OP1 0002 Is Tumour Staging Possible by Hydrocolonic Sonography?

*A.E. Elewaut[1], M. Afschrift[2], A. Elewaut[1]

[1] Dept. of Gastroenterology, University Hospital, Ghent, Belgium

[2] Dept. of Ultrasound, University Hospital, Ghent, Belgium

Introduction By filling the bowel with water, a precise study of the bowel wall is possible using ultrasonography: this technique is known as hydrocolonic sonography. A normal bowel wall consists of five layers that can be recognised on ultrasound. The first echogenic and the second echopoor layer correspond to the mucosa. The third echogenic layer is the submucosa, the fourth echopoor layer the muscularis and the fifth echogenic layer the serosa.The aim of the study was to investigate whether hydrocolonic sonography can allow a correct preoperative staging of colon tumours.

Methods After a laxative orthograde intestinal lavage and a retrograde instillation of water into the bowel, a transabdominal sonographic examination is performed with the 5 and 7.5 MHz transducer. To achieve an optimal distention of the bowel and to suppress the urge for elimination, 20 mg scopolamine is given intravenously.A tumour is classified as T1 when it invades the mucosa and submucosa, T2 when the infiltration is confined to the muscularis, T3 when the infiltration extends to the serosa and T4 when there is invasion of other organs or perforation to the visceral peritoneum.320 patients underwent a hydrocolonic sonography after informed consent.The proposed staging was compared to the pathologic anatomy of the resected specimen.

Results 36 colon tumours were detected by hydrocolonic sonography and confirmed by colonoscopy. 16 were localised in the sigmoid, 4 in the descending colon, 10 in the transverse colon and 6 in the ascending colon. 15 were substenosing tumours. In three patients the hydrocolonic sonography detected a synchronic small polyp which was confirmed pre- or postoperatively.One tumour was classified as T1, 2 as T2, 15 as T3, 18 as T4. Two of the distal sigmoid (0–25 cm) tumours were understaged as T3. The sensitivity of staging by hydrocolonic sonography was 94.4%, when excluding the distal tumours 100%.

Conclusion Hydrocolonic sonography is an easy, cheap and sensitive technique which allows a correct preoperative staging of colon tumours. For the distal sigmoidal and rectal tumours an echo-endoscopic approaches still necessary. The usefulness of staging of colon tumours is until now not proven, but future therapeutic approach (e.g. laparoscopic surgery) may benefit of it.

OP2 0008 **Virtual Colonoscopy — A Pig Model for Optimization of Study Parameters**

*L. Aabakken[1], C.L. Kay[1], H. Evangelou[1], R. Hawes[1], P.B. Cotton[1], J.R.W. Young[2]

[1] Digestive Disease Center, Medical University of South Carolina, Charleston, USA

[2] Dept of Radiology, Medical University of South Carolina, Charleston, USA

Purpose The increasing incidence of colorectal cancer calls for a simple, safe, accurate and cost-effective screening technique. However, the general acceptance of available screening methods remains disappointingly low.Virtual colonoscopy is an exciting new imaging modality, combining spiral CT scanning with newly developed virtual reality computer software. The reconstructed images simulate the endoluminal view obtained by the endoscopists and also allows visualization of colons where passage of a colonoscope is impossible. However, the optimal scanning parameters and inter-study variation is currently poorly defined. The aims of the present study were to determine the feasibility of a pig model to address some of these problems.

Methods A 80 cm proximal segment of pig colon was resected and lavaged thoroughly. After partial eversion, artificial polyps were created by invagination of the mucosa and suture of the base. A set of one large ""index"" polyp and two smaller polyps ranging from 2 to 9 mm were positioned at intervals throughout the colon segment. The bowel was completely surrounded by 6 liters of ultrasound gel and was placed in a Picker PQ5000 spiral CT scanner and a series of scans obtained with various parameter changes according to a predefined protocol. A continuous volume CT dataset was reconstructed and reformatted into the virtual endoscopy presentation (Epi-scope'), and the virtual reality images were reviewed by two independent observers.

Results Preliminary data indicate that optimal resolution is obtained by a combination of reduced slice thickness, slow table speed and increased kV and mA. For practical purposes, it appears that the most important factor is minimizing slice thickness. Additional data are currently being collated with respect to inter-observer and inter-study variability.

Conclusions This simplified pig colon model appears to be a useful tool to study the technical aspects of virtual colonoscopy, and an important adjunct to clinical studies in humans.

OP2 0010 **A Randomized Trial Comparing Endoscopic Balloon Dilation (EBD) and Endoscopic Sphincterotomy (EST) for Removal of Bile Duct Stones (BDS)**

*J.J.G.H.M. Bergman, E.A.J. Rauws, P. Fockens, G.N.J. Tytgat, K. Huibregtse

Dept. of Gastroenterology, Academic Medical Center, Amsterdam, Netherlands

Aim EST is effective for removal of BDS but carries a 10% risk for acute complications. Furthermore, the long-term effects of loss of biliary sphincter function after EST are unknown. EBD of the biliary sphincter may be an alternative to EST since it has a potentially lower risk for acute complications, such as bleeding, and preserves the function of the biliary sphincter. EBD, however, may be less effective than EST and may carry an increased risk for pancreatitis. We performed a randomized trial comparing EST and EBD in 202 consecutive patients with BDS.

Methods EBD was performed with a 8 mm Maxforce' dilatation balloon (Microvasive, Boston). EST was performed according to standard guidelines. Mechanical lithotripsy (MLT) was allowed to fragment stones prior to extraction. In case of failed stone removal after EBD, a secondary EST was performed during the same ERCP. Primary outcome was the rate of complete stone removal in one ERCP. Treatment outcome was assessed at 24 hours and 30 days by personal interview, questionnaires and blood tests. Complications were graded by a panel of experts who were blinded to the treatment allocation.

Results EBD (N = 101) EST (N = 101)Median stone number (range) 2 (1–14) 1 (1–15)Median stone diameter (mm) 10 (3–36) 9 (4–27)Direct success 81 92Success after sec. EST 9 N.A.Overall success 90 92MLT (*$p < 0.005$) 31* 13*Acute pancreatitis 7 7Other acute complications 10 17

Conclusions After EBD, BDS of all sizes can be completely removed in one ERCP in 80% of cases (81/101). If necessary, secondary EST can further increase success rate up to 89% (90/101). The overall success rate of EBD is hereby comparable to that of EST (91%). MLT is more often required after EBD than after EST. The risks for pancreatitis after EBD and EST seem to be comparable. EBD is an effective and safe alternative to EST for patients with BDS. "P P 1 0022"P 1 0022 **Lung Cancer Staging — Comparison of Endoscopic Ultrasound and Mediastinoscopy Cost Effectiveness for Assessing Lymph Node Involvement**

*L. Aabakken, G. Silvestri, R. Hawes, C. Reed, A. Van Velse, B. Hoffman

Digestive Disease Center, Dept. of Pulmonary Medicine, Medical University of South Carolina, Charleston, US

Dept. of Thoracic Surgery, Medical University of South Carolina, Charleston, US

Purpose The use of endoscopic ultrasonographic (EUS) guidance for fine needle aspiration (FNA) of mediastinal lymph nodes has become an important adjunct in the staging of bronchogenic carcinoma. In many cases, it may be an alternative to mediastinoscopy (MED), but the cost-effectiveness of the techniques has not been compared.

Methods A decision model was developed to compare EUS/FNA and MED in patients with known or suspected lung cancer to stage the mediastinum. Based on available literature, the baseline estimates for negative predictive value of EUS/FNA and MED were 0.87 and 0.91, respectively. Baseline cost estimates, derived from prevailing Medicare reimbursement rates, were $ 20 000 for thoracotomy, $ 7 400 for mediastinoscopy and $ 765 for EUS with FNA. The mean life expectancy for resected non-disseminated disease was 5 years, and for non-resectable disease 1 year. Baseline pickup-rate of EUS and MED was 0.59. Sensitivity analysis was performed on all probabilities and utilities. in the model.

Results Using our baseline estimates, cost/efficacy analysis favored EUS/FNA over mediastinoscopy with a marginal cost/effectiveness of $ 130 000.-/year of survival. The average cost per year survival was $ 3,810.- and $ 6,471.- in the EUS/FNA and MED arm, respectively. The cost-effectiveness advantage of EUS/FNA increases when enlarged lymph nodes are documented prior to the sampling procedure.

Conclusion This decision analysis, strongly favors EUS/FNA over mediastinoscopy for staging of patients with lung cancer. The advantage is even more pronounced when lymph nodes are visualized before the procedure. "P P 1 0023"P 1 0023 **Accuracy of a 20 MHz Radial Probe in Staging Small Digestive Tumors**

*O. Keriven-Souquet, J.C. Souquet, B. Napoleon, B. Pujol, R. Lambert

Department of Digestive Diseases, Hospital E Herriot, Lyon, FranceStaging of small cancers of the digestive wall is essential for the choice between surgery and local treatment. While endoscopic ultrasound (EUS) is the best available staging method, metastatic lymph nodes detection is not optimal with EUS in such setting. High frequency probe could allow the distinction between mucosal (T1m) and submucosal cancer (T1sm), only the latest having a significant risk of metastatic nodes, especially in esophageal cancer. The aim of this study was thus to evaluate the accuracy of a 20 MHz prototype probe in staging small digestive tumors.

Methods The prototype from Olympus Co is similar to GFUM 20 but has 2 frequencies 7.5/20 MHz. It was used from December 94 to May 96, in 136 patients. In these 136 patients, 12 with uT1 or uT2 tumors were operated on, allowing comparison between EUS results and the operative specimen. Tumor localization was esophagus (n = 4), cardia (n = 1), stomach (n = 2), ampulla of Vater (n = 1), rectum (n = 4).

Results For T1 vs T2 staging (8 pT1 and 4 pT2), accuracy of Olympus prototype 20 MHz was 92% (11/12). The only error concerned a large (5 cm) polypoid rectal villous tumor classed uT2, in fact pT1. For N staging (7 pN0, 4 pN1, 1 not staged – local excision), accuracy of EUS was 73% (8/11). In an esophageal cancer, a small (4 mm) paratumoral lymph node was considered metastatic; the lymph node, was indeed found at pathology but was benign. The 2 last errors concerned small metastatic nodes missed by EUS respectively in an esophageal cancer staged uT1sm (partial invasion) and in a rectal cancer staged uT2 (4 mm node seen at EUS considered as benign). For the distinction T1m vs T1sm, visualization of the muscularis mucosae was possible only in esophageal and gastric cancer (5 T1, 3 pT1sm and 2 pT1m). Accuracy was 3/5 cases (2 T1sm, 1 T1m). There were 1 overstaging (uT1sm pT1m for a squamous cell carcinoma of the esophagus) and 1 understaging (uT1m, pT1sm for a gastric carcinoma at the level of the angulus).

Conclusions The 20 MHz probe was accurate for the TN staging of small GI cancers. It could improve the distinction between mucosal and submucosal cancer in gastric and esophageal tumors, but more experience is needed to increase fiability. "P P 1 0028"P 1 0028 **Palliative Treatment of Malignant Esophageal Stenosis with Tygon Plastic Prostheses**

*S. Bohnacker, U. Seitz, K.F. Binmoeller, M. Hinner, H. Seifert, F. Thonke, N. Soehendra

Dept. of Endoscopic Surgery, University Hospital Hamburg, GermanyPalliative endoscopic treatment of malignant esophageal stenosis with plastic stents has been reported to have the following disadvantages: 1. high procedural complication rates, 2. high dislocation rates, 3. exclusion of patients with cervical stenoses (distance to upper esophageal sphincter (UES) < 2 cm). We evaluated a modified design and implantation technique of plastictygon stents with the aim of determining whether these disadvantages apply.

Methods All patients underwent palliative treatment of dysphagia resulting from obstructing malignancies of the esophagus. Stents were made of Tygon and came in 3 sizes (9, 12 and 14 mm). The stent length was tailored to the stenosis. The funnel was short; a proximal funnel could be added as well as flaps at the distal end to prevent caudal and cranial dislocation, respectively. Bougienage was performed stepwise, usually over several sessions (dilatation to 33 F, 38 F, 42 F for 9, 12, and 14 mm stents, respectively). The stent was loaded onto a bougie, then inserted over a guide wire without fluoroscopy under iv sedation.

Results Between 7/94 and 1/96 54 consecutive patients with inoperable malignant esophageal stenoses (11 upper, 12 middle and 31 lower) were treated by endoscopic insertion of Tygon plastic stents. Implantation was performed after a median of 2 (1–4) sessions of bougienage. Two 9 mm, 35 12 mm and 17 14 mm stents were implanted. In 10 patients the stent was inserted {\'a3} 1 cm below the UES. In 2 of these patients the stent had to be replaced within 24 h because of thoracic pain or immediate dislocation. Perforation or bleeding did not occur. During a median follow-up of 55 d (9–407), 88% of patients reported improvement, or at least no progression, of dysphagia. Fifteen patients required further interventions: 8 had stents repositioned or replaced due to dislocation, pain or pressure-induced ulcer, 4 required recanalisation for bolus obstruction, and 3 treatments for tumor overgrowth. Eight patients who had persistent dysphagia and/or inappetence received nutrition via a duodenal feeding tube or PEG.

Conclusions Previously described disadvantages of plastic stents in treatment of patients with malignant esophageal stenosis can be overcome with modifications of stents and implantation technique. The results of treatment with these stents are comparable to those of self-expanding metal stents, but their costs are much lower. "P P 1 0029"P 1 0029 **Treatment of Malignant Stenosis of the Esophagus by Placement of Self-Expanding Coated Stents (SECS). Results in 35 Patients**

*M. Giovannini, D. Houtin, P. Thomas[1], J.F. Seitz, R. Giudicelli[1], P. Fuentes[1]

Digestiv Oncology Unit, Paoli-Calmettes Institute, 232 bd St-Marguerite, 13273 Marseilles Cedex 9-France

[1] Thoracic Surgery Unit, St-Marguerite Hospital, Marseilles France

The purpose of this study was to assess the placement, tolerance and efficacy of SECS for malignant stenosis of the esophagus.

Patients and Methods From december 1993 to january 1996, placement of SECS was attempted in 35 patients (29 men and 6 women) with a mean age 61 years (range 43 to 86 years). The indication was squamous cell carcinoma of the esophagus (SCCE) with stenosis in 13 cases, SCCE with eso-bronchial fistula (EBF) in 15 cases, an adenocarcinoma of esophagus (AE) with stenosis in 4 cases, a bronchial carcinoma with EBF in 2 cases and 1 extrinsic compression by a bronchial cancer. 3 types of SECS were used. “Song” type were placed in 31 patients, “Boston Scientific” type in 3 patients and “Endocoil Instent” in 1 patient.

Results Dilatation of the esophagus stenosis beyond bougie n° 12.8 was not required prior to placement. The SECS was properly placed in 34/35 patients. In 1 case, it was impossible to open the SECS (Song type). Early migration occurred in 3 cases (8.5%) 3–7 days after placement. Hard thoracic pain occurred in 4 cases (3 Song+ 1 Endocoil) and in 1 case (Endocoil stent) it was necessary to remove the stent. The success rate for functionnal SECS was 30/35 (85.7%). 16/17 EBF were closed but only 15/16 were able to resume intake of both solids and liquids. The success rate for SECS in case of EBF is 15/17 (88.2%). SECS obstruction occurred in 1 case 6 months after the placement, the SECS (Song type) was removed and an other was placed. Three patients are still alive at 2, 3 and 8 months after placement. The mean duration of patency of SECS for these patient was 2.5 months (range: 1–14 months) and for the patients with EBF mean duration of patency of SECS was 3.5 months.

