K.J. Lee, J.H. Kim, S.W. Cho

Dept. of Gastroenterol., Ajou Univ. School of Med. and Research Lab., Dong-A pharmaceutical, Suwon, KoreaThe aim of the present study was to investigate the effect of DA-9601, extracts of *Artemisia asiatica,* which was known to possess mucoprotective effect either by free radical scavenging effect or increase of mucus secretion, against experimental colitis induced by trinitrobenzene sulfonic acid (TNB) in a rat model of inflammatory bowel disease. Colitis was induced in 7 week-old male SPF Sprgue-Dawley rats by a rectal administration of TNB (20 mg in 1 ml of 30% ethanol). To investigate the effects of DA-9601 on experimental colitis, rats were provided with diet containing mesalazine 25 mg/kg/day (group 1), mesalazine 50 mg/kg/day (group 2), DA-9601 5 mg/kg/day (group 3), DA-9601 25 mg/kg/day (group 4), and DA-9601 125 mg/kg/day (group 5) or vehicle (saline 1 ml). 10 rats participated in each treated group and control group. Rats were sacrificed at the 7th and 15th day after each drug treatment. Macroscopic and microscopic damage score of the last 10 cm of colon was determined according to the criteria by Wallace (J Physiol Pharmacol 66: 422, 1987) and Murthy (Dig Dis Sci 38: 1722, 1993). Thiobarbituric acid-reative substances (TBA-RS) and myeloperxidase (MPO) activities in the colonic homogenates were determined. TNB induced severe colonic lesions and significant decreases in antioxidants in the colonic mucosa. In all TNB colitis group treated with DA-9601 (group 3, 4, 5), histologic damage scores were significantly improved when compared with their respective controls and mesalazine group. Macroscopic damage scores were significantly lower in DA-9601 treated group compared with those of control or mesalazine treated group (0.60 – 0.8 vs 3.7 – 2.8, $P < 0.01$). In comparison with control and group 1, 2, group 3, 4, 5 showed decreased MPO and TBA-RS activities dose-dependent manner. In conclusion, DA-9601 was effective in reducing macroscopic and histologic scores in TNB induced colitis and could be a promising drug for the therapy of inflammatory bowel disease.
Intestinal disorders: IBD, therapy }" "Beneficial Effects of DA-9601, Extract of Artemisia Asiatica, in TNB-Induced Experimental Colitis in the Rat"

[3] Department of Human Pathology, ""G. D'Annunzio"" University, Pierangeli Clinic, Pescara, Italy

[4] Institute of Visceral and Transplantation Surgery, University of Berne, Switzerland*Purpose and aims:* The etiology of inflammatory bowel disease is not clearly understood; there is evidence that several neuropeptides, including substance P, play a role. Therefore, we evaluated the ability of a novel SP-antagonist (SR140333) in modifying the course of experimental colitis induced in the rat by trinitrobenzensulfonic acid (TNB). *Methods:* Colitis was induced in 12 rats using TNB administered with an intrarectal enema. Six rats were treated with SR 140333 by intraperitoneal route (1.0 mg/kg) 30 minutes before the administration of TNB and every day until the sacrifice. Ten rats receiving only an intrarectal 0.9% saline served as controls. Rats were killed 14 days after the induction of colitis. 1 cm strips were collected for morphological and contraction studies. *Results:* The TNB group showed a higher score of inflammation, as assessed by histology and a greater weight of strips than controls; in addition, smooth muscle contractility was significantly reduced in inflamed colon than in controls. SR 140333 reduced inflammation and motor alterations caused by TNB. TNB Controls TNB + SP antagWeight (gr.) 0.303 – 0.03 * 0.135 – 0.01 0.191 – 0.03#Infl. score 8.6 – 0.27 * 1.6 – 0.19 4.0 – 0.7#CARB (mg/mm^2) 91.3 – 24.4 * 257.1 – 32.2 150.9 – 15.3#SP (mg/mm^2) 22.1 – 4.4 * 83.4 – 9.3 32.5 – 3.1#KCl (mg/mm^2) 47.7 – 1.7 * 89.9 – 15.1 125.9 – 12.1#*p < 0.01 vs. controls; #p < 0.01 vs. TNB*Conclusions:* Treatment with SR140333 reduces the degree of inflammation and the concomitant alterations of contractility during TNB colitis. These findings suggest a role by substance P in the pathogenesis of colitis. The blockade of substance P may represent a reliable strategy in the treatment of intestinal inflammation. "P P 62 1496"P 62 1496**Recombinant Factor XIII Replacement Therapy: Studies in a Rat Model of Experimentally Induced Intestinal InflammationA. Grossmann, K.H. Sprugel, C. Hart, P. Strange,**

*P.D. Bishop

ZymoGenetics, Inc., Seattle Washington USA and D'Argenio G, Cosenz V. Cattedra di Gastroenterologia, Universita' Federico II, Napoli, ItalyCoagulation factor XIII (FXIII) is the plasma borne transglutaminase which serves as the terminal enzyme in the clotting cascade. There is growing evidence that FXIII levels in the plasma of UC and CD patients are lower than normal and that there is a significant inverse correlation of FXIII with clinical severity.In order to better understand the potential use of FXIII replacement therapy in IBD, we have investigated the effects of recombinant FXIII treatment in a widely used animal model for IBD; TNBS induced chronic inflammation and ulceration of the rat colon. The effects of FXIII were assessed vis a' vis both positive (5-ASA), and negative (BSA) controls over a 28 day time course. The severity of lesions was determined by colon weight, macroscopic and histologic scores and transglutaminase activity was measured in both serum and colon tissue.Results indicate that in this model, lesion severity inversely correlated with transglutaminase levels. Consistent with these observations, rFXIII treatment restored serum and tissue transglutaminase levels and very significantly reduced lesion severity. Additionally, rFXIII treatment reduced the time to recovery for both developing and established lesions and was efficacious for at least 18 days after treatment was discontinued.These results indicate that FXIII replacement therapy is effective in an animal model of induced colitis and suggests its potential usefulness in the treatment of human inflammatory bowel disease. Intestinal disorders: IBD, basicIntestinal disorders: IBD, therapyIntestinal disorders: IBD diagnosis, monitoring }" "Recombinant Factor XIII Replacement Therapy: Studies in a Rat Model of Experimentally Induced Intestinal Inflammation"

*K. Ariake[1], T. Ohkusa[1], S. Hosi[2], T. Yajima[2], I. Takashimuzu[1], K. Fujiki[1], A. Araki[1], K. Shimoi[1], K. Honda[1], Y. Enomoto[1], T. Sakurazawa[1], T. Horiuchi[1], S. Suzuki[1], K. Ishii[1]

[1] First Department of Internal Medicine, Tokyo Medical and Dental University School of Medicine, Tokyo

[2] Nutrition Science Institute, Meiji Milk Products Co., Ltd., Tokyo, JapanWe reported that *Bacteroidaceae* significantly increased in the intestinal microflora of mice with experimental colitis induced by dextran sulfate sodium (DSS). It was reported that succinic acid was a major fatty acid by-product of *Bacteroidaceae* metabolism and impaired phagocytic killing function of neutrophils. Therefore, we investigated the relation between fecal short-chain fatty acids (SCFA), included succinic acid, and the occurrence of colorectal ulceration in this colitis model.*Methods:* Experimental colitis was induced by 14 days-administrations of 3% DSS (M.W. 52,000) to CBA/J female mice. Control mice were given distilled drinking water for 14 days. After sacrifice, stool specimens were obtained from cecum, proximal colon, and distal colon. Fecal SCFA were measured by HPLC.*Results:* Histological observation indicated predominant severity of ulceration on the distal colon with less ulceration on the cecum and proximal colon in DSS mice. In fecal SCFA analyses, succinic acid significantly increased in cecum, proximal and distal colon ($p < 0.05$) of DSS mice.Mean fecal succinic acid concentrations were significantly higher ($p < 0.05$) in the distal colon (3.42 \'b5mol/g) than in the proximal colon (1.71 \'b5mol/g) and in the cecum (1.90 \'b5mol/g). Butylic, acetic, and propionic acids significantly decreased in cecum, proximal and distal colon of DSS mice ($p < 0.05$) when compared with the control.*Conclusion:* Fecal succinic acid mainly produced by *Bacteroidaceae* spp. may be the ulcerogenic agent of this experimental ulcerative colitis. "P P 62 1499"P 62 1499**Comparison of OR-1384 and Hydrocortisone in a Rabbit Colitis Model**

*A. Koponen, P. Aho, K. Haasio, I.-B. Lind\'e9n

Orion Pharma Research, Espoo, FinlandOR-1384 (3-[[4-(methylsulfonyl)phenyl]methylene]-2,4-pentanedione) is a novel thiol modulating agent intended for the treatment of inflammatory bowel disease (IBD). This compound has been effective in several animal models of ulcerative colitis. In this study the effect of OR-1384 was studied in rabbit immune complex colitis and compared to that of hydrocortisone (HC).*Methods:* The colitis was induced in New Zealand White rabbits by introducing dilute formalin into the lumen of the colon and by injecting preformed immune complexes into the marginal ear vein two hours later. Different concentrations of formalin (1% or 0.45%) were used in order to induce \lquotesevere\rquote or \lquotemild\rquote colitis, respectively. The rabbits were killed two days (\lquotemild\rquote colitis) or three days (\lquotesevere\rquote colitis) after formalin application. The colonic lesions were scored and the tissue was examined histologically. The colonic mucosal eicosanoid production was also measured. The rabbits were treated with OR-1384 or HC enemas (2 ml/kg): 10 mg/kg for the \lquotesevere\rquote colitis and 3 mg/kg for the \lquotemild\rquote colitis. OR-1384 was dosed once daily and HC twice daily. The dose dependency of OR-1384 was tested in the \lquotesevere\rquote colitis using doses 3, 10 and 30 mg/kg.*Results:* OR-1384 induced a dose related protective effect against the \lquotesevere\rquote rabbit colitis. The dose 10 mg/kg inhibited the lesion score by 61% and reduced the formation of prostaglandin E2 (PGE2) by 50% and leukotriene B4 (LTB4) by 58%. HC was not effective in the \lquotesevere\rquote colitis. In the \lquotemild\rquote colitis both compounds had a favourable effect. However, OR-1384 was more effective protecting against mucosal lesions by 79% and decreasing PGE2 by 61% and LTB4 by 82%. The corresponding figures for HC were 44%, 51% and 13%. The results from the histological evaluation were in line with the macroscopic scores.*Conclusion:* In the rabbit immune complex colitis locally administered OR-1384, dosed once daily, was shown to be more effective than HC, dosed twice daily. "P P 62 1500"P 62 1500**Fish-Oil Enriched Diet Inhibited Leukotriene Release in Experimental Trinitrobenzene Sulfonic Acid (TNB) Colitis in Rats**

*H. Y\'fcceyar, \'d6. \'d6z\'fctemiz, A. H\'fcseyinov, M. Alkanat, S. Bor, I. \'c7oker, Y. Batur

Depts. of Gastroenterology & Pathology, University of Ege, Izmir, TurkeyThe etiology of inflammatory bowel disease (IBD) is still unknown and the treatment of recurrences of IBD is also insufficient. In this study, we investigated that the protective role of fish oil (FO)-enriched diet in a rat model of TNB colitis. 20 male Wistar- Albino rats were randomized into 2 groups (n = 10). All of them were fed along 6 weeks with standard diet (group-1) and standard diet plus FO (%8) [group-2], At the end of this period, TNB (30 mg in 0.25 ml of %30 ethanol) were intrarectally administered. After two weeks, rats were sacrificed and the distal colon was removed. Specimens were histopathologically evaluated. Myeloperoxidase (MPO) enzyme activities (Ug/wet weight) were measured and leukotriene B4 (LTB4) (pg./mg tissue protein) and leukotriene C4 (LTC4) levels (pg./mg tissue protein) were determined by radioimmunoassay. The results were showed in table. Groups MPO LTB4 LTC4 Pathologic scoresGroup 1 30.41 – 1.9 372.1 – 65.2 450.0 – 6.45 2.125 – 0.3Group 2 2.43 – 0.4 34.5 – 8.1 64.0 – 10.46 1.555 – 0.2There were significant differences in MPO activities, LTB4 and LTC4 levels and histopathological scores between two groups (respectively p = 0.0108, p = 0.0034, p = 0.0024, p = 0.002). In conclusion, FO-enriched diet could reduce the colon damage in TNB colitis in rats. Intestinal disorders: IBD, basicIntestinal disorders: IBD, therapy }" "Fish-Oil Enriched Diet Inhibited Leukotriene Release in Experimental Trinitrobenzene Sulfonic Acid (TNB) Colitis in Rats"

"P P 62 1501"P 62 1501**The Effect of Fish on Enema in Trinitrobenzene Sulphonic Acid (TNB) Induced Colitis in the Rat**

*H. Y\'fcceyar, \'d6. \'d6z\'fctemiz, A. H\'fcseyinov, M. Alkanat, S. Bor, I. \'c7oker, M. Tun\'e7y\'fcrek, C. \'c7oker, Y. Batur

Depts. of Gastroenterology & Pathology, University of Ege, Izmir, TurkeyIn recent studies, it has been shown that fish oil (FO)-enriched diet has a protective role in experimental colitis models. However, there was no sufficient knowledge about using of intrarectally FO administration during long periods. In this study, we investigated whether intrarectally FO administration has a protective role in TNB colitis. In the first step, 20 male rats were randomized into two groups (n = 10). TNB (30 mg in 0.25 ml of %30 ethanol) was intrarectally administered into each group. After one day, 1 ml of saline or FO enemas were administered in every day along two weeks. At the end of this period, the distal colons were removed. The specimens were histopathologically evaluated. Myeloperoxidase (MPO) enzyme activity (Ug/wet weight) and leukotriene B4 (LTB4) and LTC4 levels (pg/mg tissue protein) were measured by RAI (Mean – SEM). While there was no significant difference between group-1 and 2 in the comparison of MPO activities and pathologic scores. The LTB4 and LTC4 levels of FO group were less than the measurements of saline group (respectively p = 0.0081 and p = 0.0051). In the second step, 20 male rats were randomized into two groups. 1 ml of saline (group-3) or FO (group-4) enemas were administered in every day along three days. At the fourth day, TNB was given 0.25 ml intrarectally. After 24 hours, rats were sacrificed. We could not find any significant difference between group-3 and 4 in all parameters. In conlusion, although FO-enriched diet could reduce the colon damage in experimental TNB colitis, according to our results (in the first and second steps) the short periods of FO enemas do not play protective role in TNB colitis. Groups MPO LTB4 LTC4 Pathologic scoresGroup-1 6.5 – 2.3 257.1 – 60.6 514.2 – 23.9 2.25 – 0.31Group-2 4.0 – 0.9 138.1 – 25.6 146.5 – 36.9 1.87 – 0.29Group-3 25.01 – 3.5 285.0 – 59.6 502.1 – 124.5 2.85 – 0.14Group-4 19.7 – 3.1 394.5 – 64.3 652.3 – 125.6 2.14 – 0.33 Intestinal disorders: IBD, basicIntestinal disorders: IBD, therapy }"

"P P 62 1502"P 62 1502**The Effect of Fish Oil Enema in Acetic Acid-Induced Colitis and Ethanol-Induced Colonic Damage in Rats**

*H. Y\'fcceyar, \'d6. \'d6z\'fctemiz, A. H\'fcseyinov, M. Alkanat, S. Bor, \'c7. Din\'e7er, A. \'c7oker, Y. Batur

Depts. of Gastroenterology & Pathology, University of Ege, Izmir, TurkeyThe importance of dietary fish oil (FO) is a well-known concept in the treatment of inflammatory bowel disease (IBD). In recent studies, it has been shown that FO-enriched diet reduces the level of some mediators -PAF, leukotrienes- which have noxious effects on the colonic mucosa. But there are a few reports indicating the effect of FO enema in the treatment of IBD. In this study, we investigated the protective role of FO in acetic acid (AA)-induced colitis and ethanol-induced colonic injury. 60 male Wistar rats was divided into AA and ethanol groups (n = 30). Each group was divided into FO, corn oil (CO) and saline subgroups (n = 10). Each subgroup was given 1 ml of FO, CO or saline via rectal route into to lumen of the colon using a rubber cannule. 1 hour later, 1 ml of 4% AA was given to the AA group and 0.25 ml of 30% ethanol was given to the ethanol group in the same manner. The rats were sacrificed two days later and the distal colons were scored histopathologically and myeloperoxidase (MPO) activity (U/g wet weight) was determined. Groups MPO Pathologic scoreFO + AA 8.72 – 4.87 1.142 – 0.142CO + AA 11.28 – 0.28 1.428 – 0.331Saline + AA 13.55 – 1.78 1.571 – 0.534FO + ethanol 12.60 – 3.26 1.285 – 0.289CO + ethanol 13.72 – 2.82 1.571 – 0.369Saline + ethanol 14.45 – 3.77 1.571 – 0.202No significant differences was found between subgroups. In conclusion, FO and CO does not play a protective role in acetic acid-induced colitis and ethanol-induced colonic damage in rats.

"P P 63 1503"P 63 1503**Ten-Year Outcome of Restorative Proctocolectomy for Ulcerative Colitis**

*C. Penna, P. Gasne, R. Parc

Service de Chirurgie Digestive, Hopital Saint-Antoine, Paris, FranceRestorative proctocolectomy (RP) is the treatment of choice for patients with ulcerative colitis. However, little is known about complications, risk of pouchitis and bowel function over the long term.*Aim:* To study the results of RP for UC in a cohort of patients with a minimum of 10 years follow-up.*Patients and Methods:* Among 500 RP patients, 40 consecutive subjects (18 males, median age 40 at operation) were identified who had the operation for UC prior to 1986. The occurrence of late complication, pouchitis and the bowel function were prospectively recorded.*Results:* One patient died of unrelated cause. Two patients (5%) were identified has having Crohn's disease 2 and 3 years after RP and pouch removal was mandatory in one case. There was no other pouch failure. Six complications occurred after the first year: 1 bowel obstruction and 3 anastomotic strictures were treated medically, 2 incisional hernias were operated. Pouchitis occurred in 5 patients (13%) and was chronic in only one case.Between the first and the 10th year bowel function remained unchanged. Median bowel frequency was 5.3 at 1 year and 4.9 at 10 years, daytime continence was perfect in 86% at 1 year and 91% at 10 year, nighttime continence was perfect in 69% at 1 year and 77% at 10 year. At 10 year only 11% of patients followed a strict diet (versus 33% at 1 year, $p < 0.05$).Nine patients were more than 50 years old at RP and bowel function was also unchanged in this subgroup after 10 years.*Conclusions:* Long term follow-up of RP for UC showed that late morbidity was minimal, pouchitis easily amenable to treatment and that bowel function did not deteriorate with time, conforting RP as the treatment of choice for most patients with chronic UC. Intestinal disorders: IBD, therapy }" "Ten-Year Outcome of Restorative Proctocolectomy for Ulcerative Colitis"

"P P 63 1504"P 63 1504**What Are the Functional Results of Colonic Pouch Anal Anastomosis (CPAA) in Aged Patients?**

*N. Dehni, J.D. Singland, R.D. Schlegel, M. Guiguet, E. Tiret, R. Parc

Centre de chirurgie digestive, Hospital Saint Antoine, Paris, FranceMany low rectal cancers can be treated radically by proctectomy with mesorectal excision followed by CPAA. In aged patients, the fear of a poor function might reduce indications of CPAA in favour of abdomino-perineal excision with end stoma. The aim of this study was to evaluate the long term results of CPAA in patients over 75 years. *Methods* Among 198 patients with CPAA operated on between 1984 to 1992 for low rectal cancer, 20 patients over 75 years old were alive without recurrence at the time of telephone interview (July 95). Minimal follow up was 3 years for all patients. *Results* mean age at intervention was 74 years (66–87), mean age at interview was 82 years (75–93). Mean time follow up was 8 years. The functional results are listed herein. No bowel movements/day 1.1 (0.4–3.5) Urgency* 3 (15%)Fragmented defecation* 5 (25%) Constipation 8 (40%)Needs for micro-enemas* 7 (35%) Laxatives* 6 (32%)Incontinence for feces* 3 (15%) Satisfaction 18 (90%)Incontinence for flatus* 8 (40%)*events occurring once or more per week.Incontinence for feces was only occasional in 3 cases. *Conclusion* These results show that functional outcome may be good to excellent in aged patients after CPAA and compare well with those obtained in younger patients in our series. However, constipation may be more frequent in the aged. Age is not a contraindication for CPAA if the sphincter tone is clinicaly normal.

"P P 63 1505"P 63 1505**Lack of Postprandial Motor Response in Pouches with Temporary Ileostomy**

*A. Mularczyk, G. Basilisco, E. Contessini-Avesani, P. Bianchi

Depts. of Gastroent. and Surg., Instit. of Medical Sciences of the University, IRCCS Ospedale Maggiore, Milan, ItalyIleal and rectal tone increases after a meal in healthy subjects; this response to feeding is preserved in isolated colonic loops. In a previous study in six patients with ileal pouch-anal anastomosis (IPAA) we observed an increase in pouch tone after a meal.*Aims:* To confirm the increase in pouch tone after a meal in a larger group of patients and to verify whether this response is preserved in an isolated pouch.*Methods:* We studied 13 patients with IPAA (5 men and 8 women, age range 18–55 yr), 9 with IPAA and ileostomy closure performed 18–66 months before and 4 with IPAA and temporary ileostomy performed 3 months previously. All pouches were S-shaped. All patients were studied after an overnight fast. In patients with gut continuity the pouch was cleaned with 500 ml water enema 4 hs before the study. Pouch tone was recorded for 1 h in fasting conditions and for 1 h after a 1000 kcal liquid meal (250 ml, 20% of lipids). A polyethylene bag was placed in the pouch and connected to an electronic barostat. The bag volume reflected pouch tone; changes in bag volume > 10% of the baseline volume were considered as phasic volume events. Statistical analysis was performed with Wilcoxon's test. Data are given as mean – SEM.*Results:* The intrabag operating pressure was similar in patients with gut continuity and in those with ileostomy (6.4 – 0.5 and 7.0 – 1.6 mmHg respectively; P = NS). Pouch volumes were greater in the former than the latter group. In patients with gut continuity pouch volume decreased and the frequency of phasic volume events increased after the meal whereas both variables were unaffected by the meal in patients with ileostomy (Table). Volume (ml) Phasic vol. events (n/h) Fasting Postpr. Fasting Postpr.Pouch in continuity 149 – 5 72 – 16* 11 – 2 22 – 2*Pouch with ileostomy 69 – 3** 72 – 2 15 – 4 17 – 4*P < 0.05 vs fasting; **P < 0.05 vs patients with pouch in continuity*Conclusions:* Pouch tone is greater in patients with IPAA and temporary ileostomy than in those with gut continuity. The lack of motor response after a meal in patients with ileostomy suggests that the decrease in pouch volume observed in patients with IPAA after ileostomy closure may not be due to an increase in tone, but to the arrival of intestinal contents in the pouch. Motility, specific: Small bowel }"

"P P 63 1506"P 63 1506**Prognosis and Blood Coagulation Disorders in Venous and Arterial Mesenteric Infarction with Short Bowel**

*P. Crenn, B. Messing, G. Lerias, M.H. Horellou[1], M.C. Boffa[2], B. Rio[1], C. Matuchansky

[1] INSERM U290, Hospital de l'Hotel Dieu, Paris, France

[2] INSERM U353, Paris, FranceBlood coagulation disorders either primary through decrease in anticoagulant activity or secondary through increase in procoagulant activity might be a major problem in mesenteric infarction (MI) patients. The aim of this study was to determine in MI patients with short bowel (SB) (remaining small bowel length < 150 cm): 1) frequence and characteristics of blood coagulation disorders, 2) comparative probability of survival. *Methods:* Exhaustive blood coagulation were tested in 16 out of 34 cases of arterial MI (AMI) and in all (14 cases) of venous MI (VMI). Prognosis was analyzed in 48 patients (34 AMI and 14 VMI) by survival probability expressed in actuarial curves according Kaplan-Meier and compared by log-rank test. *Results:* Age was significantly higher ($p < 0.05$) in AMI (mean: 53 yr) than in VMI (43 yr). Small bowel (45 cm (0–130) and colon remnant lengths (66% of normal length { -}0 to 100%) were not different between the 2 groups. Among AMI 10 (63%) had blood coagulation disorders: 4 had decrease of anticoagulant activity, 3 with protein S or C deficiency, one with resistance to activated protein C; 7 had antiphospholipid-antibody syndrome (APAS). Among VMI 5 (36%) had blood coagulation disorders: 2 had decrease of anticoagulant activity, one with resistance to activated protein C and one with hypoplasminogenaemia; 3 had APAS. Among the 15 patients with blood coagulation disorders 12 had previous vascular events and 12 had counfounding vascular risk factors. Five-year survival probability was 66 (95% CI: 49–83)% with a worse prognosis for AMI (53%, 95% CI: 33–73) than VMI (100%) ($p < 0.05$). Six of the 11 deaths in AMI group were related to vascular extradigestive complications. *Conclusion:* Blood coagulation disorders were highly prevalent in MI (50%) regardless of site, A *versus* V, and counfounding risk factors. APAS was the most frequent abnormaly (33%). The worse prognosis observed for AMI was mainly linked to extradigestive vascular events. Intestinal disorders: Splanchnic circulation, ischemiaIntestinal disorders, absorption: Malabsorption syndromesClinical practice: Management strategy }" "Prognosis and Blood Coagulation Disorders in Venous and Arterial Mesenteric Infarction with Short Bowel"

"P P 63 1507"P 63 1507**DNA-Aneuploidy in Mucosal Biopsies with No or Slight Atrophy from the Ileal Pelvic Pouch in Patients with Colonic IBD**

*D. Stahlberg, K. Gullberg, L. Liljeqvist, B. Veress, B. Tribukait, R. L\'f6fberg

Department of Medical and Surgical Gastroenterology, Huddinge University Hospital, Sweden*Background:* Total colectomy followed by formation of a pelvic pouch (PP) is an established treatment for patients with ulcerative colitis (UC). Some UC-patients with a PP develop atrophy in the PP-mucosa. We have previously shown that patients developing moderate and severe atrophy of the PP mucosa also are at risk for development of DNA-aneuploidy and dysplasia.*Aim:* To determine if no or slight atrophy in the PP-mucosa also is associated with subsequent development of dysplasia and/or DNA aneuploidy.*Patients and Methods:* Twenty-five patients with PP colectomized due to ulcerative or indeterminate colitis and with no or only slight atrophy in the PP mucosa were included in the study. The median PP-duration was 73 months (range 20–182 months). The patients were examined with a flexible video endoscope and biopsies were taken from 5 locations [the afferent small intestine, upper portion of the pouch, mid portion (2 locations), and lower portion of the pouch]. From each location 1–2 biopsies were taken for histological assessment of dysplasia and 1–2 biopsies were taken for flow cytometric DNA-analyses.*Results:* DNA-aneuploidy was found in three of the patients. In one of them aneuploidy was seen also in the afferent small intestine. In three further patients hyperploidy was seen. No dysplasia was found. One of the patients with aneuploidy was colectomized due to colonic cancer and one patient with hyperploidy underwent surgery due to dysplasia/DALM.*Conclusion:* Patients colectomized due to colonic IBD with a PP displaying no or only slight mucosal atropy also have a risk for neoplastic transformation of the pouch mucosa as detected by an aneuploid DNA-content. The risk seems to be lower than in patients displaying moderate or severe mucosal atrophy. We suggest that all patients with PP due to IBD should be monitored with endoscopy and biopsy sampling. "P P 63 1508"P 63 1508**Pre- and Postoperative Diagnosis in Colonic IBD Patients Undergoing Colectomy — Is There a Shift in Diagnosis Towards Crohn's Disease? A Four Year Follow Up Study**

*R. Befrits, A. Johansson, C. Rubio, O. Brostr\'f6m, I. Magnusson, B. Kollberg, C. Johansson, R. L\'f6fberg