Conclusion This easily inserted SECS constitues a significant advance for endoscopic management of esophageal stenosis and EBF. "P P 1 0030"P 1 0030 **Metal Stent for Palliative Treatment of Recurrent Dysphagia in Esophagojejunostomy**

*P. Ricci, F. Farroni, G. Mariotti, A. Maselli, S. Mosca, R. Ricci, F. Barzi

Digestive Endoscopy, Dept. of Surgery, Dept. of Radiology, University of Perugia, ItalyAfter ""curative"" resection of gastro-esophageal carcinoma, late severe dysphagia almost invariably indicates loco-regional recurrence. Surgery and radiation therapy are not commonly used because of the associated high morbidity and mortality rates. The only option for most pts. is palliative treatment for rapid relief of dysphagia and restoration of passage of fluids and solids. The best treatment is intubation with self-expanding metal stents for an easy and safe inserction and effective palliation.Six pts., all males, mean age 70 years-old (range 58–79) who had total gastrectomy for esphageal malignancies with recurrent anastomotic stricture underwent palliative treatment with self-expanding metal stent (4 Ultraflex Microvasive, 1 covered Ultraflex Microvasive, 2 silicone covered Gianturco Zestents). The median tumor length was 6.5 cm. (range 5–9 cm.). Two pts. were on TPN for aphagia. Before intubation all pts. received dilation. Four pts. were treated with LASER.Stent insertion was technically successfull in all pts. with good symtomatic relief. Complications: 1 stent migration in esophagus (Gianturco) after 3 months with additional placement of Ultraflex stent which gave satisfactory results; severe pain in 1 pt. (Gianturco) who had also delayed massive bleeding after 21 days. Median survival was 90 days (range 21–294). One pt. is still alive after 45 days.The insertion of self-expanding metal stent is a optimal palliative treatment for pts. with anastomotic recurrent cancer. Ultraflex stent in our small series seems to work better for its pliability in esophagojejunostomy recurrence.

"P P 1 0031"P 1 0031 **Self-Expandable Covered Stents for Esophageal Fistulas**

*J.-M. Dumonceau, J. Deviére, M. Cremer

Department of Gastroenterology, Erasme University Hospital, University Libre de Bruxelles, BrusselsEsophageal fistulas complicate 15% of esophageal cancers and are associated with severe morbidity and mortality. Their managent is particularly difficult when a stricture is absent (e.g. after radiotherapy), rendering stent placement non feasible or inefficient.

Aim To prospectively assess the feasability and efficacy of esophageal fistula sealing with (1) self-expandable covered stents and (2) salvage treatments.

Patients and Methods From December 1993 to April 1996, stent placement was attempted in 19 patients [male: 12, age: 61 – 18 yrs (range: 6–82)] with esophageal fistulas. These were related to primary or secondary esophageal cancer (N = 12) as well as a variety of benign disorders (N = 7). The lesion was proximal in 4, mid-esophageal in 10, distal in 3 and at the gastro-esophageal junction in 2. Strictures (present in 8 cases) were dilated up to 15 mm. Covered Ultraflex' (N = 14), Wallstent' (N = 3) and Wilson-Cook Z' (N = 2) stents were inserted under general anesthesia and fluoroscopic control. Salvage treatments used for initial failures of fistula sealing as well as recurrent fistulas consisted of repeated stent insertion or injection of tissue adhesive (Histoacryl') or fibrin sealant (Tissucol').

Results Stent insertion and correct positioning were successfull in all cases. No procedure-related complication were noted. Fistula sealing was evidenced by esophagogram with Ultraflex' or other stents in 14/14 and 1/5 cases (p = $10^{\{-}$3}, 2-tailed Fischer exact test), respectively. Failures to seal fistula were due to passage of fluids between the esophageal wall and stent (N = 3) or early stent migration (N = 1). Allthough salvage treatments (glue injection, N = 2 or repeated stent insertion, N = 2) achieved fistula sealing as assessed by esophagogram in 3 additional cases, only 1 patient could resume oral intake without aspiration. Among 15 patients with fistula sealing evidenced on their first esophagogram, 12 could start oral intakes while the 3 other patients died early after stent placement. After a mean F/U of 127 – 131 days (range 18–498), fistula sealing remained complete (solids + liquids) in 10/12 (83%) cases and partial (solids only) in 1 (8%) case. This result was achieved with salvage treatments which were attempted in 5/6 cases of recurrent fistulas. These were due to stent migration (N = 2), covering rupture (N = 1), spontaneous fistula enlargement (N = 1), passage of liquids between the esophageal wall and stent (N = 1), bouginage of a stricture due to mucosal hyperplasia.

Conclusion Ultraflex' covered stent is more effective than other covered metallic stents in sealing esophageal fistulas. This is probably due to the softness of meshes which embed in the esophageal wall, avoiding passage of liquids around the stent. After sealing, fistula may recur for a variety of reasons and can often be successfully treated with well-fitted salvage treatment modalities. }" "Self-Expandable Covered Stents for Esophageal Fistulas"

"P P 1 0033"P 1 0033 **""Wallstent"" Self Expanding Prostheses for Palliation of Malignant Dysphagia**

*F.J. Jim\'e9nez, F. Urtasun, J. Barberena, R. Aznarez, I. Mart\'edn-Granizo, F. Borda

Hospital de Navarra, Pamplona, SpainImplantation of self expanding stents in the palliative treatment of malignant esophageal strictures has become a widespread established procedure. We report our experience with esophageal ""Wallstent"" for palliation of malignant esophagocardial tumors.

Material and Methods 35 patients, 26 males/9 females, aged between 41 and 81 years, were referred for endoscopic palliation of malignant dysphagia. All patients had contraindications for radical surgery. 31 patients had squamous cell carcinoma and 4 cardial adenocarcinoma. Three patients had an esophagobronchial fistula (EBF). 36 ""Wallstent"" prostheses were inserted (one patient requiered two overlapped stents) after balloon dilation to a diameter of 12–15 mm and under continuous fluoroscopy. In patients with EBF, silicone covered stents were implanted. No dilation was needed after stent placement as the stent widens by its own expansile force.

Results Technical success with correct stent placement was achieved in all patients without major complications. Immediate improvement of dysphagia was observed in all cases and patients were discharged within the first 48 hours. Dysphagia recurred in 6 cases due to tumor overgrowth and a new stent was placed overlapping the first. In patients with EBF a complete seal was achieved and no stent migration was observed.

Conclusions 1. Wallstent esophageal prostheses offer excellent palliation of malignant dysphagia 2. Covered silicone stents have proved to be safe and effective in patients with EBF. 3. Dilation requierements are modest due to the small diameter of the delivery catheter and stent own expansile force. "P P 1 0034"P 1 0034 **Prognostic Factors in Patients with Malignant Esophageal Stenosis and Palliative Treatment with Self-Expanding Mesh Stents**

*D. Ludwig, A. Dehne, E. Burmester[1], J. Dagef\'f6rde, E.F. Stange

Dept. of Medicine I, University of L\'fcbeck, L\'fcbeck, Germany

[1] St\'e4dtisches Krankenhaus S\'fcd, L\'fcbeck, GermanyWe previously reported on the prognostic parameters in patients with esophagogastric carcinoma during laser treatment (Endoscopy 21, 254). The palliative endoscopic treatment of malignant stenoses of the upper gastrointestinal tract by self-expanding mesh stents is an alternative and novel procedure. Factors influencing clinical outcome and survival rates in these patients have not yet been defined.From July 1992 to August 1995 40 patients (11 females, 29 males, mean age 63 (22–82) yrs.) were treated with 51 mesh stents (Ultraflex[R] 35, Wallstent[R] 16). Survival rates (Kaplan Meier) were analyzed with regard to the degree of dysphagia (grades 0–3), Karnofsky's score, additional therapy by chemo- and radiotherapy. Complication and reintervention rates have also been analyzed.Dysphagia improved significantly in all patients within 24 hours (2.1 – 0.7 pre vs. 0.5 – 0.7 post implantation; $p < 0.05$). Survival of patients without residual dysphagia was prolonged (180 – 31 vs. 137 – 26; $p < 0.05$). During a median follow-up period of 60 days (range 51–116 days) 23 patients (53%) reported a worsening of dysphagia which could be relieved by endoscopic reintervention in 21 (91%) of them. 15 of 28 patients (54%) with primary weight loss stabilized or increased their body weight and experienced superior survival (234 – 49 vs. 179 – 22, $p < 0.05$). A subgroup receiving additional radio-chemotherapy ($T_3N_1M_0$) survived longer compared to a matched subgroup without additional therapy (499 – 83 days vs. 166 – 22 days; $p < 0.001$). Acute complications within 7 days included insufficient stent expansion (n = 15) and epigastric or retrosternal pain (n = 8); severe complications (bleeding, perforation) did not occur.Survival of patients with stenosing esophageal carcinoma and mesh stent implantation is prolonged significantly by additional cancer therapy, early stabilisation of body weight and without residual dysphagia. "P P 1 0038"P 1 0038 **Combined Endoscopic Treatment of Nonresectable Esophageal Carcinoma**

*W. Otto, P.M. Paczkowski, W. Gackowski, B. Najnigier, A. Karwowski

Medical Academy of Warsaw, Warsaw, PolandOver 30 patients are treated each year for squamous cell esophageal carcinoma in our Department. More then 80% of them present with TNM stage III/IV. The purpose of the study was to introduce and evaluate laser endoscopy and stenting, combined with additional radiotherapy as a method of palliation in these cases.One hundred patients (36 F, 64 M, m.a. 68) have been treated prospectively since 1991. They were qualified to the procedure because of advanced age, extensive carcinoma infiltration, concomitant disease excluding surgery or loss of more then 20% of body weight. The procedure consisted of endoscopic Nd:YAG laser vaporization alone in 37 patients and laser vaporization followed by radiotherapy in 63 patients. In 12 of them a self-expanding prosthesis was introduced to the recanalized part of the esophagus. Efficacy of the procedure, time of survival and quality of patients' life were evaluated.There were 14 deaths (14%) related to the procedure itself, 6 of them caused by esophagus perforation and 8 – related to the failure in recanalization. In 86 patients recanalization was achieved, although in 23 was not complete. In the latter group the quality of life was poor and just 16% of patients survived more then 6 months (no 1-year survival). In the remaining 63 patients, who underwent radiotherapy (12 of whom were prosthesised) quality of life was good or acceptable and 39% of them survived more then 12 months. The longest period of survival is 19 months in 6 patients.We conclude that endoscopic laser treatment is useful for palliation of nonresectable esophageal carcinoma. Satisfactory results may be achieved if it is applied relatively early and is followed by additional radiotherapy. Stenting simplifies the procedure and helps to maintain the patency of recanalized occlusion. "P P 1 0039"P 1 0039 **Real Benefits in Conventional Vs. Expandable Stents for Esophageal Cancer: In What Cases?H. Mart\'ednez, N. Chopita, N. Landoni, A. Jmelnitzky**

La Plata University Medical School, Hospital San Mart\'edn, Gastroenterology Service, La Plata, Argentina

Aims To compare our experience with conventional endoscopic stents for palliative management of esophageal cancer with our results in a recent series using self-expanding metal stents, related to early mortality and morbidity, survival and cost-benefit relation.

Material and Method from November 1992 up to July 1995, 25 patients underwent palliative treatment for esophageal cancer receiving 32 self-expanding metal stents: 9 Strecker, 16 Gianturco-Rosch, 6 Wallstent and 1 esophacoil type. Results were compare with a series of 60 patients receiving plastic prosthesis.

Results Plastic stents Self-expanding stents N = 60 n (%) N = 25 n (%)Early mortality 10 (16.6) 1 (4.0)Early morbidity 4 (6.6) 2 (8.0)Late mortality 4 (6.6) 1 (4.3)Late morbidity 17 (28.2) 5 (21.7)Survival ({\'b4} months) 4.8 6.0

Conclusions In our experience self-expanding esophageal stents seem to show a trend to a lesser early mortality than the classic type, without significative difference in other parameters; due to the great difference in costs (10 times) in Argentine, we suggest to reserve self-expanding stents for patients with difficult malignant stenosis not easily amenable to other methods and with fistulas Endoscopy, specific: Oesophagus }" "Real Benefits in Conventional Vs. Expandable Stents for Esophageal Cancer: In What Cases?"

"P P 1 0041"P 1 0041 **Diagnosis and Treatment of Superficial Esophageal Carcinomas**

*T. Kawano, K. Yoshino, K. Nagai, H. Inoue, M. Endo

First Department of Surgery, Tokyo Medical and Dental University School of Medicine, Tokyo, JapanWe studied the accuracy of pretreatment diagnosis of the superficial esophageal carcinomas (SECs) and the reliability of endoscopic esophageal mucosectomy (EEM), and discuss a strategy for the treatment of SEC.

Patients and methods 191 patients with SEC treated by esophagectomy in our department during a recent 11 year period and 71 patients with SEC or dysplasia treated by mucosectomy were evaluated retrospectively.

Results Clinicopathological study of patients with mucosal carcinoma revealed the rare occurrence of lymph node metastasis (1.1%) and no lymph node metastasis in patients with tumors showing no vascular involvement. On the other hand, many patients with submucosal carcinoma had lymph node metastasis. The accuracies of pretreatment diagnoses of the depth of tumor invasion and lymph node metastasis by a combination of endoscopic observation, endosonography, and computed tomography were 86% and 75%, respectively, which were considered to be unsatisfactory. On the other hand, specimens obtained by mucosectomy offered precise and detailed information about tumor extension, i.e. depth of tumor invasion, vascular involvement, etc. Moreover, mucosectomy using the negative pressure method was not difficult and was safe for wide mucosal lesions.

Conclusion Almost all mucosal cancers of the esophagus should be treated by esophagus-preserving methods, and endoscopic mucosectomy should play a role not only as a therapeutic modality, but also as an important diagnostic tool for use in patients with SEC in which invasion is suspected of being at the mucosal or superficial submucosal layer. "P P 1 0044"P 1 0044 **A New Instrument for Endoscopic Esophageal Mucosectomy**

*T. Kawano, K. Nagai, H. Inoue, K. Yoshino, M. Endo, K. Takeshita[1]

First Department of Surgery and Endoscopic Division, Tokyo, Japan

[1] Tokyo Medical and Dental University School of Medicine, Tokyo, JapanEndoscopic esophageal mucosectomy (EEM) is somewhat difficult because the esophagus is a narrow tubular organ. We devised a technique for EEM using a transparent overtube with negative pressure (np-EEM, Dig. Endosc., 1991). We altered the commercially available tube for this technique and performed EEM. However, alteration of the tube is troublesome, and now the tube for np-EEM is commercially available (Multipurpose guide tube (MDU type), Create Medic Inc., Tokyo, Japan,: MP tube). Here we describe the MP tube and how to use it.Instrument and techniques: The MP tube is made totally of silicone, is almost transparent, 60 cm in length, 15.5/12.0 mm in outer/inner diameter, and has a proximal balloon for making intraluminal negative pressure, a distal outer balloon for hemostasis after EM, a working channel, and a side hole for mucosectomy. The preparation is the same as for usual endoscopy, and the MP tube overlaid on the panendoscope is inserted after endoscopic observation.

IntroductionThe protruding mucosa induced by negative pressure and submucosal saline injection is strangulated by the snare and cut with high frequency current.

Results We performed EEM using an MP tube in 23 patients. The tube enabled us to achieve a relatively wide (2.5–3.5 cm times; 2.0–3.0 cm in size) mucosectomy and repetitive mucosectomy was also easy. No perforations and no uncontrollable bleeding occurred.

Conclusion A multipurpose guide tube (MDU type) is very useful when performing EEM with the negative pressure method. Endoscopy, general: Instrumentation, therapyEndoscopy, specific: Oesophagus }" "A New Instrument for Endoscopic Esophageal Mucosectomy"

"P P 1 0045"P 1 0045 **The Non Surgical Chemoradiation Protocol of Advanced Esophageal Cancer: Is Endoscopic Laser Helpful?R. Lambert,**

*P. Jacob, G. Bernard, F. Desseigne, F. Mornex, F. Descos

Federation Digestive, Hospital E. Herriot, 69453, Lyon, FranceThis randomized prospective study aims to determine whether, in the non surgical chemoradiation treatment of advanced esophageal cancer, a single session of laser esophageal desobstruction after the first chemotherapy course will improve symptoms, tumor response or survival.

Methods From 1992 to 1993, 20 patients (16 men and 4 women, mean age, 62 years; age range, 46–79 years) with advanced esophageal squamous cell cancer were submitted to a non surgical chemoradiation protocol with 5 chemotherapy courses (5FU-CDDP) and 3 radiation courses (20, 20 and 10 Gy). All patients had dysphagia (grade 1 or 2 in the Atkinson scale). They were randomized in 2 groups. –

Group I 10 patients with chemoradiation alone – sex: 7 men, 3 women, mean age: 60 y, mean weight: 62 kgs, dysphagia score 1.4, EUS stage: uT3, N+ in 8, uT4, N+ in 2. –

Group II 10 patients with laser and chemoradiation – 9 men, 1 woman, mean age 63 y, mean weight 63 kgs, dysphagia score 1.4, EUS stage: uT3, N+ in 6, uT4, N+ in 4). A single Nd YAG laser session (mean: 3370 Joules) was performed after the first chemotherapy session. Criteria in the follow up were: – at 2 months: dysphagia score and EUS response – at 6 months: Weight variation, mean number of dilation sessions, tumor response as complete or incomplete (macroscopic and histological) – Finally the death rate during follow up and median survival were evaluated.

Results The average follow-up was the same in the 2 groups (45 months). At 2 months, the mean improvement in dysphagia score were 0.7 and 1.2 respectively in groups I and II. A reduction in EUS staging was notified in 4 patients in groups I (40%) and 5 in group II (50%).At 6 months, no significant weight variation between the 2 groups was notified. The mean N° of dilation sessions was 3.1 in group I and 2.1 in group II. The tumor response was complete in 3 patients in each group (30%).During follow up, death rate was 80%, in group I and 100% in group II. The median survival was higher in group II (14.5 months) than in group I (7 months), but this difference was not significant (Wilcoxon test).

Conclusions in advanced esophageal cancer, an endoscopic laser session in addition to the chemoradiation protocol results in a slight improvement of the dysphagia score, no change in the rate of complete tumor response. The increased median survival rate is not associated in a reduction of the high death toll. Its main justification is the relief of dysphagia in the initial period; the procedure is therefore recommended in polypoid obstructive tumors only. "P P 7 0161"P 7 0161 **Lymph Node Detection by Ultrasound within the Hepatoduodenal Ligament in Patients with Primary Biliary Cirrhosis**

*C.F. Dietrich, C. Rees, M. Leuschner, U. Leuschner

Dept. of Internal Medicine, JW Goethe University, Frankfurt, Germany

Purpose Viral, bacterial infections and enterotoxins have been proposed as etiopathological factors causing primary bilary cirrhosis (PBC). Therefore we prospectively investigated the number and size of lymph nodes (LN) within the hepatoduodenal ligament (HDL) in 35 consecutive patients with PBC and in 30 healthy controls.

Methods Sonographic detection of LN within the HDL was validated in 20 human bodies including histological examination of the respective LN to exclude malignant infiltration. In the present study the LN ventral of the portal vein (PV) and between the PV and inferior vena cava were evaluated by high resolution ultrasound (Acuson 128, 3.5 MHz) in 35 consecutive patients with primary bilary cirrhosis (age: 56 – 9 years) and in 30 healthy controls (30 – 8 years) in a 15\'b0 degree left lateral position in a standarized fashion by one examiner. The area (ellipse function) of all LN detected was recorded for each region. The stages I–IV of PBC were biochemically and histologically proven in all patients.

Results In 32/35 patients (91.4%) and in 28/30 healthy controls (93.3%) adequate visualisation of the region of the HDL was achieved. LN were detected in 30/32 patients with PBC (93.8%) and in 12/28 controls (46.4%). The mean LN area size was 461 – 325 mm^2 in the PBC group and 81 – 45 mm^2 in the controls ($p < 0.0001$). Number and size of the lymph nodes showed no significant correlation to liver function tests.

Conclusion Enlarged lymph nodes within the hepatoduodenal ligament are sonographically detectable in almost all patients with PBC. This lymph node enlargement could reflect extrahepatic immunological activity and could be helpful in the diagnosis of PBC. "P P 7 0162"P 7 0162 **Intraductal Ultrasound (IDUS) and ERCP — A New Diagnostic Dimension?**

*J. Menzel, W. Domschke, J. Konturek, E.-Ch. Foerster

Department of Medicine B, University of Muenster, GermanyEndoscopic retrograde cholangiopancreatography (ERCP) is able to depict diseases affecting the pancreatobiliary tract fluoroscopically. To allow a diagnosis additional information on adjacent tissue is usefull. Intraductal ultrasonographic imaging (IDUS) with newly developed probes is feasible during ERCP.During ERCP ultrasound miniprobes (Aloka, Microvasive, Endosonics) with diameters of 3.5 up to 6.2 French were inserted via the working channel of a routine duodenoscope (Olympus JF1T20).53 patients underwent intraductal ultrasound with these probes. In 32 patients (17 women, 15 men) the probe was inserted into the biliary tract, in 21 patients (9 women, 12 men) into the pancreatic duct. IDUS of the tail of the pancreas was possible in 48%, of the body in 90% and of the head of the pancreas in 95%. Due to ultrasound frequencies of 12.5 to 30 MHz imaging of stenoses in microscopic dimension of a magnifiying glass was possible. Malignant infiltration of the pancreatic duct appeared inhomogeneously echopoor, whereas carcinoma of the bile duct appeared echodense. Lymph nodes of a size of 5 mm in diameter adjacent to the bile duct were visualized. Infiltration of the tumor into the portal vein system is detectable. However, the high ultrasound frequency of the probes limits the penetration depth. Thus the extension only of large tumors could not be demonstrated completely. Rotation of the cable in mechanical probes sometimes limits the flexibility of the probes. On average intraductal ultrasound examination during ERCP took 4:16 minutes (1:23 up to 13:36). There was no indication of any injury to the duct system or the pancreas.Intraductal ultrasound of the pancreatobiliary tract is a secure, easy and quick examination which can be performed during ERCP. IDUS gives important supplementary information on the periductal tissue. Controlled studies to compare the diagnostic value of IDUS with that of conventional techniques (EUS, CT) are currently underway. Endoscopy, specific: BiliaryEchoendosonography: EchoendoscopyEchoendosonography: Therapy }" "Intraductal Ultrasound (IDUS) and ERCP / A New Diagnostic Dimension?"

"P P 7 0163"P 7 0163 **Endoscopic Ultrasound and Helical CT Scan for Bilio-Pancreatic Cancer: Preliminary Prospective Study of 40 PatientsF. Jellouli, O. Keriven-Souquet, L. Henry, B. Napol\'e9on, B. Pujol, P.J. Valette, T. Ponchon,**

*J.C. Souquet

Department of Digestive Diseases, Hospital E Herriot, Lyon, FranceEndoscopic ultrasound (EUS) is nowadays a recognized method for bilio-pancreatic imaging: it has been shown superior to CT scan for the diagnosis of small pancreatic tumors and tumor staging. Helical CT scan is a promising improvement, that could increase the efficiency of CT. Here we prospectively compared these 2 methods for the study of bilio-pancreatic carcinomas.

Methods 50 patients referred for EUS (search of bilio-pancreatic tumor) were prospectively included. EUS (Olympus JF or GF M20) were performed under intravenous sedation. For helical scan (Philips SR 7000), patients absorbed 1000 ml water and received IV 15 mg Tiemonium. A first acquisition (general examination of the pancreas) was obtained with 10 mm continuous slices. A second acquisition (fine imaging of the pancreas) was obtained 30 s after contrast injection with thirty-five 3 mm continuous slices. A third acquisition (study of veins) was obtained 80 sec after the injection with 10 mm continuous slices. EUS and helical CT were performed independantly within 48 hours, in a randomized order and with the same level of clinical background. Results were compared to the final diagnosis obtained by surgery, cytoponction or follow-up.

Results Final diagnosis was obtained in 40 patients (surgery in 13, cytology in 8, follow-up superior to 8 months in 19 – ERCP in 11). It consisted in bilio-pancreatic tumors in 16 (pancreatic adenocarcinoma, n = 8; cholangiocarcinoma, n = 4; ampulloma, n = 2; pancreatic endocrine tumor, n = 1; mucinous ductal ectasia, n = 1) and non tumoral diseases in 24 patients (ampullary sclerosis, n = 2; bile duct stone, n = 3; chronic pancreatitis, n = 4; pancreatic cyst, n = 5; no abnormality, n = 10). For the diagnosis of bilio-pancreatic tumor (absence or presence of such a tumor), EUS was right in 38/40 cases (95%) while helical CT was right in only 27/40 cases (68%). For determining the true nature of the visualized tumor, EUS was accurate in 11/14 cases (79%) and helical CT in 6/9 only (67%). For lymph node staging, in the 9 patients operated on and evaluable, EUS was correct 6 times and helical CT 4 times. For the determination of vascular invasion (present in 3 cases, absent in 11 cases), helical CT was always right, while EUS missed invasion of the mesenteric vein by a pancreatic adenocarcinoma in one case.

Conclusions while helical CT scan appeared an improvement in comparison to classical CT scan, it remained inferior to EUS in this preliminary study regarding the diagnosis of bilio-pancreatic tumor. "P P 7 0165"P 7 0165 **Endoscopic Ultrasonography in the Evaluation of Dilated Common Bile Duct of Unexplained Origin in Transabdominal Ultrasonography**

*Y. Song\'fcr, U. Yilmaz, A. Serin, \'dc. Saritas, G. Temu\'e7in, B. Sahin

Dept. of Gastroenterology, Y\'fcksek Ihtisas Hosp., Ankara, TurkeyAbdominal ultrasonography (US) is the procedure of the first choice in the demonstration of a dilated common bile duct (CBD), but the cause can be determined in only two third of patients.The aim of this prospective study was to assess the value of EUS in detecting the cause of CBD dilatation in the patients in whom US failed or revealed equivocal results to diagnose the cause of dilatation.

Methods Between June 1995 and May 1996, ninety consecutive patients (54 women, 36 men, range 21–74 years) who had enlarged (the diameter 7 mm or more) CBD of unexplained origin during US examination were included in this study. Twenty-eight patients had had previous cholesistectomy. All patients underwent EUS examination. Final diagnosis was determined by endoscopic retrograd cholangiopancreatography (ERCP) with or without sphincterotomy (n = 53) or surgical exploration (SE) (n = 23).

Results The following diagnoses were correctly made by EUS: choledocholithiasis in 38, tumor of the papilla of the Vater in 8, benign distal stricture in 8, distal cholangiocarcinoma in 4, choledochal cyst in 2, ova of *Ascaris* in 1 patient. In two patients, ERC did not show choledocholithiasis seen by EUS. In one patient, EUS did not show choledocholithiasis seen by ERC. The diagnosis of distal cholangiocarcinoma was not confirmed by ERC in one patient. In two patients, the transducer could not be inserted into the second duodenum because of duodenal stenosis. EUS findings were normal in 23 patients, except for CBD dilatation. In 9 of the 23 patients, EUS result was confirmed by ERC. ERCP or SE was not performed in the remaining 14 patients. Excluding the 14 patients who had only dilated CBD, EUS provided an accurate explanation for CBD dilatation in 70 of the 76 patients (92%).We conclude that EUS is a highly accurate modality for the detection of the cause of CBD dilatation. EUS can demonstrate the type, location and extent of biliary obstruction. Endoscopy, specific: BiliaryEchoendosonography: EchoendoscopyRadiology and ultrasound: Diagnosis }"

"P P 7 0166"P 7 0166 **Percutaneous Transhepatic Ultrasound-Guided Puncture of the Gallbladder for Acute Cholecystitis**

*M. Ichikawa, O. Takahara, A. Ishihara, H. Hamada, A. Toyoshima, J. Kanou

Department of Internal Medicine, Anjo Kosei Hospital, Anjo, JapanThe aim of the present study was to assess experience with percutaneous transhepatic ultrasound-guide puncture of the gallbladder (PTUPG) in resolving the acute episode of cholecystitis.

Patients and methods Thirty-one consecutive patients (18 men, 13 women) with a clinical diagnosis of acute cholecystitis (25 cholelithiasis, 13 acalculous) underwent the procedure on an emergency basis. The median age was 61 years (range 39–84). Twelve of the 31 patients were considered high-risk patients. PTUPG was performed as a bedside procedure under local anaesthesia. Under ultrasonic guidance, a 21-gauge PTC needle was used. After complete aspiration of the gallbladder, the PTC needle was withdrawn. All patients were taking antibiotics systematically before and after the procedure.

Results PTUPG was performed successfully and rapid resolution of symptoms occured in almost all patients. Sixty-six percent of aspirates were positive for a variety of organisms. No complications related to the puncture were seen.

Conclusion PTUPG should be considered a simple, safe and efficacious means of conservative management of the patient with acute cholecystitis. "P P 7 0167"P 7 0167 **Usefulness of Endoscopic Ultrasonography for Detecting Gallbladder and Common Bile Duct Lesion in Patients with Anomalous Connection of Pancreato-Billiary Ducts**

*A. Murakami, A. Kano, K. Yoneyama, S. Kaga, H. Ishikawa, T. Sakuma, N. Tomichi

Divisions of Internal Med. of Gastroenterology, Iwate Prefectural Central Hospital

Divisions of Pathology

Introduction The relation between carcinoma of the gallbladder and an anomalous connection of pancreato-billiary ducts is well known. We encountered 24 cases of anomalous connection of the pancreato-billiary ducts [9 males, 15 females, mean age 46.7 (range 18 – 76)]. Eleven cases demonstrated choledochal cysts, but 13 cases demonstrated common bile duct (CBD) with no dilatation. Associated conditions included gallbladder (GB) cancer in 7, CBD cancer in 3, CBD stone in 3, pancreatitis in 8.