Karolinska Hospital, Huddinge University Hospital, S\'f6der Hospital, Danderyds Hospital, Karolinska Institute, Stockholm, Sweden*Background:* In ulcerative colitis (UC), but not Crohn's disease (CD) or indeterminate colitis (IC), patients undergoing colectomy are usually offered a restorative proctectomy. Difficulties to separate these entities, both clinically and histologically, have caused problems in selecting cases for this type of operation.*Aim:* To compare the pre- and postoperative diagnosis in colonic IBD patients undergoing colectomy, and reviewing diagnosis at follow up four years after surgery.*Methods:* All patients with IBD undergoing colectomy during 1986 to 1990 at the four major hospitals in Stockholm were investigated. The clinical diagnosis at the time of operation was accepted as the preop diagnosis. Postop diagnosis was based on the macroscopical findings at operation as well as the histology. All case records were followed up four years after surgery.*Patients:* 83, 52, 45, and 26 patients from the 4 different hospitals, all-together 206 (96 women) were included. The median age at diagnosis was 28 (range 4–78) years, the duration of disease at operation was 7 (1–61) years and the median age at operation 39 (19–78) years. Subtotal colectomy with ileostomy was done in 147 (71%), IRA in 24 (12%), proctocolectomy in 16 (8%) and pelvic pouch procedure in 19 (9%).*Results:* The preop diagnosis were UC 145 (70%), probable UC (pUC) 5 (3%), IC 4 (2%), CD 41 (20%), and probable CD (pCD) 11 (5%). 34/145 (23%) UC cases were reclassified as CD postop. Another 7 patients (5 from pCD, 1 each from IC and pUC) were changed to CD, adding up to 41 ""new"" CD cases. During follow up, 5 more patients with CD were added. In total, CD increased from 41 preop to 80 postop and 85 at follow up compared to a decrease in UC from 145 to 107. The increase in CD was most evident at the two hospitals with the largest numbers of patients operated. The initial CD cases were only reduced by 2, that were reclassified as UC postoperatively.*Conclusions:* One fifth of all patients with UC before colectomy, had this diagnosis questioned with a subsequent suggestion of CD. This may be due to lack of sufficient histological information preoperatively, and the final numbers may more truly reflect the prevalence of UC and CD in the society. Different patterns from different hospitals suggest that pathologists and clinicians look differently on histological signs supportive of CD. The benign course in the reclassified CD cases may justify surgery with pouch procedure in such CD patients. Intestinal disorders: IBD diagnosis, monitoring }" "Pre- and Postoperative Diagnosis in Colonic IBD Patients Undergoing Colectomy / Is There a Shift in Diagnosis Towards Crohn's Disease? "P P 63 1510"P 63 1510**Mucosal Associated Ileal Flora after Ileocolic Resection for Crohn's DiseaseE. Lederman, C. Neut, P. Desreumaux, O. Klein, P. Baron, L. Gambiez, P. Quandalle,**

*J.F. Colombel

C.R. Inserm-4U004B, Laboratoire de bact\'e9riologie, Facult\'e9 de Pharmacie, CH et U, F-59037 Lille*Background/Aim:* After an ileocolic resection for Crohn's disease (CD), an endoscopic recurrence occurs in the neoterminal ileum in 40–60% of cases 3 months after surgery and almost in 80% of cases at 1 year. Clinical and experimental evidence support the role of bacterial flora in this recurrence. The aim of this study was to identify mucosal associated bacterial flora in the neoterminal ileum of patients operated on for CD in relation to the presence or not of an endoscopic recurrence. *Methods:* Ileal biopsies were obtained per-operatively in the healthy ileum of 10 patients at time of an ileocolectomy for CD, 3 months after surgery in 17 patients and 12 months after surgery in 18 patients. An endoscopic recurrence defined as score {\'b3} 2 (according to Rutgeerts et al., 1990) was documented in 7/17 patients at 3 months and 11/18 at one year. Samples were inoculated and incubated under aerobic or anaerobic conditions. After counting predominant colonies were subcultured and identified.*Results:* log 10 Colony Forming Unit/g of tissue (mean – SD) Per-operative samples 3 months 12 months (n = 10) (n = 17) (n = 18)Aerobic incubation 4.2 – 0.5 6.1 – 1.1* 7 – 1.5[*$]Anaerobic incubation 4.7 – 0.8 7 – 1.1* 7.9 – 0.9[*$]*$p < 0.001$ vs per-operative samples; [$]$p < 0.05$ vs 3 months.Among the aero-anaerobic flora, the predominant species at 3 and 12 months were: *Escherichia coli, Bacteroides* and *Clostridium* species. There were no quantitative differences in the bacterial flora in patients having or not an endoscopic recurrence either at 3 or 12 months.*Conclusion:* Mucosal associated ileal flora is significantly increased after surgery in CD with predominant species characteristic of a fecal-type flora. Other factors appear necessary for the onset of an endoscopic recurrence. "P P 63 1511"P 63 1511**Influence of Azathioprine on Postoperative Recurrence after Ileocecal Resection for Crohn's DiseaseF. Mauvais,**

*Y. Panis, J. Nemeth, P. Hautefeuille, P. Valleur

Digestive Surgical and Pathology Departments, University Hospital Lariboisiére, 2 rue Ambroise Par\'e9, 75010, Paris, FranceRecently, it has been demonstrated that mesalamine was effective in decreasing postoperative recurrence rate after surgery for Crohn's disease (CD). The possible effect of azathioprine on postoperative recurrence remains unknown.*The aim of this retrospective study* was to assess the possible effect of postoperative azathioprine administration (and 5-ASA) on long-term clinical recurrence rate after ileocecal resection for CD.*Patients and Methods:* From 1980 to 1995, 93 patients (pts) underwent ileocecal resection for CD. There were 49 women and 44 men (mean age – SD: 31 – 12 years). Indication for resection was: failure of medical therapy (n = 47); obstruction (n = 6); fistula (n = 23); abscess (n = 9); peritonitis (n = 6) and miscellaneous (n = 2).*Results:* Mean follow-up was 71 – 42 months (extr. 1–178); 6 pts were excluded: 4 for azathioprine disruption early after surgery; 2 patients received other treatment (methotrexate and solupred enemas). No treatment Azathioprine 5-ASA (n = 53) (n = 15) (n = 19)Mean follow-up 88 – 41 44 – 34 53 – 26(months)Total recurrence rate (%) (a) 64% (34/53) 13% (2/15) 26% (5/19)5-year recurrence rate (%) 52% 17% 50%Mean delay of recurrence 40 – 38 39 – 33 29 – 21(months)(a): No treatment vs azathioprine or vs 5-ASA: $p < 0.02$; azathioprine vs 5-ASA: N.S.*Conclusions:* This preliminary study suggests that azathioprine could be effective for reducing postoperative recurrence rate after surgery for CD. A randomized study comparing azathioprine versus 5-ASA after surgery for CD should be undertaken. Intestinal disorders: IBD, therapy }" "Influence of Azathioprine on Postoperative Recurrence after Ileocecal Resection for Crohn's Disease"

"P P 63 1512"P 63 1512**Therapeutic Implications of Endoscopic and Histologic Informations Collected after Subtotal Colectomy for Fulminant Colitis**

*C. Penna, O. Chapuis, R. Parc

Service de Chirurgie Digestive, St. Antoine Hospital, Paris, FranceFulminant colitis unresponsive to medical therapy requires sub-total colectomy (STC). Examination of the specimen and of the rectal remnant may help to better classify the colitis between ulcerative colitis (UC) and Crohn's disease (CD) and consequently to guide the type of restoration of bowel continuity (ileorectal (IRA) or ileoanal (IAA) anastomosis).*Aim:* to evaluate the consequences of the changes in initial diagnosis made after a STC for fulminant colitis.*Patients and methods:* between 1984 and 1994, 89 patients (mean age 33 years, 57 men) had STC for a fulminant colitis of 3 to 12 days duration. Bowel continuity was restored 4 to 7 months later. Preoperative diagnosis was compared to the diagnosis before restoration of bowel continuity and to the definitive diagnosis taken on clinical, endoscopic and pathological basis after a mean follow-up of 42 months (14 to 111).*Results:* initial diagnosis was UC in 62 cases, CD in 8, indeterminate colitis (IC) in 19. Between the STC and the restoration of bowel continuity, the diagnosis was changed in 24 cases. The 8 CD were confirmed, patients had an IRA but definitive diagnosis appeared to be UC in 2 cases. UC was confirmed in 57 patients who had a IAA but 4 further appeared to have CD. UC was changed in CD in 5 patients (aphtoid ulcerations, granulomas) who had IRA but for whom follow-up confirmed UC. IC were classified in 6 CD and 13 UC with 1 error in each group at follow-up.*Conclusions:* endoscopic and histologic examinations after STC was useful for IC but did not preclude to perform IAA for CD and diversion colitis was responsible for erroneous changes from UC to CD. Intestinal disorders: IBD diagnosis, monitoringIntestinal disorders: IBD, therapyEndoscopy, specific: Colon, rectum }" "Therapeutic Implications of Endoscopic and Histologic Informations Collected after Subtotal Colectomy for Fulminant Colitis"

"P P 63 1513"P 63 1513**Adaptative Hyperphagia and Net Digestive Absorption after Massive Small Bowel Resection**

*P. Crenn, L. Beloucif, M.C. Morin, F. Thuillier, J.C. Rambaud, B. Messing

Hospital Saint-Lazare and INSERM U290, 75010 Paris, France*Aim:* to quantitatively describe free oral intake and net digestive absorption (NDA) of protein and fat in Short Bowel (SB) patients. *Methods:* Nonactive digestive SB (n = 90) patients, mean age 51 yr (range: 19–81), were studied during 3-day periods for oral ingesta and fecal excreta, with a total of 247 exams. Digestive losses were measured for protein and fat using Kjeldahl and Van de Kamer techniques respectively. We analyzed: a) last NDA exam after (43 (1–240) month) resection (n = 90), b) NDA before and after (2.2 (0.5–14) month) re-establishment of colonic continuity (n = 12), c) early (< 6 month, mean: 2.3) and late (> 6 month, mean: 29.6) NDA after re-establishment of colonic continuity (n = 14). *Results:* a) Remnant length for jejunum and ileum (opisometry) was 71 cm (0–200) and 9 cm (0–120) respectively; the remnant colon in continuity was 66% (0–100) of normal length. The 47 – 15 kcal-kg{ ˉ1}.day{ ˉ1} (mean – SD) oral diet consisted of 46% carbohydrate, 34% fat and 20% protein. NDA (%: In – Out:In) was 53 – 24% for fat, and 60 – 22% for protein ($p = 0.05$ *vs* fat). Stool weight was related to percent colon in continuity ($p < 0.0001$), jejunum ($p < 0.001$) and ileum length ($p < 0.05$) and calorie ingesta ($p < 0.05$). NDA for protein was related to jejunum ($p < 0.001$) and ileum length ($p < 0.01$), and presence of rectum ($p = 0.05$); NDA for fat was related to jejunum ($p < 0.01$) and ileum length ($p < 0.05$), presence of ileocecal valve ($p = 0.05$) and fat ingesta ($p = 0.05$). b) After re-establishment of colonic continuity there was a decrease in stool weight (4000 *vs* 1215 g, $p < 0.001$), an increase in NDA for protein (32 *vs* 69%, $p < 0.001$) and fat (38 *vs* 66%, $p < 0.01$). c) Between early and late periods despite a significant increase in ingesta (39 – 14 *vs* 51 – 21 kcal-kg{ ˉ1}.day{ ˉ1}) ($p < 0.05$) there was a non significant change of stool weight (2038 *vs* 1838 g), of NDA for fat (51 *vs* 49%) and of NDA for protein (48 *vs* 57%). *Conclusion:* These data confirms hyperphagia in SB patients and show the importance of colonic continuity for an increase in protein and fat NDA. Over time, since hyperphagia increase and % NDA do not change an increase of NDA *per se* was observed. Intestinal disorders, absorption: Malabsorption syndromesNutrition: Nutrients and gut function }" "Adaptative Hyperphagia and Net Digestive Absorption after Massive Small Bowel Resection"

"P P 63 1514"P 63 1514**Small Intestine Transplantation in the Rat- Comparison of Imunogenicity of Foetal and Adult AllograftsM. Francelina Lopes, A.S. Cabrita, J.A.B. Patr\'edcio**

Laboratory of Animal Experimentation, University Hospital of Coimbra, and Faculty of Medicine, University of Coimbra, Portugal*Introduction:* Rejection remains one of the principal causes of morbidity in clinical intestinal transplantation. Ontogenic studies have shown that foetal intestine has a relatively immature immune system, therefore the use of foetal intestinal grafts for small bowel transplantation might have some immunological advantages over the use of adult donor intestine.This experiment was designed to study this hypothesis as an immunological bi-directional rat model, with different histocompatibility barriers.*Materials and methods*Fifty-six small bowel transplantation were made, across a minor histocompatibility barrier (outbred Wistar-Wistar and a stronger one (Wistar-Sprague Dawley). Donor rats were Wistar and recipients were Wistar and Sprague Dawley.Animals dying on the first 48 h pos-transplantation were excluded.Experimental Groups:Adult rats (Wistar and Sprague-Dawley) underwent accessory jejunal (4 cm) transplantation, using the technique described by Zhong et al (Microsurgery 12: 268–274, 1991). They were grouped as follows: Group A: Wistar-Wistar, N = 9 and Group B: Wistar-Sprague-Dawley, N = 10.Jejunal grafts (4 cm) of Wistar foetuses (gestation age of 19 days), were transplanted into omentum of adult Wistar or Sprague-Dawley rats, using the technique of Kellnar et al (J Pediatr Surg 27: 799–801, 1992). They were grouped as follows: Group C: Wistar-Wistar, N = 18 and Group D: Wistar-Sprague-Dawley, N = 18.The recipients of the groups A, B, C and D were further divided into three subgroups, which received intramuscular cyclosprine A, for 21 days, beginning on the day of transplantation, 10 mg/Kg/day (subgroups A1-N = 3, B1-N = 3, C1-N = 6 and D1-N = 6) and 2 mg/Kg/day (subgroups A2-N = 3, B2-N = 3, C2-N = 6 and D2-N = 6) or no imunossupressive therapy (subgroups A3-N = 3, B3-N = 4, C3-N = 6 and D3-N = 6). Sixteen adult rats (Wistar and Sprague-Dawley) were used as controls: they underwent a sham operation, without imunossupressive therapy or with intramuscular cyclosporine, for 21 days (2 mg/kg/day and 10 mg/kg/day).All recipients of intestinal grafts were weighed and inspected daily for the typical signs of graft-versus-host disease (GVHD) and rejection, until dead or until 21 days after transplantation. All animals were submitted to autopsy. Relative spleen weight was calculated; is an indication of GVHD, if > 1. Specimens for histology were obtained from graft, native intestine, liver, spleen, mesenteric lymph-nodes and skin. Graft specimens were assessed using a histologic grading system considering the appearance of the villi, cripts, lamina propria, and muscularis mucosa. According to this criteria rejection was divided in severe (without villi, epithelium and cripts and significant cellular infiltration), moderate (partial loss of villi, focal epithelium denudation, significant cellular infiltration) or mild (few slightly shortened villi, mild oedema and initial cellular infiltration).*Results:* Subgroups A1 and B1: jejunal grafts were well vascularized and had a normal appearance at autopsy. Histological study showed normal intestinal appearance or slightly short villous.Subgroups A2, A3, B2 and B3: Jejunal grafts with turner aspect, with intense fibrous reaction. Two of 13 recipients had a relative spleen weight > 1. Histological signs of moderate to severe rejection were observed in all cases.Subgroups C1 and D1: all foetal grafts were well developed with histhological appearance of normal intestine of slightly short villi.Subgroups C2 and D2: all foetal grafts had visually detectable growth but in all cases there were signs of rejection (moderate or severe).Subgroups C3 and D3: 8 of 12 of the transplanted fetal intestine segments were detectable but fibrotic. All of them with signs of moderate or severe

rejection.*Conclusions:* Our study indicate that in our model, foetal intestine allografts, under no imunossuppressive or low dose therapy, failed to grow and at least were rejected even across a minor histocompatibility locus. None of foetal intestinal recipients suffered from graft-versus-host disease, but doubts remain about this immunological advantage. }" "Small Intestine Transplantation in the Rat- Comparison of Imunogenicity of Foetal and Adult Allografts"

"P P 63 1516"P 63 1516**Superoxide Dismutase Increases Oxygen Consumption and Arterial Flow in Acellular Reperfusion of Small Bowel Grafts**

*C. Emparan, M.R. Perez-Beltran, I. Garcia-Alonso, J. Mendez

Laboratorio de Cirug\'eda Experimental, Departamento de Cirug\'eda, Facultad de Medicina, Universidad del Pa\'eds Vasco*Introduction:* the protector effect of SOD in ischaemic-reperfusion syndromes is related to enzyme administration prior to ischaemic or reperfusion damage, and use to be related to act in the neutrophil's physiopathologic pathway.*Aim of the study:* to determine the role of S.O.D. in a model of acellular reperfusion.*Material and Methods:* 30 male WAG rats (250 g) were used for harvesting the small bowel graft with a modificated technique of gut procurement. The isolated bowels were stored in Collins solution during a period of 6 hours, therefore divided in three experimental groups (n = 10) and perfused during 40 min.: A) guts perfused with Ringer's with glucose and bicarbonate (pH 7.4, 300 osmoles/kg). B) guts perfused after harvesting with a modified Ringer's (pH 7.4, 31 osmoles/kg) solution with verapamil and norepinephrine. C) Same solution as group B but adding SOD.Aliquots of arterial flow, portal outflow, gut luminal effluent, were recollected during the experiment, and O_2, CO_2, pH, Na^+, K^+, and Ca^{++} measured. At the end of the perfusion ileal tissue was excised and microscopically evaluated (Chiu scale). The data was collected and studied with the repeated measures ANOVA, and the Mann-Wihtney test.*Results:* in group A the experiments failured after 15 min. of perfusion. Groups B and C maintained the perfusion during 40 minutes. Arterial flow, portal outflow, edema, oxygen consumption, mean arterial pressure and histologic damage was significantly different ($p < 0.001$) in SOD treated small bowel grafts.*Conclusions:* SOD ameliorates preservation-reperfusion injury in a cell free perfusate, improving the tissue perfusion of the graft, due to a protector effect produced during the reperfusion injury in endothelial layers. Intestinal disorders: Splanchnic circulation, ischemia }" "Superoxide Dismutase Increases Oxygen Consumption and Arterial Flow in Acellular Reperfusion of Small Bowel Grafts"

"P P 63 1518"P 63 1518**Malnutrition Induces Perturbation in Jejunal Mucosa Permeability *in vitro* in Rats Starved before Bowel ResectionMikael Wiren**

Surgery, University Hospital, 581 85 Link\'f5ping, SwedenIntestinal integrity is essential to avoid gut associated septic states after major abdominal surgery. Malnutrition as well as surgical trauma affects the intestinal mucosa. The purpose of this study was to analyze whether malnutrition, surgery, anesthesia or a combination of factors was responsible for increased permeability of ^{51}Cr-EDTA.*Methods:* Male Wistar rats, weight 240–270 g, were used. One group was starved for 48 h until the time of analysis (S = starvation). One group had a 5 cm small intestinal resection of mid-jejunum performed (R = resection). One group was given anesthesia without surgery (A = anesthesia). The control group had free access of food and water (C = control). One group of animals was starved for 48 h and subjected to anesthesia and resection (S + R = starvation + resection). After 2 h. recovery the anesthesia was repeated and jejunal segments starting from 5 cm. distal to the ligament of Treit'z were taken out and immediately immersed in cold, oxygenated Kreb's buffer. Stripped mucosal segments (R; n = 16, S; n = 15, S + R; n = 16, A; n = 8, C; n = 15) were mounted in Ussing chambers where transepithelial potential difference (PD) and electrical resistance (ER) was continously recorded. Transmucosal flux of ^{51}Cr-EDTA was studied for 60 min. and analyzed by { g}-counting. The appearent permeability coefficient P_{app} was calculated.*Results:* PD and ER were stable during experiments. Jejunal permeation of ^{51}Cr-EDTA was significantly increased in the combined starvation and resection group compared to the controls ($p < 0.001$). The P_{app} of the starved animals (S) was also significantly increased compared to controls ($p < 0.01$). Surgery or anesthesia alone did not increase permeability compared to controls significantly. On the other hand the P_{app} of the starved animals was lower than in the combined starvation and resection group and the addition of permeability perturbation achieved by surgery was needed to reach the same degree of change in permeability.*Conclusions:* We consider malnutrition mainly responsible for the disturbance in intestinal integrity seen in this *in vitro* rat model. However, there can be additive effects of malnutrition and trauma causing an increase in intestinal permeability very early after surgery. Intestinal disorders, absorption: Enterocyte biologyIntestinal disorders, absorption: Epithelial transportNutrition: Nutrients and gut function }" "Malnutrition Induces Perturbation in Jejunal Mucosa Permeability in vitro in Rats Starved before Bowel Resection"

"P P 64 1519"P 64 1519**Is Pancreatitis an Important Risk Factor for the Development of Pancreatic Cancer? A Brazilian ExperienceR. Dani, C.E.D. Nogueira**

Santa Casa de Miseric\'f3rdia and Hospital Israel Pinheiro, Belo Horizonte, BrazilThe aim of this study is to report on the possible relationship of pancreatic carcinoma (PC) and chronic calcifying pancreatitis (CCP) as observed in a southeast brazilian city. *Methods:* From January 1963 to January 1996 the authors prospectively cared for 528 cases of CCP and 200 cases of PC, including here 15 cases with the association of the two diseases. Twelve of the 15 patients were males and the mean age was 50.3 – 9.8 years (range 33–64); 10 patients were white and 5, colored. Eight were male heavy chronic alcoholics and 7 were considered idiopathic CCP cases. Mean age of the alcoholics was 53.4 – 9.3 years (range 40–64) and 46.7 – 10 years (range 33–57) for the idiopathic group. PC was diagnosed 94 – 124 and 45 – 95 months after the clinical onset of CCP, respectively for alcoholics and abstemious patients. Four out of the 8 alcoholics showed pancreatic calcifications whereas all idiopathic cases had pancreatic calcifications. Tabagism was present in 7 alcoholics and in 2 idiopathic CCP patients. Clinical changes that signalized the possibility of cancer were noticed from 1 to 36 months before the diagnosis of cancer was set, mean of 12.5 – 15 months for the alcoholics and 4.6 – 3.6 for the idiopathic cases. The incidence of PC in the general population is 1.9/100,000 inhabitants. *Results:* The incidence of PC among CCP patients was 2.8%. Considering that 473 of our patients with CCP were alcoholics (89%), 42 idiopathic (8%), 10 ""tropical"" CCP (1.9%), and 3 (0.6%) were hereditary CCP cases, it seems that PC is much more common in patients with idiopathic CCP (16.7%) than in alcoholic CCP (1.7%), and the difference is significant ($p < 0.05$). It seems, also, that the risk of PC is increased in CCP patients, especially in idiopathic cases. *Conclusion:* PC seems to be more frequent in CCP patients, particularly among idiopathic cases. Pancreas: Pancreatitis, chronicOncology, general: EpidemiologyOncology, specific: Pancreas }" "Is Pancreatitis an Important Risk Factor for the Development of Pancreatic Cancer? "P P 64 1520"P 64 1520**Serum Neurotensin in Human Pancreatic Cancer**

*G. Tessari, T. Meggiato, C. Ferrara, M. Plebani[1], M. De Paoli[1], G. Del Favero

Dept. of Gastroenterology

[1] Laboratory Medicine, University of Padua, ItalyThe role of neurotensin as a physiological regulator of exocrine pancreatic secretion is known, but only recently it has been recognised as important mitogen in vitro on human cancer cells. The aim of this study was to evaluate the variations of serum neurotensin levels in pancreatic cancer as compared to other pancreatic and extrapancreatic diseases. We studied 58 patients: 13 control subjects (CS), 20 pancreatic cancer (PC), 11 chronic pancreatitis (CP) and 14 extrapancreatic diseases (EPD). Serum neurotensin was found significantly different among groups (one way Anova $F = 2.82$, $p < 0.04$); significantly higher levels were detected in CP as compared to PC ($p < 0.05$). No difference was found between PC and the other groups studied. In CP patients the serum neurotensin correlated to serum amylase ($r = 0.95$, $p < 0.01$). Lower values were found in stage IV PC as compared to stage I–II ($t = 1.82$, $p < 0.04$). and in grade II as compared to grade I ($t = 2.21$, $p < 0.05$). Significant correlations were found between neurotensin and two indices of nutrition: albumin ($r = 0.60$, $p < 0.05$) and the percentage reduction in body weight ($Z = 2.20$, $p < 0.02$). No correlations were found between serum levels of this hormone and size of tumour ($t = 1.18$, p: ns), or the survival of the patients (< 12 vs > 12 months) ($t = 0.65$, p: ns). We can conclude that serum variations of neurotensin do not seem to be related to the progression of human pancreatic cancer. The variation of serum levels of the hormone can be linked to a patient's poor nutritional status. "P P 64 1521"P 64 1521**How to Deal with Serous Cystoadenoma of the Pancreas?**

*C. Bassi, M. Falconi, R. Salvia, A. Bonora, E. Caldiron, N. Sartori, L. De Santis, G. Butturini, G. Bogina[1], A. Guarise[2], P. Pederzoli

Surgical Department, University of Verona, Italy

[1] Pathological Department, University of Verona, Italy

[2] Radiological Department, University of Verona, ItalyOut of 108 pts. suffering from cystic tumour of the pancreas who underwent surgery from 1985 to 1995, thirty one (28.7%) had a histologically proven Serous Cystoadenoma (CAS). The male/female ratio was 7/1. The mean age was 58.8 years (range 27.8–72.7). The more frequent symptom was abdominal pain in 19 (61.3%), anorexia in 4, vomit and weight loss in 2, diarrhea in one. The diagnosis was occassional in 10 pts. (32.2%). All underwent preoperative US and CT.The underlined lesions were in average of 4.5 cm. (range 1–15). The imaging has been able to set diagnosis of CAS in the 55.5% of the cases; in the remainder 45.5% a mucinous neoplasm was suspected, because of the macrocystic aspect of the lesion. No pseudocyst was diagnosed. Preoperative needle aspiration, performed in 10 pts, recognized the CAS in 6 cases (60%), in 3 was not diagnostic. In one case (still alive at the follow up after 80 months) an adenocarcinoma, then disavowed from the histology, was suggested. Twenty-one patients (67.7%) underwent radical resection, 7 a cystojejunoanastomosis and 3 a laparotomy. Perioperative mortality was zero. Postoperative stay was 17.3 days in average. Seven pts. (22.6%) experienced complications; 4 low output pancreatic fistulas and 1 biliary fistulas, abdominal collection and bleeding (requiring operation) respectively. All patients are alive and symptoms free in a mean follow up of 45 months (range 3–118). No resected patients present recurrence. The problem in distinguishing the potential malignant pancreatic cystic tumours is still open. Moreover a careful follow up is necessary because 4 cases of serous cistoadenocarcinomas of the pancreas are reported in the literature. These considerations justify the aggressive attitude we adopted in the last decade. Our policy is conservative only in the microcystic CAS, of small dimensions, symptom free and particularly when located in the head. "P P 64 1522"P 64 1522**Cystic Neoplasms of the Pancreas: Study of 72 CasesM.A.C. Machado[1],**

*G. Spiliopoulos[1], P. Volpe[2], A.L. Montagnini[2], C. Stasik[1], T. Bacchella[2], J.E.M. Cunha[2], J.P. Campion[1], M.C.C. Machado[2], B. Launois[1]

[1] Department of Surgery and Transplantation Unit., University of Rennes, France

[2] Department of Surgery and Transplantation Unit., University of S\'e3o Paulo, BrazilCystic neoplasms are an uncommon group among pancreatic tumors. These lesions are seen more frequently in recent surgical practice, probably because of advances in diagnostic and surgical techniques. The aim of this study is to describe the diagnostic features and therapeutical options in the management of cystic tumor of the pancreas. We report here our experience with 72 patients with pancreatic cystic tumors over a ten-year period. Sixty-two four patients were women and ten were men. The mean age of patients was 55.2 years (range, 21 to 81 years).Mild abdominal pain was the main symptom in 70% of patients. The lesion were incidental finding in 10% of patients. CT scan provided the diagnosis of cystic tumor in 94% of patients while ultrasonography provided the same diagnosis in 78% of patients. All patients underwent surgical treatment. The pathological diagnosis was: thirty patients with mucinous cystadenoma (41.7%), thirty-two patients with serous cystadenoma (44.4%), ten patients with mucinous cystadenocarcinoma (13.9%). There was no operative mortality. Seven of ten patients with cystadenocarcinoma ultimately died of the disease. One patient with extended resection is still alive 3 years after surgery without recurrence of the tumor. The survival rate was 20.5% at 3 years. All patients with cystadenomas (mucinous or serous type) that underwent complete resection are alive or died from other causes.Only complete resection of the cystic tumors of the pancreas provides certain pathological diagnosis, the best chance of cure and may remove the risk of malign transformation of the cystadenomas, particularly of the mucinous type, with minimum operative risk. *J.D. Evans[1], S.R. Bramhall[2], I.A. Donovan[1], J.P. Neoptolemos[2], M.C. Eggo[3]

[1] Department of Surgery, City Hospital, Birmingham, UK

[2] Department of Surgery, Queen Elizabeth Hospital, Birmingham, UK

[3] Department of Medicine, Queen Elizabeth Hospital, Birmingham, UKThe growth and progression of cancer may involve both an increase in cell proliferation and a reduction in apoptosis (programmed cell death). Protein kinase C (PKC) is a serine/threonine kinase which has an important role in cell proliferation and survival including the control of apoptosis. This study aims to investigate the effect of phorbol esters on cell proliferation and whether down regulation of PKC isoforms is associated with the induction of apoptosis.Pancreatic cancer cell lines (SUIT 2 and BXPC3) grown in serum-free conditions were treated for 24 hours with tumour promoting phorbol esters 12-0-tetradecanoylphorbol-13-acetate (TPA) and 12-deoxyphorbol-13-0-phenylacetate-20 acetate (DOPPA) which activate PKC. Cell proliferation was assessed by the incorporation of ^{3}H thymidine. DNA laddering and acridine orange staining was used to assess apoptosis. Western antibody blotting was used to assess PKC isoform expression.Treatment of SUIT 2 and BXPC3 pancreatic cancer cell lines with TPA, a pan activator of PKC isoenzymes inhibited cell proliferation in a dose-dependent manner and induced apoptosis ($p < 0.02$). In SUIT 2 cells, down regulation of PKC { d} and { g} at 6 hours was associated with the earliest detection of apoptosis. Doppa which is thought to be specific for the { b} isoform of PKC induced apoptosis at 24 hours and also induced down-regulation of PKC isoforms.Phorbol esters inhibit proliferation and induce apoptosis of pancreatic cancer cell lines. This effect appears to be mediated by the down-regulation of selective isoforms of PKC. A greater understanding of mechanisms of apoptosis may enable the development of new therapeutic strategies in the future. Dipartimento di Medicina di Laboratorio, Universita' degli Studi di Padova, Italy

[1] Malattie del Metabolismo, Universita' degli Studi di Padova, Italy

[2] Clinica Medica I, Universita' degli Studi di Padova, ItalyMIA PaCa2 cell culture supernatants cause hyper-glycemia ""in vivo"". The aim of the present study was to verify the effects of MIA PaCa2 cell culture medium on liver glucose metabolic pathway. MIA PaCa2 cells were cultured in DMEM with 10% FCS. Conditioned medium (A) was collected after 6 days. Medium B was non conditioned DMEM. Five separate sets of experiments with hepatocytes, isolated from in situ perfused rat liver, were made. The hepatocytes were divided into 4 fractions: 2 were incubated with medium A with or without insulin (100 nM) and the other 2 with medium B with or without insulin. The hepatocytes were placed in an oxygenated atmosphere at 37 C for 3 hours. Every 5 min. glucose, lactate, pyruvate and insulin were measured in the supernatant, while pyruvate kinase (PK) and hexokinase (HK) (spectrophotometric assays) and cAMP (RIA) were measured in hepatocyte lysates. Protein kinase C activity (PKC) was measured in hepatocyte cytosolic and membrane fractions after PMA stimulation, measuring phosphate incorporation from ATP into saturating amounts of a PKC selective peptide. Glucose slowly decreased when hepatocytes were incubated with both medium A or B, treated or not with insulin. Lactate progressively increased in medium B (increase = 1.3 + 0.4 mmol/L, mean + SEM) and was not influenced by insulin; this increase was significantly higher than that found in medium A (0.4 + 0.1 mmol/L; Student's t test: $t = 2.19$, $p < 0.05$). Pyruvate behaved closely to lactate. HK slightly increased in each set independently from the medium and insulin presence and correlated with glucose (r = { -}0.82, $p < 0.01$). PK activity in hepatocytes incubated in medium B after insulin stimulation, peaked after 5 minutes (activation) and between 20 and 45 minutes (gene induction); these activations completely lacked in the presence of medium A. In the hepatocytes treated with medium A a significant increase of cAMP was observed in the first 10 minutes (20 + 6%, mean + SEM; % vs basal) as compared to the hepatocytes treated with medium B (4 + 3%) ($t = 2.42$, $p < 0.05$). A reduced activation of PKC after PMA stimulation was found in hepatocytes incubated in medium A, suggesting that this enzyme has been previosly activated. In conclusion: MIA PaCa 2 cells release one or more factors which interfere with hepatic glucose metabolism. These factos block both glucose metabolism to lactate and insulin action, possibly through adenylate cyclase and PKC intra-cellular signal pathways which could counteract the cascade of insulin activated protein kinases. "P P 64 1525"P 64 1525**Pancreatic Cancer Growth and Spread Are Differently Influenced by Epidermal Growth Factor (EGF), Interleukin-1 Alpha (IL-1a) and Beta (IL-1b) and Transforming Growth Factor Beta 1 (TGFb)**

*M.P. Panozzo, M. De Paoli, D. Basso, P. Carraro, D. Burighel, M. Plebani

Department of Laboratory Medicine, University of Padova, ItalyThe integrity of extracellular matrix (ECM) surrounding neoplastic cells may counteract tumor spread from the primary site. A reduced production or an enhanced degradation of ECM components (e.g. collagen, fibronectin, laminin, etc.) could represent one of the first steps in metastasis. Aims of the present study were to evaluate the effects of EGF, IL-1a, IL-1b and TGFb on 1. the pancreatic cancer cell line MIA PaCa 2 growth, 2. the production by the above cell line of the aminoterminal propeptide of type III procollagen (PIIIP), plasminogen activator (uPA) and plasminogen activator inhibitor (PAI1), the latter two both involved in the regulation of ECM degradation. MIA PaCa 2 cells (100,000/25 cm2 flasks) were cultured in DMEM supplemented with 10% FCS for the first three days, followed by 1% FCS for the subsequent three days. EGF (10 and 100 ng/mL), TGFb (0.1 and 1.0 ng/mL), IL-1a and IL-1b (10 and 100 pg/mL) were daily added to cell culture medium from day 3 to day 6. On days 4, 5 and 6 the cells were harvested and counted; PIIIP was measured in cell lysates (ELISA, CIS-France), while uPA and PAI1 were assayed in cell culture media (ELISA, Biopool-USA and Diagnostica Stago-France). Each experiment was run in triplicate; the results from day 5 will be further reported, being in agreement with those found on days 4 and 6. EGF stimulated cell growth in a dose dependent manner (128% and 160% for 10 and 100 ng/mL respectively), while inhibiting PIIIP (83% and 46%), uPA (76% and 52%) and PAI1 (74% and 51%) levels. An opposite pattern was found when TGFb was used at the dosage of 0.1 ng/mL: cell growth was inhibited (78%), while PIIIP (109%), uPA (142%) and PAI1 (165%) levels were increased. TGFb used at a higher dosage (1 ng/mL) exerted only minor effects on the analysed parameters. IL-1a and IL-1b had similar effects; when used at the dosage of 10 pg/mL they slightly stimulated cell growth (120% and 125%) while inhibiting PIIIP (64% and 56%), uPA (38% and 83%) and PAI1 (60% and 47%) levels. At a higher dosage (100 pg/mL) they did not significantly influence the parameters studied. *Conclusions:* Cytokines which exert a positive effect on cell growth (EGF, IL-1a and IL-1b) seem at the same time to favour tumor spread by reducing the production of ECM components like PIIIP and by altering the balance between ECM degrading enzymes and their inhibitors. On the contrary cytokines which inhibit pancreatic cancer cell growth (TGFb) seem to inhibit also tumor spread. These findings might have in the future therapeutical implications. "P P 64 1526"P 64 1526**Resection for Pancreatic and Periampullary Tumours in 956 Patients: Results from UK Specialist Units**

*J.P. Neoptolemos, UK Pancreatic Cancer Group (UKPACA)

Dept. Of Surgery, Queen Elizabeth Hospital, Birmingham B15 2TH, UK*Background:* A survey of 13,560 patients of pancreatic cancer from general surgical units in the UK of whom 2.6% underwent resection revealed a post-operative mortality of 28%. No data are available from specialist units in the UK. Moreover, previous studies have suggested no relationship between caseload and surgical outcome.*Aims:* The purpose of this study was to review the outcome from specialist units for comparison with the previous study in the UK and also 5 surveys of general units and from nine large specialist units published since 1990.*Summary of Results:* There were 956 resections reported by 30 surgeons from 20 units in the UK with 56 (5.8%) re-operations for complications and with 57 (5.9%) post-operative deaths. Mortality was significantly lower in the specialist units compared to the general units from the UK ($\{ ?\}^2{}_1 = 43.1$, $2p < 0.0001$). Combining the UKPACA data from those from published specialist units (n = 29 units; n = 1750 cases) they were compared with the published surveys from general units (n = 338 units; n = 1396 cases). The median [95% CI] mortality was lower in the specialist units (4.9%, [3.1%, 8.0%]) compared to general units (9.8% [2.5%, 23.2%]; 2p = 0.008). The caseload was significantly lower in specialist units (8.2 [7.0, 13.5] cases per unit per year) compared to general units (0.4 [{ -}0.3, 2.0] cases per unit per year; 2p = 0.007).*Conclusion:* Specialist units from the UK have comparable results to other specialist units in other countries. Overall specialist units have a significantly lower post-operative mortality and a higher caseload than general surgical units. Dept. of Internal Medicine I, University of Ulm -Germany-

[1] Dept. of Gastroenterology, University of Padova -Italy-

[2] Dept. of Pathology, University of Padova -Italy-Colecystokinin (CCK) can stimulate pancreatic acinar cell growth. To study the effects of in vivo stimulation with cerulein (a CCK analog), we analyzed the expression of the proto-oncogenes jun, myc and fos in terms of both mRNA and protein expression. RNA and proteins were extracted from the pancreas of rats administered an infusion of cerulein 10 ug/kg/h (Group A) or 0.25 ug/kg/h (Group B), or saline (Group C) and sacrificed 2, 4, 6 hours after beginning of the infusion and 0, 12, 24 hours and 2, 4, 6 days after completing a 12-hours cerulein (submaximal or supramaximal dosages) or saline infusion period. Transcript levels were analyzed using Slot Blot and in-situ hybridization. Protein expression was studied using Western Blot and Immunohistochemistry. No changes were found for the expression of proto-oncogenes myc and fos either on the transcript or protein levels. Significantly higher jun mRNA levels were found in Group A than in Groups B or C ($P < 0.05$), particularly after 2 h of infusion and 12, 24, and 48 hours after the end of 12 h cerulein infusion. No significant difference was observed in Groups B and C. The jun protein behavior seemed similar in Groups A and B, revealing an early peak during infusion and another later on, after the end of 12 h cerulein infusion. Jun mRNA and jun protein were found in the acinar cells. In conclusion: (1) acinar cells respond to cerulein stimulation by increasing the expression of jun, a proto-oncogene mainly involved in cell proliferation; (2) in vivo, high dosages of cerulein increase jun mRNA and jun protein levels, whereas low dosages only raise protein levels; (3) myc and fos are apparently uninfluenced by cerulein administration. *J. Ringel, R. Jesnowski, J. Rychly, B. Nebe, J. Emmrich, K. P\'fcschel, P. Dall[1], G. Sparmann, S. Liebe, M. L\'f6hr

Dept. of Medicine, University of Rostock, Germany

[1] Dept of Ob/Gyn, University of D\'fcsseldorf, Germany*Purpose* The reasons for the aggressive growth and metastatic behaviour of pancreatic cancer are poorly understood. Recently, we showed the expression of matrix proteins, integrins, and growth factors in pancreatic tumours (Br J Cancer 69: 144–151, 1994; Pancreas 12: 248–259, 1996). Other studies indicated the possible role of overexpressed growth factors and their receptors suggesting paracrine and/or autocrine effects in tumour development. Furthermore, CD44variants, VLA { a}6, and ICAM-1 may be involved in tumourigenicity and metastasis of pancreatic cancer. In the present study we examined whether TGF{ b}1 can influence the expression of different cell adhesion molecules. *Methods* The an pancreatic tumour cell line PANC1 was transfected with an expression vector containing full length TGF{ b}1 using the DOTAP method (Boehringer). The TGF{ b}1-production was assayed with a TGF{ b}1 ELISA (R&D). The expression of CD44st, CD44v5-v7, ICAM-1, and VLA { a}2 and { a}6 was measured by flow cytometry. Untransfected PANC1 cells were incubated with TGF{ b}1 (Sigma) for 48 hrs and ICAM-1 expression was assayed, too. *Results* Transfected cells showed an increase in TGF{ b}1 production. Transfected cell expressed slightly increased CD44 v5–v7. Expression of { a}6 was unchanged and decreased of { a}2, CD44st, and ICAM-1 in comparison to the untransfected cells. The incubation of untransfected PANC1 with various concentrations of TGF{ b}1 reduced the ICAM-1 expression, too. *Conclusion* The overexpression of transfected TGF{ b}1 as well as exogenous TGF{ b}1 modulated the expression of different adhesion molecules associated with cell-matrix interaction and metastasis. Further investigations are neccessary to determine the role of these effects on tumour progression and metastatic potential. "P P 64 1529"P 64 1529**Growth Inhibitory Effect of an Essential Fatty Acid Containing Lipid Emulsion on Pancreatic Cancer Cell Lines in-vitro**

*D. Ravichandran, A. Cooper, C.D. Johnson

University Surgical Unit, Southampton General Hospital, SO16 6YD, UKTreatment of inoperable pancreatic carcinoma is unsatisfactory at present and a new chemotherapeutic agent with minimal side effects would be welcome. Essential fatty acids (EFA) such as gamma linolenic acid (GLA) and eicosapentaenoic acid (EPA) have antitumour effects. We tested the effect of a lipid emulsion containing GLA and EPA on 2 human pancreatic ductal carcinoma cell lines Panc1 and MIA PaCa2.Cells were grown as monolayer on plastic under standard conditions in culture medium containing 10% FBS, harvested and seeded at 2500 cells in 100 \'b5l of medium per well in 96 well cell culture plates. GLA/EPA emulsion (containing 10 g of each EFA in 100 mls) (Scotia, Stirling, UK) in 100 \'b5l of medium was added 24 hours later to achieve final concentrations varying from 2.5 to 640 \'b5mol/l of each fatty acid. Control experiments were run with culture medium alone and a with a control lipid emulsion (Ivelip, Clinitec, UK) to exclude a nonspecific fat overload effect. Cell growth was assessed by a microculture tetrazolium (MTT) assay after 7 days.GLA/EPA emulsion showed a significant dose and time dependant growth inhibitory effect on both cancer cell lines. Cell growth was not affected by the control lipid emulsion. Preliminary nude mice studies have shown that this compound is well tolerated when administered IV, with no toxic effects.GLA/EPA emulsion is a non-toxic formulation of both EFA's and may provide a useful therapeutic adjunct in patients with pancreatic cancer. "P P 64 1530"P 64 1530**Effect of Liposomal Lithium Gamma Linolenic Acid in Pancreatic Cancer**

*D. Ravichandran, A. Cooper, S.J. Karran, C.D. Johnson

University Surgical Unit, Southampton General Hospital, SO16 6YD, UKLithium salt of Gamma Linolenic Acid (LiGLA) has been reported to prolong the survival of patients with inoperable pancreatic cancer. We studied the effect of LiGLA on 2 pancreatic ductal cancer cell lines (Panc1 and MIA PaCa2) in vitro and the effect of liposomal LiGLA on MIA PaCa2 derived pancreatic tumour in athymic mice.For in vitro study the cells were seeded in 96 well culture plates. LiGLA (Scotia, Stirling, UK) was added 24 hrs later (5–490 \'b5mol/l). A human fibroblast cell line was used as the control. Oleic acid (OA), Palmitic Acid (PA) and Lithium Chloride (LiCl) controls were used to exclude a nonspecific fat overload effect and a lithium effect. The cell growth after 7 days was assessed by the MTT say. For in vivo studies, Balb c nude mice were inoculated subcutaneously with 5 times; 10^6 MIA PaCa2 cells. Once progressive tumour growth was confirmed they were treated with liposomal LiGLA IV over 10 days (total dose 0.8 mg/g body weight). Control animals received blank liposomes. The tumour size was measured weekly for 4 weeks following therapy.LiGLA showed a selective and significant dose and time dependent growth inhibitory effect on both cancer cell lines in vitro. The IC50 of cancer cell lines were 10 times lower than the IC50 of fibroblasts. OA, PA and LiCl had no effect. A reduction of tumour growth was also achieved in nude mice with pancreatic tumours that received liposomal LiGLA, compared with controls.LiGLA has no side effects of conventional chemotherapy and may prove useful in patients with pancreatic cancer. Oncology, specific: Pancreas }" "Effect of Liposomal Lithium Gamma Linolenic Acid in Pancreatic Cancer"

"P P 64 1532"P 64 1532**Preoperative Laparoscopy: Do We Need it in Patients with Pancreatic Malignancies?**

*H. Friess, H.U. Baer, W. Uhl, Ch. Seiler, J.-C. Silva, Ch. Sadowski, M.W. B\'fcchler

Department of Visceral and Transplantation Surgery, University of Bern, SwitzerlandThe role of laparoscopy prior to laparotomy in patients with pancreatic or periampullary malignancies is controversial. Recently, several studies have been published reporting that in up to 36% of the patients, metastasis can be detected by laparoscopy which were not found by contrast-enhanced computed tomography (CT) or magnetic resonance imaging (MRI).The aim of our present study was to investigate the potential role of laparoscopy prior to laparotomy in patients undergoing laparotomy for pancreatic or periampullary malignancies.*Patients:* Between 11/1993 and 12/1995, 127 pats (57 women, 70 men, median age: 67 years, range: 29–84 years) underwent laparotomy due to pancreatic (97 pats) or periampullary (30 pats) cancer. Preoperatively, all pats underwent CT scanning to assess resectability of the tumor. In addition, ultrasonography or MRI was performed facultatively before the operation. According to the findings of these imaging techniques, the pats were scheduled either for tumor resection or for a palliative operation.*Results:* 25 pats were preoperatively scheduled for non-resectional surgery due to distant metastasis or retroperitoneal tumor infiltration. In none of these pats was the operative strategy changed. In 102 of 127 pats (80%) a pancreatic resection was planned preoperatively. 71 pats (70%) underwent pancreatic resection. In the remaining 31 pats preoperatively planned for tumor resection, removal of the tumor was not possible: in 21 this was due to tumor infiltration into the retropancreatic vessels, and in 10 this was because liver or peritoneal metastasis could be detected for the first time intraoperatively. Those 10 pats (10%) could have benefited from laparoscopy. Similar results were found in 97 pats with pancreatic cancer. 71 pats were planned for tumor resection and 26 pats for palliative operation. Of 71 pats preoperatively planned for tumor resection, 46 pats (65%) underwent pancreatic resection. In the remaining 25 pats preoperatively planned for tumor resection, removal of the tumor was not possible: in 16 this was due to tumor infiltration into the retropancreatic vessels, and in 9 this was because liver or peritoneal metastasis could be detected for the first time intraoperatively. These 9 pats (13%) would also have benefited from laparoscopy.*Conclusion:* Preoperative computed tomography is a reliable technique to detect tumor metastasis in patients with pancreatic or periampullary cancer. In contrast to other studies, we found that only 10% of pats with periampullary/pancreatic cancer and 13% of pats with pancreatic cancer might profit from laparoscopy. Due to this low percentage, laparoscopy cannot generally be recommended in pats with pancreatic or periampullary cancer prior to laparotomy, particularly if we take into account the risk of tumor dissemination probably caused by laparoscopy. Laparoscopic surgery: DiagnosisOncology, specific: Pancreas }" "Preoperative Laparoscopy: Do We Need it in Patients with Pancreatic Malignancies?"

"P P 64 1533"P 64 1533**Indeterminate Pancreatic Masses: Failure of Modern Imaging Methods to Exclude Malignancy**

*T. R\'f6sch, J.R. Roder, T. Decassian, P. Born, H.J. Dittler, W. Bautz, H.D. Allescher, P. Gerhardt, J.R. Siewert, M. Classen

Dept. of Internal Medicine II, Surgery and Radiology, Technical University of Munich, GermanyThe precise differential diagnosis of indeterminate pancreatic masses is still a major problem in deciding on the appropriate diagnostic approach. In this retrospective study we blindly assessed the accuracy of computed tomography (CT), ERCP and endoscopic ultrasonography (EUS) in the differential diagnosis of these tumors. Follow-up information about patient survival was also obtained.75 patients (47 male, age 36–76 years) with pancreatic head tumors undergoing a Whipple procedure over a period of 5 years were included. ERCP and CT images as well as EUS tapes were reviewed completely blindly by three different examiners. Sensitivity and specifity were calculated for diagnosis of malignancy. Follow-up information was obtained from hospital charts, interviews with patients' physicians or through a local tumor registry.Of the 75 patients, 51 had cancer, 5 benign tumors (3 endocrine, functionally inactive) and 19 focal chronic pancreatitis. During follow-up (mean: 38 months), 2 patients originally diagnosed as focal chronic pancreatitis returned with liver metastases and histological work-up of the previous resection specimen in one revealed a very small cancer focus. Sensitivity and specifity for the diagnosis of malignancy were as follows: 73%/73% for the tumor marker CA 19-9, 19%/86% for CEA, 81%/50% for CT, 86%/43% for ERCP and 81%/27% for EUS. 61% of patients underwent some form of preoperative biopsy (ERCP or percutaneous) which had a sensitivity of 50% only. In 50% of cases post-operative complications were encountered (half of them minor) which necessitated relaparotomy in 16% of all cases. Follow-up revealed a 3 year survival of 10% for tumors and 95% for focal chronic pancreatitis.Since imaging procedures and also biopsy attempts often fail to diagnose malignancy with a sufficient specifity, our data show that proceeding to a Whipple operation is currently the best way to establish the diagnosis, although the prognosis of cancer patients is very poor. "P P 64 1534"P 64 1534**Effects of CCK, Bombesin and EGF on Growth of Human Pancreatic Cell Lines PANC-1 and CAPAN-2**

*B. Burghardt, K. Barab\'e1s, Z. Marcsek[1], L. Flautner[2], T. Gress[3], G. Varga

Inst.-Experimental Med., HAS, Budapest

[1] Dept. Cell Biol., HAS-SUM, Budapest

[2] 1st Dept. Surgery, Semmelweis Univ. Med., Budapest

[3] Dept. Med. I, Univ. UlmNumerous studies have reported diverse effects of gut-derived regulatory peptides on growth of the normal pancreas, pancreatic neoplasms induced experimentally in animals, and pancreatic cancer cell lines. The results of these investigations are rather controversial.In the present study the growth of human adenocarcinoma cell line PANC-1 and CAPAN-2 were characterized in vitro, and the effects cholecystokinin (CCK), bombesin and epidermal growth factor (EGF) were determined. Cells were maintained at 37\'b0C in a humidified atmosphere of 5 percent CO_2 and 95 percent air in DMEM medium supplemented with 10 percent fetal calf serum (FCS). In each experiment cells were initially plated in media containing FCS for 24 h. Then cells were incubated with medium devoid of FCS in the absence (control) or the presence of the peptides. Growth effects of peptides were determined by cell counting after 6 days, and by [^{3}H]thymidine incorporation into DNA after 24 h incubation.Our data show that FCS is not required for maintaining growth in PANC-1 and CAPAN-2 cell lines. In serum free medium the number of PANC-1 cells more than doubled during the six days incubation period (day 0: 100.000 cells, day 6: 265.000 – 37.000 cells). Either bombesin or cholecystokinin (both in $10^{\{-}$11}–$10^{\{-}$8} M) did not significantly affect the growth of the cells during this six-day treatment. DNA synthesis in PANC-1 and CAPAN-2 cell lines evaluated by [^{3}H]thymidine incorporation increased 106% and 64%, respectively, over controls in response to EGF ($10^{\{-}$8} M) treatment ($P < 0.01$). Neither bombesin nor CCK altered significantly the incorporation of [^{3}H]thymidine in concentration range $10^{\{-}$11}–$10^{\{-}$8} M in these two cell lines.These data support a role for EGF as a growth factor for human pancreatic cancer cell lines PANC-1 and CAPAN-2. CCK and bombesin do not affect the cell proliferation in these pancreatic carcinoma cell lines. Hormones and receptors: Receptor characterizationHormones and receptors: Growth factorsOncology, specific: Pancreas }" "Effects of CCK, Bombesin and EGF on Growth of Human Pancreatic Cell Lines PANC-1 and CAPAN-2"

"P P 65 1535"P 65 1535**Factors of Weight Loss in HIV-Infected Patients with Chronic Diarrhea: A Multidimensional Study**

*L. Beaugerie, F. Carbonnel, F. Carrat, A. Abourached, P.M. Girard, J. Cosnes, W. Rozenbaum, J.P. Gendre

Departments of Gastroenterology and Infectious diseases, Hospital Rothschild, and INSERM U444, Paris, FranceBody weight loss is a prominant clinical feature in HIV-infected patients with chronic diarrhea. The purpose of our prospective study was to look for the links between the degree of wasting, the level of food intake, and the severity of diarrhea. *Patients and Methods:* Between 1989 and 1996, 116 consecutive HIV-infected patients (109 males, 7 females, mean CD4 count 50/mm^3) with chronic diarrhea underwent a standardized gastrointestinal and nutritional evaluation, including: a) a questionnaire on the clinical severity of diarrhea; b) a prospective evaluation of 48-h food intake; c) a measurement of fecal weight, lipid and nitrogen output; d) a measurement of nutritional biological parameters from blood; e) a stool examination for bacteria and parasites; f) an upper gastrointestinal endoscopy and a rectosigmoidoscopy. *Results:* Diarrhea was associated with an infection by cryptosporidia, microsporidia, or other enteric pathogens in 27%, 24%, and 22% of the patients, respectively. Diarrhea appeared idiopathic in 27% of the patients. By multiple regression, the weight loss since the onset of diarrhea (15 – 8% of the initial weight, m – SD) was significantly related to four independent variables: the spontaneous caloric intake (25 – 8 kcal/kg/d), the maximal frequency of stools within the week before evaluation (8 – 7 movements/d), the stool weight (575 – 470 g/d), and the fecal nitrogen output (2.5 – 1.5 g/d). No significant correlation was found between the level of spontaneous caloric intake and the fecal parameters, neither by univariate study or multiple regression. *Conclusions:* Our results suggest that, in HIV-infected patients with chronic diarrhea, the degree of wasting is significantly related to the level dietary intake, and to the severity of diarrhea. However, no significant correlation can be demonstrated between the level of dietary intake and the severity of diarrhea. Immunology and microbiology: GI infections in adults }" "Factors of Weight Loss in HIV-Infected Patients with Chronic Diarrhea: A Multidimensional Study"

"P P 65 1536"P 65 1536**Intestinal Absorption in HIV Infected Patients**

*S. Mouly, J.F. Bergmann, O. Chassany, C. Caulin

Unit of therapeutic research, Lariboisiére Hospital, Parish, France*Objective:* To assess prospectively intestinal absorption and its relation to nutritional status, immunodeficiency, presence of diarrhea and/or parasites in stools, in 36 unselected HIV-infected patients.*Methods:* 29 men and 7 women HIV-positive with and without diarrhea (mean age, 40 years) were consecutively enrolled. A physical examination, with determination of Body Mass Index (BMI) was performed. The immunologic status was assessed by total blood CD4 cell count and detection of P24 antigenemia. Albumin and transferrin serum levels were performed, and 2 stool samples were analysed for the presence of parasites. Absorption tests were a standard D-Xylose test and a 72-hours fecal fat measurement.*Results:* 20 patients fulfilled criterias of AIDS-defining illness, 17 of whom presented with one or more secondary infections at the time of the study. Wasting Syndrome (WS) was present in 9 patients. CD4 cell count was below 200/\'b5l in 24 cases, 7 of whom had positive P24 antigenemia. 13 patients had diarrhea (D), associated with WS (n = 6), and low CD4 cell count (n = 9). Weight, BMI, albumin and transferrin serum levels were all significantly lower in patients with diarrhea and/or WS (*p* {\'a3} 0.01). Eight patients had parasites in stools: cryptosporidia (n = 4), microsporidia (n = 4). Their mean CD4 cell count was 31/\'b5l. Six patients fulfilled criterias of ""HIV-induced enteropathy"", with malabsorption (n = 4), WS (n = 3), and a mean CD4 cell count of 146/\'b5l ($p < 0.05$). Association between diarrhea, WS and intestinal malabsorption are shown in the following table: CD4 < 100 CD4 > 100 D No D WS No WSParasites in stools 6 2 5 3 3 5Xylosemia < 1.7 mM/l 4 3 5 2 4 3Fecal fat > 6 g/day 2 1 2 1 1 2Intestinal malabsorption was not correlated with respectively, nutritional and immune status, diarrhea and parasites in stools among these unselected consecutive HIV-infected patients.*Conclusion:* In this prospective study, intestinal malabsorption was independent of nutritional and immune status, diarrhea and parasites in stools. Evaluation of intestinal absorption in HIV-infected patients might be helpful to improve therapeutic management at any stage of the disease. "P P 65 1537"P 65 1537**Clinical Aspects of Pancreatic Disorders in 280 Patients with Aids, Submitted to *Post-Mortem* Studies**

*I.C. Barros, C.A.B. Oliveira, C.E. Brand\'e3o-Melo, J.M.C.O. Coelho, M.C. Torres, P.A. Lima-F.