Aim and Method To evaluate the diagnostic efficacy of endoscopic ultrasonography (EUS) for anomalous pancreato-billiary ducts 11 patients which had undergone EUS preoperatively, were reviewed.

Result Abdominal ultrasonography (US) was perfomed in 24 cases. US revealed GB wall thickness (n = 7), GB polyp (n = 2), GB tumor (n = 9), GB tumor with stone (n = 1), debris (n = 2), commet echo (n = 1), and no abnormality (n = 1). EUS was perfomed in 11 cases. Using EUS, we could detect GB or CBD tumor in 5, GB polyp in 2, and thicking of the first GB layer in 4. EUS images were compared with histological findings of surgical materials in each case. Pathological findings were GB cancer in 3, CBD cancer in 1, hyperplasia of the gallbladder wall in 1, and adenoma in 2, being compatible with EUS findings. Four patients with thickening of the first GB layer had GB cholesterosis. Although EUS showed a common channel of an anomalous connection of pancreato-billiary ducts was successful in 9 of 11 (82%).

Conclusion EUS produces better images of the GB and CBD in patients with anomolous connection of pancreato-billiary ducts than US does. Thorough evaluation of the common channel by EUS, however, was not possible and additional evaluation with ERCP (endoscopic retrogrde cholangiopancreatography) is required. "P P 7 0168"P 7 0168 **Magnetic Resonance Cholangiography (MRC) in Cholestatic Jaundice**

*G. Macarri, G. Feliciangeli, A. Giovagnoni[1], C. Guidarelli, V. Berdini, L. Costarelli[1], A. Benedetti, F. Orlandi

Dept. of Gastroenterology, University of Ancona, Ancona, Italy

[1] Dept. of Radiology, University of Ancona, Ancona, ItalyThe MRC allows a tridimensional visualization of biliary tree based on Fast Spin Echo sequences. Its clinical value has not been evaluated yet. *Aim* of this study was to prospectively evaluate the diagnostic accuracy of MRC in the cholestatic jaundice. *Patients and Methods.* 34 consecutive patients (19 male, median age 66.1 years, range 39–85 years) with cholestatic jaundice (total bilirubin > 5 mg/dl), elevated serum indexes of cholestasis and common bile duct diameter > 7 mm as determined by ultrasonography have been enrolled. MRC and ERCP were performed on the same day by investigators unaware of the results of the other procedure. ERCP with or without surgery was used as the diagnostic gold standard. *Results.* MRC and ERCP were carried out in 32 of 34 patients. Choledocholithiasis (13 patients), somatostatinoma (1 pat), ampullary adenocarcinoma (2 pat), pancreatic adenocarcinoma (5 pat), haemobilia (1 pat), benign stricture of the common bile duct (CBD) (2 pat), carcinoma of gallbladder wall (1 pat), cholangiocarcinoma (1 pat) and 6 patients with normal biliary tree have been admitted to the study. MRC was negative in 4/6 patients with normal biliary tree (specificity 66.6%) and was positive in 24/26 patients with abnormalities of biliary tree (sensitivity 92.3%). Particularly MRC identified 10/14 patients (71.5%) with filling defect of CBD and 12/13 patients with stenosis (92.3%). In 2 cases of CBD stricture at MRC, small extractable stones were present at ERCP. Overall Positive Predictive Value (PPV) was 92.3%. No side effects at MRC were observed. *Conclusions.* Our results show that in patients with cholestatic jaundice MRC was very sensitive to show CBD abnormalities but less accurate to define their nature. Major limitation of MRC is its inability to offer therapeutic intervention. "P P 7 0169"P 7 0169 **Magnetic Resonance Cholangiopancreatography, Alternative Method in Bile Duct Obstruction Diagnosis**

*B. Dupas, J.C. Le Neel, C. Masliah, F. Leaute, J.P. Galmiche

University Hospital, HOTEL-DIEU, NANTES, FRANCE

Purpose Magnetic resonance cholangiopancreatography (MRCP) was evaluated and assessed as an alternative to endoscopic ultrasonography (EU), endoscopic retrograde cholangiopancreatography (ERCP), percutaneous transhepatic cholangiography (PTC).

Methods MRCP was performed in 46 patients using half fourier single shot turbo spin echo sequence (HASTE s\'e9quence) with coronal, oblique or sagittal images. The imaging time was 18 seconds (breath-hold) for sequential acquisition of multislice technique with 5 mm slice thickness. All the patients presented clinical symptoms and/or biochemical studies consistent with gallstone disease and/or bile duct obstruction or pancreatic desease. Final diagnosis was established with surgery (n = 35) ERCP (n = 10) EU (n = 10) PTC (n = 3)

Results In gallstone disease (n = 20) the sensitivity of MRCP was 82% for gallbladder calculi; 89% for choledocholithiasis. Common bile duct and main pancreatic duct were seen in 100% patients, cystic duct in 64%. Biliary tree obstruction by tumors (n = 16) was showed by MRCP in all cases. In chronic pancreatitis (n = 5) common bile duct dilatations, pancreatic duct features and pseudocyst formations were visualized. Accurate level of benign biliary stricture (n = 5) was demonstrated.

Conclusion MRCP is a useful non invasive tool for the evaluation of bile duct obstruction. It may replace percutaneous transhepatic cholangiography and can be an alternative when endoscopic retrograde cholangiopancreatography or endoscopic ultrasonography are unsuccessful. "P P 7 0170"P 7 0170 **Is Magnetic Resonance Cholangiopancreaticography Able to Take the Place of Endoscopic Retrograde Cholangiopancreaticography?**

*R.E. Hintze, A. Adler, W. Veltzke, R. Hammerstingl, T. Vogl, R. Felix

Depts. of Gastroenterology, Central Interdiscipl. Endoscopy and Radiology, Virchow-Klinikum Humboldt-University of Berlin, Germany

Introduction By the technical development of magnetic resonance tomography (MR) there are efficient devices available for MR-cholangio-pancreatography (MRC-P) in the meantime. For the first time their high resolution makes a direct comparison to the established endoscopic retrograde cholangio-pancreatography (ERC-P) possible. In an initial series the clinical value of this non-invasive imaging technique in diseases of the bile and pancreatic duct system could be evaluated.

Methods As MR-tomograph a 1.5 Tesla Gyroscan (Philips^{R}) for static MRC-P with special adapted turbospinechosequences was available. MRC-P was performed with a T2-weighted IR-sequence with a layer of 3 mm and a 1.5 mm overlapping tomography in coronary orientation and respiratory triggering and an IR-delay time of 90 ms.

Results In 22 patients MRC-P was performed, in 9 of them a malignant process was diagnosed (3x Klatskin-tumors, 3x bile duct carcinomas, 2x pancreatic carcinomas, 1x carcinoid of the pancreas). In 3 patients a chronic pancreatitis was found, in 2 with liver cirrhosis a thin intrahepatic bile duct system was shown, in 4 alterations of the extrahepatic bile duct system after orthotopic liver transplantation were demonstrated. A stenosis of the common bile duct could be proved in 3 patients after laparoscopic cholecystectomy, in 1 patient a CBD-stone. In 20 of those patients an ERC was performed. In 18 cases was a right positive correlation, in 2 a wrong negative result of the MRC. With MRC-P the pancreatic duct could be sufficiently demonstrated only in 8 patients. In localisation and definition of bile duct stenoses MRC and ERC are comparable. In the definition of the extension of Klatskin-tumors MRC is better than ERC. In general imaging of the papillary near duct segments is of better quality in ERC than in MRC.

Conclusions MRC as a non invasive imaging procedure is qualified for planning therapeutic ERC and PTC-techniques as well as for review of endoscopic placed drainages especially in cases with Klatskin-tumors. MRC makes a very important contribution to visualise hepatic branches that are not demonstrable with ERC due to tumor growth. "P P 7 0171"P 7 0171 **Usefulness of Endoscopic Ultrasonography in Diagnosing Elevated Lesions of the Gallbladder: With Emphasis on Its Usefulness in the Diagnosis of Adenomyomatosis**

*N. Muguruma, S. Okamura, S. Hayashi, M. Yasuda, T. Yokoi, T. Okahisa, H. Shibata, S. Ito

Second Department of Internal Medicine, School of Medicine, The University of Tokushima, Tokushima, Japan

Purpose The usefulness of endoscopic ultrasonography (EUS) in diagnosing elevated lesions of the gallbladder, especially its usefulness in distinguishing adenomyomatosis (ADM) from other gallbladder diseases, was assessed in comparison with other imaging techniques.

Subjects and Methods The subjects of this study were 30 patients who underwent cholecystectomy following the detection of elevated lesions of the gallbladder by EUS at our department between April 1992 and March 1996. The EUS-based diagnosis of elevated lesions of the gallbladder was compared with their histopathological diagnosis. For cases where a diagnosis of ADM was made histopathologically, we compared the accurate diagnosis rate, the wall hypertrophy detection rate and the Rokitanski-Aschoff sinus (RAS) detection rate using abdominal ultrasonography, abdominal CT, ERCP and EUS.

Results The diagnosis made by EUS was cholesterol polyp in 10 cases, adenoma in 1 case, ADM in 11 cases, cancer in 7 cases and not detected in 1 case. The histopathological diagnosis was cholesterol polyp in 9 cases, adenoma in 1 case, ADM in 11 cases, cancer in 6 cases and others in 3 cases. Thus, the EUS-based diagnosis had an accuracy of 70.0%. For the 11 cases where a diagnosis of ADM was made histopathologically, the accurate diagnosis rate was 54.5% by ultrasonography, 18.2% by abdominal CT, 63.6% by ERCP and 81.8% by EUS.

Conclusion 1. EUS was found to be useful in qualitative diagnosis of elevated lesions of the gallbladder. 2. A diagnosis of ADM seems reasonable if its three major signs of ADM (a 3 mm or greater hypertrophy of the gallbladder wall, the presence of two or more RAS within a 1 cm segment of the gallbladder wall, preservation of the three-layer structure of the gallbladder wall are detected using EUS. "P P 8 0172"P 8 0172 **Ampullary Carcinoma: Analysis of Prognostic Factors for Survival**

*F. Scotto, A. Valentini, V. Guerra, P. Giorgio, C. Leoci, A. Penna, G. Di Matteo

Endoscopic unit and Laboratory of Epidemiology of IRCCS ""S. De Bellis"", Castellana (Ba), Italy

Aim To evaluate ampullary carcinoma survival prognostic factors by studying a series of patients who underwent ERCP for obstructive jaundice.

Methods From 1989 to 1995, 49 consecutive patients (33 M and 16 F; median age 70, range 34–92 years) with ampullary carcinoma were diagnosed by ERCP and histology and followed-up (mean follow-up 639 days, range 1–2370). The following data were retrospectivelly reviewed for all patients: clinical data, laboratory results (bilirubin, ALP, GGT, ASAT, ALAT, amylase, hemoglobin, leucocyte count), imaging investigations (UES, CT), ERCP data (endoscopic findings, CBD fluoroscopic findings, sphincterotomy and/or endobiliary stent), histologic findings, operative procedures (pancreaticoduodenectomy, surgical bypass procedure, endoscopic biliary drainage). Survival rates were calculated by using the Kaplan-Meier method, the Log-Rank test was utilized for the univariate analysis of the suvival curves and the Cox regression model for the multivariate survival analysis.

Results In the total group the 1- and 3-year survival was 66% and 30% respectively. By using univariate analysis, factors affecting negatively survival were: age > 60 ($p < 0.1$), leucocite count > 10000 ($p < 0.0005$), poor differentiation grade of the tumor ($p < 0.1$), surgical or endoscopical biliary drainage ($p < 0.02$). By multivariate analysis factors influencing survival were: age > 60 R.R. = 8.28 (95% C.I. 1.52–45.08), leucocyte count > 10000 R.R. = 52.24 (95% C.I. 5.99–455.61), moderate or poor tumor differentiation R.R. = 2.94 (95% C.I. 1.25–6.91). Operative procedures were not significatively associated with survival but a strong collinearity between age and operative procedures existed.

Conclusions No ERCP findings had influence on survival. A significant correlation was found between age, high leucocite count (showing cholangitis), tumor differentiation and survival.

"P P 8 0174"P 8 0174 **Tumors of the Papilla of Vater — Improvement of Diagnostic Imaging by Intraductal Ultrasound (IDUS)**

*J. Menzel, E.-Ch. Foerster, J. Konturek, W. Domschke

Department of Medicine B, University of Muenster, GermanyAn adenoma-carcinoma-sequence also applies to adenomas of the papilla of Vater. ERCP alone does not provide any information on infiltrative growth. Imaging of polypoid processes of the papilla of Vater has an influence on the choice of therapeutical procedures. Endoscopic ultrasound (EUS) is usually limited in detection small processes. High-frequency ultrasonic probes adjusted to the dimension of the pancreatic and biliary tract can, if applied during ERCP, visualize the peripapillary tissue at highest resolution.Ultrasound miniprobes (Aloka', Microvasive') 2 mm in diameter (6 French) were inserted via the operating channel of a routine duodenoscope (Olympus JF1T20) during ERCP. 35 patients (18 female, 17 male; \'d8 65 years, from 31 up to 85) with polypoid processes of the papilla of Vater were examined. The sonomorphologic images were compared with biopsy and if available with the resection specimen. IDUS was correlated with findings of EUS as well as with the CT findings.Using sonographic frequencies of 12.5 up to 30 MHz the peripapillary tissue was demonstrated in microscopic dimension of a magnifiying glass. Malignant infiltration of the papilla of Vater was depicted sonographically inhomogenous and echopoor in echoes whereas benign papillary stenosis were shown homogenously echodense. Insertion of the probe and ultrasonic examination during ERCP took 5 minutes on average, indications of any trauma to the papilla or the surrounding tissue could not be found. Eight of the 35 patients underwent surgery: Three had a carcinoma, five an adenoma of the papilla of Vater. Sensitivity of IDUS was 100%, specificity 80% and accuracy 87%. Endoscopic ultrasound (EUS): sensitivity 12%, specificity 40%, accuracy 37%; CT scan: sensitivity, specificity and accuracy 0%.Though only a limited number of patients has been evaluated by intraductal ultrasound up to now, imaging of the papilla of Vater with IDUS seems to be superior to conventional imaging techniques in diagnosing polypoid processes of the papilla. IDUS provides a view behind the surface and visualizes the adjacent tissue at high resolution. Controlled studies have been initiated to define the value of IDUS in the diagnostic procedure concerning diseases of the papilla of Vater. "P P 8 0176"P 8 0176 **New Approach to the Endoscopical Treatment of Bening Tumors of the Terminal Part of Choledochus (TPCH)**

*A.A. Boudzinski, S.U. Orloff, N.V. Sitnikova, M.A. Ivantsova

Medical Center of Russian Central Bank, Moscow, Russia

Russian State Medical University, Moscow, Russia

31th City Hospital, Moscow, Russia

Dept. of Medicine, Novouralsk, Russia

Purpose The present study was designed to develop and investigate the new method of endoscopical excision of bening tumors of the TPCH.