H.U. Gafr\'e9e Guinle, UNI-RIO, HUAP, Universidade Federal Fluminense, Rio de Janeiro, BrazilAiming at evaluating the incidence, the main etiologies and the clinical profile of pancreatic disorders in AIDS, the authors analysed the *post-mortem* studies of 280 patients, from which they selected 82 with some form of pancreatic disease. These encompassed 31 cases with non-specific disorders (13 with acute pancreatitis, 14 with chronic fibrosis and/or duct dilation of the pancreatic canaliculus and 4 with vascular alterations); 11 cases with neoplastic involvement (9 with Kaposi's sarcoma and 2 with metastatic adenocarcinoma) and 40 cases with pancreatic opportunistic infections (14 with *Mycobacterium tuberculosis,* 11 with *Cytomegalovirus* (CMV), 8 with *Cryptococcus neoformans,* 5 with *Hystoplasma capsulatum* and 2 with *Toxoplasma gondii.*) On a second phase, the authors made a correlation between these data with those obtained from a 40 patients group with no pancreatic alterations. In this control group we observed a higher incidence of abdominal symptoms that, in clinical practice, could simulate a pancreatopathy. The majority of these patients died due to infectious or neoplastic causes, which affected either the nervous system or the respiratory tract. None of the patients received the diagnosis of pancreatopathy as *""causa mortis"".* After the statistical analysis, the authors concluded that: 1. The pancreatic disorder in AIDS was less frequent in our group when compared to previous reviews ($p < 0.001$); 2. The behavior of the pancreatic disorders in AIDS is subclinical, benign and completely atypical if compared to the classical forms; 3. Tuberculosis stood out as the major cause of pancreatopathy ($p < 0.001$) and CMV's pancreatitis was less frequent in our study than in other communications ($p < 0.001$); 4. Pancreatic involvement by *Hystoplasma capsulatum,* not previously reported, was identified in 5 cases. "P P 65 1540"P 65 1540**Immunohistological Study of the Mesenteric Nodes in Deceased Children with AIDS**

*R. Ilie[1], N. Tudose, C. Ilie, M. Lesovici[1]

[1] University of Medicine and Pharmacy Timisoara-Romania

Clinical Children Hospital ""Louis Turcanu"" Timisoara-RomaniaAcquired immunodefiency syndrom (AIDS) in children is a multisystemic disease with the modification of the proportions of T-helper and T-suppressor cells in sense of increase the latter in the mesenteric nodes is in accordance with blood lymphocitic values achieving an ""mirror"" appearance. *Materials and method.* There was taken mesenteric nodes, necroptic pices. There were 9 deceased children with AIDS in the ""Children Hospital Louis Turcanu"" and ""Infectious Diseases Clinic"" Timisoara from which the samples were obtained. The confirmation of the diagnose was intra-vitam made by sequential serological determination of the virus through ELISA and Westtern-Blott techniques. The prelevated pieces were fixed in neutral formalin and then was performed ordinary procedure for processing until we obtained the paraffine blocks and studied that by comparing the Hematoxylin-eosin and immunohistochemical coloration. *Results:* 1. Numerical increase sometimes excessive of the CD8, T lymphocytes into the germinative centers and lymph node sinuse and spleen. 2. A depletion of different degrees of CD4, T lymphocytes into the germinative centers and profound cortex of the lymph nodes, in the periarteriolar lymphoid muffs and speen's Malpighi corpuscles. 3. The variable fragmentation of dendritic cells from germinative ganglionic centers and epitheloid cells from thymic paramedular zone. The described modifications were constantly present to all studied cases confirming the different degrees of immunodepession in AIDS. The germinative ganglionic centers are the most important virus tank in the patients with AIDS, they being precociously infected in the course of the disease. The progressive and slowly destruction of germ centers takes place over all the length of disease. "P P 65 1541"P 65 1541**Cytotoxicity Influences Hydrophobic Surface Properties of Helicobacter PyloriD. Risberg, H. Enroth, L. Engstrand, A. Uribe**

Department of Medicine, Karolinska Institute, Danderyd Hospital, Stockholm, Sweden

Department of Microbiology, University Hospital, Uppsala, SwedenBacterial adherence to epitelial cells is dependent on their surface hydrophobicity, which is of importance for an unspecific attachment of the microorganism to the mucosal surface. Thereafter a specific, receptor-mediated, binding may occur. Our aim was to examine the surface hydrophobicity of different strains of Helicobacter pylori (H. pylori) by means of contact angle measurements.*Methods:* 18 different strains of *H. pylori* including knock-out mutants lacking vac A cytotoxic protein (A5 vac A and 17874 vac A), and *H mustelae,* were processed for contact angle measurements. After cultivation, the viable bacteria were centrifugated and the pellets were evenly spread on glass slides. After 30 minutes of air drying, a droplet of saline was applied and the contact angle was measured using a goniometer. A mean value of four different measurements on each slide was calculated.*Results:* The contact angles of the strains A5 vac A and 17874 vac A were lower than those of A5 and 17874 respectively ($p < 0.001$). Similarly, the contact angle of SVA40 was lower than that of GZSVA40 ($p < 0.001$). Urease-negative H. pylori, H. mustelae and strains of H. pylori obtained from patients with duodenal ulcer disease, antral gastritis or gastric cancer showed significant differences in contact angles ($p < 0.01$).*Conclusions:* The presence of vacuolisating A protein increases surface hydrophobicity which may contribute to bacterial adherence and facilitate their cytotoxic action. The differences in contact angles observed in the various examined strains may be of importance for the pathogenic actions of certain Helicobacter pylori strains on the human gastric mucosa. "P P 65 1542"P 65 1542**Oral Cavity as Permanent Reservoir of *Helicobacter Pylori* (Hp) and Potential Source of Gastric Reinfection**

*J. Pytko, E. Karczewska, J. Majka, S.J. Konturek

Inst Physiol & Dept Conserv Dent, Univ Sch Med, Krakow, Poland*Purpose:* Studies in developed countries showed that neither dental plaques (DP) nor dentures are important reservoir for Hp, whereas studies in developing countries revealed a high prevalence of Hp in DP, though elsewhere successful bacterial culture in the material from mouth cavity was rare. This study was designed to compare the incidence of Hp in mouth cavity and in the stomach of 10 healthy and 100 peptic ulcer (PU) patients 18–69 yr old.*Methods:* ^{14}C-oral urea breath test (UBT) (with ^{14}C-urea dissolved in water and confined for 5 min only to the mouth cavity — without swallowing), CLO-test, Hp culture on special ""Hp Agar"" and PCR for Hp DNA in saliva, gingival pockets and DP were used to assess the presence of Hp in mouth cavity. In the stomach, ^{14}C-gastric UTB (^{14}C-urea 1 \'b5Ci in capsule dissolved in the stomach), endoscopy with biopsy for CLO-test, histology and culture were used to identified the Hp infection.*Methods:* Ten healthy subjects without symptoms and in 100 symptomatic patients with gastric or duodenal PU were tested just before the start and 4 weeks after the termination of 2 wk triple therapy (omeprazole 20 mg bd, clarithromycin 500 mg td and metronidazole 500 mg bd) when endoscopically PU were healed. All 10 healthy subjects were found to be Hp-positive in the mouth cavity but only 7 in the stomach. All PU patients before the therapy were found to be Hp positive both in the mouth and in the stomach. Following triple therapy in PU 86 patients became Hp negative in their stomach but only in 5 of them the Hp was not detected in the mouth by culture and PCR.*Conclusions:* the mouth is permanent reservoir of Hp both in healthy subjects and in PU patients before and after successful eradication of Hp from the stomach, being a potential source of reinfection. "P P 65 1543"P 65 1543**Helicobacter Infection in AIDS Patients: Correlation between Morphologic Findings and Serum Levels of Pepsinogen I–II and Gastrin**

*C. Giannelli, R. Paloscia, A. Cianetti[1], S. Ciarletti, M.G. Graziani, M. Luminari

Department of Gastroenterology

[1] Clinical Laboratories, S. Camillo Hospital, Rome, ItalyThe prevalence of H. Pylori infection in HIV positive pts is much lower than for HIV negative population (10–15% vs 70%). The cause of this lower prevalence is not yet known. Several authors believe that this can be consequence of reduced chloridropeptic secretion which can create an hostile environnement. Shaffer in 1992 clearly demonstrated a normal chloridric secretion in these patients. Aim of our study was to verify the peptic secretion as well, by pepsinogen I and II serum levels, (RIA Sorin) correlating it with serum gastrin (RIA-Sorin) and endoscopic and histologic findings, (Giemsa) in 26 AIDS pts. 21 of them were males and 5 females, mean age 37.6 y (28–51). All were symptomatic for dyspepsia or epigastric pain. The HP infection (only in antral biopsies) was present in 8 pts (31%).This prevalence was higher than 10% reported in our previous study in 423 unselected patients. The results of serum data, endoscopic and histologic findings are showed in Tab 1 Gastrin \'b5g Pepsin. I \'b5g Pepsin. II End. posit. Activ. c. gastr.Total 99 (DS37) 74 (DS55) 17 (DS15) 14/26 (50%) 6/23 (23%)H.P. pos. 108 (DS35) 70 (DS39) 24 (DS23) 4/8 (50%) 4/8 (50%)H.P. neg 99 (DS37) 76 (DS61) 14 (DS10) 10/18 (55%) 2/18 (11%)Our experience indicates normal peptic secretion and normal gastrin serum levels in AIDS pts, without difference between HP pos. and HP neg groups. Only Pepsinogen II serum levels were higher in HP pos. pts. This higher level could be related to the active c. gastritis usually present in these patients (50% vs 11%).

"P P 65 1544"P 65 1544**Relevance of Splenic Histopathology in Early Diagnosis of Disseminated Infections in 150 Patients with Aids, Submitted to *Post-Mortem* Studies (1984–1995)**

*I.C. Barros, A.R. Cordovil Pires, P.E. Helayel, D.P. Fernandes, P.A. Lima-F.

Universidade Federal Fluminense, Rio de Janeiro, BrazilWith the purpose to evaluate the relevance of spleen biopsy in clinical practice, the authors analyzed the *post-mortem* studies of 150 patients with AIDS. Some form of splenic disorder was found in 123 of these patients (82%). This group encompassed 85 cases with non-specific disorders (40 with splenitis, 18 with white hyperplasia, 12 with splenic congestion, 7 with lymphocitary depletion, 5 with splenic infarcts, and 3 with abscesses); 33 cases with splenic opportunistic infections (13 with miliary tuberculosis (39%), 5 with cryptococcosis (15%), 4 with hystoplasmosis (12%) and 3 with splenic toxoplasmosis (9%)) and 5 patients with neoplastic disorders (4 with Kaposi's sarcoma and 1 case with metastatic adenocarcinoma). On a second phase, our purpose was to outline the profile of such patients, the authors made a correlation between the data gathered from the clinical and *post-mortem* reports and the data obtained from the 27 patient control group (with no splenic disorders). After the analysis of the data, the authors concluded that: a) the splenic disorders in AIDS were assymptomatic and more frequent in our environment when compared with the current medical literature 82% {\'b4} 30% ($p < 0.0001$); b) non-specific disorders, stood out as the major cause of splenic involvement in our study; c) there was high statistical significance between the evidence of splenic involvement by opportunistic agents in patients with disseminated infections, frequently not detected in life ($p < 0.0001$). Clinically, we observed opportunistic infections in 45 cases (30%), acute neurologic symptoms in 20 cases (13%), neoplasias in 14 (9%). Severe gastrointestinal complaints were detected in 9 cases (6%). Prospective studies should be done to confirm the clinical benefits of the laparoscopic biopsy of the spleen in the management of patients with AIDS complications. Clinical practice: Epidemiology (non cancer)Immunology and microbiology: GI infections in adultsPancreas: Pancreatitis, chronic }" "Relevance of Splenic Histopathology in Early Diagnosis of Disseminated Infections in 150 Patients with Aids, Submitted to Post-Mortem Studies (1984-1995)"

"P P 66 1545"P 66 1545**Butyrate Inhibits Cyclin-Dependent Kinase 2 (cdk2) and Stimulates Cyclin D Expression in HT-29 Epithelial CellsS. Siavoshian,**

*H.M. Blottiére[1], C. Cherbut[1], B. Kaeffer[1], J.P. Galmiche

Human Nutrition Research Center INSERM, CHU 44035 Nantes Cedex, France

[1] INRA-LTAN, CHU 44035 Nantes Cedex, FranceButyrate, a four-carbon fatty acid produced by colonic fermentation of resistant starch and dietary fibre, can modulate colonic epithelial cell proliferation *in vitro.* In a variety of cell systems, butyrate has been found to block cells in G_1 phase. The G_1 phase is controlled by kinases which consist of a regulatory subunit (primarily one of the D cyclins) and a catalytic subunit (named cyclin-dependent kinase). In human cells, cdk2 can combine with cyclin E in the G_1 phase, and regulate the progression toward S phase, moreover, it can be associated with cyclin A during S phase. The aim of our study was to investigate the mechanisms by which butyrate may inhibit cell cycle progression toward S phase.*Methods:* HT-29 cells were synchronized by exposing the culture to fetal calf serum-deprived DMEM medium. Cells were then exposed to complete medium (10% fetal calf serum) in the presence or absence of increasing concentration of sodium butyrate (from 2 to 8 mM) for 4 days. Proteins were extracted, and cyclin D and cdk2 expression were studied by Western blotting.*Results:* After exposition to 2 mM sodium butyrate, a strong stimulation of cyclin D expression was observed which was optimal at 8 mM. This stimulation was associated with a decrease in cdk2 level in the presence of butyrate. Expression of cdk4 and cdk6 was not affected by butyrate at all the concentrations tested.*Conclusions:* These results confirm that butyrate blocks cell proliferation in G_1 phase. The increased level of cyclin D may not be involved directly in the inhibitory mechanism, but be a marker of the blockade in G_1 phase. However, the decreased expression of ckd2 which leads to the inhibition of events that are essential for DNA replication, may participate directly in the mechanism of action of butyrate on cell proliferation.

"P P 66 1546"P 66 1546**G-Protein Activator Mastoparan Decreases Transepithelial Permeability of T_{84} Cells by Activating Potassium Channels and Actin DisassemblingR. Gerhard, J. Ries, W.F. Caspary, J. Stein**

II. Dep. of Internal Medicine, J.W. Goethe-University Frankfurt/M., Germany*Background:* Mastoparan (MP), a tetradecapeptide isolated from the vasp venom, is known to stimulate heterotrimeric and small molecular GTP-binding proteins. The aim of this study was to investigate the role of mastoparan stimulated GTP-binding proteins in the regulation of tansepithelial resistance and ion secretion of the intestinal cell line T_{84}. *Methods:* Cells were grown on filters in DMEM/F12 supplemented with 5% newborn calf serum, 100 mg/ml streptomycin and 100 U/ml penicillin until confluency and mounted in modified Ussing chambers to measure electrical parameters. Cyclic AMP was measured by ELISA, Ca^{2+} was determined by using fura-2. Cells were labelled with myo[2-^{3}H]inositol to study the generation of inositol-phosphates by HPLC after stimulation with MP. F-actin was estimated by bound rhodamin-phalloidin, G-actin was measured by ist ability to inhibit Dnase. *Results:* Mastoparan decreased the transepithelial resistance up to 80% in a range of 5 \'b5M to 10 \'b5M only when added apically. Stimulation with mastoparan did not elevate the cAMP level in the cells, but led to an increase of intracellular calcium without affecting inositol phosphate metabolism. Chloride-free medium as well as blocking the $Na^+/K^+/Cl$-cotransport by 100 \'b5M bumetanide reduced the chloride secretion of T_{84} cells from 8.3 – 3.5 \'b5A/cm^2 to 3.9 – 3.1 ($p < 0.01$) and 5.1 – 1.9 ($p < 0.1$) respectively, but did not abolish the effect of mastoparan on the transepithelial resistance. Addition of the potassium channel blocker barium (2 mM) prevented both, the decrease in the resistance and ion secretion, indicating that mastoparan does not directly activate chloride channels, but that chloride secretion is only due to K^+ efflux. F-actin content showed a biphasic modulation with initial increase and subsequent decrease, G-actin content showed 2.5 fold increase after 45 min. *Discussion:* From these data we hypothesize; that changes in the transepithelial resistance of T_{84} cells after stimulation with mastoparan are based on selective activation of G-proteins that directly activate potassium channels. Efflux of K^+ results in membrane hyperpolarisation and activation of voltage dependent calcium channels and leads to an increase of intracellular calcium and remodeling of the cytoskeleton. }" "G-Protein Activator Mastoparan Decreases Transepithelial Permeability of T84 Cells by Activating Potassium Channels and Actin Disassembling"

"P P 66 1547"P 66 1547**Edible Mushroom (Agaricus Bisporus) Lectin, a Reversible Inhibitor of Cell Growth, Concentrates around the Nuclear Envelope after Internalization and Blocks Nuclear Protein Import**

*L.G. Yu, J.A. Smith[1], O.V. Gerasimenko[2], O.H. Petersen, J.M. Rhodes

[1] Department of Medicine Biochemistry, University of Liverpool, Liverpool L69 3BX, UK

[2] Department of Physiology, University of Liverpool, Liverpool L69 3BX, UK*Purpose:* The Thomsen-Friedenreich (TF) antigen (Gal{ b}1-3GalNAc{ a}-) is a common onco-fetal carbohydrate antigen in intestinal epithelia. Our previous work has shown that the non-cytotoxic TF-binding lectin from the edible mushroom *Agaricus bisporus* (ABL) inhibits proliferation in a range of malignant and normal epithelial cells (Cancer Res. 1993; 53; 4627) and has to be internalized to produce its inhibitory effect (Gastro. 1995; 108 (4); A558). The present study was designed to investigate the mechanism of its effect on cell proliferation.*Methods:* 1) HT29 colon cancer cells were incubated with FITC-ABL for 6 hours in 1% FCS Dulbecco's Modified Eagle's Medium and the distribution of FITC-ABL was observed by confocal microscopy. 2) The SV40 T antigen wild type nuclear localization sequence (NLS) containing peptide (cgggPKKKRKVED) was synthesized and conjugated to bovine serum albumin (BSA) and FLUOS (carboxyfluorescein-N-hydroxysuccinimide ester). HT29 cells cultured in chamber slides were permeabilized in 40 \'b5g/ml digitonin for 6 mins at 4\'b0C before application of cellular cytosol extract, ATP-generated system and NLS-BSA-FLUOS with or without the presence of 100 \'b5g/ml ABL for 30 mins at 30\'b0C. Distribution of NLS-peptide was observed by fluorescence microscopy.*Results:* FITC-ABL was observed to accumulate around the nuclear membranes after internalization. This led us to speculate that the lectin might interfere with transport through nuclear pores. Almost total inhibition of nuclear import of NLS-peptide was demonstrated in the cells treated with ABL (n = 3).*Conclusion:* These results suggest that inhibition of nuclear protein import is a likely explanation for the anti-proliferative effect of ABL. This has further implications for the importance of O-glycosylation in the regulation of proliferation. "P P 66 1548"P 66 1548**Inhibition by Heparin of Neutrophil Adhesion to Human Intestinal Microvascular Endothelial Cells *in Vitro***

*J. Wilson, S.L. Bloom, J.M. Rhodes

Department of Medicine, University of Liverpool, Liverpool, L69 3BX, UK*Purpose.* There have been several reports of clinical improvement and histological evidence of remission associated with use of heparin in patients with Ulcerative colitis (UC). Patients with UC have extensive infiltration of neutrophils into the lamina propria and as adhesion of leucocytes to the gut endothelium is a central event in the inflammatory process, we have used isolated human intestinal microvascular endothelial cells (HIMECs) to examine the effects of heparin on the adhesion of neutrophils *in vitro.Methods.* HIMECs were isolated from specimens of bowel (colon and small intestine) obtained from patients undergoing resection for colonic cancer or inflammatory bowel disease as previously described (Gut 38: A635, 1996), and cultured in endothelial growth medium (Clonetics) containing 20% pooled human AB serum. Neutrophils were derived from fresh peripheral venous blood using Mono-Poly resolving medium (ICN) and labelled with ^{51}Chromium for 1 hour. Endothelial monolayers grown to confluence in 24 well plates were treated with various concentrations of either high molecular weight heparin (Monoparin) or low molecular weight heparin (Fragmin) for up to six hours, and then overlaid with 5 {\'b4} 10^5 neutrophils/well. After 30 minutes, neutrophil adhesion was assessed by scintillation counting and expressed as counts/well.*Results.* Untreated endothelial monolayers bound 5% of the neutrophils added, however, pre-treatment of endothelial monolayers with both high and low molecular weight heparin significantly blocked the adherence of neutrophils by up to 50% (n = 3; * $p < 0.05$ ANOVA) Untreated Heparin concentration (Units/ml) 0.1 1.0 10High M.W. 190 – 3.7 92 – 10* 119 – 2.7* 124 – 5.7*Low M.W. 184 – 12.4 105 – 15.9* 102 – 16.4* 120 – 5.1**Conclusions.* The pre-treatment of HIMECs with both heparins inhibits the binding of neutrophils indicating that they disrupt the adhesion mechanisms involved in leucocyte-endothelial interactions. This suggests that low molecular weight heparin may have therapeutic potential in the treatment of Inflammatory Bowel Disease. *P. Planchon[1], R. Benamouzig[1], E. Jullian[2], S. Chaussade[2], D. Couturier[2], J. Rautureau[1]

[1] Hospital Avicenne, 93009 Bobigny Cedex

[2] Facult\'e9 de M\'e9decine de Cochin, 75014 ParisColorectal cancer is a frequent malignancy in western countries and despite recent progress, current treatment strategies have little effect on survival. Experimentally, NSAIDs have chemopreventive effects in rodent models of colorectal carcinogenesis, reducing the incidence and multiplicity of premalignant and malignant lesions. NSAIDs such as aspirin and sulindac have recently shown considerable promise as agents effective in the chemoprevention of colorectal cancer and large trials are conducted. Although the NSAIDs mechanisms of action remain unknown. In vivo as well as in vitro preliminary studies in HT-29 cells have suggested a salicylate-induced apoptosis mechanism.The aims of our study were to evaluate the effects of indomethacin, aspirin and lysin acetylsalicylate (Aspegic) in the RER+ phenotype human colon cancer cell-line SW480 which also present Ki-ras and p53 mutations. Indomethacin 25 to 400 \'b5M induce a 17 to 90% decrease in SW480 cellular proliferation. A 10- and 20-fold higher doses are needed to observe a similar effect with aspirin and aspegic respectively. In this way a similar dose-effect pattern was observed in cell cycle analysis showing a G0/G1 cell accumulation. Indomethacin induced a strong apoptosis phenomenon (45% at 72 h) which was not observed with neither aspirin nor aspegic at the concentrations used.In conclusion, our results shown differences in apoptosis induction by indomethacin and salicyled derivatives in SW480. "P P 66 1550"P 66 1550**Interaction of ICAM-1 and E-Selectin in Gastrointestinal Tumor Cells**

*B.M. Wittig[1], U. Treichel[1], R. Blaheta[2], R. Thees[1], K.H. Meyer zum B\'fcschenfelde[1], W. Mayet[1]

[1] 1. Depart. of Internal Medicine, University of Mainz, Langenbeckstrasse 1, 55101 Mainz, Germany

[2] Surgical Department, University of Frankfurt, Theodor Stern-Kai 7, 60590 Frankfurt, GermanyRegulation of cell adhesion is decisive for morphogenesis and integrity of solid tissue as well as immune defense. In many respects hematogenous metastasis of solid tumor cells is equivalent to the extravasation of leukocytes to inflammatory sites. Inflammatory cytokines, such as interleukin 1 and tumor necrosis factor { a}, stimulate the expression of several adhesion molecules on vascular endothelium and on tumor cells. However, the regulation of the individual adhesion molecules seems almost independent. Therefore, the interaction of E-selectin and the intercellular adhesion molecule ICAM-1 was studied in gastrointestinal tumor cells. Soluble immunoglobulin chimera consisting of the extracellular domain of E-selectin or ICAM-1, joined to the hinge region of IgG1 were immobilized in an adhesion assay (*Walz 1990, Science*). Two gastrointestinal tumor cells (liver, gallbladder) and the promyelocytic cell line HL60 were tested and it was shown, that cell adhesion to E-selectin plus ICAM-1 was up to 10 times stronger than to each single adhesion receptor. To further investigate costimulation of adhesion molecules tumor cells were incubated with the soluble fusion proteins of E-selectin and ICAM-1 for 1 h and 24 h and the expression of the adhesion receptors E-Selectin, ICAM-1 and VCAM and their ligands was determined in a flow cytometric analysis. The CD4-IgG chimera served as a negative control. We could demonstrate, that soluble E-selectin-IgG caused an specific increase of ICAM-1-positive tumor cells from 1% to 13% (1 h) and 70% (24 h) in the tumor cell lines. The ICAM-1-IgG1 fusion protein did not influence the expression of adhesion molecules. Stimulation was specifically blocked using monoclonal antibodies to E-selectin and ICAM-1. Our data indicate an interaction between the two adhesion receptors E-selectin and ICAM-1. We therefore suggest, that soluble E-selectin might result in a cell signal that directly stimulates ICAM-1. "P P 66 1551"P 66 1551**Expression of the Placenta-Specific, 100 kDa *Ras* GTPase Activating Protein (*Ras* GAP 100) in Several Human Cancer Cell Lines and Normal Human Tissues**

*Y. Araki, K. Nakamura, Y. Chijiiwa, T. Kabemura, H. Nawata

Third Department of Internal Medicine, Faculty of Medicine, Kyushu University, Fukuoka, JapanPoint mutation of c-*ras* are frequently observed in human tumors, especially in colon cancers, and alteration of the Ras-mediated signal transduction may contribute to carcinogenesis. The *ras* GTPase activating protein (*ras* GAP), a regulator of Ras activity, has two isoforms; *ras* GAP 120 and *ras* GAP 100. The latter, whose molecular size is about 100 kDa, is generated by alternative splicing from the *ras* GAP 120 gene and has been considered to be placenta-specific, though the former is expressed ubiquitously.We evaluated the expression of *ras* GAP 100 in several human cancer cell lines, using immunoprecipitation and immunoblot analysis with an anti-GAP monoclonal antibody as well as reverse transcription-polymerase chain reaction. A protein of about 100 kDa was detected in some of colonic, gastric and lung cancer cell lines. The incidence of *ras* GAP 100 protein expression seemed to be higher in colonic cell lines than in those derived from other tissues. *ras* GAP 100 mRNAs were present in all cell lines and their amount tended to be higher in 100 kDa-expressing cell lines. In human normal tissues, we detected *ras* GAP 100 message in colon, stomach and liver.These findings demonstrate that *ras* GAP 100, previously thought to be placenta-specific, is expressed in other normal human tissues at mRNA level and its expression is augmented in some cancer cell lines, especially in colon cancer cell lines. So far, the function of *ras* GAP 100 is unknown, but further investigation for its role in cell proliferation is now on progress. "P P 66 1552"P 66 1552**Is Ornithine Decarboxylase Really a Marker of Premalignancy in the Gastrointestinal Tract?**

*T. Wocial, K. Przytulski, W. Bartnik, J. Ostrowski, E. Butruk

Department of Gastroenterology, Medical Centre for Postgraduate Education, Institute of Oncology, Warsaw, PolandThere is no biochemical marker of premalignancy that is known to antedate the appearance of histological changes in the gut epithelium. Although increased ornithine decarboxylase (ODC) activity has been described as a useful marker of neoplastic potential, longitudinal studies to assess the serial use of this measurement have not been reported. The aim of this study was to determine the value of mucosal ODC activity in patients with premalignant conditions of the GI tract and to try to identify high risk patients. Mucosal biopsy samples were obtained during endoscopy from 214 patients. ODC activity was measured using [^{14}C]-ornithine bioassay and results were expressed in pmol/mg protein/h. Conventional histology was used to detect the presence of dysplasia which was graded according to established criteria.ODC activities obtained in the studied groups are shown in Table. Diagnosis n Median RangeNormal stomach 15 164 2–558Gastritis 25 652 201–4247Gastric adenomas 15 896 28–4287Operated stomach 20 1204 199–8023Gastric cancer 15 1821 762–11369Normal duodenum 11 121 10–961Duodenal polyps 15 1176 57–2900Ca. of the papilla of Vater 10 2686 401–5818Normal colon 10 185 1–695Ulcerative colitis 20 526 2–7422Familiar polyposis 11 929 5–3142Colon adenomas 30 1423 185–3981Colon cancer 17 3852 640–16561ODC activity was significantly higher in all premalignant and malignant conditions than in normal tissue. However, our results have shown that high activities do not always indicate malignancy and low activities do not exclude the increased neoplastic potential. No significant difference according to the degree of dysplasia in the epithelium was observed (results not shown).This work was supported by the Polish Committee for Scientific Research (4 4335 92 03). "P P 66 1553"P 66 1553**Characterization of Polyamine-Transport Systems in the Cell Line Caco-2Vladan Milovic, Wolfgang F. Caspary, J\'fcrgen Stein**

Division of Gastroenterology, Johann Wolfgang Goethe University, Frankfurt/MainPolyamines are polycationic molecules, essential for growth and differentiation in all eukaryotic cells. Recent work has focused on cell polyamine-transport systems as a way to regulate intracellular polyamine levels. We investigated the effects of epidermal growth factor (EGF) on polyamine uptake in Caco-2 cell monolayers. Caco-2 cells were exposed to 100 ng/ml EGF and the effects of treatment on putrescine uptake (putrescine, spermine) was measured over time. *Methods;* Caco-2 cells were grown in DMEM on porous filters. Serum was removed 24 h prior to uptake studies. Uptake was investigated after confluence (7 day old cells) or after differentiation (14 day old cells) *Results:* EGF stimulated polyamine uptake into Caco-2 cells in a dose- and time dependent manner. 100 ng/ml EGF had a maximally stimulatory effect on polyamine uptake at 12 h. Both basal and EGF-stimulated uptake rates were higher in 7 than in 14 day old Caco-2 cells. EGF increased both the affinity and capacity of the polyamine transporter (K_m = 33.7 *vs.* 19.4 \'b5mol/L for putrescine [$p < 0.05$] and 23.6 *vs.* 12.6 \'b5mol/L for spermine [$p < 0.05$], in controls *v.s* EGF-stimulated cells, respectively; V_{max} 44.7 vs 82.5 \'b5mol/10^6 cells/2 h for putrescine [$p < 0.05$] and 32.3 *vs.* 55.1 \'b5mol/10^6 cells/2 h for spermine [$p < 0.05$], in controls *vs.* EGF-stimulated cells, respectively). The enhanced polyamine uptake induced by EGF was not inhibited when protein synthesis was blocked by cycloheximide, implying that additional protein was not required for the effect of EGF on polyamine uptake. Similarly, brefeldine A had no effect indicating that EGF does not stimulate vesicular transport from the Golgi apparatus. However, the tyrosine kinase inhibitor, genistein, completely inhibited EGF-stimulated polyamine uptake, pointing to a possible role for tyrosine phosphorylation(s) in EGF-stimulated polyamine uptake in Caco-2 cells.*Conclusion:* In the present study we demonstrate that EGF stimulates polyamine uptake in Caco-2 cells. The mechanism of EGF-induced polyamine uptake likely includes an increase in the number of functional transporters in the plasma membrane, and/or modification of the transporter itself. }" "Characterization of Polyamine-Transport Systems in the Cell Line Caco-2"

"P P 66 1554"P 66 1554**Inflamed Synovial Tissue from Patients with Spondyloarthropathy is Enriched with Activated Cells Carrying { b}7 Integrins**

*D. Elewaut[1], F. De Keyser[1], A. Lazarovits[2], M. De Vos[3], C. Cuvelier[4], H. Mielants[1], E. Veys[1]

[1] Dpt. of Rheumatology, University Hospital, Ghent, Belgium

[3] Dpt. of Gastroenterology, University Hospital, Ghent, Belgium

[4] Dpt. of Pathology, University Hospital, Ghent, Belgium

[2] Dpt. of Nephrology, University of Western, Ontario, Canada*Introduction:* An intriguing relationship between gut and synovium exists in patients with spondyloarthropathy (SpA). Previously, we demonstrated microscopically inflammatory gut lesions in 62% of these patients. A fraction of them (6.5%) ultimately evolved to clinically overt inflammatory bowel disease. The origin of the gut-synovium axis is as yet unknown. In this study, we tested the hypothesis that antigen-primed gut-derived lymphocytes would migrate into synovial tissue of patients with SpA, thereby mediating synovial inflammation (gut-iteropathy concept).*Methods:* Synovial biopsies were obtained by needle-arthroscopy from 5 patients with SpA and 6 with rheumatoid arthritis (RA) with peripheral synovitis (knee). All but one patients had less than 6 months of disease duration. To minimize sampling error 8 to 10 biopsies were taken from different sites within the inflamed joint. Activated T-cells were generated by expansion with IL-2 for 3 to 5 weeks from each single biopsy. In total 25 cell-lines were obtained (RA:14; SpA:11). Cell-lines were characterized by flowcytometry, with special reference for { a}4{ b}7 and { a}E{ b}7, { b}7 integrins playing a critical role in the homing of lymphocytes to the gut. Results are expressed as mean % positive T-cells – SEM. The Wilcoxon rank sum test was applied for statistical analysis.*Results:* Activated T-cells from RA-synovium consist almost exclusively of CD4+ T-cells (RA:93.4 – 3.4; SpA:61.4 – 10.7, $p < 0.01$), contrasting to SpA in which CD8+ T-cells are more abundant (SpA:36.5 – 10.0; RA:5 – 3.1, $p < 0.01$) In contrast to RA, cell-lines from SpA patients highly expressed one of the gut homing integrins, either { a}4{ b}7 or { a}E{ b}7 (SpA:66.6 – 9.3; RA:35.3 – 7.4, $p < 0.02$). The observed differences between SpA and RA are not merely due to the discriminating CD4/CD8 ratio, as the increase in { b}7 integrins in SpA was similar on CD4 and CD8+ T-cell.*Conclusion:* Inflamed synovial tissue from SpA-patients with recent onset disease is enriched with activated T-cells expressing { b}7 integrins { a}4{ b}7 or { a}E{ b}7. Intestinal disorders: IBD, basic }" "Inflamed Synovial Tissue from Patients with Spondyloarthropathy is Enriched with Activated Cells Carrying ß7 Integrins"

"P P 66 1555"P 66 1555**Type IV Collagenase Expression is Integral to MMP Induced In-Vitro Invasion and is Inhibited by BB2516 and BB94**

*S.R. Bramhall, D. Williams, D. Youngs, J.P. Neoptolemos

University Department of Surgery, Queen Elizabeth Hospital, Birmingham, B15 2TH, UKThe matrix metalloproteinases (MMPs) are proteolytic enzymes that are capable of degrading the extracellular matrix. Their functional activity is controlled by the tissue inhibitors of the metalloproteinases (TIMPs). MMP activity is increased in most tumours but type IV collagenase activity appears to be the most important. Interest in this field has lead to the development of low molecular weight MMP inhibitors (MMPIs), two of these (BB94 & BB2516, British Biotech, Oxford, UK) have been the subject of clinical trials.We studied the in-vitro invasion of a radiolabelled endothelial cell basement membrane by two pancreatic cancer (SUIT2 & BxPC3) and one breast cancer (MDA-MB231) cell lines. Each experiment was performed in triplicate and repeated three times. The ability of BB94 and BB2516 to inhibit invasion was then compared to the cell line expression of 72 & 92 kDa type IV collagenase and TIMP 1 & 2. The MMP and TIMP expression were measured using a quantitative RT-PCR technique.The MDA cell line were significantly more invasive than either the SUIT2 ($p < 0.001$) or BxPC3 ($p < 0.01$) cell lines. The addition of MMPIs to the MDA cell line resulted in a significant and dose dependent reduction of invasion ($p < 0.03$) but this was not seen with either of the other two cell lines. All three cell lines produced TIMP mRNA but the MDA cell line produced significantly more type IV collagenase mRNA than either the SUIT2 or BxPC3 cell lines ($p < 0.05$).This study supports the hypothesis that type IV collagenase action is necessary for basement membrane degradation and malignant cellular invasion and can be inhibited by both BB94 and BB2516 MMPIs. Oncology, general: Molecular biology, geneticsOncology, general: Proliferation, carcinogenesisOncology, general: Therapy }" "Type IV Collagenase Expression is Integral to MMP Induced In-Vitro Invasion and is Inhibited by BB2516 and BB94"

"P P 66 1556"P 66 1556**HIP/PAP Is an Adhesive Molecule Expressed in Hepatocellular Carcinoma, Normal Paneth and Pancreatic Cells****L. Christa[1], F. Carnot[2], M.T. Simon[1], F. Levavasseur[3], M.G. Stinnakre[4], C. Lasserre[1], D. Thepot[4], B. Clement[3], E. Devinoy[4], C. Brechot[1]**

[1] INSERM U-370 and Liver Unit, CHU Necker, Paris, France

[2] Hospital Laennec, Paris, France

[3] INSERM U-49, Rennes, France

[4] INRA, Jouy-en-Josas, FranceWe have previously identified a gene ""HIP"" overexpressed in around 25% of HCCs and not in normal nor cirrhotic livers. HIP is expressed in normal pancreas and intestine and is identical to pancreatitis associated protein (PAP). We have subsequently shown that HIP/PAP encodes for a C-type lectin, raising the hypothesis that it might be implicated in liver cells adhesion and spread.In the present study, we have established transgenic mice to drive the production of soluble recombinant HIP/PAP protein in the milk of lactating animals; in this model we showed that HIP/PAP protein was secreted after proper cleavage of the potential signal peptide. We have also produced HIP/PAP protein by *E. Coli* cultures to generate specific antibodies. These antibodies allowed us to detect the HIP/PAP protein in the cytoplasma of tumorous, but not non-tumorous hepatocytes. HIP was not detected in normal liver but present in normal intestine and pancreas: neuroendocrine and Paneth cells, pancreatic Langerhans islets and acinar cells. Finally, we tested HIP/PAP protein activity, showing that HIP/PAP induced adhesion of rat hepatocytes, and bound to the extracellular matrix proteins: laminin-1, fibronectin; HIP also bound, yet to a lesser extent, to types I and IV collagens and not to heparan sulfate proteoglycan. *In conclusion,* our results show that: 1. the recombinant HIP/PAP protein we have produced can be matured upon secretion. 2. HIP/PAP protein is specifically expressed in hepatocarcinoma, and not cirrhotic tissue 3. HIP/PAP acts as an adhesion molecule on hepatocytes and binds to key extracellular matrix proteins. Altogether, these results suggest that HIP/PAP protein might be implicated in HCC progression. }" "HIP/PAP Is an Adhesive Molecule Expressed in Hepatocellular Carcinoma, Normal Paneth and Pancreatic Cells"

"P P 67 1557"P 67 1557**Hereditary Fructose Intolerance — Case Report with Molecular Study**

*A.I. Lopes, A.G. Almeida, A.E. Costa, A. Costa, M. Leite

Pediatric Gastroenterology Unit, Pediatric Department, Hospital Santa Maria, Lisboa, Portugal*Hereditary Fructose Intolerance (HFI)* is a rare metabolic disorder, resulting from a deficiency of aldolase B (fructose-biphospate-aldolase) in the liver, kidney and intestine. Though classically considered an autosomal recessive condition, genetic heterogeneity is increasingly being recognized. Recent molecular studies [1] have identified the mutation A149P in most european affected patients.We describe the first case of HFI with molecular analysis in a portuguese patient (a caucasian boy, second child of nonconsanguineous healthy parents), presenting the same mutation of the aldolase B gene (A149P). The child presented at 3.5 months of age with vomiting, coincident with the introduction of a sucrose containing formula. Diagnosis was confirmed at 7 months of age by conventional methods (enzymatic assay in liver tissue). Liver biopsy showed slight periportal fibrosis and hepatocyte fatty changes. Family study extensive to the mother and sibling, confirmed the presence of same single mutant aldolase B allele (A149P). This finding, associated with a typical nutritional history in the older brother, may be considered highly suggestive of the disorder and sufficient confirmatory evidence, avoiding more invasive tests.We emphasize diagnostic contributory role of molecular studies in risky patients for HFI and their families.The authors thank Prof. T.M. Cox University of Cambridge School of Clinical Medicine, Addenbrooke's Hospital, Cambridge, UK, who kindly performed molecular studies in patient and family.

"P P 67 1558"P 67 1558**Structural and Functional Analysis of Apolipoprotein A-I**

*C. B\'fcttner, M. Dogar, R. Haas, J. Genschel, S. Wagner, M.P. Manns, H.H.-J. Schmidt

Dept. of Gastroenterology and Hepatology, Medizinische Hochschule Hannover, D-30623 Hannover, GermanyApoliprotein A-I (apoA-I) serves as an excellent predictor for liver protein synthesis. It is an important determinant of the concentration of HDL in plasma. We used normolipemic rabbits (NZW) as an in vivo model to gain more insights about apoA-I metabolism and its structural functions (Schmidt et al., *J. Biol. Chem.* 1995, 270: 5469–5475). ApoA-I has been shown to contain repeated sequences that presumable arose by intragenic duplication of 11- or 22-amino acid amphipathic segments. To study differences of metabolic behaviour and association with lipoprotein particles of various apoA-I variants we isolated apoA-I from different animal species (rabbit, human, macaca, mouse, rat, pig, calf and chicken) using ultracentrifugation, SDS gel electrophoresis, and electroelution, subsequently. The various apoA-I forms were analyzed by the in vivo catabolism. In addition mouse and rat apoA-I had a higher percentage of non-lipoprotein associated apoA-I. Comparing the protein sequence of the rabbit with rat and mouse apoA-I the major difference occurs within the amino acids 180–186, which represents a turn between helices using the predicted secondary structure of human apoA-I. In contrast the region of amino acid 125–135 seems to have no major impact on the catabolic rate of apoA-I. Therefore, we assume that the difference in metabolism among the studied proteins can be explained by their structural differences. Interestingly, the overall predicted hydrophobicity between mouse, rat and human apoA-I is almost identical.In conclusion, the structural properties of apoA-I may explain the association with human and rabbit HDL, which in turn determines its rate of catabolism. Therefore, the kinetic analysis of proteins isolated from different species have major implication to define their functional regions. *G. Addolorato, E. Capristo, G. Mingrone, A.V. Greco, G.F. Stefanini, G. Gasbarrini

Cattedra di Medicina Interna II. Universita' Cattolica del S. Cuore, Rome and Universita' di Bologna, ItalySeveral controversies are still present in the literature on body weight (BW) and on alcohol energy contribution on the body mass in alcoholics. Aim of the study was to evaluate the effect of alcohol addiction on energy expenditure (REE) (measured with indirect calorimetry) and body composition (assessed by both anthropometry and bioimpedance) in 12 alcoholics (A) (6 men and 6 women) enrolled in the study on the basis of DSM III R criteria, with mean alcohol intake of 187 – 57.4 g/die for at least 5 years compared to a group of healthy social drinkers (C) with mean alcohol intake of 38.4 – 12.0 g/die (mean – SD) matched for sex, age and height. The caloric intake was computed on the basis of a food diary, compiled during the last 7 days and the calories provided by alcohol were also computed. 24 h urine and fecal collections were performed. The BW average of A was lower than that of C (60.7 – 9.99 vs 66.7 – 5.86 kg; p = ns) with a significant decrease in fat mass (FM) in A (14.8 – 5.39 kg vs 19.0 – 3.50; $p < 0.05$), while no difference was found in fat free mass (FFM). REE was not statistically different in the two groups, however, normalizing REE by BW, A showed higher values than C (27.1 – 3.21 vs 23.4 – 3.81 kcal/kg_{bw}; $p < 0.001$). REE resulted higher than that predicted in A ($P < 0.05$), while not statistically different in C. The non-protein respiratory quotient was significantly lower in A than in C (0.76 – 0.03 vs 0.86 – 0.03; $p < 0.001$) and A showed a significantly higher lipid oxidation and a lower carbohydrate oxidation than C ($p < 0.05$). No statistical differences were found in dietary intake, urinary nitrogen excretion and fecal losses over 24 hrs. In conclusion alcoholics showed an increased REE over predicted values suggesting a possible cause of their lower BW. They showed a preferential lipid oxidation and this finding might be responsible for their reduced FM. "P P 67 1560"P 67 1560**Alcohol Consumption in an Italian General Population: The CO.A.LA. Project**

*E. Scafato, A.F. Attili, A. Giorgi Rossi, L. Capocaccia, CO.A.LA. Group

Dept of Clinical Medicine, Rome University ""La Sapienza"", Italy*Background:* Lack of data from studies on general population rates of subjects at higher risk for alcohol-related problems. *Objective:* To study dietary habits and alcohol intake in a general population with special focus on drinking patterns and differences related to age, sex, education, occupation, census, history of alcohol consumption, lifetime changing in alcohol consumption, diseases, geographical distribution. *Design:* Prospective population study. *Setting:* COALA Project, Latium, Italy. *Field activities:* January 1994–January 1995. *Partecipants:* 1660 family clusters, 1709 males (M) and 1878 females (F) (total 3587), over 15 years old, randomly sampled from the municipal censuses of 20 local authorities and stratified according to the size of the local authority. *Measurements:* Participants filled in a semi-quantitative food frequencies questionnaire. Total alcohol intake was calculated by summing the alcohol content of each beverage according to a standard glass of wine, can of beer and shoot of liquor (eleven precoded response categories for each alcoholic beverage). *Main outcome measure:* Age standardized prevalence, mean alcohol consumption, drinking patterns, drinking categories according to the targeted variable. *Results:* 1325 of the 3567 subjects (43.9%; 30.6 M, 56.1 F) declared to be teetotaller and/or abstinent and 2242 to be drinkers (56.1%; 69.4 M, 43.9 F). Of the latter 51.4% (63.4 M, 39.7 F) drank wine, 25.6% beer (36.2 M, 16.4 F) and 20% spirits (30.7 M, 10.3 F). The 15–20 year old age group had the lowest prevalence of drinkers (35.7% M, 25.2% F) of whom 19.3% drank wine, 24.8% beer, 6.9% spirits. The highest number of drinkers were males in the 31 50 age group and for females in the 21–30 and 61–70 age groups. 83.3% of these (87.1 M, 78.9 F) drank wine, 39.8% (47.4 M, 29.9 F) beer, 31.9% (41.5 M, 19.5 F) spirits. Alcohol was prevalently consumed at mealtimes (80% of M and 91.4% of F). Wine was consumed daily by 78% of M, 57.9% of F for wine, beer by 16.7% of M, 7.4% of F and spirits by 11% of M and 2% of F. Per capita alcohol consumption among drinkers was 25.8 gr/day (32.9 gr M, 15.5 gr F). 32.7% of M exceded 40 gr/day, 29.7% of F 20 gr/day. *Conclusions:* A lower prevalence and a more moderate alcohol consumption was found among women and younger subjects. Alcohol consumption was within accettable limits (low risk) for 67.3% of M and 70.3% of F drinkers but 1/3 of subjects could be considered at higher risk for alcohol related problems. The prevalent drinking pattern is wine consumption at mealtime althought young people seem to promote new, less traditional patterns.(COALA PROJECT was supported by a grant from the Ministry of Agricultural, Food and Forestry Resources. "P P 67 1561"P 67 1561**Frequency of the Beta 3-Adrenergic Receptor Trp64Arg Mutation in Obese and Non-Obese Subjects in Germany**

*R. B\'fcttner, A. Sch\'e4ffler, H. Arndt, Diabetomobile Study Group, J. Sch\'f6lmerich, K.-D. Palitzsch

Dept. of Internal Medicine I, University of Regensburg, Regensburg, Germany*Objective:* To analyse the frequency of the Trp64Arg mutation of the beta 3-adrenergic receptor gene in relation to the body mass index (BMI) in a randomly collected sample of the German population. *Methods:* Out of 5800 participants in the Diabetomobile Study, an epidemiological survey to investigate the prevalence of diabetes mellitus and other metabolic disorders being carried out in Germany from 1993 up to now, 645 participants were randomly chosen and divided into four groups according to their BMI: [1] BMI < = 20, [2] BMI < = 25, [3] BMI < = 30 and [4] BMI > 30. PCR and restriction digestion were performed on genomic DNA from these subjects. The Trp64Arg mutation of the beta 3-adrenergic receptor gene could then be recognised by restriction-fragment-length polymorphism. Subjects carrying the mutation were further analysed with respect to age, sex, and prevalence of diabetes mellitus, high blood pressure and hypercholesteremia. *Results:* The frequencies of the heterozygous mutation and the homozygous mutation were as follows: group [1] 10.32% and 0.00%; group [2] 8.85% and 1.04%; group [3] 8.62% and 1.15%; group [4] 8.50% and 0.65%. The overall frequency of the heterozygous mutation was 8.99% and of the homozygous mutation 0.78%, respectively. There were no significant differences between the prevalence of the homozygous or the heterozygous mutation in the group with high BMI [4] compared with the groups with lower BMI [1–3]. There were also no significant differences between age and sex distribution and prevalence of diabetes mellitus, hypertension or hypercholesteremia when comparing normal subjects with subjects carrying the mutation in the same subgroups. *Conclusions:* The heterozygous Trp64Arg mutation of the beta 3-adrenergic receptor gene is found commonly in Germany (8.99%), the homozygous mutation relatively rarely (0.78%). Neither the homozygous nor the heterozygous mutation are correlated with higher BMI, higher prevalence of diabetes mellitus, hypertension or hypercholesteremia. "P P 67 1562"P 67 1562**Glucose Control and Incretine Hormone Release Following Ingestion of Different Liquid Diets in Non-Insulin Dependent Diabetics**

*H. Printz, B. Recke, A. Wagner, H.C. Fehmann, R. Arnold, B. G\'f6ke

Department of Internal Medicine, Philipps-University of Marburg, Marburg/Lahn, GermanyRecently, for enteral nutrition of non-insulin dependent diabetics balanced liquid diets have been formulated. However, their beneficial influence on glucose control and metabolism still needs to be proven. In the present study, 10 non-insulin dependent diabetics (7 men, 3 women, age: 56 – 11 years) with a mean body mass index of 26.2 – 3.6 kg/m^2 orally ingested 500 ml of either a standard liquid diet (Biosorb' Sonde) or a fibre containing diet (Biosorb' Plus Sonde) or a carbohydrate modified, fructose containing special ""diabetes diet"" (Fresubin' Diabetes). Oral antidiabetic therapy consisted in 6 patients of an average dose of 9.3 – 1.8 mg/die glibenclamide plus an average oral dose of 175 – 113 mg/die of the glucosidase inhibitor acarbose. Four patients were treated with diabetes diet plus an average oral dose of of 4.8 – 1.7 mg/die glibenclamide without acarbose. Prior to testing, mean blood glucose values (07:00 am preprandial, 10:00 am, 04:00 pm) were 133 – 37, 166 – 51 and 135 – 50 mg/dl, respectively. HbA_{1c}- (8.4 – 2.2%) and fructosamine concentrations (308 – 86 \'b5mol/l) prior to liquid diet testing showed a satisfactory antidiabetic control. Intravenous glucagon stimulation indicated a sufficient residual { b}-cell insulin secretion capacity (10 – 4 versus 36 – 30 \'b5U/ml insulin 0 or 6 min after 1 mg glucagon iv). Each type II diabetic ingested in randomized order with 10 days intervals each liquid formula (with comparable carbohydrat amounts of { @} 60 g) after intake of the usual oral morning medication. Blood samples were collected at intervals for up to 180 min following diet consumption for determination of blood glucose, as well as IR-insulin, C-peptide, IR-GIP and IR-GLP-1 in plasma. Considering minor variations in the nutritional values of the diets, all liquid diet formulations showed comparable responses during the observed time period. Based on this data, we conclude that all diets challenged the entero-insular axis in non-insulin dependent diabetics to a comparable extent. "P P 67 1563"P 67 1563**Paper- or Computer Based Quality-of-Life Questionnaires — Does It Matter?**

*L. Aabakken[1], P. Tarnasky[1], Y. Palesch[2], H. Evangelou[1], P. Cotton[1]

[1] Digestive Disease Center, Medical University of South Carolina, Charleston, US

[2] Dept. Of Biometry, Medical University of South Carolina, Charleston, US*Purpose:* The replacement of manual paper questionnaires with a computer based data acquisition system offers several potential practical advantages, but the validity of such a transition must be documented. The purpose of the present study was to compare data acquired by computer and data acquired by traditional paper questionnaires.*Material and methods:* Eighty-three consecutive patients attending our outpatient GI clinic were included in the study. After informed consent was obtained, they completed a 28 items standardized quality-of-life questionnaire, both a standard, self-administered paper form, and a computer based form, in a randomized order. The computer was a self-explanatory touchscreen-based system with a sound feature that reads out the questions, as well as the reply alternatives and additional explanations on demand. The paper-based questionnaire used a standardized 5 point Likert scale scoring frequency (of a symptom/complaint) or agreement (with a statement). The computer entry was done with an identical scale (n = 44) or with a visual analogue scale (n = 40) that was subsequently normalized symmetrically to a 5 point scale. Zero or one item difference between paper and computer was regarded concordant data.*Results:* The mean concordance between the paper and computer version was 91% with the normalized VAS and 92% with the Likert scale, and over-all statistically significantly greater than 80% for both scoring models. The mean time to complete the questionnaire was 345 seconds for the paper and 240 seconds for the computer version. However, in the paper form, 8 questions were not filled in by 7 patients, and another two patients entered erroneous data, circling more than one reply on individual questions. In contrast, all the computer data were complete. Moreover, 83% of the patients preferred the computer version on direct questioning while only 3% preferred the paper questionnaires.*Conclusion:* We found an acceptable concordance between paper- and computer-acquired quality of life data. The inherent error-control and additional practical advantages of using a computer makes this a promising technique for the routine acquisition of patient-based questionnaire data. Clinical practice: Management strategyClinical practice: Quality assurance }" "Paper- or Computer Based Quality-of-Life Questionnaires / Does It Matter?"