Methods Between III/91 and IV/96 endoscopical operations were performed in 39 patients with the bening tumors of TPCH. There were 11 men and 28 women; age from 31 to 85. The leading clinical manifestations were: pancreatites (16) and biliary hypertension (23) with obstructive jaundice (16). The sizes of tumors were from 3 {\'b4} 4 mm to 8 {\'b4} 15 mm. Hystological types were: 28 cases of adenomas (mainly villous forms) and 11 cases of polyps (mainly adenomatous forms). Tumors were treated by endoscopical monopolar electrocoagulation with preliminary endoscopic sphincterotomy (EST) and insertion of pancreaticoduodenal stent. Due to this method the excision of the tumors was completed without direct damage of the main pancreatic duct (MPD) orifice. The prolonged insertion of pancreaticoduodenal drainage (for 4–6 months) prevented last formation of the strictures of the MPD orifices. During two last years double biliary and pancreatic stents were inserted in 7 cases for 4–6 months after excision of the tumors to prevent stenosis of the both orifices. All manipulations were performed with apparatus and accessories of the firm ""Olympus"" (Jp.).

Results In all cases the tumors were deleted. Mild forms of acute pancreatites as early complications were developed in 3 cases. There were no mortality. Recoagulations of the remains of tumor tissue were made in 10 cases during the next 1–5 months after control endoscopical interventions. There were no relapses of the tumors and cases of malignant transformation during the next 0.5–5 years. EST and virsungotomy were performed in 9 cases after 5–12 months later the first excision because of the stenosis of the orifices of choledochus (5) and MPD (4). There were no mortality and complications in this group of patients. Sings of biliary hypertension disappeared in all cases, pancreatites in mild forms retained in 4 cases out of 16, so the efficiency of treatment of pancreatites was 75%. In 7 patients with double stents there were no cases of restenosis.

Conclusion Presented method of TPCH tumors treatment is effective and safe. According to our experience it will be sufficient to insert double biliary and pancreatic stents after excision of large size tumors (more than 5 mm in diameter) for 4–6 months to prevent stenosis of the orifises of choledochus and MPD. "P P 8 0177"P 8 0177 **Reliability of Preoperative Biopsy in the Diagnosis of Ampullary Malignancy**

*B. Launois, A. Dorandeu, B. Meunier, B. Chareton, C. Stasik, G. Spiliopoulos, J.F. Bretagne, M. Gosselin

Department of Digestive Surgery and Transplant Unit, CHR Pontchaillou, Rue Henri Le Guilloux, 35033 Rennes, FranceThe choice treatment of malignant ampulloma is pancreaticoduodenectomy. Before engaging in such major surgery, some clinicians prefer to have histological confirmation of malignancy. In case of negative biopsies, surveillance, ampullectomy and endoscopic sphincterotomy have been advocated.

Patients and methods 35 patients with adenocarcinomas of the Ampulla of Vater confirmed by pathological analysis of the surgical specimens (3 ampullectomies, 31 pancreaticoduodenectomies, 1 total pancreatectomy) underwent preoperative endoscopic biopsy. There were 22 males and 13 females with a mean age of 62.5 – 9.5 years. Jaundice, abdominal pain, poor general health status and gastrointestinal bleeding were present in 19, 21, 22 and 8 patients respectively.

Results Specimens showed protuberant and hemorrhagic papillary tumor (n = 17), a pseudovillous tumor (n = 2), an enlarged papilla (n = 5), a common bile duct dilatation (n = 4), a common bile duct nodule (n = 4) and a papillary obstruction (n = 1). Data was not available for 2 patients. 17 of 35 biopsies showed infiltrating adenocarcinoma, 1 biopsy having been obtained only after sphincterotomy. Biopsies showed an adenovillous tumor suspect of malignant transformation, an unspecified suspect lesion and a positive smear in 1 case each. Other biopsies showed mild (n = 1), medium (n = 2), or severe dysplasia (n = 4), benign tumors (n = 4), inflammation (n = 1) and hyperplasia (n = 1). No anomalies were noted in 2 patients.

Conclusion In some patients preoperative endoscopic biopsies are capable of ascertaining malignancy for tumors of Vater's ampulla. However the possibility of malignancy should not be discarded in the presence of a negative biopsy and patients should be denied the benefits of resective surgery solely on the basis of a negative biopsy. "P P 9 0181"P 9 0181 **A Endoscopic Survey of Colonic Diverticuloses in Singapore**

*D.S. Sutedja, J.Y. Kang[1]

Division of Gastroenterology, Department of Medicine, National University Hospital, Singapore

[1] James Paget Hospital, Norfolk, United Kingdom

Objective We studied the prevalence and characteristics of colonic diverticuloses in patients undergoing colonosopy performed by the Division of Gastroenterology in the National University Hospital, Singapore, from January 1992 to April 1995.

Methodology The results of colonoscopy performed on 1628 patients (mean age 52, range 13 to 91, 51% males, 82% Chinese, 7% Indians, 4% Malay) were reviewed. Patient data, indications for colonoscopy and the presence or absence of diverticuli were obtained from structured recording forms.

Results 118 (7%) patients (98 Chinese, 5 Malays, 6 Indians) had diverticuli in at least one part of the colon. This group was significantly older (mean age 62 yrs vs 51 yrs, $p < 0.001$) and there were more males (61% vs 50%, $p = 0.02$) than those without diverticuli. There were 30 patients (25%) with left-sided diverticuloses only, 73 (62%) with right sided diverticuloses only, 3 (3%) had involvement of the transverse colon only, 11 (9%) had both left-and right-sided diverticuli, and one patient had diverticuli in all parts of the colon. Patients with right-sided diverticuli were younger (59 yrs vs 68 yrs, $p = 0.001$) and there were more Chinese (92% vs 67%, $p = 0.009$) than patients with left sided involvement. There were no differences in the indications for colonoscopy in patients with and without diverticuli, and in patients with right-sided vs left-sided diverticuli.

Conclusions (1) The prevalence of diverticuloses in this survey of colonoscopic examinations was 7.2%, which is lower than previously published local autopsy and barium studies. This could be because endoscopy may be a less sensitive method for detecting diverticuloses. Also, ours being a medical series seldom include patients with suspected diverticulitis. (2) Patients with diverticuloses tend to be older and male. (3) Right-sided diverticuloses is commoner in Singapore, and these patients are younger and more likely to be Chinese. "P P 9 0183"P 9 0183 **Endoscopy Defines the Therapeutical Options of Non Occlusive Ischemic Colitis**

*A. Adler, W. Veltzke, R. L\'fcsebrink, P. Neuhaus, K.E. Hampel, R.E. Hintze

Depts. of Gastroenterology, Central Interdisciplinary Endoscopy and Surgery, Virchow-Klinikum of the Humboldt-University of Berlin, Germany

Introduction While the occlusive form of ischemic colitis (IC) is caused by embolic or thrombotic vessel occlusions, the reason for the non occlusive form is often a cardiogenic circulation deficit of the colon nearly almost in intensive care patients. Diagnosis of the non occlusive form can be proved angiographically only exceptionally. Aim of our study is the evaluation of endoscopy for diagnosis and treatment of this IC.

Patients From 7/91 to 10/95 in 236 intensive care patients with different primary diseases 373 colonoscopies due to prolonged intestinal atony and meteorism (thereof 122x diarrhoea and blood loss per anum) were performed under emergency circumstances. 210 patients needed artificial respiration due to their cardiorespiratory situation and they were dependent on catecholamines. 78 patients were female, 158 male, mean age: 58.6 years (min. 28–max. 78).

Results All 236 patients suffered from a colonic pseudoobstruction with massive meteorism (Ogilvie's-syndrome). Endoscopy demonstrated in 41.9% minor signs of ischemic damage: 22.0% (n = 52) showed a lividity with erosive aphthous lesions (grade I), 19.9% (n = 47) flat, non confluent ulcerations (grade II). Severe ischemic alterations were found in 22.9%: 15.7% (n = 37) with deep confluent ulcerations over the total colon (grade III) and 7.2% (n = 17) with gangrenous findings, sometimes with perforation (grade IV). Rare findings (chronic inflammatory bowel disease, neoplasia) in n = 6 (2.5%). In 32.7% a definitive classification of the colonic damage was not possible due to not eliminable stool masses. As therapy in all patients a colon decompression could be performed, in n = 154 (65.3%) with application of an indwelling decompression tube.

Conclusions While the cause of IC with vessel occlusion is to be proved angiographically, the non occlusive IC can only be diagnosed endoscopically. The endoscopic classification of the non occlusive IC defines the severity and therapeutical option: In IC grade I and II a primary endoscopic therapy with follow-up controls will be successful besides other measures; in grade IV a primary surgical intervention dependent of the operability is always indicated. In the intermediate stage grade III an individual decision in coordination with the surgeon is necessary. "P P 9 0189"P 9 0189 **Endoscopic and Pathological Examination of Colorectal Lesions in Immunocompromized Hosts**

*J. Haruta, K. Kusugami[1], T. Yamaguchi[1], M. Ito[2], Y. Oka, K. Kusakabe, Y. Samejima, N. Takeda, K. Nobata, T. Okada, H. Saito[1]

Department of Gastroenterology, the Japanese Red Cross Nagoya First Hospital, Nagoya, Japan

[1] First Department of Internal Medicine, Nagoya, Japan

[2] Department of Pathology, Nagoya University School of Medicine, Nagoya, Japan

Purpose This study aimed to characterize pathological and immunohistochemical findings in the colonoscopic biopsy specimens obtained from two cases of graft versus host disease-associated colitis after bone marrow transplantation and one case of cytomegalovirus (CMV) induced colitis.

Materials and Method The examined cases included a 13-year old male with acute lymphocytic leukemia (case 1) and a 13-year old male with non Hodgkin lymphoma (case 2) who had watery diarrhea and anal bleeding after bone marrow transplantation and a 42-year old female with aplastic anemia who had hemorrhagic diarrhea after immunosuppressive therapy with ALG, CsA, anabolic steroids, and G-CSF (case 3). Colonoscopic biopsy specimens were obtained from the lesion and were immunohistochemically stained with monoclonal antibodies against CD3, CD45RO, L26, and CD43.

Results Colonoscopic examination showed hemorrhage, edema, and erosion in the rectum and sigmoid colon in case 1 and 2. Histological sections of biopsies (HE) showed apoptotic lesions on crypt basement membrane. Most infiltrating cells were matured memory T lymphocytes with CD43 and CD45RO. In case 3, colonoscopy revealed solitary ulcer with round wall in the anterior wall of the rectum. Histological section (HE) disclosed two CMV inclusion bodies around the venules in the lymphocyte infiltrated region, and anti-HRP-C7 antibody was positive in the serum. We diagnosed the lesion as rectal ulcer formed by CMV reactivation.

Conclusion In immunocompromized hosts with intestinal hemorrhage, detailed histological examination of colonoscopic biopsies may be useful in understanding the pathogenesis of colonic lesions as well as decision of therapeutic plans. "P P 11 0208"P 11 0208**The Role of Ultrasound (US) in the Detection of the Colonic Cancer in the Elderly**

*C. Petrogiannopoulos, A. Zacharof, A. Tzoumani, J. Panagopoulos, N. Papageorgiou, J. Poulikakos

2nd Department of Medicine, Hellenic Red Cross Hospital, Athens, GreeceUsually colonic malignancies are investigated with barium enema (BE) colonoscopy or both of it.

The aim of the study was to evaluate the efficacy of the ultrasound (US) of the abdomen in the detection of these colonic lesions in elderly people.

Material and methods We studied 42 old patients (32 men and 10 women m. age 78 – 6 years old) who were suspected for colorectal cancer. Ultrasound of the abdomen has been performed before doing BE or colonoscopy.

Results A colonic lesion was identified on US in 39/42 (92.8%) patients. In 36/42 (85.7%) this was correct for the site and nature of the lesion. In four patients the nature was correct but the site was fault and in three patients which had cancer in the sigmoid colon with BE, the lesion was missed on US.

Conclusions The above data show that with US we can detect the colonic cancer in 85.7% of patients. It cannot be the main examination but it can complete the BE or the colonoscopy and it may be very useful in the elderly or in a difficult patient. A bigger number of patients is required to confirm the exact value of this noninvasive procedure. "P P 11 0209"P 11 0209**Comparison of Endorectal MR Imaging and Transrectal Ultrasound with Pathology in Rectal Tumors**

*H. Sch\'e4fer[1], A. Gossmann[2], W. Heindel[2], K. Lackner[2], A.H. H\'f6lscher[1]

[1] I Department of Surgery, University of Cologne, Germany

[2] I Department of Radiology, University of Cologne, Germany*Purpose*To study the accuracy and limitations for staging rectal lesions by comparing endorectal MR imaging with transrectal ultrasound and histopathological correlation.*Material and Methods*19 patients with known rectal lesions underwent MR imaging with an endorectal surface coil and transrectal ultrasound. All patients underwent biopsy before imaging.*Results*Transrectal ultrasound and endorectal MR imaging allowed an evaluation of the normal rectal wall and separation of ist layers. The depth of wall invasion by rectal tumors was correctly staged with MR in 16/19, with Ultrasound in 17/19 and with both methods in 15/19 tumors. In the detection of perirectal adenopathy use of ultrasound as well as MRI enabled correct indentification of positive perirectal nodes only in 1/3 patients; both imaging methods gave one false positive and one false negative result.*Conclusion*Endorectal imaging methods are especially helpful for staging in patients with an adenoma or a T1 tumor where the abdomino-perineal resection of the rectum can be avoided. While MR imaging is more expensive technically as well as financially as compared to endorectal ultrasound, it is well accepted from clinicians due to objective documentation of findings. "P P 11 0210"P 11 0210**Hidrocolonic Ultrasonography in the Detection of Tumoral Processes in the Inferior Gastrointestinal Tract**

*J.M. Segura, E. Molina, M.A. Berges, A. Herrera, J.C. Erdozain, P. Conde, J.M. Su\'e1rez de Parga

Departments of Gastroenterology, La Paz Hospital, Madrid, Spain

Objectives To determine the value of hidrocolonic ultrasound (H.U.) in the detection of proliferative lesions in the colon and to compare it with other techniques of already proven value.

Material and Methods We performed a prospective blinded trial including 155 patients (82 males and 73 females) with ages ranging from 33 to 94 years (average of 58) and clinical, analytical criteria suggesting the existence of colonic proliferative lesions. Patients with rectal mass or those with deficient bowel preparation were excluded.Ultrasound findings were compared to those obtained by colonoscopy (133 cases) and by barium RX studies (22 cases) and all diagnoses were always confirmed by histologic exams.

Results 165 patients were studied. 50 of them had cancer and 46 of these 50 were diagnosed by H.U. (92%) 26 had polyps > 7 mm. and 15 of these polyps were diagnosed by H.U.H.U. failed to detect all the polyps < 7 mm.. The overall sensitivity, specificity, positive predictive value, negative predictive value for identifying colon carcinoma were 92%, 98%, 95.8% and 96.2% respectively and for polyps > 7 mm. were 78.9%, 100%, 100% and 97.1% respectively.The mean time for examination was 14 minutes. Tolerancy was good in 114 patients (73.5%), 29 showed a slight discomfort (18.7%) and 12 (7.7%) showed a great discomfort. There were no complications. 49.7% of the patients had complete studies and 68.6% had satisfactory studies.