"P P 67 1564"P 67 1564**Utility of a Touch Screen Computer-Based Quality of Life Questionnaire**

*L. Aabakken[1], P. Tarnasky[1], Y. Palesch[2], S. Javed[1], H. Evangelou[1], P. Cotton[1]

[1] Digestive Disease Center, Medical University of South Carolina, Charleston, US

[2] Dept. Of Biometry, Medical University of South Carolina, Charleston, US*Purpose:* Quality of life data are becoming increasingly important for assessment of efficacy and overall outcomes of treatment, but data acquisition may be cumbersome. The aim of the this study was to assess the feasibility of computer based acquisition of quality-of-life data in a routine outpatient clinic setting.*Material and methods:* 127 consecutive outpatients (mean age 42, range 15–78) were studied. After informed consent and explanation by a nurse, they completed in randomized order both a paper version and a computer version of our standardized quality of life questionnaire of 28 questions. The computer consists of a touch screen with large screen buttons, and it has sound capabilities, that reads aloud questions, replies and explanations on demand. Patients were randomized to a visual analogue scale (VAS) or a 5 point Likert scale, and after completing the 28 questions, the first five questions were repeated, using the other scale, for intraindividual comparison.*Results:* Seventy-seven males and 47 females participated. 3 subjects refused both the paper and computer questionnaire. Seventy-seven percent of the participants liked the computer questionnaire, and an additional 20% found it acceptable, leaving only 3% that did not like it. Moreover, 82% felt the computer to be *better* than the paper form, and only 3% preferred the paper version. The sound feature was felt to be *very helpful* by 51%, and *somewhat helpful* by another 20%. No difference was found as to preference to VAS versus 5 point Likert scale. The mean time to complete the 28 questions was 240 seconds. The concordance between VAS and Likert scale scores was acceptable, but with a tendence toward end-point accumulation in the VAS scores.*Conclusion:* The touch screen computer with sound capabilities was very well accepted by the patients in this feasibility study. Only 3% preference to the paper version and a mean entry time of 4 minutes, together with the inherent simplification of data handling makes this a promising method for administering QOL instruments in a routine clinical setting. Clinical practice: Management strategyClinical practice: Quality assurance }" "Utility of a Touch Screen Computer-Based Quality of Life Questionnaire"

"P P 67 1565"P 67 1565**Direct Measurement of the Intraabdominal Pressure in Normal Subjects and Pathologic Conditions**

*A. Shafik, A. El-Sharkawy, W.M. Sharaf

Department of Surgery, Cairo University, Cairo, Egypt*Purpose:* to standardize a method of direct measurement of the intraabdominal pressure (IAP), to correlate the results with the intrarectal pressure and to apply the method for surgical diseases.*Method:* Thirty-four subjects were studied in 4 groups: control (no = 11), hernia (no = 8) mass (no = 7) and obese (no = 8). A Veress needle was introduced into the peritoneal cavity through a 5 mm subumbilical incision and was connected to a Statham pressure transducer. Measurements of the IAP were recorded at rest and during straining, in supine and erect positions, and before and after anesthesia administration. Recording of the intrarectal pressure was done simultaneously with the IAP.*Results:* The hernia group showed significant IAP pressure reduction at rest ($p < 0.01$) and on straining ($p < 0.01$) compared to the controls. In both the mass and obese groups, the IAP showed no significant difference from controls at rest ($p > 0.05$) and was higher on straining ($p < 0.05$). All the groups exhibited significant IAP drop ($p < 0.05$) after anesthesia. There was no significant difference ($p > 0.05$) between the intrarectal pressure and IAP in the 4 groups.*Conclusion:* a method for direct IAP measurement is described in the control group and in subjects with some surgical conditions. The intrarectal pressure represented the IAP and can thus replace it. Motility, general: Functional GI disordersIntestinal disorders: ConstipationIntestinal disorders: Anorectal disorders }" "Direct Measurement of the Intraabdominal Pressure in Normal Subjects and Pathologic Conditions"

OT77 1566**A Novel Target Therapy for Squamous Cell Carcinomas Overexpressing EGF-Receptors with Apparent Safety: The Fusion between Human Pancreatic Ribonuclease1 and Human EGF**

*K. Psarras, M. Ueda, S. Jinno, S. Ozawa, M. Kitajima, M. Seno[1], H. Karibe[2], S. Komatsu[2]

Dept. of Surgery, Keio University School of Medicine, Tokyo, Japan

[1] Dept. of Bioengineering, Faculty of Engineering, Okayama University, Okayama, Japan

[2] Dept of Mol. Biology, Nat. Instit. of Agrobiol. Resources, Tsukuba, JapanMany of the immunotoxins constructed up to the present, have been evaluated over clinical trials for future use as anticancer agents, but toxicity or immunogenicity seem to be the dose limiting factors. In order to improve the whole immunotoxin concept we used two endogenous human proteins to construct a recombinant totally human ""immunotoxin-like"" agent.Ribonucleases have been shown to have antitumor activity. The gene coding for human pancreatic ribonuclease1 (hpRNase1), lately cloned from human pancreas by Seno et al., was fused with a gene coding for human epidermal growth factor (hEGF). The DNA was expressed in E. coli, the recombinant hpRNase1-hEGF was purified to homogeneity and assayed in vitro by the MTT colorimetric assay, for cytotoxic potential on several squamous cell carcinomas expressing different amounts of EGF-Receptors (EGFR).The protein was cytotoxic, EGFR number dependently with an IC50 ranging between 10^{-7} M and 10^{-6} M whereas the IC50 of free hpRNase1 was 10^{-4} M. A mixture of free hEGF and free hpRNase1 had no greater effect than free hpRNase1 alone and a molar excess of hEGF blocked the cytotoxicity dose dependently. No cytotoxicity was detectable for EGFR deficient control cells suggesting that the fusion protein enters via EGFR and kills the cells presumably by RNA brake down.It has been demonstrated that many squamous cell carcinomas, especially those of esophagus, lung, head and neck and bladder appear with EGFR overexpression, are closely correlated to high aggressivity and poor prognosis and cannot be cured by surgery alone. Our data suggest that hpRNase1-hEGF may be a candidate for a safer approach in the multidisciplinary treatment of such carcinomas than conventional immunotoxins.

OT77 1567**Unfrequent Microsatellite Instability in &Diphtong;sophageal CancerF. Muzeau[1], J.F. Fl\'e9jou, F. Potet[1], J. Belghiti[3], G. Thomas[4],**

*R. Hamelin[4]

[1] INSERM U410, Facult\'e9 Bichat, Paris, France

[2] Service d'Anatomie Pathologique, Paris, France

[3] Service de Chirurgie Digestive, Hospital Beaujon, Clichy, Paris, France

[4] INSERM U434, Institut Curie, Paris, France*Background and Aims:* Genetic defects in the mismatch repair system can be monitored by examining Replication ERrors (RER) at microsatellite loci in cancer cells. Microsatellite instability (MI) was first described in hereditary nonpolyposis and sporadic colorectal cancers. It has been reported that MI may play a role in the development of various cancers, but its role in &diphtong;sophageal cancer is debated. The aim of this study was to determine the frequency of MI in the two main types of &diphtong;sophageal cancer, squamous cell carcinoma (SCC) and Barrett's adenocarcinoma (BA).*Methods:* Surgically resected specimens were collected from 20 patients with SCC and 26 patients with BA, treated in the same hospital. Genomic DNA was extracted from primary tumours and adjacent normal gastric mucosa, and amplified by PCR at 39 poly CA microsatellite loci scattered throughout the genome. The PCR products were electrophoresed on denaturing gels and visualized by autoradiography.*Results:* Four of 20 SCC showed MI at one locus. Among 26 BA, 5 and 3 tumors showed MI at one and two loci, respectively. No MI was demonstrated in any of the remaining cases. The instability affected different loci on chromosome 3, 4, 6, 9, 17 and 18. There were no differences between tumors with and tumors without MI regarding the clinicopathological characteristics.*Conclusion:* We show that the frequency of MI in cancer of the &diphtong;sophagus is very low. The presence of few loci showing MI could be explained by the existence of a background of instability (< 10%) independent of genetic defects in the mismatch repair system. In this study, none of the &diphtong;sophageal tumors had a typical RER+ phenotype. These data suggest that genetic defects in the DNA mismatch repair system do not play a role in esophageal cancer. OT77 1568**The Incidence of Esophageal Adenocarcinoma in Barrett's Esophagus in an Italian Population: First Report from Southern Europe****R. Ferraris[1], L. Bonelli[2], M. Conio[3], H. Aste[3]**

[1] e G.O.S.P.E. Servizi di: Endoscopia Digestiva Osp. Mauriziano Torino

[3] e I.S.T. Genova

[2] Epidemiologia Clinica, I.S.T. GenovaThe incidence of adenocarcinoma (ADC) of the esophagus is increasing in the U.S.A., Northern and Central Europe. Data from Southern Europe are still lacking. Since the alimentary attitudes and the lifestyle in these areas are different, it could be interesting to compare these data. *Aim:* to report the results of the prospective endoscopic histological surveillance of a large cohort of Barrett's esophagus (BE) patients enrolled in the Italian multicentric study G.O.S.P.E. (Gruppo Operativo Studio Precancerosi Esofagee). *Methods:* 345 BE patients with 3 or more cm. metaplasia were eligible to the yearly endoscopic follow up. 59 patients with esophagitis but not histologically proven BE were also eligible for a parallel follow up. *Results:* the mean duration of the follow-up period was 3 years (Range 12–81 months). 202 out of the 345 eligible BE patients (253 males and 92 females; aging 19–75 years) complied to the follow-up study (at least one follow-up examination). The compliance for the two main histological types of BE i.e.: gastric and intestinal metaplasia (IM) was similar, 58% and 60% respectively. Overall, BE was confirmed in 90% of the cases during the follow up, being the rate or confirmation higher in the IM. 29 of the 59 patients (50%) without histologically proven BE at the entry, showed BE at the final examination. At the entry, dysplasia was found in 5 patients who complied to follow-up, all with low grade dysplasia. During the surveillance period, dysplasia increased in frequency as well as in severity and was found exclusively in the IM type of BE. Dysplastic changes were found in 10 patients (8 low-grade; 2 high-grade) and ADC developed in 3 patients, all in the IM group. This prospective study shows an incidence of ADC in BE of 1 in 185 patient-year. When only IM patients were considered, the risk of ADC was about two folds higher than the whole BE group, suggesting a close surveillance for this high-risk subgroup. *Conclusion:* the present ""ad interim"" report of a prospective endoscopic study shows that the incidence of ADC in Italian BE patients is in the range of that reported from other Western countries. Our data may be representative of the epidemiology of the disease in Southern Europe. OT77 1569**Oesophageal Cancer: Aggressive Growth Behaviour Correlates with the Expression of Adhesion Molecules**

*P. Berberat, H. Friess, M. Schilling, L. Zhao, A. Zimmermann, H. Graber, Lz. Horvath, M. Korc, M.W. B\'fcchler

Department of Visceral and Transplantation Surgery and Institute of Pathology, University of Bern, Switzerland

Departments of Medicine and Biological Chemistry, University of California Irvine, USAThe intercellular adhesion molecule 1 (ICAM-1), the vascular cell adhesion molecule 1 (VCAM-1) and the endothelial leukocyte adhesion molecule 1 (ELAM-1) are cell-surface bound glycoproteins, which contribute to cell-cell interactions. Alteration of adhesion molecules have been suggested to play an important role in tumor progression and the development of blood-born metastasis. In the present study, we examined the expression of ICAM-1, VCAM-1 and ELAM-1 in oesophageal tissues obtained from patients with oesophagus cancer.*Patients:* Oesophageal cancer samples were obtained from 13 male patients with a median age of 58 years (range: 42–73) undergoing surgery for oesophageal cancer. Normal human oesophageal tissues, obtained from either 6 previously healthy organ donors or from resection material (6 patients) adjacent to cancer (1 female, 11 males, median age: 43.5 years), served as control.*Methods:* The tissues were frozen using O.C.T. compound medium in liquid nitrogen for histological analysis. For RNA analysis freshly resected tissue samples were frozen in liquid nitrogen and stored at { -}80\'b0C until analysis. Using Northern blot analysis and immunohistochemistry the expression and cellular localisation of ICAM-1, VCAM-1 and ELAM-1 were assessed.*Results:* ICAM-1, VCAM-1 and ELAM-1 mRNA expression was markedly increased in the oesophageal cancers in comparison with the normal controls. By densitometric analysis there was a 7-, 4.5-, and 4-fold increase in ICAM-1, VCAM-1 and ELAM-1 mRNA expression, respectively ($p < 0.05$) in the oesophageal cancer samples compared with the normal controls. By immunohistochemistry intense ICAM-1, VCAM-1 and ELAM-1 immunoreactivity was found in the oesophageal cancer tissues, whereas weak to moderate immunoreactivity was present in the normal controls.*Conclusion:* The strong overexpression of the adhesion molecules, ICAM-1, VCAM-1 and ELAM-1, in oesophageal cancer, may have a crucial role in the dissemination of tumor cells and might contribute to the development of a metastatic disease. OT79 1570**Ileal Pouch-Anal Anastomosis for Distal Ulcerative Colitis**

*C. Penna, M. Brunel, R. Parc

Service de Chirurgie Digestive, Hopital Saint-Antoine, Paris, FranceDistal ulcerative colitis (UC) seldom require surgery for chronic debilitating symptoms and failed medical management.*Aim:* This study was designed to assess the outcome of ileal pouch-anal anastomosis (IPAA) in such patients.*Patients and methods:* From 1984 to 1994, among 263 IPAA for UC, 27 patients (16 men) were operated for distal UC. Bowel function and quality of life before and 1 year after IPAA were compared.*Results:* The mean duration of UC was 11 – 6 years. In the year before IPAA, those patients had a mean of 2 – 1 attack of colitis, 1 – 1 coloscopy, 2 – 2 rectoscopies, 11 received oral steroids and 10 had a microrectum. IPAA was performed at a mean age of 46 – 10 years, all the pouches were ""J"" shaped and protected with an ileostomy. The mean hospital stay was 25 – 10 days, 3 patients were reoperated (1 small bowel obstruction, 2 intra-abdominal abscesses). Previously unknown severe dysplasia was discovered on the colectomy specimen in 2 patients.After IPAA there was a significant decrease in day-time stool frequency (8.2 – 4 vs 4.7 – 2, $p < 0.05$), night-time stool frequency (2 – 2 vs 1 – 1, $p = 0.05$), and in the number of patients having urgencies (25/27 vs 1/27, $p < 0.001$). Sexual life was improved in 8 patients, social life in 26 and professional life in 8. Twenty-six patients were satisfied with the results and 20 whished to have been submitted to surgery earlier in the course of their disease.*Conclusion:* IPAA can improve bowel function and quality of life in patients presenting disabling chronic symptoms of distal UC. Intestinal disorders: IBD, therapy }" "Ileal Pouch-Anal Anastomosis for Distal Ulcerative Colitis"

OT79 1571**Longterm Outcome of Proctocolectomy with Ileal Reservoir for Ulcerative Colitis**

*E.K. Philipsen, M. Carstensen[1], E. Bruun[1], J. Christiansen[1], V. Binder

[1] Dept. of Gastroenterology, dept. of Surgery, Herlev Hospital, University of Copenhagen, Denmark*Aim:* To assess the outcome of ileal pouch-anal anastomosis (IPAA) in patients colectomised for severe or refractory ulcerative colitis.*Patients and Methods:* In all 151 patients were colectomised during 1980–1994. 52 patients had a permanent ileostomy performed primarily and 99 (66%) had an IPAA carried out.All patients who in April 1996 had a functioning pouch for > 12 month underwent interview by the same gastroenterologist.*Results:* 71/99 (72%) of the patients were included for interview, while 17/99 (17%) had had the pouch removed. 5/99 (5%) had a loop ileostomy and 6 (6%) were lost to follow up.71 patients were interviewed, 35 men and 36 women, median age 36, range 18–71. 13/71 (18%) had J-pouch, and 58/71 (82%) had S-pouch. Median time since IPAA was 75 months, range 6–191.Subjective global assesment was: *satisfied* in 59 (83%) and *not satisfied* in 12 (17%). 61/71 (86%) stated that they would go through the same again to obtain their present condition.66 (93%) had spontaneous defecation while 5 (7%) had to tubulate and 4 did both. Perfect continence was achieved in 23 (32%) while 22 (31%) had minor incontinence, and 26 (37%) had periodical incontinence (> 1 per month).Median number of bowel movements was 6, range 3–13. Nocturnal defecation was present > once per week in 45/71 (63%), in median 7, range 2–49 per week.Pouchitis occurred in 28/71 (39%) first time at a median of 8 months (range 1–138) after closure of the loop-ileostomy.Social life function was generally intact: 58/71 (82%) were working full-time, 53/71 (75%) were active in sport, 70/71 (99%) participated in social events, and 63 (89%) were able to travel abroad.34 (97%) men and 25 (69%) women had unchanged active sexual activity, 2/35 (6%) men and 10/36 (28%) women had some fear of incontinence during sexual intercourse.*Conclusion:* Despite technical and individual difficulties, IPAA is an attractive alternative to ileostomy. The majority of patients are satisfied and have an intact social life. OT79 1572**Post-Operative Recurrence of Crohn's Disease: A Study for the Development of Lesions in Treated and Untreated PatientsR. Caprilli, A. Viscido,**

*G. Taddei, G. Corrao, P. Torchio, D. Assisi

Univ. of L'Aquila, Italy and Gruppo Italiano per lo Studio del Colon/Retto*It has been hypothised that aphtae are the earliest lesions in Crohn's disease (CD). Ulcers seem to result of coalescence of aphtae and then spread superficially or transmurally leading to abscesses and fissurings. Stenosis seems to be a reparative late event. Nevertheless such a sequence of evolving lesions has never been demonstrated due to the lack of techniques which enable a continuous observation. By using the GISC trial data on 5-ASA (Aliment Pharmacol & Therap 1994; 8: 35–43) in the prevention of post-operative recurrence of CD, we have elaborated a mathematical model based on the hypothesis that CD's lesions develop following the aphtae-ulcer-fisuring-stenosis sequence. It was assumed that each endoscopic lesion observed during follow-up controls at 6, 12, 24, 36 months after surgery occurred between (half period) the previous negative observation and the present positive control. The cumulative probability of every lesion occurrences has been estimated using the life-table method and applied in both arms of patients, those treated with ASACOL 4 gr/day (55 pts) and those who remained untreated (55 pts). The *results* of the study is referred only to the development of aphtae and ulcers (fistula and stenosis were scarcely represented). The cumulative proportion of lesions reappearance after radical resection are shown in the diagram. Mean time of lesions recurrence were 423 days for aphtae and 584 days for ulcers in untreated pts and 580 and 704 days respectively in pts treated with ASACOL. The development of aphtae and ulcers resulted to be significantly delayed in pts treated with ASACOL vs those untreated ($p = 0.006$ and $p = 0.03$ respectively). The earliest lesions observed at 6 month after surgery were aphtae (20% of the cases), ulcers (8% of the cases) and aphtae associated with ulcers (10% of the cases). The multivariate analysis ""Marginal Proportional Hazard"" showed a relative risk (RR) of aphtae development of 0.4 ($p < 0.01$) and a RR of ulcers development of 0.5 ($p < 0.05$) in treated vs untreated pts. Limiting the results of the study to the observations made in untreated pts, the mean time of aphtae appearance was estimated to be about 14 months and that of ulcers 19 months. However about 30% of pts show aphtae already at 6 months after surgery. These data may be helpful for the study of natural history of recurrence and possibly of the disease.

OT79 1573**Outcome of Restorative Proctocolectomy after Recurrence of Crohn's Disease in the Reservoir**

*Y. Panis, A. Dusoleil, X. Penna, P. Francois, P. Lehur, A. Vignal, F. Carbonnel, L. Spiroudhis, L. Gosselin, L. Descos, R. Parc, P. Valleur, D. Couturier, S. Chaussade

Service de chirurgie et de gastroent\'e9rologie, Hospital Lariboisére, Saint Antoine, Rotschild, Paris, Rennes, Lyon, Nantes, FranceRestorative proctocolectomy with construction of an ileal pouch anastomosis is a procedure which is mainly proposed in the treatment of ulcerative colitis. Patients with Crohn's disease are generally regarded as unsuitable candidates for reservoir procedure because of the risk of recurrent ileal and anal disease. The consequence of the recurrence of a CD after ileo anal anastomosis is unknown.*The aim of this study* is to describe the clinical features and the evolution of the anal function of patients presenting a CD after an ileoanal procedure.*Method-Material:* 21 patients (6 males, 15 females) from 7 centers were included in this study. Proctocolectomy with ileo anal anastomosis and reservoir (J = 19, W = 2) was performed for severe colitis (19%), cortico-dependance (33%) or cortico-resistance (48%). The inclusion criteria to assume the recurrence of a CD was as follow: 1-Occurrence of ano-perineal disease suggestive of CD (abcess, fistula, anal ulcerations), 2-Occurrence of pochitis with an inflammation in the small intestine at a distance of more than 10 cm beyond the reservoir or pochitis with granuloma in any part of the gastrointestinal tract, 3-Occurrence of a fistula between the reservoir and the skin, the vagin on an other part of the small bowel at least 1 year after the surgical procedure.*Results:* CD have been suspected in 5 cases before the recurrence in the reservoir (presence of granuloma on the colonic specimen in 3 cases and chronic ileitis in 2 cases). The diagnosis of CD was made 36 – 20 months (12–94) after the construction of the reservoir. The diagnosis of CD was performed in 3 situations: pouchitis and ileitis proximal to reservoir (n = 3) or pouchitis with granuloma (n = 3), perianal disease (n = 10), or fistula between the reservoir and the skin, the small bowel or the vagin (n = 5). One or several surgical procedures were indicated in 16/21 cases (76%). Pouch excision or end ileostomy was performed in 30%.*Conclusion:* After ileo anal anstomosis, recurrence of a suspected or of an unknown CD is associated with pouch excision or ileostomy in 30% of the patients mainly for perianal disease. Intestinal disorders: Anorectal disorders }" "Outcome of Restorative Proctocolectomy after Recurrence of Crohn's Disease in the Reservoir"

[2] Dept. of Medical Microbiology, Academic Medical Center, Amsterdam, The Netherlands

[3] Dept. of Histopathology, Academic Medical Center, Amsterdam, The Netherlands

[4] Dept. of Clinical Epidemiology, Academic Medical Center, Amsterdam, The Netherlands*Background:* It is unknown whether the presence of *cagA* selects patients (pts) who will have more benefit of *H. pylori* eradication therapy. We conducted a large prospective study to assess the relation of *cagA* status and clinical outcome of pts randomized for omeprazole-amoxicillin dual therapy. *Methods:* The relation between *cagA* and gastro-intestinal disease characteristics, the eradication success and the degree of gastritis (according to modified Sydney classification) before and after eradication therapy (4–6 weeks and a mean of 1 year) was assessed. *Results:* 155 consecutive *H. pylori*-positive (culture and histology) pts, were enrolled in the study. *cagA*$^{+}$ *H. pylori* were recovered from 122/155 pts (79%). *H. pylori* eradication was successful in 74% of *cagA*$^{+}$ and 52% of *cagA*$^{\{-}$} strain ($p = 0.017$). Pretreatment degrees of gastritis activity, superficial epithelial damage (SED), intestinal metaplasia (IM) and atrophy were significantly more pronounced in pts infected with *cagA*$^{+}$ *H. pylori* as compared to those infected with *cagA*$^{\{-}$} strains ($p < 0.001$). Following eradication therapy a significant improvement of the gastritis activity occurred ($p < 0.001$), however, the final gastritis scores were similar in both in *cagA*$^{+}$ and *cagA*$^{\{-}$} infected pts. *H. pylori* eradication did not affect the degree of IM and atrophy. Dysplasia was noticed in only one patient infected with *cagA*$^{+}$ *H. pylori. Conclusions:* Eradication efficacy and the degree of activity of gastritis, atrophy and IM correlated with the presence of *cagA*$^{+}$ *H. pylori.* Improval of the degree of active gastritis, following *H. pylori* eradication, was also correlated to the presence of *cagA*$^{+}$ *H. pylori,* although the final degree of gastritis was independent of the *cagA* status. The degree of IM and atrophy was unchanged despite cure of *H. pylori* infection. Oesophageal gastric duodenal disorders: Helicobacter Pylori }" "CagA Status and Clinical Outcome in H. Pylori Infected Patients Treated with Omeprazole and Amoxicillin: A Prospective Study"

OT80 1575***In vivo* and *in vitro* Analysis of Inducible Nitric Oxide Synthase (iNOS) in Gastric Epithelial Cells in CagA Positive & CagA Negative *Helicobacter Pylori* Infections**

*J.E. Crabtree, P. Pasini[1], F. Bazzoli[1], S. Perry, S. Farmery, J.I. Wyatt, E. Roda[1], A. Roda[1]

St. James's Hospital, Leeds, UK

[1] University of Bologna, Italy*Purpose:* Increases in iNOS are associated with intestinal inflammatory conditions. Products of NO, such peroxynitrite, may be important mediators of mucosal damage. This study investigates i) whether infection with CagA$^+$ and CagA negative *H. pylori* results in quantitative differences in iNOS enzyme in the gastric epithelium using immunochemiluminescence imaging and ii) the ability of CagA$^+$ and CagA negative *H. pylori* to induce iNOS mRNA in a gastric epithelial cell line *in vitro.Methods:* Cryosections of antral biopsies (n = 23) were incubated with rabbit anti-iNOS antibody or normal rabbit serum. Bound antibodies were detected using a low light imaging luminograph following incubation with enzyme labelled second antibodies and chemiluminescent substrate. Kato-3 cells were cultured *in vitro* with CagA$^+$ and CagA neg *H. pylori.* At 3–30 hrs post-stimulation cells were harvested and mRNA for iNOS and an internal control gene G3PDH was examined by RT-PCR.*Results:* 14/18 (78%) HP$^+$ patients with chronic gastritis and 1/5 (20%) Hp negative with normal histology had a chemiluminescent signal for iNOS in the epithelium. No signal was detected with control rabbit sera. Median (IQR) iNOS levels were respectively 42.6 (10.8–66.4) photons/sec/unit area (HP$^+$) and 0 (0–22.1) (HP neg; $p < 0.05$ versus HP$^+$). 7/8 (88%) CagA seronegatives and 7/10 (70%) CagA seropositives were iNOS positive. Median iNOS values were 48.1 (21.7–72.9) (CagA neg) and 41.3 (0–63) (CagA$^+$). iNOS mRNA was not present in unstimulated Kato-3 cells. Culture with CagA$^+$ and CagA negative *H. pylori* resulted in iNOS mRNA expression with maximum expression at 3 hrs.*Conclusions:* Sensitive chemiluminescence techniques can quantitatively detect iNOS in gastric epithelial cells. Infection with both CagA$^+$ and CagA negative strains is associated with increased epithelial iNOS message and protein. *H. pylori* induction of epithelial iNOS is mediated by factors common to both CagA$^+$ and CagA negative strains. OT80 1576**Rate of Apoptosis in Chronic Gastritis and Correlation with Antigastric AutoantibodiesH. Steininger, E. Dewald,**

*G. Faller, Th. Kirchner

Institute of Pathology, University of Erlangen-N\'fcrnberg, Germany*Introduction:* Gastric atrophy is an obvious feature in autoimmune gastritis and in some cases of H. pylori gastritis. In the latter it has recently been shown that the occurrence of autoantibodies to canaliular structures within parietal cells is associated with atrophic changes in the gastric mucosa. Since apoptosis is an important mechanism leading to cell death we aimed to investigate its role in different types of gastritis.*Methods:* Human gastric biopsy specimens from normal mucosa (n = 16), from H. pylori gastritis with (n = 19) and without (n = 16) anticanalicular autoantibodies and from autoimmune gastritis (n = 7) were included in our study. The rate of apoptosis was assessed in each case with the TUNEL-method using a commercially available Apoptosis Detection Kit (Oncor, USA). Autoantibodies to human gastric epitopes were detected by immunohistochemistry.*Results:* Normal gastric mucosa showed only very few apoptotic cells. In H. pylori gastritis the number of apoptotic cells in the foveolar epithelium and in the glands was significantly higher both in the antrum and in the body ($p < 0.01$). Furthermore in the H. pylori positive group *with* anticanalicular autoantibodies the rate of apoptosis was significantly higher in the gastric glands when compared with H. pylori gastritis *without* this type of autoantibodies ($p = 0.01$). In type A gastritis the rate of apoptosis in the body glands was highest in all groups tested ($p = 0.0005$).*Conclusion:* According to our data apoptosis seems to be an important mechanism leading to gastric atrophy not only in autoimmune (type A) gastritis but also in H. pylori gastritis. Furthermore in H. pylori gastritis, the host's antigastric autoimmune response in combination with apoptosis possibly induced by antigastric autoimmune reactions could determine the transition to chronic atrophic gastritis. }" "Rate of Apoptosis in Chronic Gastritis and Correlation with Antigastric Autoantibodies"

OT80 1577**Relationship between H. Pylori Infection, Histological Gastritis and Non-Ulcer Dyspepsia**

*B. Glasbrenner, S. Weiler, V. Ellenrieder, P. M\'f6ller[1], G. Adler

Dep. of Internal Medicine, University of Ulm, Germany

[1] Dep. of Pathology, University of Ulm, GermanyIt is still controversial whether or not HP infection, histological gastritis and non-ulcer dyspepsia (NUD) are intercorrelated. We designed a prospective study to clarify this.*Methods.* 88 prospective NUD patients (age range 18–84 y) who did not show other disease than gastritis were investigated. In a questionnaire they were asked to report the presence or absence of 8 upper GI symptoms and to score from 0 (absence) to 3 (severe), whereupon a sum score was calculated. 40 age-matched patients with a NUD sum score < 3 served as controls (C). Biopsy specimens for histology and rapid urease test were taken.*Results.* HP infection was present in 43% of NUD and in 35% of C subjects (n.s.). None of the symptoms was correlated with HP infection. The median NUD score was 8.5 in HP-positive and 9.5 in HP-negative NUD pts.. Histological gastritis was not correlated with any of the symptoms. Medians of NUD scores were 10 in pts. without gastritis (G0), 7.5 in pts. with gastritis characterized by lymphoplasmacellular infiltration of the lamina propria (G1) and 9.0 in pts. featuring granulocytic epithelial lesions (G2). G2-gastritis was present in 34% of NUD pts. and in 30% of C subjects. Prevalence of G0/G1/G2 gastritis was 5%/32%/63% in HP-positive and 64%/24%/12% in HP-negative pts..*Conclusions.* HP infection is not correlated with clinical symptoms of NUD. The same applies for histological gastritis. In contrast but well-documented, HP infection is associated with histological signs of gastritis. Our data imply that HP gastritis is not an important condition in the pathogenesis of dyspeptic symptoms. OT80 1578**A Serologic Survey of Helicobacter Pylori (HP) Infection in 3281 Patients Referred to Endoscopy through ItalyD. Varia, The Italian Helicobacter pylori Study Group**

1st Medical Clinic, S. Orsola Hospital via Massarenti, 9, 40138, Bologna, Italy*Purpose:* To assess: 1. the seroprevalence of HP in a large series of patients with upper gastrointestinal symptoms referred for their first upper gastro-intestinal endoscopy through Italy, 2. to evaluate the reliability of a commercially available ELISA (HELORI-TEST, EUROSPITAL, Trieste, Italy).*Methods:* A total of 3,281 patients referred to endoscopy in 93 Medical Centers through Italy were enrolled. For each participant a blood sample for assessment of anti HP IgG antibodies by ELISA, and two biopsies of the antral gastric mucosa for histology (Hematoxilin & Eosin and Giemsa stain) were obtained. Presence of HP by Giemsa was considered the ""gold standard"".*Results:* Endoscopic diagnosis ranged between normal mucosa (25.3%), gastro-duodenitis (51.6%), gastric and duadenal ulcers (3.7 and 14.9%, respectively) and other conditions including gastric cancer (0.8%). Overall, the seroprevalence of HP resulted 71.3% with a strong positive association with increasing age and male sex and a negative one with education level. According to endoscopic diagnoses, the association with HP seropositivity was highest for duodenal and gastric ulcer (OR: 6.1 and 2.2 respectively) and lowest for carcinoma (OR: 1). The comparison between serology and the Giemsa stained specimen showed a good reliability of IgG by ELISA particularly in a subgroup (n = 2.056) for which the histological interpretation was performed by a single dedicated pathologist: sensitivity and specificity reached 92 and 78%, respectively.*Conclusions:* 1. We confirm an high prevalence of HP in dyspeptic patients through Italy with a positive association with age, male sex and low educational level; 2. a key factor for obtaining a real histological ""gold standard"" seems to rely in having a dedicated histopathologist. Oesophageal gastric duodenal disorders: Helicobacter PyloriClinical practice: Epidemiology (non cancer) }" "A Serologic Survey of Helicobacter Pylori (HP) Infection in 3281 Patients Referred to Endoscopy through Italy"

OT81 1579**Central Effect of Pituitary Adenylate Cyclase Activating Polypeptide (PACAP) on Gastric Emptying and Small Intestinal Transit in Conscious Rats**

*M. Ozawa, K. Mizuta, M. Aono, M. Moriga

The First Department of Internal Medicine, Faculty of Medicine, Kyoto University, Kyoto, JapanPACAP is new member of the secretin-glucagon-VIP peptide family. PACAP is widely distributed not only in the brain, but also in gastrointestinal tract. The present study was to designed to investigated a possible effect of central administration of PACAP on gastric emptying (GE) and small intestinal transit (SIT) of a liquid meal in concious rats.Male Wistar rats weighing 250–280 g were used. Rats were deprived of food for 24 hr but given free access to water in wide-mesh wire cages to prevent coprophagia. Under light ether anesthesia, saline, PACAP38 (2, 4, 8 nmol/rat) was administered intracisternally 1 min before ingestion of phenol red solution as liquid meal through an oral tube. The animals were sacrificed by deep ether anesthesia 1 hr after phenol red ingestion. The small intestine was divided into two segments of equal length. To examine the mechanism of the effect of PACAP, carbachol (50 ug/kg), atropine (1 mg/kg), hexamethonium bromide (10 mg/kg), phentolamine (2 mg/kg) or propranolol (2 mg/kg) was injected intraperitoneally 5 min before PACAP adminstration.Intracisternal administration of PACAP38 inhibited GE and SIT in a dose dependent manner. By contrast, intraperitoneal administration of PACAP (4 nmol) did not affect GE and SIT. Intracisternal administered PACAP partially suppressed GE and SIT accelerated by carbachol. The inhibitory effect of PACAP was additive to the inhibitory effect of atropine or hexamethonium bromide pretreatment. Pretreatment with propranolol or phentolamine did not affect the effect of PACAP.These results suggested that central administration of PACAP inhibited gastrointestinal transit in part by inhibition of vagal tone at peripheral level but not central level. Hormones and receptors: Brain gut axisMotility, specific: StomachMotility, specific: Small bowel }" "Central Effect of Pituitary Adenylate Cyclase Activating Polypeptide (PACAP) on Gastric Emptying and Small Intestinal Transit in Conscious Rats"

OT81 1580**Stress-Induced Visceral Hypersensivity in Rats Involved Central CRF PathwayM. Gu\'e9[1], C. Del Rio, J. Fioramonti, L. Bu\'e9no**

Dept of pharmacology, INRA, Toulouse, France

[1] Institut de recherche Jouveinal, Fresnes, FranceEnhanced abdominal pain and colonic motor disturbances are commonly observed in IBS patients. Psychologic factors have long been implicated in the aetiology of IBS. In rats, stress alters colonic motility through central CRF pathway. Consequently, the aims of this study were to evaluate the influence of partial restraint stress (PRS) on abdominal cramps, in response to rectal distension (RD) and to determine the involvement of CRF; in addition, we have evaluated the effect of PRS on a somatic pain, such as tail flick and on rectal compliance.*Methods:* Male Wistar rats weighing 250 to 300 g were surgically prepared for electromyography with Ni/Cr electrodes implanted in the striated muscle of the abdomen and with a small polyethylene catheter for intracerebroventricular (ICV) injection. In a 1st series, 8 rats were leaved in cage (sham PRS) for 2 hours, whereas the 2nd group was submitted to PRS, consisting to restrain forelimbs with paper tape, for 2 hrs. Thirty min later, RD was performed by rectal insertion of a balloon (diam: 2 mm, length, 2 cm) at 1 cm from the anus, increasingly inflated with water step by step from 0.4 up to 1.2 ml. each step lasting 5 min. In a 2nd series, 8 rats were ICV injected with { a}-helical CRF (5 \'b5g) 5 min before PRS, then rats were submitted to RD as in the 1st series; in a last series, 8 rats were ICV injected with CRF (0.5 \'b5g/kg) 30 min before RD. Finally, in a group of 8 rats the tail-flick test was used. The distal 4 cm of the tail was dipped into 48\'b0C water and the latency of the withdrawal reflex was recorded at 15, 30 and 45 min after sham PRS or PRS.*Results:* In sham PRS rats, RD induced a volume-related increase in the number of abdominal cramps (0.4 ml: 5.0 – 1.3; 0.8 ml: 17.3 – 1.9; 1.2 ml 28.7 – 1.4). PRS significantly ($p < 0.05$) enhanced the number of abdominal cramps at all volumes of distension (0.4 ml: 8.7 – 1.2; 0.8 ml: 27.6 – 1.4; 1.2 ml 38.8 – 1.8). This hypersensitivity to PRS was mimicked by ICV CRF (0.4 ml: 8.1 – 0.6; 0.8 ml: 26.1 – 1.3; 1.2 ml 36.9 – 1.8) and was antagonized by ICV pretreatment with { a}-hel CRF. PRS-induced a significant delay on tail flick latency, at 30 and 45 min after PRS session. Furthermore, PRS had no effect on rectal compliance since none of the rats exhibited an increased pressure response to balloon inflation.*Conclusion:* These results show that, in contrast to its effects on somatic pain, stress enhances abdominal contractions in response to RD in rats and that these effects are mediated through central CRF pathway. }" "Stress-Induced Visceral Hypersensivity in Rats Involved Central CRF Pathway"

OT81 1581**Assessment of Rectal Sensitivity by a Reflexologic Technique in Healthy Humans**

*J.M. Sabate, D. Bouhassira, B. Coffin, B. Flourie, M. Lemann, J.C. Rambaud, J.C. Willer, R. Jian

INSERM U290, Saint-Lazare and Saint-Louis Hospitals, and INSERM U 161, Paris, FranceRectal distension studies with pharmacological tests and verbal questionnaires, have suggested the existence of two types of mechanoreceptors stimulated by different methods of distension. *Our aim* was to confirm this functional duality by using a reflexologic technique based on the recording of a nociceptive somatic reflex, the RIII reflex, which allows an objective evaluation of visceral sensitivity [1].*Methods:* The effects of rectal distension on the RIII reflex were measured in 10 healthy volunteers. Rapid (900 mL/min) phasic distensions in a random order at 10, 20, 30, 40 mmHg, lasting 3 min each, and slow (40 ml/min) ramp distension up to a maximal volume of 600 ml or to discomfort threshold were performed with an electronic barostat. The RIII reflex was continuously stimulated and recorded on the lower limb for both types of distensions, and on the upper limb for phasic distensions. Reflex responses were recorded before (control period), during, and after each distension for 3 min, and expressed as percentages of control values. Volumes distending pressure and sensations (7 steps on verbal scale) were also measured. Results (m – SD) were evaluated by ANOVA.*Results:* On the lower limb, the RIII response was significantly increased (facilitation) by phasic distensions (129 – 15%, 160 – 20%, at 20 and 30 mmHg respectively $P < 0.05$). At 40 mmHg, a biphasic response with a facilitation (128 – 20%, $P < 0.05$) followed by an inhibition (66 – 18%, $P < 0.05$) was noted. By contrast, the RIII response on the lower limb was significantly inhibited by slow ramp distension (53 – 17%, $P < 0.05$) for a maximal distending volume of 397 – 101 mL, and the magnitude of inhibition was correlated with the intensity of the sensation elicited by the distension ($r = 0.76$, $P < 0.05$). On the upper limb, the RIII reflex response was significantly inhibited by phasic distensions (46 – 16% at 40 mmHg, $P < 0.05$).*Conclusions:* Convergence onto the same spinal cord segment of afferent pathways coming from the rectum and from the somatic territory involved in the RIII reflex could explain the facilitation we noted. The inhibition of the RIII reflex corresponds to the classical phenomenon of counter irritation triggered by heterotopic stimulations. Our results give an objective confirmation for the presence in the rectum of healthy humans of two types of mechanoreceptors with different afferent pathways.Funded in part by the Institut de Recherche Jouveinal, Fresne, France.

OT81 1582**Differences in Response of Proximal and Distal Colonic Smooth Muscle Cells to Relaxant AgentsC. Severi, V. Carnicelli, A. Di Giulio, A. Bozzi, R. Strom, G. Delle Fave**

GI Unit 1 and Dept. of Biopathology, Univ. La Sapienza, Rome, Italy

Dept. of Biochem. Sci. and Technology, Univ. of L'Aquila, ItalyPatterns of motor activity differ between the various segments of the colon and regional differences have also been observed in receptors and neurotransmitters distribution. We aimed a study to both characterize the patterns of relaxation and determine the relative signalling pathways involved in order to investigate in colonic smooth muscle cells (SMC) if cellular differences could reflect the different pattern of motor activity. The two main relaxant putative neurotransmitters are Nitric Oxide and VIP which induce respectively a cGMP-dependent and a cAMP-dependent response. SMC, isolated by collagenase digestion separately from proximal and distal circular muscle layer of guinea pig colon, were exposed to a maximal dose of carbachol (Cch) (30 nM) for 30 sec in order to determine peak contraction or preincubated, before Cch exposure, for 60 sec with a relaxant agent to examine relaxation. Contraction was expressed as % decrease in cell length while relaxation as % inhibition of contraction. cGMP-dependent response was induced by activation of guanilate cyclase with sodium nitroprusside (SNP: 1 \'b5M) or by cGMP (1 mM) while cAMP-dependent relaxation by activation of membrane receptors with VIP (1 \'b5M, 1 nM) or isoproterenol (ISO: 0.1 mM, 0.1 \'b5M), of adenylate cyclase with forskolin (FK: 0.1 mM, 0.1 \'b5M) or by cAMP (1 mM). Contractile responses were similar between proximal and distal SMC (Cch: 21.9 – 3.2 and 25.8 – 2.0% respectively). Differences were instead observed in relaxation depending on which intracellular pathway was activated. Proximal SMC relaxation was in fact cGMP-dependent while distal response was cAMP-dependent. cGMP-dependent agents relaxed proximal SMC without having any effect on distal SMC (SNP: 70 – 10 vs 6.8 – 3.6%, cGMP: 58.6 – 10% vs 6.9 – 3.6%). Maximal doses of each cAMP-dependent agent instead induced an higher degree of relaxation of distal than proximal SMC (VIP: 62 – 10 vs 37.6 – 10%, ISO: 53.2 – 2.4 vs 36.2 – 8.8%, FK: 54.4 – 10 vs 24.7 – 10%, cAMP: 58.2 – 10 vs 18.4 – 9.8%). Submaximal doses of these agents were still effective (20%) on distal SMC while were ineffective on proximal SMC, confirming that the high intracellular levels of cAMP stimulated by maximal doses are also able to activate cGMP-kinase. These results suggested that the distinct intracellular patterns of relaxation between proximal and distal colon might in part contribute to explain the different regional functional motor activities of this organ. Motility, general: Receptors and signalsMotility, specific: Colon, anorectum }" "Differences in Response of Proximal and Distal Colonic Smooth Muscle Cells to Relaxant Agents"

OT81 1583**Anal Sensitivity: What Does It Measure and Do We Need It?**

*R.J.F. Felt-Bersma, A.C. Poen, M.A. Cuesta[1], S.G.M. Meuwissen[2]

[1] Dept. of Surgery, University Hospital ""Vrije Universiteit"", Amsterdam, The Netherlands

[2] Dept. of Gastroenterology, University Hospital ""Vrije Universiteit"", Amsterdam, The Netherlands*The aim of the study* was to determine the anal sensitivity (AS) in controls and in different patient groups and to determine factors that determine AS.*Methods.* Anorectal function tests were performed in 387 patients with different anorectal diseases. AS was measured in 36 controls. AS is measured by means of mucosal electrosensitivity using a catheter with 2 electrodes placed in the anal canal. A constant current (square wave stimuli 100 \'b5sec, pulses per second) was stepwise increased from 1–20 mAmp until the threshold sensation was reached. Other tests were anal manometry (maximal basal pressure (MBP), maximum squeeze pressure, (MSP), rectal compliance (maximal rectal volume and pressure (MRP)), endosonography (defects and thickness internal (IST) and external sphincter EST), submucosal thickness (SMT), EMG (maximal contraction pattern (MCP grade 1 (solitary contractions) to 4 (interference pattern)) and pudendal nerve terminal motor latency (PNTML). Multiple regression analysis was performed. Postulated was that age, local conditions (anal scars, anal fissures, hemorrhoids, mucosal prolapse, proctitis, SMT, IST and EST) and neurologic factors could influence anal sensitivity.*Results.* Controls had an AS of 3.4 – 1.7. AS was significantly diminished compared to controls in patients with fecal incontinence, soiling, hemorrhoids, mucosal prolapse, constipation, anal scars, anal surgery and sphincter defects; patients with fecal incontinence had the lowest AS (6.7 – 4.3, $p < 0.0001$). Patients with anal fissures and proctitis showed no differences compared to controls. AS correlated significantly with age (R = 0.29), MBP (R = { -}0.29), MSP (R = { -}0.32), SMT (R = 0.19), MCP (R = { -}0.39), SF-EMG (R = 0.39) and MRP (0.14). Multiple regression analysis showed that age, IST and SMT significantly influenced AS, but explaining only 10% of the variance.*Conclusion:* AS is diminished in all patients with anorectal diseases except for anal fissures and proctitis. There are correlations with other anorectal function tests. AS is determined for 10% by age and thickness of submucosa and anal sphincter. It therefore has limited clinical value and should be used in conjunction with other tests in a research setting. Motility, specific: Colon, anorectumIntestinal disorders: Anorectal disordersMotility, general: Innervation }" "Anal Sensitivity: What Does It Measure and Do We Need It?"

OT81 1584**A Study of the Functional Activity of the Sigmoid Colon and Rectum during Fecal Storage in the SigmoidA. Shafik**

Faculty of Medicine, Cairo University, Cairo, Egypt*Purpose:* The incomplete information in the literature on the mechanism of sigmoid storage and evacuation and its relation to the rectum has initiated our study.*Methods:* In 18 mongrel dogs, a condom-ended catheter was introduced into the sigmoid and infused with carbon dioxide (CO_2) at 2 rates: slow and rapid. The pressure responses of sigmoid colon, rectosigmoid junction (RSJ), rectum and rectal neck to sigmoid distension were determined; the EMG activity of the external anal sphincter and levator ani was also evaluated.*Results:* Upon slow sigmoid distension up to a mean of 93.6 – 3.2 ml, no pressure response occurred in the sigmoid, RSJ, rectum or rectal neck. Distension above this level induced an increase of sigmoid pressure ($p < 0.001$), a decrease of RSJ pressure ($p < 0.05$), but no change in rectal or rectal neck pressure ($p > 0.05$); balloon was dispelled to rectum. EMG of external anal sphincter and levator showed no activity. Balloon expulsion to the rectum effected a pressure increase in the rectum ($p < 0.001$), a decrease in the rectal neck ($p < 0.01$), and an increase in the RSJ ($p < 0.01$), while the sigmoid showed no response ($p > 0.05$), and the balloon was dispelled to the exterior. Rapid sigmoid distension induced an increase of sigmoid pressure ($p < 0.001$) and a decrease of RSJ pressure ($p < 0.05$) at approximately half the volume needed with slow distension.*Conclusion:* Sigmoid colon adapts to the new contents until a certain volume is attained, when it contracts dispelling its contents to rectum. Rapid distension induces sigmoid contraction at a smaller volume than slow distension. Rectum and rectal neck did not respond to sigmoid distension or contraction, and vice versa. Sigmoid contraction initiates RSJ relaxation, while rectal contraction evokes RSJ contraction. OT82 1585**Segmental Reversal of the Small Bowel: An Alternative to Intestinal Transplantation in Patients with Short Bowel Syndrome?**

*Y. Panis, B. Messing, P. Rivet, B. Coffin, P. Hautefeuille, C. Matuchansky, J.C. Rambaud, P. Valleur

Digestive Surgical and Gastroenterology Departments, Lariboisiére and St Lazare Hospitals, Paris, FranceAlthough long-term survival is possible in patients with short bowel syndrome requiring home parenteral nutrition (HPN), its cost and morbidity rate have maintained interest in developing surgical alternatives to HPN. Intestinal transplantation has gained interest in clinical practice. However, actuarial patient and primary graft survival rate at 2 years are still about 60 and 50% respectively, making transplantation still a difficult and unreliable procedure.*The aim of this work* was to report the results of segmental reversal of the small bowel in patients with very short bowel syndrome definitely dependent on HPN.*Methods:* Eight patients with short bowel syndrome underwent segmental reversal of the distal (n = 7) or proximal (n = 1) small bowel. The mean length of the remnant small bowel was 46 – 18 cm (extr. 25–70), including a mean length of reversed segment of 12.7 – 2.8 cm (extr. 8–15). Five patients presented with jejunotransverse anastomosis, and one each with jejunorectal, jejuno-left colonic, or jejuno-caecal anastomosis with left colostomy.*Results:* There were no postoperative deaths. Three patients were reoperated early, respectively for sepsis of unknown origin, wound dehiscence and acute cholecystitis. Three patients experienced transient intestinal obstruction which was treated conservatively. Mean follow-up was 38 – 36 months (extr. 2–108). One patient died 7 months postoperatively, of pulmonary embolism. By the end of follow-up, 3 patients were on 100% oral nutrition, and one patient had hydroelectrolytic perfusions only. For the three other patients, parenteral nutrition regimen was reduced. Parenteral nutrition cessation was obtained in 3/5 cases at 1 year, and 3/3 cases at 4 years.*Conclusion:* Segmental reversal of the small bowel could be proposed, as an alternative to intestinal transplantation, in the early stage of short bowel syndrome, before the possible occurrence of parenteral nutrition-related complications. OT82 1586**Correction of Malnutrition Following Gastrectomy with Cyclic Enteral Nutrition**

*X. H\'e9buterne, F. Vaillon, J.L. P\'e9roux, S. Schneider, P. Rampal

Service de Gastroent\'e9rologie et Nutrition, Hospital de l'Archet, 06202 Nice cedex 03, FranceThis prospective study was designed to evaluate the efficacy and tolerance of cyclic enteral nutrition (CyEN) in gastrectomized patients.*Methods.* 28 consecutive gastrectomized patients were treated with CyEN for at least two weeks. CyEN was performed during the night with a pump and the flow rate was maintained constant at less than 3 mL/min. We used a commercially available polymeric diet at the concentration of 1.33 kcal/mL to provide 20% protein, 45% carbohydrated and 35% fat. During the day, patients were allowed and encouraged to eat normally and to have physical activities. A Global Nutritional Deficit (GND), was calculated before the beginning of the treatment (D0), after two weeks (D15), and at the end of CyEN (Dn), using 10 anthropometric and biological parameters. After renutrition, patients were followed-up for one year.*Results.* Total (enteral + oral) energy intake (292% and 284% of resting energy expenditure in gastrectomized and non-gastrectomized patients, respectively) and the duration of CyEN (mean: 27 days) were similar in both groups. Tolerance was good and not different in the two groups. The GND significantly improved (P < 0.0001) in the two groups with six of the ten nutritional parameters studied being significantly improved by renutrition (body weight, triceps skinfold, medium arm circumference, serum prealbumin, serum transferrin, 24 h. urinary creatinine). At Dn, the GND improved by 42.7 – 17.3% in the gastrectomized patients and 40.0 – 17.4% in the non-gastrectomized patients (P = 0.55). After one year, the probability to be alive without relapse was 77.8% in the gastrectomized and 72.2% in the non-gastrectomized patients (P = 0.70). Among the patients who did not relapse, oral energy supplements were still being given after one year to ten (48%) gastrectomized and eight (30%) non-gastrectomized patients. The efficacy of renutrition was similar regardless of the type of gastrectomy, and the GND improved by 39.4 – 16.5% in the patients with partial gastrectomy (20 patients) versus 50.3 – 17.8% in the patients with total gastrectomy (8 patients) (P = 0.14).*Conclusion.* CyEN is a safe, effective and durable treatment for undernutrition in gastrectomized patients suitable for more widespread utilization. Clinical practice: Management strategyClinical practice: PsychosomaticsNutrition: Techniques of nutrition }" "Correction of Malnutrition Following Gastrectomy with Cyclic Enteral Nutrition"

OT82 1587**Demonstration of Transforming Growth Factor Alpha (TGF-Alpha) in Neuroendocrine L-Cells of the Human Colon Mucosa by Immunoelectron Microscopy**

*W. Back[1], G. Rohr[2]

[1] Dep. of Pathology, Klinikum Mannheim, University of Heidelberg, 68135 Mannheim, Germany

[2] Dep. of Gastroenterology, Klinikum Mannheim, University of Heidelberg, 68135 Mannheim, GermanyProteins of the epidermal growth factor (EGF) family are important for the maintenance of cell renewal and epithelial regeneration in the gastrointestinal tract. There are still open questions about the cellular depots, the source and the pathophysiological role of these growth factors in the gastrointestinal tract.Biopsies and surgical mucosa probes of the colon (n = 15) and of the gastroduodenum (n = 10) were parallelly processed through plastic embedding (Araldite and Lowicryl K4M) and paraffin histology. Single and double labelling immunohistologic techniques, serial sectioning and immunoelectron microscopy were applied to localize growth factors, hormones and other neuroendocrine markers on mucosal cells.Immunohistochemically TGF-alpha is localized in parietal cells of the gastric corpus and in a special subgroup of neuroendocrine cells of the colon mucosa. As evidenced by serial sectioning every colonic crypt harbours about 5 TGF-alpha positive cells in the lower half of the crypt and in the crypt neck. Double labelling experiments with neuroendocrine markers and other hormones show TGF-alpha to be present in 30% of all neuroendocrine colon cells and in 80% of colonic enteroglucagon-containing cells (so called L-cells). Ultrastructurally TGF-alpha is found to be copackaged along with other neurosecretory peptides within neurosecretory dense core granules of colonic L-cells. In acute inflammatory reactions of the colon mucosa the number of TGF-alpha cells is significantly reduced.This is the first study, which gives morphologic evidence of growth factor reservoirs in human neuroendocrine colon cells. Our results strongly support the idea of a growth factor secretion by neuroendocrine cells in the colon. These TGF-alpha cells are an interesting new element in the understanding of the colonic microenvironment, where the release of TGF seems to be under neuroendocrine control. Hormones and receptors: Growth factorsHormones and receptors: Brain gut axisOncology, general: Proliferation, carcinogenesis }" "Demonstration of Transforming Growth Factor Alpha (TGF-Alpha) in Neuroendocrine L-Cells of the Human Colon Mucosa by Immunoelectron Microscopy"

OT84 1592**Epinephrine Alone Vs Epinephrine Plus Ethanol for Injection Therapy of Bleeding Peptic Ulcers: An Interim Report of a Prospective Randomized Trial**

*M.H. Lee, H.-Y. Jung, S.-K. Yang, W.-S. Hong, Y.I. Min

Department of Internal Medicine, Asan Medical Center, College of Medicine, University of Ulsan, Seoul, Korea*Aim:* A prospective randomized trial was performed to assess whether the additional injection of absolute ethanol improves the results achieved by injection of 1:10,000 epinephrine alone in the therapy of bleeding peptic ulcers.*Methods:* Among 157 patients who had peptic ulcer bleeding over a 8-month period, only patients with active bleeding (n = 20) or a nonbleeding visible vessel (n = 20) were randomized to receive injection therapy with epinephrine alone (group I, n = 20) or epinephrine plus ethanol (group II, n = 20).*Results:* The two groups were comparable in age, size and site of ulcer, and severity of bleeding. The volume of injected epinephrine in group I and group II was 17.7 – 7.3 ml and 14.1 – 6.1 ml, respectively ($p > 0.05$). The volume of injected ethanol in group II was 1.9 – 0.7 ml. Initial hemostasis was achieved in 20 (100%) of group I and 19 (95%) of group II. Rebleeding occurred in 8 (40%) of group I and in 2 (11%) of group II ($p < 0.05$). Of 10 rebleeders, seven received a second injection with the same agents and five of them achieved ultimate hemostasis; one received surgical intervention directly; two received no intervention due to comorbid illness and died soon. Ultimate hemostatic rates of injection therapy were 80% (16/20) in group I and 90% (18/20) in group II ($p > 0.05$). No differences were found between the two groups in terms of surgery (10 *vs.* 10%) or mortality (15 *vs.* 0%).*Conclusion:* There was a trend towards lower rebleeding with the epinephrine plus ethanol injection, as compared with the epinephrine injection alone. The final results of this ongoing study may clarify the value of additional injection of absolute ethanol after preinjection of epinephrine in the endoscopic hemostasis of bleeding peptic ulcers.