Conclusions H.U. is an inocous, fast, well tolerated technique for detecting colonic proliferative lesions > 7 mm. Its usefulness was limited for detecting lesion < 7 mm.H.U. can be considered as a useful complementary technique to other more expensive and invasive such as barum RX studies and colonoscopy Radiology and ultrasound: Diagnosis }" "Hidrocolonic Ultrasonography in the Detection of Tumoral Processes in the Inferior Gastrointestinal Tract"

"P P 11 0211"P 11 0211**Endoscopic Ultrasonography in the Diagnosis of Submucosal Lesions of the Large Intestine**

*H. Kameyama, H. Goto, S. Hase, Y. Niwa, T. Arisawa, K. Nishimura, N. Hasegawa, M. Matsui, N. Nomura, Y. Naito, T. Hayakawa

Second Department of Internal Medicine, Nagoya University School of Medicine, Nagoya, Japan

Purpose Submucosal tumors and extraluminal tumorous compression by neighboring organs and lesions are sometimes difficult to detect by x-ray or endoscopic examinations. In this study, we discuss the usefulness of endoscopic ultrasonography (EUS) in the diagnosis of submucosal lesions of the large intestine by the determination of their imaging characteristics.

Materials and Methods From September 1989 to April 1996, EUS was performed in 44 patients who were suspected to have submucosal lesions in the large intestine by x-ray and endoscopic examinations. The EUS systems used in this study were the Olympus CF-UM3/UM20 and the Aloka MP-PN 15-08L (ultrasound probe). Of the 44 patients, 26 were confirmed histologically by endoscopic or surgical resections, and their EUS images were compared with resected materials.

Results Lipomas (n = 15) were visualized as hyperechoic masses located in the submucosa. Lymphangiomas (n = 9) were visualized as cystic lesions with septal structures located in the submucosa. The ultrasonographic images of leiomyomas (n = 6), leiomyosarcomas (n = 3) and enteric endometriosis (n = 7) were all hypoechoic lesions located in the muscularis propria. Leiomyosarcomas tended to be larger and more inhomogeneous than leiomyomas (mean 47 mm: 14 mm). The shape of enteric endometriosis was round like myogenic tumors when the size was small; but large lesions were shaped like a spindle or a half-moon. On the other hand, myogenic tumors were lobulated. EUS images of recurrence of colorectal carcinomas (n = 3) showed hypoechoic masses with irregular borders in the muscularis propria. Appendiceal mucocele (n = 1) was extraluminally observed as a hypoechoic mass with hyperechoic spots.

Conclusion EUS is useful in the diagnosis of submucosal lesions of the large intestine and can have an important role in the choice of therapy as it provides precise information about their sizes, layers of origin and nature. "P P 11 0212"P 11 0212**Evaluation of Endosonography for the Diagnosis of Rectal Cancer**

*N. Joksimovik, V. Serafimoskic, M. Neshkovski, D. Trajanovski, M. Miloshevski, R. Popova Jovanovska, J. Mishevcki, M. Genadieva, K. Stardelova

Clinic of Gastroenterohepatology, Medical Faculty, Skopje, MacedoniaBetween March 1990 and May 1996, endosonography was used as a complementary method in 377 patients with symptoms as perianal pain, rectal bleeding, change in bowel habit and tenesmus that had been investigated at the Clinic. Rectal cancer was diagnosed by endoscopy and pathohistologically confirmed in 221 cases. Endosonography was performed in all cases and I Grade neoplastic infiltration was found in 17 cases (resectable cases), II Grade neoplastic infiltration (resectable cases) in 75 cases and III Grade neoplastic infiltration (irresectable cases) in 129 cases. Endosonographic findings have been correlated with the pathohistological specimens after surgery, according the modified Dukes classification for rectal cancer, and high accuracy was obtained (92%). In 156 out of 377 patients, endosonography revealed 69 uterus tumors, 58 prostate tumors, 21 ovarial tumors, 3 perirectal abscesses, 2 Hirschsprung's disease, and volvulus of the sigmoid colon in one patient.The utility of endosonography is evident, the method is non-invasive, there are no contraindications, permits precise evaluation of the rectal cancer extension as well as the diseases of the neighboring organs. "P P 11 0213"P 11 0213**Evaluation of Endoscopic Ultrasonography for the Diagnosis of Early Colorectal Cancer Invasion**

*K. Kobayashi, T. Katsumata, K. Yokoyama, H. Takahashi, M. Kida, M. Igarashi, K. Saigenji, Y. Otani, Y. Hiki, H. Mitomi, I. Okayasu

Dept. of Gastroenterology, Surgery, and Pathology, Kitasato University East Hospital, Sagamihara, JapanThe purpose of this study was to evaluate the effectiveness of endoscopic ultrasonography (EUS) in the differential diagnosis between mucosal and submucosal invaded colorectal carcer (so called early colorectal cancer). Colorectal cancer limited to the mucosa (m-cancer) can be treated completely by only endoscopic polypectomy, but submucosal invaded cancer (sm-cancer) have a risk of lymphnode and distant metastasis except of lesions with minute invasion into the submucosa, so most sm-cancers were suitable for surgical operation.

Subjects & Methods We performed EUS for 75 lesions of m-cancers and 65 lesions of sm-cancers. EUS diagnosis of the depth of invasion were compared with histological findings of the resected specimens. The instruments employed were CF-UM3 (7.5 MHz and 12 MHz) and UM-3R (20 MHz) (Olympus).

Results 1) The depth of invasion of early colorectal cancer was accurately diagnosed by EUS in 89% (67/75 lesions) in m-cancers and 74% (48/65 lesions) in sm-cancers respectively. Generally early colorectal cancer with mucosal or minute submucosal invasion (Group A) are treated endoscopically and cancer with massive submucosal invasion (Group B) are suitable for surgical operation. The differentiation between Group A and Group B was possible in 92% (129/140 lesions) successfully. 2) The correct diagnostic rates for lesions of the descending – ascending colon was 78% (21/27 lesions), which were poor when compared to the others. Diagnostic accuracy of each macroscopic form of the lesion were almost of the same. 3) The reasons of incorrect assessment for diagnosing early colorectal cancer invasion by EUS were microscopic tumor infiltration, peritumorous fibrotic reactions and incomplete visualization of the lesions.

Conclusion It was concluded that EUS is useful in diagnosing the depth of early colorectal cancer invasion and in planning therapeutic methods (endoscopic polypectomy or surgical operation). Oncology, specific: Colon, rectumEchoendosonography: Echoendoscopy }"

[2] Department of radiotherapy, Centre Hospitalier Lyon Sud, 69495 Pierre Benite, France

Aim to compare the prognostic values of pretherapeutic clinical and endosonographic stagings for squamous cell anal carcinoma.

Methods From sept 87 to june 95, 57 patients with squamous cell anal carcinoma (51 F, 6 M, mean age 63 years, range 42–88), were evaluated by transanorectal ultrasonography (TRUS), before combined chemotherapy and radiotherapy treatment. We used a 7 Mhz Bruel & Kjaer echoprobe. Clinical staging was assessed by digital evaluation according to the UICC 87 classification.

ResultsI – Nine tumors in clinical stage cN0 had an involvement of lymph nodes at ultrasound examination. All lymph nodes missed at clinical evaluation were located at more than 8 cm from the anal margin. 10% of cT1 tumors had lymph node involvement at ultrasound examination, versus none of the tumors staged uT1. II – Three years disease specific survival rates failed just short of being significatively different between uN0 and uN1 stages (97.4% vs 85.4%), whereas the difference was far from being significatively different between cN0 and cN1 stages (91.2% vs 88.2%). III – Concordance between cT and uT stages was low ({ k} = 0.37) and none of the two classifications was more accurate in predicting patients outcome, perhaps due to the low number of cancer related deaths (5) during the follow-up.

Conclusions TRUS is more accurate than digital evaluation in detecting peri-rectal lymph node involvement, specially for nodes distal to the anal margin. As this factor seems to be the most closely related to the patients survival in our study, TRUS appear warranted in the pretherapeutic staging of squamous cell anal carcinoma. "P P 11 0215"P 11 0215**Magnifying Colonoscopic Findings Reflect Mucosal Inflammation in Ulcerative Colitis Patients**

*M. Shinoda, H. Yamamoto, M. Ohsuga, T. Hosokawa, A. Imada, T. Shimizu, T. Yamaguchi, T. Ando, K. Ina, K. Kusugami

First Department of Internal Medicine, Nagoya University School of Medicine, Nagoya, Japan

Purpose We sometimes encounter a discrepancy between conventional colonoscopic findings and histological activity in ulcerative colitis (UC) patients. Therefore, in the present study, we evaluated the pit pattern of rectal mucosa affected with UC using magnifying colonoscopy (MCS) and compared the MCS findings with histological findings or the levels of IL-6 and soluble IL-6 receptor (sIL-6R) secreted in the organ culture supernatants.

Patients and Methods Twenty-nine UC patients (13 males and 16 females, mean age 33 years) were evaluated. Ten patients had total colitis, 13 had left-sided colitis and 6 had proctitis. After preparation with polyethylene glycol electrolyte lavage, the rectal mucosa was observed by MCS (Fujinon EC410CM) after 0.1% methylene blue staining. The pit pattern was classified into 4 grades; Grade 1: small round pits with regular arrangement, Grade 2: slightly deformed and large pits with slight irregular arrangement, Grade 3: various shaped pits with irregular size and arrangement, Grade 4: scattered pits with various shape and size.

Results MCS-grades showed a correlation with histological inflammatory indexes (mononuclear cell infiltration, polymorphonuclear cell infiltration, enterocyte loss, crypt inflammation, glandular atrophy and goblet cell depletion). MCS-grades also showed a correlation with IL-6 levels (ng/mg biopsy protein; median, Grade 1: 93, Grade 2: 410, Grade 3: 634, Grade 4: 592) and sIL-6R levels (median, Grade 1: 6.3, Grade 2: 34.0, Grade 3: 59.9, Grade 4: 68.4) in the organ cultures.

Conclusion MCS grades reflect histological inflammation and inflammatory cytokine activity. MCS may be useful in the follow-up and evaluating drug effects in UC patients. Intestinal disorders: IBD diagnosis, monitoringEndoscopy, general: Instrumentation, diagnosis }"

"P P 11 0216"P 11 0216**Effect of Addition of Cisapride to Colonoscopy Preparation with Polyethylene Glycol Solution. A Prospective Single-Blind Randomized Trial**

*G. Gizzi, V. Stanghellini, M. Cianci, V. Villani, K. Jadallah, G. Elia, A. Ferri, A.M. Morselli Labate, R. Corinaldesi

Department of Internal Medicine and Gastroenterology, University of Bologna, Italy

Purpose We assessed the effect of the addition of cisapride (CIS) to colon lavage with polyethylene glycol (PEG) solution.

Methods In a prospective single-blind study, 157 consecutive outpatients scheduled for total diagnostic colonoscopy were prepared with two different regimens. The day before endoscopy, the patients (pts) were randomly allocated to two different cleansing preparations: a) 73 pts (37 M, 36 F: 56.3 – 16.0 yrs, mean age – SD) received 4 litres of PEG solution; b) 84 pts (34 M, 50 F: 56.6 – 16.1 yrs) received PEG as above with the addition of oral CIS 20 mg b.i.d. Before colonoscopy, pts completed a questionnaire about the presence and severity of four symptoms: abdominal cramps, nausea, vomiting and dizziness (scale from 0 to 3: 0: absent, 1: mild, 2: moderate, 3: severe). The quality of colon cleansing was semiquantitatively scored 0 to 3 (0: poor, 1: fair, 2: good, 3: excellent) by an endoscopist who was unaware of the administered preparation.

Results The presence of symptoms (score {\'b3} 1) and the frequency of good-excellent colon cleansing (score {\'b3} 2) are shown in the table. Preparation Cramps Nausea Vomiting Dizziness Cleansing(no. pts) % % % % %PEG (73) 6.8 34.5 11.0 8.2 54.8*PEG + CIS (84) 9.5 24.7 4.8 7.1 75.3**p < 0.01. Mann-Whitney U test.

Conclusions The addition of cisapride to the colonic preparation with PEG solution results in a significantly better colon cleansing, without significant changes in symptoms related to PEG ingestion. "P P 11 0217"P 11 0217**The Clean Colon — Is Cisapride Useful in Preparation for Colonoscopy?A. Nagorni, T. Tasic, H. Milovanovic, S. Petrovic-Nagorni**

Clinic for gastroenterology Faculty of medicine Nis, YugoslaviaThe clean colon is important factor for safety and accurate diagnostics during colonoscopy. Sometimes, residual fecal or/and liquid contents make colonoscopy difficult for performing. Cisapride is a powerful prokinetic drug and has been shown to enhance propulsive motor activity of the entire gastrointestinal tract, including colon. The aim of our study was to analyse the role of cisapride in preparation of patients for colonoscopy, measuring volumes of residual liquid content in colon after preparation with 3 litters of electrolyte lavage solutions. There were 2 groups of patients: I group – 52 patients in whom 10 mg cisapride was administrated 30 minutes before preparation with electrolyte lavage solutions, II group – 51 patients in whom cisapride was not administrated. Residual liquid was aspirated through working channel of colonoscope and volumes were measured in ml. In I group fecal contents were observed in 4 (7.6%) patients and residual liquids in 7 (13.4%) patients. Residual liquids were measured 10 to 150 ml (mean 35 ml). In group II, fecal contents were observed in 9 (17.6%) patients and residual contents in 22 (43.1%) patients. Residual liquids were measured 35 to 350 ml (mean 85 ml). Patients in group II had statistically more frequent residual liquids than patients in cisapride group – group I ($p < 0.05$). Residual liquid volumes were higher in group II than in cisapride group ($p < 0.05$).

Conclusion Enhancement of the colon propulsive motor activity by cisapride improves preparation for colonoscopy with electrolyte lavage solutions. Colonoscopic preparation with addition of cisapride may reduce time for performing and may reduce risk for complications during colonoscopy. Endoscopy, general: Preparation, managementEndoscopy, specific: Colon, rectum }" "The Clean Colon / Is Cisapride Useful in Preparation for Colonoscopy?"

"P P 11 0218"P 11 0218**A Randomized Prospective Trial Comparing 45 and 90-ml Oral Sodium Phosphate with X-Prep in the Preparation of Patients for ColonoscopyS. \'dcnal,**

*\'dc.B. Dogan, Z. \'d6zt\'fcrk, M. Cindoruk

Gazi University, Faculty of Medicine, Department of Gastroenterology, Ankara, TurkeyForty-six patients were randomized to receive either 45 or 90-ml oral sodium phosphate (NaP) (Fleet Phospho-Soda), or X-Prep (a Senna preparation) before elective colonoscopy to compare the quality of colon cleansing, ease of preparation, and gastrointestinal intolerance. Before colonoscopy, one of us administered a questionnaire to the patient to assess how well the preparation was tolerated (scale from 1 to 5: 1 = easy, to 5 = unable to finish) and about the presence of four symptoms: abdominal pain, nausea, vomiting, and dizziness. The quality of colon cleansing was graded by two gastroenterologists (1 = excellent, 2 = good, 3 = fair, 4 = poor), who were unaware of how the patient was prepared or tolerated the preparation. The overall quality of bowel preparation with 90-ml oral NaP was better than with X-Prep and 45-ml NaP ($p < 0.01$). Patients found preparation with NaP to be easier than X-Prep ($p < 0.002$). No difference was seen in the incidence of abdominal pain, nausea, vomiting or dizziness. In the 90-ml NaP group, a significant rise in sodium and chloride occurred. However, increments were not greater than 5%. Hyperphosphatemia was noted with NaP, but was transient, and no concomitant decrease in calcium was seen. We conclude that, in the groups of patients studied, 90-ml NaP is a safe colonic cleansing agent that is better tolerated and more effective than others. Endoscopy, general: Preparation, management }" "A Randomized Prospective Trial Comparing 45 and 90-ml Oral Sodium Phosphate with X-Prep in the Preparation of Patients for Colonoscopy"

"P P 11 0219"P 11 0219**Urgent Colonoscopy for Melena in Children**

*K. Hazama, T. Amatsu[1], H. Kitae, M. Ando, H. Tsujiguchi, T. Yonehara, S. Koyama, C. Shimamoto[2], Y. Takao, Y. Tahashi, I. Hirata, K. Katsu

[1] Hirakata Municipal hospital, Osaka, Hirakata, Japan

[2] 2nd Dept of Int Med. Osaka Medical College, Osaka, Takatsuki, Japan

Background Colonoscopic examination is the first choice for melena in adult patients today. But for children's cases it was very difficult to perform colonosopic examination because of that their lumen were narrow and fragile, and children could not well understand the necessity of the examination. Recently, as the improvement of endoscopic instruments and insertion technics, we are able to do it easily. So in the present study, we evaluated the usefulness of urgent colonoscopy for melena in children.We studied the cases of 47 children with melena who received colorectal endscopy at our department during a five period between August 1989 and July 1993. Of these 47 children, 36 (77%) were found to have some underlying disease. Colorectal polyps were seen in 6 cases (including 5 cases of juvenile polyps). Colorectal polyps were the most frequent underlying disease for children between 1 and 5 years of age. Ulcerative colitis and Crohn's disease were seen in the children in their early youth (over 11 years of age). Lymphfolliculosis had the highest prevalence (7 cases) in the population studied. This disease was seen in all age group, with a particulary higher incidence in infants younger than 12 months.Colorectal endoscopy seems to provide a useful means for the diagnosis and treatment of melena in children. "P PP0 0224"PP0 0224 **Diagnosis of Invasion of Superficial Esophageal Carcinomas by Infrared Electronic Endoscopy**

*H. Iishi, K. Iseki, M. Tatsuta

Department of Gastrointestinal Oncology, Osaka Medical Center for Cancer and Cardiovascular Diseases, Osaka, JapanSuperficial esophageal carcinomas (SEC) were defined as those which were confined to the mucosa or the submucosal layer with or without lymph nodes metastasis. The depths of involvement of SEC were classified as follows: m_1, intraepithelial; m_2, intramucosal not in contact with the muscularis mucosae; m_3, intramucosal in contact with the muscularis mucosae; sm, submucosal. Because SCE confined to m_1 or m_2 seldom have lymph nodes metastasis, they are thought to be curable by endoscopic resection only. Therefore, it is very important to differentiate SEC of m_1 or m_2 from others. However, it is not always easy to diagnose their depths exactly, especially in intramucosal cancers.Infrared images were obtained through the electronic endoscope (GIF-Q200IR, Olypmus) in which the infrared cut filter was removed, combined with the light source in which the narrow band filter for infrared range was inserted before the xenon lamp. After the routine endoscopic examination including iodine staining, i.v. bolus injection of 2 – 5 mg/kg body weight of indocyanine green (ICG) was given to intensify the infrared images.We examined 14 SEC in 12 patients (10 males and 2 females) by the infrared electronic endoscopy. In all of 8 SEC of m_1 or m_2, the entire lesions were uniformly stained after ICG injection. However, in 6 SCE of m_3 or sm, the lesions were partially stained after ICG injection.In conclusion, the infrared electronic endoscopy is very useful in differentiation of SCE of m_1 or m_2 from those of deeper invasion. "P PP0 0225"PP0 0225 **Endoscopic Injection of Mitomycin Adsorbed on Carbon Particles for Advanced Esophageal Cancer: A Pilot Study**

*M. Ortner, A. Buchali, F. Noak, S. Dinges, S. Schreiber, J. Wirth, H. Lochs

4th Med. Department, Charit\'e9 Univ., Berlin, Germany

Background Dysphagia is the main problem for patients with advanced nonresectable esophageal tumors. Local palliation can be achieved by laser therapy, brachytherapy or stent placement. The

Aim of this study was to evaluate the efficacy of local injections of mitomycin adsorbed on activated carbon particles (MMC-CH) in nonresectable esophageal carcinomas. The primary outcome parameter was time to local tumor progress, secondary parameters were dysphagia, Quality of Life (Karnofsky index) and survival time.

Methods 10 Patients with esophageal carcinoma stage IV (age: median 58 a (95% CI: 42–78), tumor length 10.7 (5–15)) received four weekly injections of 10–15 mg MMC-CH via a 5 mm sclerotherapy needle into endoscopically visualised tumor. Tumor staging (chest CT, endosonography, gastroscopy, esophagogramm), symptom scores, and life quality index, were performed before and bi-monthly after therapy. The results were compared with 10 historical controls from the same center (4 Stage IV, 6 stage III, age 67 a (55–96), tumor length 6 cm (4–10)) who were treated immediately before the study by implantation of nitinol stents (Ultraflex, Boston Scientific Inc.).

Results Local injections were tolerated well with no side effects. Median time to local tumor progress was longer in the MMC-CH group (Fig.). Dysphagia (p = 0.0012) as well as Karnofsky Index (p = 0.0034) improved after MMC-CH (Table). By stenting dysphagia improved as well (p = 0.03, Table) but Karnofsky index did not change (p = 0.21). Median survival time after MMC-CH therapy was 16 weeks (11.7–20.4) versus 4.5 weeks (2.7–14.9) after stenting (p = 0.019).

Conclusions Endoluminal MMC-CH therapy seems to be an effective, well tolerated treatment for nonresectable esophageal tumors which inhibits local tumor progress, improves dysphagia and quality of life. A randomised, prospective study is currently conducted.

"P PP0 0226"PP0 0226 **Is Radiation Useful after Photodynamic Therapy (PDT) of Superficial Esophageal Cancer?**

*Ph. Jacob, R. Lambert, M. Diculescu, F. Descos

Department of Digestive Diseases, Hospital E. Herriot, Lyon, FranceEndoscopic treatment of superficial (T1) esophageal cancer has been proposed as an alternative to surgery, however T1 tumors often enter the submucosa having then a risk (around 35%) of lymphatic invasion. Therefore, a benefit could be expected from a complement regional therapy (radiation). This retrospective non randomized study aims to determine whether radiation after PDT improved the response rate of a superficial esophageal cancer and the 5 year survival rate (5 y.SR)

Methods From 1986 to 1995, 80 patients (74 men and 6 women – age: mean = 63 y. range = 41–82 y.) with squamous cell cancer in the esophagus, staged UT1 N0 at endoscopic ultrasonography, were included in a protocol based upon endoscopic destruction by PDT. The photosensitizer (Photofrin, QLT Canada, 2 mg/kg, or Hematoporphyrin Derivative, Quentron, Australia, 2.5 mg/kg) was injected 72 h. before laser irradiation with 630-nm dye laser (200/300 J/cm2 of tumor surface). –

Group I no other treatment was proposed in 40 patients –

Group II a course of radiotherapy was applied two months later (45 Gy) in the other 40 patients. The tumor response at 6 months was estimated complete in presence of normal or cicatricial endoscopic pattern and negative biopsies. The treatment was repeated in patients with incomplete response. Global and Disease Specific 5 y. SR were computed according to the Kaplan-Meier method.

Results in all patients the mean follow up was 40 months; the respective values for the Global and Disease Specific 5 y. SR were 45.1% – 6.3% and 71.2% – 6.4%.

Results by groups The Complete Response rate at 6 months were similar in Group I (79.4%) and in Group II (86.4%). Recurrences occured after the initial complete response in 9 out of 27 patients in Group I and in 5 out of 32 in Group II. The Global 5-y. SR was 48% – 9% in Group I and 38% – 8% in Group II. The respective values of the Disease-Specific 5 y. SR were 70% – 9% and 71% – 8%.

Complications – in relation to PDT: esophageal stricture in 22 and cutaneous photosensitization in 7. – in relation to radiation (Group II): radiodermatitis in 3 and pericarditis in 2.

Conclusions The 45% Global 5 y. SR suggests that endoscopic treatment (PDT) is an acceptable alternative to surgery in superficial (UT1, N0) esophageal squamous cell cancer. This study does not show a benefit from addition of radiotherapy after endoscopic treatment. "P PP0 0238"PP0 0238 **Investigation on Endoscopic Treatment of Early Gastric Cancer**

*H. Takahashi, T. Kojima, R. Fujita

Department of Gastroenterology, Fujigaoka Hospital, Showa University Yokohama, Japan

Purpose Evaluation of the endoscopic treatment of early gastric cancer.

Material and method The cases included in this study were 131 in total, 101 cases received Endoscopic Resection (ER) only, 16 cases were followed by surgical resection and the rest 14 cases received Laser therapy after ER. The indication for Resection ""en bloc"" was determined by the depth of invasion and the size of the lesion.

Results In the protruded type, 22 of the 30 lesions limited to the mucosa (m-cancer) less than 10 mm were resected totally. In relation to the lesions invading the submucosal layer (sm-cancer), 1 case was resected totally and the other one underwent piecemeal resection. Among the lesions of 11–20 mm in size, 12 cases were resected totally and the rest 15 cases were piecemeal resected. 31 of 43 of the depressed lesions less than 10 mm were resected totally and in the rest 12 cases piecemeal resection was performed. Evaluating the recurrence rate of these lesions, we found that 6 cases were multiple cancers and in 4 cases a new focus was detected during the follow up after ER. This represents about 8% of the total.

Conclusions Considering the efficacy of the ER, no local recurrence or distal metastasis were found in those which the surgical margin was sufficient. It was possible to resect horizontally even the m-cancers by piecemeal resection. In the piecemeal resected cases there is the possibility of local recurrence so we consider necessary to add surgical resection or at least continue a sufficient follow with those patients not allowed to received surgical treatment. Furthermore we encourage to continue following the patients, even those with total resection because of the possibility of newer findings. "P PP0 0255"PP0 0255 **Follow-Up with Colonoscopy after Polypectomy. A 15 Years Prospective Study**

*O. Croizet, J. Moreau, M. Delvaux, J. Salcedo, J. Frexinos, J. Escourrou

Department of Gastroenterology, Rangueil Hospital, 1 avenue J. Poulhes, 31054 Toulouse Cedex, France

Introduction The adenoma-carcinoma sequence is now well established. This fact has provided a basis for the excision of all polyps detected at colonoscopy. Indeed the risk for invasive colorectal cancer may be lowered by this polypectomy. The risk of new polyps is high after polypectomy and these patients are at risk for further colorectal cancer.

Objective The aim of this study was to evaluate the incidence of metachronous polyps after polypectomy and to identify factors of recurrence.

Methods 840 patients (582 male and 258 female with a median age of 58 years) with no prior history of polyps or colon cancer had a complete colonoscopy with removal of all polyps detected and were included in a follow-up study. 1339 polyps were excised (mean 1.59 – 0.96 polyps/patient, range 1 to 5), 2% were juvenile polyps, 11% of patients had only hyperplastic polyps and 87% had at least one adenoma (105 patients had a malignant adenoma, 67% with non invasive carcinoma, 23% with invasive carcinoma). The mean time of follow-up was 53.6 months (range 3 to 120) for the 72% of patients who had at least one endoscopic control examination (mean 2.6, range 1 to 12).

Results The cumulative rate of metachronous polyps was 12% at 1 year, 30% at 2 years, 50% at 3 years, 62% at 5 years and 76% at 10 years. Most of these new polyps were small (mean 4.93 – 3.45 mm) adenomas with mild dysplasia. Number of adenomas at index colonoscopy and age of patients at entry were the only risk factors for further adenomas ($p < 0.001$). 5% of patients developed adenomas with severe dysplasia. The only risk factor for severe lesions was the number of adenomas at entry ($p < 0.02$). Sexe, family history, nature (villous or not), grade of dysplasia and size of polyp were of no value in predicting the occurrence of further adenomas or severe lesions.

Conclusions The cumulative risk of polyps after polypectomy is about 50% at 3 years. Age and number of adenomas at index colonoscopy were the only predictive factors of metachronous polyps. As the surveillance should not be increased with age of the patient, the follow-up strategy should depend on the number of polyps at index colonoscopy. "P PP0 0257"PP0 0257 **Correlation between Colonoscopy and CT-Based Virtual Endoscopy (VE) in Detecting Space-Occupying Lesions of the Colon**

*L. Aabakken[1], C.L. Kay[1], H. Evangelou[1], R.H. Hawes[1], P. Tarnasky[1], P.B. Cotton[1], J.R.W. Young[2]

[1] Digestive Disease Center, Medical University of South Carolina, Charleston, USA

[2] Dept of Radiology, Medical University of South Carolina, Charleston, USA

Purpose Colonoscopy is currently regarded as the most accurate technique of diagnosing colonic lesions, but an ideal method would be safe, simple, sedationless and non-invasive. Recently, a new technique has been described which combines abdominal spiral CT scanning and virtual reality computer technology — known as virtual colonoscopy (VC). The reconstructed images provide a simulation of the interior of the colon as viewed by endoscopy. The purpose of our study was to compare VC to conventional colonoscopy in patients with suspected or known space-occupying lesions of the colon.

Patients/methods Seventeen patients, in whom there was a high likelihood of colonic polyps or cancer, underwent a non-contrast spiral CT scan (Picker PQ5000) of the abdomen after regular colonoscopy bowel preparation. The colon was distended by rectal air insufflation via an enema tube, and i.v. glucagon was administered to paralyze the bowel. A continuous volume CT dataset of the abdomen was reconstructed and reformatted into the VE presentation (Epi-scope') by one of the investigators blinded to the results of other imaging. A regular colonoscopy was performed on the same day by an experienced endoscopist, and the studies were documented with standardized videotape recording.

Results VC correctly identified the three patients with normal findings on colonoscopy, one patient with fecal loading, four with diverticulosis and all four lesions > 8 mm in diameter. VC failed to detect all but one polyp < 8 mm. Also, there were two false positive diagnoses on VC, which were an ""ascending colon structure"" (focal spasm) and a ""cecal polyp"" (prominent ileocecal valve).