[2] Dept of Pathology, University Paris V, France

[3] Dept of Biological Hematology, University Paris V, France

[4] INSERM Unit 429, Necker Hospital, University Paris V, France*Background.* The etiology of refractory sprue remains a matter of debate. To get further insight into its mechanism, phenotype and T-cell clonality of intestinal lymphocytes were studied in five adult patients.*Methods.* Small bowel and/or rectal biopsies were obtained from 5 adult patients with refractory sprue, 10 patients with uncomplicated active celiac sprue, 19 patients with normal intestinal histology and 2 patients with invasive intestinal T-cell lymphoma. Phenotype of intestinal lymphocytes was studied by immunohistochemistry on cryostat sections and, in two patients, by fluocytometric analysis of lymphocytes isolated from biopsies. Clonal T{ g} gene rearrangement was studied by multiplex PCR.*Results.* In patients with refractory sprue but not in controls, both the epithelia of the small intestine (5/5) and of the rectum (3/5) were infiltrated by $CD103^+$ $CD7^+$ lymphocytes of normal cytological appearance. Yet, these lymphocytes had an abnormal phenotype. They contained intracytoplasmic CD{ e} chain but lacked surface expression of CD3-TcR complexes and were CD4$^{\{-}$} CD8$^{\{-}$}. Clonal T { g} gene rearrangements in the V{ g}1 or V{ g}III families were detected in small intestinal (5/5) and rectal (3/5) biopsies of patients with refractory sprue, in the two specimens of invasive intestinal T cell lymphoma and not in controls. In one patient with refractory sprue, the study of lymphocytes isolated from biopsies indicated the clonal T { g} gene rearrangement was only detected in the phenotypically abnormal subset of $CD103^+$ lymphocytes lacking surface expresssion of CD3-TcR$^{\{-}$}.*Conclusions.* These results suggest that refractory sprue may be indicative of the onset of low-grade intraepithelial T cell lymphoma. Intestinal disorders, absorption: Malabsorption syndromesIntestinal disorders, absorption: Gluten enteropathy }" "Intraepithelial Clonal T Cell Proliferation in the Gut of Patients with Refractory Sprue"

OT85 1594**Extensive Small Intestinal Low-Grade T-Cell Lymphoproliferative Disease without Evidence of Celiac Sprue**

*H. D'Almagne[1], F. Carbonnel[1], A. Lavergne[2], C. Matuchansky[2], J.C. Brouet[3], L. Beaugerie[1], B. Coffin[2], J. Cosnes[1], J.P. Gendre[1], J.C. Rambaud[1]

[1] Depts of Gastroenterology & Pathology, Hospital Rothschild, Paris, France

[2] Depts of Gastroenterology & Pathology, Saint Lazare, Paris, France

[3] Dept of Hematology, Saint Louis, Paris, FranceMost reported cases of small intestinal T-cell lymphoma are associated with celiac disease and termed Enteropathy Associated T-cell Lymphoma (EATCL). *Methods.* Among 22 cases of small intestinal T-cell lymphoma (including 11 EATCL), we observed 4 patients (between 1975 and 1995) whose clinicopathological picture was that of an extensive small intestinal low-grade T-cell lymphoproliferative disease (ESILT). *Results.* These 4 patients (3 male and one female) were aged 28–59 years, had long-standing chronic diarrhea with malabsorption and weight loss. Delay to diagnosis was 5 months to 7 years. Peripheral-blood count and smears were normal in 4/4 patients. Search for HIV, HTLV1 and antiendomysium/antigliadin antibody was negative in 3/3 patients. In the 4 patients, the small intestinal lamina propria was extensively and diffusely infiltrated by small T-lymphocytes with irregular pleomorphic nuclei which were CD2+ and CD3+ in 4/4 cases and CD4+, CD5+ and TCRF1+ in 3/3 cases. Noncaseating granulomas and eosinophils were found within the infiltrate in 3/4 cases. In no case there was evidence of associated enteropathy. Lymphoid cells were negative for HML-1 in 3/3 cases. Nucleic acid studies of the lymphoid infiltrate (2 cases) showed monoclonal rearrangement of the T-cell-receptor-chain gene in one case and monoclonal rearrangement of T-cell-receptor -chain gene in the other. Although none of the 4 patients responded to single or multiple drug chemotherapy, median survival was of 5 years being only 7.5 months in 11 EATCL patients. *Conclusion.* We suggest that ESILT is a new entity distinct from EATCL, characterized by heavy lamina propria infiltrate by small lymphoid cells expressing mature T-cell antigens and associated with a longer survival than EATCL. OT85 1595**Interaction between Food Proteins and Intestine: Antigen Absorption and ProcessingK. Terpend, P. Lanier, F. Boisg\'e9rault[2], J.F. Desjeux,**

*M. Heyman[1]

[1] INSERM U290, Paris France

[2] INSERM U396, Paris France*Purpose:* The main function of Major Histocompatibility Complex class II (MHC II) molecules is to present antigenic peptides produced in antigen presenting cells to T lymphocytes. During intestinal inflammation, an overexpression of MHC II molecules in enterocytes is associated with an increased macromolecular transport. This study examines the relationship between MHC II expression and transepithelial transport and processing of the exogenous protein horseradish peroxidase (HRP). *Methods:* Transwell-grown HT29-19A intestinal cells were treated on their basal or apical side with IFN{ g} (100 U/ml). Surface expression of MHC II molecules was assessed. Transepithelial transport and processing of ^{3}H-HRP were also measured in HT29-19A cell monolayers mounted in Ussing chambers and ionic conductance (G) and ^{22}Na and ^{14}C-mannitol fluxes were used as markers of the paracellular pathway. *Results:* HT29-19A cells did not express MHC II molecules in basal conditions. IFN{ g} induced an increase in MHC II molecules. When IFN{ g} was placed on the basal compartment of intestinal monolayers, G, ^{22}Na, ^{14}C-mannitol and intact-HRP fluxes rose significantly (G: 7.2 – 0.2 vs 22.7 – 4.3 mS/cm^{2}, ^{22}Na: 63 – 2 vs 184 – 24 \'b5g/h.cm^{2}, C-Mannitol: 5.6 – 0.3 vs 25 – 5 \'b5g/h.cm^{2}, intact HRP: 31 – 4 vs 193 – 56 ng/h.cm^{2} in control vs IFN{ g}-treated cells) suggesting a paracellular leakage. Degraded-^{3}H-HRP fluxes, reflecting a transcellular pathway, were also significantly increased in IFN{ g}-treated cells compared to controls. No such changes in permeability were observed when IFN{ g} was applied in the apical compartment. In IFN{ g}-treated cells, at least one additional peptide is found in the chromatographic profile compared to control cells, suggesting a different processing. *Conclusion:* These results suggest a possible relationship between MHC II expression and transepithelial transport of exogenous antigens in the HT29-19A intestinal cell line. OT85 1596**{ d} T Cell Receptor Repertoire in Monozygotic Twins Concordant for Celiac Disease**

*W. Holtmeier, D.L. Rowell, A. Nyberg, M.F. Kagnoff

Laboratory of Mucosal Immunology, Dept. of Medicine, University of California, San Diego, CA, USAGenetic factors determine host susceptibility to celiac disease. Thus, approximately 75% of monozygotic twins are concordant for celiac disease and disease susceptibility is associated with specific HLA class II alleles in the DQ subregion. One of the hallmarks of celiac disease, both active and treated, is an increased number and proportion of { g}/{ d} intraepithelial T lymphocytes in the small intestinal mucosa, and an increased number of { g}/{ d} T cells in the small intestinal mucosa has been associated with the inheritance of specific HLA class II genes. Nonetheless, the contribution of genetic factors to the development of the T cell receptor { d} repertoire in celiac disease and the specific role { g}/{ d} T cells play in the pathogenesis of this disease are not known. To assess the contribution of genetic factors to development of the T cell receptor (TCR) { d} repertoire in celiac disease, we characterized the junctional diversity of TCR { d} transcripts expressed in the intestine and peripheral blood of a pair of monozygotic twins concordant for celiac disease. *Methods:* TCR V{ d}1, V{ d}2 and V{ d}3 transcripts from small intestinal and colon biopsies, and from peripheral blood mononuclear cells, were amplified by PCR and the complementarity determining region 3 domains of TCR { d} transcripts were analyzed by denaturing PAGE and direct nucleotide sequencing. *Results:* The repertoire of TCR { d} transcripts and complementarity determining region 3 amino acid motifs in the intestine and peripheral blood of monozygotic twins concordant for celiac disease exhibited no overlap. The TCR { d} repertoire in each twin was oligoclonal and complexity of the junctional regions of their TCR { d} transcripts was typical of the adult repertoire. *Conclusions:* Genetically identical individuals with celiac disease have distinct, non-overlapping TCR { d} repertoires. Genetic factors that determine disease susceptibility do not select for specific TCR { d} sequences or complementarity determining region 3 amino acid motifs.

OT85 1597**Activation and Cytotoxic Function of Intestinal Lymphocytes in Children with Ulcerative Colitis**

*P. Mariani, A. Bachetoni, M. D'Alessandro, V. Lucidi[1], A. Zaccara[1], G. Dalsasso, M. Rivosecchi[1], F. Giacovazzo, M. Castro[1]

Ist 2\'b0 Clinica Chirurgica, Universit\'e0 ""La Sapienza""; Roma, Italy

[1] Ospedale Pediatrico ""Bambino Ges\'f9"", Roma, ItalyThe phenotype characterization and the immune function of intestinal lamina propria T lymphocytes (LPL) in children with ulcerative colitis (UC) is not completely clarified. The present study defines cytotoxic and activation surface markers expression on LPL CD4 or CD8 and the cytolytic activity (CTL) exhibited by CD4+enriched and CD4{ -}depleted colonic LPL in 5 acute phase UC children (mean age 4 years) and in 4 controls (mean age 2 years). LPL were isolated by DTT-EDTA-Collagenase digestion and characterized by double fluorescence flow cytometric analysis. The CTL were measured by PHA or anti-CD3-induced lysis of K562 and P815 target after 6 hrs incubation.In UC CD4 subset there was higher expression of CD69 (72 – 5%), HLA-DR (20 – 7%), ICAM1 (15 – 3.5%), in CD8 subset was increased expression of ICAM1 (27 – 6.8%), CD11b (8 – 4%) compared to normal subset (p = 0.05). All cell population showed low levels of cytotoxicity against K562 in accordance with experiments using LPL effector cells from normal and IBD adults. In contrast, the UC patients CTL, both stimulated by PHA (1 \'b5g/ml) or anti-CD3 (1 \'b5g/ml, TR66) against P815 is absent in CD4+subset, while in CD4{ -}subset is significantly increased (10.5 – 0.1% and 9.6 – 2% respectively) compared to CD4{ -} controls (1.5 + 0.5%, 2 + 0.7%) (p = 0.03, 0.05). Cytokine analysis of UC patients CD4{ -} cells point out the { g}-IFN increased level (2.4 – 1 ng/ml) compared to CD4+ cells (0.3 – 0.02 ng/ml) (p = 0.03); IL4 and IL5 concentrations of all supernatants were undetectable. Together with phenotipic characterization, these functional studies provided further evidence that CD4+ activated subset in UC and Crohn's disease are unlikely to play a role in tissutal injury. OT86 1598**N-Terminal Peptide of Type III Procollagen: an Early Indicator of Colorectal Cancer Recurrence**

*M. De Paoli, D. Basso, F. Galeotti[1], G. Roveroni, A. Corsini[1], M. Plebani

Dipartimento di Medicina di Laboratorio, University of Padova, Italy

[1] Divisione Chirurgica II, University of Padova, ItalyColorectal cancer follow-up is needed to identify as earlier as possible any recurrent disease. The first step in colorectal cancer spread is characterized by the ability of tumor cells to degrade and invade the extracellular matrix (ECM). Aims of the present study were 1. to evaluate the serum pattern of laminin, C-terminal peptide of type I (PIP) and N-terminal peptide of type III (PIIIP) procollagens, indices of ECM synthesis, in the follow-up of patients surgically treated for colorectal cancer; 2. to assess their role in predicting recurrence in comparison with those of CEA, CA 19-9 and TPA. 32 patients, all subjected to radical surgery for colorectal cancer, were followed up from 6 to 36 months (median = 24 months) after surgery. During follow-up a serum sample from each patient was obtained every three months to measure laminin, PIP and PIIIP (immunoradiometric assays, Cis, France) and the tumor markers CEA, CA 19-9 and TPA. Every six months the patients were subjected to abdominal ultrasound examination and chest X-ray. 21 patients did not have any sign of recurrence during follow-up (group 1), while the remaining 11 developed hepatic ($n = 7$) or pulmonary ($n = 4$) metastases (group 2). Serum bilirubin, alkaline phosphatase and alanine amino transferase were in the normal range during all follow-up in all the patients. Laminin did not significantly vary in both groups 1 (Anova one-way: $F = 1.79$, p: ns) and 2 ($F = 0.67$, p: ns). PIP and PIIIP significantly increased three months after surgery in group 1 ($F = 19.93$, $p < 0.001$ and $F = 69.76$, $p < 0.001$) and, although at a lesser extent, in group 2 ($F = 10.54$, $p < 0.001$ and $F = 6.70$, $p < 0.01$ respectively). CEA, CA 19-9 or TPA did not vary in any group. The differences between basal and three months follow-up values of PIP and PIIIP discriminated group 1 from group 2 patients with a sensitivity of 36% and 91%, a specificity of 71% and 71% and an overall diagnostic accuracy of 59% and 78% respectively. In conclusion: we may suggest the use of serum PIIIP determination as an early prognostic indicator of colorectal cancer recurrence; the pathophisiological mechanism underlying this pattern is probably due to the persistence of aggressive tumor cells after surgery, which can inhibit ECM synthesis thus allowing their escape from the primary site to the metastatic foci. Oncology, specific: Colon, rectum }" "N-Terminal Peptide of Type III Procollagen: an Early Indicator of Colorectal Cancer Recurrence"

OT86 1599**Disruption of the Cadherin-Catenin Complex in Gastric Carcinoma Cell Lines**

*A.U. Jawhari[1], M. Pignatelli[2], M.J.G. Farthing[1]

[1] Digestive Diseases Research Centre, St. Bartholomew's and the Royal London School of Medicine and Dentistry, London

[2] Department of Histopathology, Hammersmith Hospital, LondonDysfunction of the cadherin-catenin complex, a key component of adherens junctions, is thought to confer invasive potential to cells. In a recent study we demonstrated abnormal expression of the cadherin-catenin complex in the majority of gastric cancers.*Aims:* 1. To examine the expression of E-cadherin, { a}, { b}, and { g}-catenin in gastric carcinoma cell lines, and look for evidence of mutations and disruption of the cadherin-catenin complex. 2. To correlate these findings with a functional assay of cell-cell aggregation.*Methods:* Expression and function of E-cadherin, { a}, { b}, and { g}-catenin and p120^{cas}, was examined in gastric (Kato3, HSC39, MKN7, MKN45, AGS) and colonic (HT29) carcinoma cell lines, using immunocytochemistry, Western blotting and cell aggregation assay. Complex composition was examined by immunoprecipitation with antibodies to { b}-catenin followed by Western blotting.*Results:* Bands of abnormal molecular weight suggesting mutations of E-cadherin (in Kato3 and MKN45), and { b}-catenin (in HSC39) were detected, while both E-cadherin and { a}-catenin were absent in AGS. MKN7 and HT29 showed bands of expected size for all components of the complex. There was loss of membranous localisation of complex components from the cell membrane, and loss of calcium dependent aggregation in all but HT29. Immunoprecipitation of { b}-catenin-associated proteins revealed loss of { b}-catenin binding to { a}-catenin in HSC39, and to p120^{cas} in MKN7, HSC39 and Kato3, suggesting functional disruption of the complex.*Conclusions:* Mutations of E-cadherin, { a}- and { b}-catenin, were associated with abnormalities of E-cadherin-catenin complex composition, loss of membranous localisation to the adherens junction and loss of calcium-dependent aggregation in 4 gastric carcinoma cell lines. These findings support *in vivo* data and suggest that these cell lines may be an appropriate model for further study of these changes.

OT86 1600**Cyclin D1 Protein Plays an Important Role in Maintaining the Transformed Phenotype in Human Colon Cancer Cells****N. Arber, Y. Doki[1], E.K.-H. Han[1], A. Sgambato[1], P. Zhou[1], N.W. Kim[1], T. Delohery[2], P.R. Holt, I.B. Weinstein[1]**

[1] Columbia Presbyterian Comprehensive Cancer Center, Columbia University, New York, NY

[2] Flow Cytometry Facility Memorial Sloan Kettering Cancer Center, Columbia University, New York, NY

[3] Division of Gastroenterology, St. Luke's-Roosevelt Hospital Center, Columbia University, New York, NY*Purpose:* Cyclin D1 is a cell cycle regulator essential for progression through the G1 phase of the cell cycle. Cyclin D1 amplification or increased expression has been implicated in the pathogenesis of several types of human cancer. The cyclin D1 gene is frequently overexpressed in human colon cancer. The functional significance of this overexpression has not been established. We have previously shown that an antisense cyclin D1 cDNA inhibits growth and reverses the transformed phenotype of human esophageal cancer cells.*Methods:* To address the role of cyclin D1 in growth control and tumorigenesis in colon cancer we have overexpressed the same antisense cyclin D1 cDNA construct in the SW480E8 cells, human colon cancer cell line which expresses high levels of cyclin D1.*Results:* The integration and expression of the antisense construct was verified by Southern and Northern blot analysis, respectively, and resulted in decreased expression of cyclin D1 and Rb proteins. In addition the hypophosphorylated form of Rb was increased in the antisense cyclin D1 cells. $p27^{Kip1}$ levels were also reduced and the levels of Cyclin E were slightly decreased. Cyclin D1 kinase activity was reduced in the antisense cells without a change in cdk4 protein level. Derivative cells expressing antisense cyclin D1 mRNA displayed an increased doubling time and were more contact inhibited. They also demonstrated decrease in saturation density, plating efficiency and anchorage-independent growth in vitro, and tumorigenecity in nude mice in vivo.*Conclusions:* These findings provide direct evidence that the increased expression of cyclin D1 in certain colon tumor cells contributes to their abnormal growth. The ability to revert the transformed phenotype of these cells with antisense cyclin D1 suggests that cyclin D1 may be a useful target in the therapy of colon cancer. OT86 1601**Overexpression of the Type I Receptor for Transforming Growth Factor { b} (TGF-{ b}) in Colorectal Carcinomas**

*R. Eskinazi, A. Resibois, P. Robberecht, M.O. Peny, M. Adler, J.L. Van Laethem

Departments of Gastroenterology, Histology and Biochemistry, Hospital Erasme and Faculty of Medicine, University Libre de Bruxelles, Brussels, Belgium*Purpose:* Transforming Growth Factor { b} (TGF-{ b}) is a potent regulator of cell growth and differentiation and is thought to play an important role in colorectal tumorigenesis. The in vitro progression from adenomas to carcinomas is accompanied by a reduced responsiveness to the growth inhibitory effects of TGF-{ b}. Recent reports suggest that the lack of growth inhibition by TGF-{ b} in several colon cancer cell lines may be due to a lack of expression of functional TGF-{ b} receptors.*Methods:* The expression of the two TGF-{ b} receptors (T{ b}R-I and T{ b}R-II) and of their mRNAs was studied in surgical samples from 16 normal colons and 21 colorectal adenocarcinomas by immunohistochemistry using specific polyclonal antibodies and by semi-quantitative Reverse Transcriptase-Polymerase Chain Reaction.*Results:* 94% and 6% of the normal colon samples showed a weak and strong expression of T{ b}R-I mRNA respectively whereas 31% and 69% of the normal samples showed a weak and strong expression of T{ b}R-II mRNA respectively.In the tumoral samples, 57% and 43% showed a weak and strong expression of T{ b}R-1 mRNA respectively whereas 29% and 71% showed a weak and strong expression of T{ b}R-II respectively.By immunohistochemistry, the T{ b}R-I and T{ b}R-II proteins were weakly or not at all expressed in normal colonic mucosa. In contrast, both receptors were abundant in glandular tumoral cells from all specimens. The surrounding inflammatory stromal cells were also positively stained in both normal and tumoral samples.*In conclusion,* the two TGF-{ b} receptors that are both required for TGF-{ b} activity, were differently expressed in normal and neoplasic colons: T{ b}R-I is weakly expressed in normal cells but abundant in tumors; T{ b}R-II is expressed similarly in normal and neoplasic tissues. "S ST3 9001"ST3 9001 **The need for quality assurance programmes**

*Dr B Holthof

Throughout the developed world, the traditional roles of players in the health-care system are changing. Governments are moving responsibility to control health-care quality and costs more and more to payers, physicians, hospitals, suppliers and patients. These changes are stimulating a move away from a fee-for-service reimbursement approach, such as a tariff for a specific operation, towards a capitation system based on a budget for each patient.Gastrointestinal (GI) conditions will be at the forefront of developments in managed care, because they are second only to hypertension in being the most expensive disease grouping to care for. This means that primary care physicians and gastroenterologists alike will have to become better in managing the quality and cost of integrated patient care processes. In support of this new task, three tools are becoming more widely available: management guidelines, practice profiling and outcomes analysis. However, most applications are still in the experimental stage. It would involve applying a management guideline such as the IGPCG plan to a group of physicians and then collecting and analysing outcomes and cost data in order to improve the guideline. This requires a comprehensive database of patient characteristics, in- and out-patient visit records, prescriptions and investigations linked to specific patients and physicians across the care continuum.In order to make the experiments successful, primary care physicians and gastroenterologists will have to create a new environment that allows them to start using these new tools. The nature of this environment will have to take into account the attitudes of the professionals involved. In particular, gastroenterologists, like most specialists, tend to be guarded about management guidelines until these can be discussed with colleagues. In addition, they are used to learning through fact-based scientific data of well-controlled trials. This implies that the best learning environment will probably be small, information-based, collaborative discussion groups of gastroenterologists and primary care physicians. These groups should adapt available guidelines such as the IGPCP plan, collect and analyse patient data to evaluate the impact of applying these guidelines and improve the guidelines over time. Unfortunately, most countries do not have the right financial incentives to encourage the formation of these professional development groups. The move form a fee-for-service approach towards a capitation system will facilitate the application of managed care principles to GI disorders to the benefit of patients, providers and payers. }" "The need for quality assurance programmes"

"S ST3 9002"ST3 9002 **The right physician managing the right patient in the right way**

*Dr M Whitaker, UKIn order to optimize the management of patients with upper gastrointestinal (UGI) disorders a number of improvements have been identified. Among primary care physicians, there is a clear need for a better understanding of the pathophysiology of UGI disorders and their role in managing these conditions. The issues of symptom management and the care of *Helicobacter pylori* patients in particular are causing confusion among primary care physicians. There is also a need to generate closer and more focused communication links between all physicians involved in gastroenterology in order to increase specialists' confidence in the gastroenterological abilities of primary care physicians.In an attempt to address these issues, an international group of primary care physicians founded a working team, the International Gastro Primary Care Group (IGPCG) in 1994. With the advice of leading gastroenterologists, the group reached a consensus on how queries should be addressed and developed guidelines to assist the primary care physician in different countries to correctly diagnose and manage patients with UGI symptoms in the primary care setting. These guidelines were first presented at the World Congress of Family Doctors in the form of an algorithm, and introduced the concept of the predominant symptom. In a recent international survey of over 900 primary care physicians in 25 countries, the IGPCG found that over half of them were able to clearly establish a predominant symptom rather than a cluster of symptoms when presented with patients with UGI disorders. However, the ability to do this varied from 100% in Sweden and Italy to less than 40% in Slovenia and the Netherlands. Not surprisingly perhaps, the most common predominant symptom established was heartburn, followed by abdominal pain, bloating, fullness, acid regurgitation and other symptoms. In the IGPCG management plan, patients with non-gastrointestinal symptoms must first be excluded while those with alarm symptoms, such as GI bleeding, dysphagia and weight loss, are referred to a specialist for consideration of endoscopy. Specific management is required for those patients on non-steroidal anti-inflammatory drugs. For the remaining patients, the IGPCG is convinced that patients can be grouped and treated on the basis of the predominant symptom and reason for consultation. These three different groups include: Abdominal discomfort, bloating, fullness and nausea Localized epigastric pain Heartburn and regurgitationThe management guidance then proceeds according to which of the three categories the patient's predominant symptom falls within. This approach, which is supported by a recent publication from Stanghellini *et al*., offers the majority of patients a more appropriate therapy and can avoid unnecessary investigations.The IGPCG management plan has now been developed into a health economic model that can be used to calculate health-care costs associated with treating dyspeptic patients in a specific manner. In addition, the IGPCG is now undertaking other projects to provide broader services to the gastroenterological community. The first is an interactive problem-based educational package developed by family physicians with the help of gastroenterologists for primary care physicians and can be adapted for different countries and different health care systems. The second is an Internet site which will include a regular newsletter and information sheets on key topics in gastroenterology. It is hoped that these activities will provide a significant contribution to addressing the needs of all physicians involved in the care of patients with UGI disorders.

"S ST3 9003"ST3 9003 **The use of economic modelling to support clinical decision making in gastroenterology**

*Dr A Haycox

Health economic models attempt to identify the therapeutic options that maximize health benefits utilizing the limited health-care resources available. Such models are being used increasingly to support clinical decision making in a wide range of therapeutic areas. The development of an economic model to support clinical decision making at the primary care level in upper gastrointestinal (UGI) disorders is of particular importance. Gastrointestinal disorders account for 10% of primary care consultations in the UK, of which UGI disorders represent approximately half of such presentations. As a consequence, gains to both the patient and the health service arising from an improvement in resource utilization in this area are potentially enormous.Clinical guidelines aimed at improving the management of UGI disorders at the primary care level have been developed by the International Gastro Primary Care Group (IGPCG). This presentation discusses the derivation, methodology and results of an economic model that analyses the resource implications arising from these clinical guidelines.In order to construct the economic model, it was necessary to identify:- Every potential therapeutic pathway that could be followed by patients- The nature and level of resources that would be consumed by patients along each pathway – The probabilities of following alternative options, at each stage of each pathway.Every branch of the algorithm represents a treatment pathway that has a defined level of resource use and a defined probability of use by patients. Where therapeutic options were not explicitly stated in the IGPCG algorithm, expert opinion and literature reviews were employed to complete the model.One crucial factor underlying the interpretation of results obtained from any economic model is the time period covered by the model. For example, expensive 'one-off' diagnostic procedures, such as endoscopy, which are undertaken in the early stages of a treatment pathway will inevitably have a greater significance in a short-term model. The model presented analysed the initial 12-month treatment period of 'new' patients presenting with UGI disorders. In order to test the implications of a longer term perspective, the model is currently being developed to analyse resource use over a 24-month period.The model has proven to be extremely accurate and demonstrates that utilizing the predominant symptom approach to the diagnosis and treatment of patients with UGI disorders appears to provide significant gains in terms of patient management and effective resource use. This factor, together with a more intensive use of eradication therapy, provides the potential to reduce the cost of drugs for the treatment of UGI disorders by approximately 15% in the UK. A major strength of the model is its adaptability to a wide range of clinical and cost scenarios. Such adaptability enables the model to effectively reflect the potential resource implications in countries exhibiting significantly different levels of cost and patient management. In this manner, the model provides one valuable method by which clinicians at primary and secondary care levels internationally can be supported in optimizing the management of UGI disorders within current resource constraints. }" "The use of economic modelling to support clinical decision making in gastroenterology"

"S ST3 9004"ST3 9004 **A vision of the primary care-gastroenterologist interface in the future**

*Professor J-R Malagelada

As we move into the 21st century, it seems likely that the management of gastrointestinal (GI) disorders will place more emphasis on broadly applicable disease-specific prevention programmes and non-invasive diagnostic methods. Drug efficacy will be expected to aim towards complete disease control, while surgery will become minimally invasive and reparative with the widespread practice of transplantations. The growth of therapeutic and diagnostic options, and the ever increasing pressure to control health care costs across Europe, has already resulted in an increased involvement of primary care physicians in the management of upper GI disorders. This is reflected by the formation of the International Gastro Primary Care Group (IGPCG). As this involvement develops, we must address how to best complement the management tasks of the primary care physician and the gastroenterologist, both generally and for specific diseases. This division of labour must also take into account how different physicians practise, patients' circumstances and different health care systems. A disease-based division of tasks would be based on the type of condition, its severity and chronicity, and the ultimate prognosis. Taking these factors into account, it would be cost-effective for conditions such as GI bleeding and inflammatory bowel disease to be managed primarily by the gastroenterologist. This might also be the case for severe cases of dyspepsia, and peptic disorders, whereas it might be more appropriate for the primary care physician to take on this role for mild cases, although with ad hoc advice from a specialist colleague. Equally, the primary care physician might be the best practitioner to manage chronic cases with a poor prognosis and requiring minimal therapeutic intervention.In proposing such a division of tasks, however, it is important not to forget the areas in which the specialist and the primary care physician can work closely together, for example during informal consultations, formal clinical teaching sessions and communication about specialist procedures. Improved interaction is clearly one of the areas where the communications revolution could have a notable impact. For example, primary care physicians could receive one-to-one on-line consultations from gastroenterologists or from a specialist group on the Internet. It seems appropriate that the gastroenterologist would be responsible for providing accurate and up to date information to primary care physicians, overseeing the implementation of quality assurance programmes and monitoring patient outcomes. In parallel, the primary care physician would review all new management guidance, request more specific advice from a gastroenterologist and provide outcomes feedback. Although such interaction already occurs, it is clear that there is a need for new methods of communication, such as primary care physicians and gastroenterologists working in teams.With this vision, primary care and specialist physicians can work together with the common aim of efficient delivery of health care to patients with GI disorders. }" "A vision of the primary care-gastroenterologist interface in the future"