Conclusions Our initial results show that virtual colonoscopy is technically feasible and capable of detecting lesions > 8 mm in size. Current technology may miss small polyps but with further developments in computer software, virtual endoscopy may supplant colonoscopy in the detection of space-occupying lesions of the colon. "P PP0 0258"PP0 0258 **Endosonographic Evaluation of Fistula-In-Ano**

*H. Hudziak, C. Goudot, J.P. Bronowicki, P. Loudu, C. Claviére, L. Chone, M.A. Bigard

Service d'HGE, CHU de Nancy, 54 511 Vandoeuvre, FranceSuccess of surgery for anal fistula depends on accurate assessment of the fistula. Unidentified primary opening is a significant factor associated with recurrence. In the literature, the site of primary opening is identified by anal endosonography (AES) in 30 to 80% cases. Our aim is to report our experience with AES evaluating 40 cases of suspected perianal abcesses and fistulas.

Methods From November 1994 to April 1996, 40 patients admitted to our hospital with the preoperative diagnosis of perianal sepsis were evaluated with the aid of AES (Br\'fcel and Kjaer type 1846 anal endoprobe with a 7-MHZ transducer). The primary opening was determined as the contact between fistula tract and internal sphincter. EAS findings were then compared with surgical findings with respect to Park's classification.

Results AES identified a fistula/abscess in 35 patients. At surgery, 32 patients were found to have abscess/fistula in ano: 10 high and 16 low transsphincteric fistulas, 2 intersphincteric abscesses and 4 complex fistulas. In 8 cases, no fistula was identified: Verneuil disease (n = 1), sepsis of perineal gland (n = 2), infected fissure (n = 1), miscellaneous (n = 4). The sensitivity, specificity, and positive and negative predictive value of AES in the diagnosis of anal fistulas/abscesses were 100%, 62.5%, 91.4% and 100%. There was an exact correlation between operative and AES findings with regard to the location of primary opening in 30/32 patients (93.7%) and to the relationship between the fistula level and the sphincter mechanism in 23/26 patients (88%) with high or low transsphincteric fistula.

Conclusions AES is a simple and inexpensive technique which is able to assess correctly the location of primary opening and thus to decrease the rate of fistula-in-ano recurrence. The good correlation according to Park's classification allows to predict and to influence operative techniques. Intestinal disorders: Anorectal disordersEchoendosonography: Therapy }"

"P PP0 0261"PP0 0261 **Transvenous Obliteration of Porto-Systemic Shunt (Tops) for Control of Solitary Gastric Varices**

*H. Kakutani, J. Sanada, Y. Tsukioka, T. Itoi, K. Takei, K. Takeda, Y. Shinohara, T. Saitou

Department of 4th Internal Medicine, Tokyo Medical College Hospital Tokyo, Japan

Purpose Gastric varices (GV) are usually associated with gastrorenal shunt. Using this hemodynamic factor, the author performed TOPS, a new method for eradicating GV. In this study we present techniques of TOPS and evaluate the efficacy between TOPS and endoscopic injection sclerotherapy (EIS).

Patients 43 patients with solitary GV were included in this study. 28 patients of them were examined by TOPS and 15 patients were treated with EIS.

Methods of TOPS Each patient received insertion of balloon-catheter through right internal jugular vein and balloon was finally located at shunt vessel as blood outlet of GV that is connected to greater circulation. The shunt vessel was obliterated by retrograde transvenous infusion of 5% ethanolamine oleate (EO).

Results Disappearance of GV was recognized in all patients in the EIS group (100%), and 26 patients in TOPS group (92.9%). The rate of rebleeding in the EIS group within 1 year, 3 year, and 5 year was 42%, 57%, and 57%, respectively. Both rebleeding and recurrence of varices did not occurred in all patients in the TOPS group through observation period (1 month–44 months, mean 17.8 months). The average volume of sclerosant per session was 18.4 ml in the EIS group, and 22.7 ml in the TOPS group. The duration of the treatment showed significant difference between the EIS and TOPS groups (2.8 weeks vs. 2.46 days). The patients whose GV were associated with inferior phrenic vein or pericardial vein in addition to main shunt vessels received significantly higher volume of EO than the patients in whom GV were not associated with those vein (33 ml vs. 13.3 ml).

Conclusions These results suggest that TOPS as self-retaining catheter method is useful in controlling blood flow of shunt vessels. TOPS could reduce the duration of therapy and eradicate GV without recurrence. "P PP0 0263"PP0 0263 **A New Multiple-Band Ligator (Speedband) for the Endoscopic Treatment of Esophageal and Gastric Varices — Preliminary Results in 63 Applications of a Prospective Ongoing Study**

*J. Hochberger, H. Reh, F. H\'f6rning, C. Ell, P. Martus, E.G. Hahn

Dept. of Medicine I, Inst. of Biomed. Statistics, Friedr.-Alexander-University, Erlangen, GermanyNew multiple-band ligators promise to remarkably simplify endoscopic ligation therapy of bleeding esophageal varices because of no need for an overtube and the rapid consecutive release of 5–8 bands without repeated withdrawal of the endoscope from the esophagus. In the following we report on our preliminary results of 63 applications in 27 pts using the Speedband multiple-band ligator set in a prospective ongoing study for esophageal and gastric varices.

MMP From July 4, 1995 to May 3, 1996 27 pts. (m = 19, f = 8; age m = 51 – 33 y, 35–75; Liv. Ci. Child A/B 24, Child C 3) were included into a first prospective one-arm treatment protocol using the ""Speedband"" (5{ -}) multiple-band ligator for hemostasis or prevention of re-bleeding (eradication) from esophageal (EV) or esophago-gastric varices (EGV). 1 set ({\'a3} 5 bands) per session was used to limit cost practice-oriented (– 100 US $/set). Because we initially observed an early loss of bands within 24 h after correct placement (DMW 1995: 1300–1; DDW 1996#186), control endoscopies were sceduled for: 1 d post and every 5–7 d until ulcer healing or eradication. Retreatment scedule: lig. ulcers {\'a3} 4 mm + varices > grade I; EV or GV or RCS. Controls every 6 weeks after eradication.

Results In 63 treatment sessions 309 bands were applied. (4.7 – 0.95; 3–5). 9 patients had EV only, 18 patients had EGV (9 Sarin I; 2 type II; 7 type I + II). 16 sess. were carried out for acute bleeding, 47 for sess. for eradication treatment. 6 of 16 acute bleeders had active bleeding at index endoscopy (""Fo.la/b""). Definitive hemostasis: 15/16 bleeders. 1 pat. with EGV II rebled from an untreated gastric varix. Loss of bands during treatment: 9/309 (3%), the following day 31% (0–100%). However, no adverse effects on rebleeding rate and eradication so far. Follow-up: m 81 d (\'b1 73 d; 2–252 d) with 20 pts. eradicated after m 2.1 (\'b1 0.7; 1–4) sessions. 3 patients died without signs of rebleeding. Recurrences of EV/GV: 6/20 pts. (22%), m 101 d (\'b1 61; 45–203) after initial eradication = > 4/6 pts. eradicated after +1 treatm. session.

Conclusions Endoscopic variceal ligation using the Speedband multiple-band ligator is a fast and reliable method for hemostasis and eradication of bleeding EV and EGV. Contrary to conventional sets also the ligation of gastric varices (EGV Sarin type II) proved safely possible in 9 pts.. A partially observed loss of bands (m 31%) within 24 h after initially correct placement showed up to now no adverse effects concerning rebleeding rate and time/effect of eradication, probably due to variceal trombosis after initial trauma of the wall. The study is ongoing. Prospective, randomized trials in a larger number of patients are needed to confirm these very promising preliminary data. "P PP0 0270"PP0 0270 **Comparison of Magnetic Resonance Cholangio-Pancreaticography (MRCP) with ERCP; Ultrasound; CT and Endoscopic Ultrasound in Patients with Bile Duct StricturesC. Zillinger,**

*T. R\'f6sch, H. Helnberger, S. Fr\'fchmorgen, P. Born, H.D. Allescher, P. Gerhardt, J.R. Siewert, M. Classen

Dept. of Internal Medicine II, Radiology and Surgery, Technical University of Munich, GermanyMRCP is a new non-invasive technique for visualization of the pancreatobiliary tree. The present study was designed to evaluate its diagnostic accuracy in patients with suspected bile duct strictures in comparison to ERCP and other diagnostic procedures such as ultrasound (US), computed tomography (CT) and endoscopic ultrasound (EUS).In this ongoing prospective study, 75 patients have been included so far, and complete data are available for 36 cases (17 male/19 female, age 33 to 86 years). Patients with suspected obstructive jaundice due to malignant and benign biliary stricture (stones were excluded) were examined by MRCP, ERCP or PTC, CT, US and EUS. Various parameters such as visualization of the stricture, determination of its nature (benign/malignant) and origin (biliary or pancreatic), tumor detection and staging were recorded. Control of findings was by histology (biopsy or surgery), unequivocal signs of malignancy such as liver metastases and/or by follow-up, especially in cases with a benign disorder.21, 11, and 4 patients had malignant, benign biliary obstruction, or a normal pancreatobiliary tract (liver disease). All procedures were performed in all patients except for 1 case of ERCP (not possible) and CT each (rejected by the patient); 13 patients did not undergo EUS for various reasons (mainly patient refusal). MRCP, ERC/PTC, CT, US and EUS reached the following results: Diagnosis of level of obstruction — accuracy 97%, 97%, 91%, 88%, 97%. Diagnosis of malignancy was correct in 88%, 86%, 80%, 60% and 72%. Diagnosis of biliary versus pancreatic origin was correct in 90%, 88%, 84%, 69% and 74%.These results show that MRCP can replace diagnostic ERCP in most cases and can even provide additional information such as about tumor staging. The diagnostic information provide by CT and EUS were consistently inferior.

"P PP0 0271"PP0 0271 **A Clinical Evaluation of MRCP (MRcholangiopancreatography), Compared with ERCP in 60 Cases**

*R. Murakoshi, A. Watanabe, M. Iwano, T. Takino, Y. Mizuma, M. Kobayashi

Yodogawa Christian Hospital, Osaka, Japan

Purpose of the study To determine the role and efficacy of MRCP, we considered the possibility of substituting MRCP for ERCP for the diagnosis of biliary and pancreatic diseases.

Methods used 60 patients with suspected biliary or pancreatic disease were examined. Of these 60 patients, ranging from 21 y.o. to 88 y.o. (average 63.3 y.o.), there were 27 males and 33 females. The type of MRI instrument was the Magnetom Impact Expert (1.0T, Siemens). MRCP was performed with a sequence of Half fourier single shot turbo spin echo (HASTE), and the images were processed by using a Maximum intensity projection (MIP) algorithm. The cases investigated were as follows: diseases of common bile duct – 21 cases, diseases of GB – 27, diseases of the pancreas – 10, and others – 4. All patients were imaged with MRCP within 1 month prior to the attempted ERCP or PTC. MRCP and ERCP images were evaluated together with additional clinical information. When ducts were abnormal, probable causes were categorized as follows: localized duct stenosis, calculas disease, duct anomalies, tumor and cystic disease. First we discussed abnormal findings according to the previous classification, and then discussed the diagnosis.

Summary of results We were able to diagnose each disease as follows. The accurate diagnoses for GB diseases were 70.4% (19 in 27 cases) by ERCP, but 92.6% (25 in 27 cases) by MRCP. Similarly, for common bile duct diseases the statistic showed 92.5% (20 in 21 cases) by MRCP. [Especially the diagnosis for CBD stones was 100% by MRCP, while it was 93.7% by ERCP (15 in 16 cases).] For pancreatic diseases and others the diagnosis showed 100% accuracy both by MRCP and ERCP.

Conclusion reached MRCP is an excellent method for diagnosis in biliary and pancreatic diseases, especially in the diagnosis of stones. "P PP0 0273"PP0 0273 **Treatment of Common Bile Duct Lithiasis, Laparoscopy Versus Endoscopy: Results of a Preliminary Prospective Randomized Trial**

*D. Lucidarme[2], A. Courtade[1], I. Atat[1], N. Corman[1], P. Vandevenne[2], B. Filoche[2], B. Desrousseaux[1]

[1] Gastro-Enterological Department, surgical unit, Catholic University of Lille, St-Philibert's Hospital, Lomme-France

[2] Gastro-Enterological Department, medical unit, Catholic University of Lille, St-Philibert's Hospital, Lomme-France

Aim of the study Treatment of common bile duct lithiasis (CBDL) associated with gallbladder lithiasis can be carried out, either in one laparoscopic operation (A) or by laparoscopic cholecystectomy with pre-operative endoscopic sphincterotomy (B). The aim of this randomized trial was to evaluate feasibility and morbidity of each approach.

Patients and Methods Between January 1994 and September 1995, among 300 cholecystectomies which began by laparoscopy, 86 CBDL high risk patients defined by clinical (jaundice, pancreatic pain) or biological or ultrasonographic (CBD > 7 mm) data were identified and endoscopic ultrasonography was performed. Criteria of exclusion were severe acute pancreatitis or uremic angiocholitis. Randomization between A and B was performed in the case of an endoscopic ultrasonographic image of CBDL. Intra-operative cholangiography was systematic. Trans-cystic extraction was always attempted, otherwise longitudinal choledocotomy with choledocoscopy was carried out. Thirty-two patients (27 F, 5 M), average age 64 years (40–83), average ASA-score 2.3, were included in this study. There were 14 hepatic colics, 4 cholecystitises, 9 angiocholitises and 5 pancreatitises.

Results Sixteen patients of each option were comparable in age, weight, ASA-score and clinical presentation. Mean hospital stay (A vs B) after first act on CBD (8.7 d – 0.7 vs 9.9 d – 1.3), was not different (NS). Morbidity of option A was, residual CBDL, which was treated by post-operative sphicterotomy; a 69 year old cirrhotic man, ASA-score 3, died on day 9. Six conversions into laparatomy were necessary in option A (1 cholecysto-colic fistula, 1 cancer of gallbladder, 3 pediculitises and one failure of cholangiography). One moderate post-sphincterotomic pancreatitis and one re-operation for hemorrhagia of gallbladder's bed were recorded as morbidity of option B. There was no conversion into laparotomy for this last option.

Conclusions Feasibility of laparoscopic CBDL's treatment in one intervention, is only 60%. Despite no significant differences in outcome due to small size of both groups, endoscopic stone removal prior laparoscopic cholecystectomy seems confer advantage to patients who desire cholecystectomy by laparoscopic methods. "P PP0 0275"PP0 0275 **Needle Knife Papillotomy, A Prospective Study**

*M. Taha, W. Schimming, U. Schentke

1rst Dept. of Internal Medicine, Technical University, Dresden, GermanyOur department is a referral center for difficult or therapeutic ERCP. We studied the success rate and safety of needle knife papillotomy (NKP) retrospectively during two years (1993 and 1994) and prospectively from 01/1995 to 05/1996 within a total number of 1319 endoscopic sphincterotomies (ES).

Methods the needle knife (Olympus KD 10 Q) was used to perform gentle cuts from the papillary orifice in an upward 11 o'clock direction, when several attempts to selectively cannulate the bile duct had failed (4–5 attempts 1993/94 and 2–3 in 1995/96).

Results success and complication rates Period No. ES No. NKP Success of Complications NKP after NKP1993/94 765 79 (10.3%) 86% 12.7%1995/96 554 119 (21.5%) 91% 5.9%Success of NKP is defined as free cannulation of the common bile duct with the standard or wireguided catheter. Sphincterotomy was then completed to perform therapeutic maneuvers. The complications were mostly mild pancreatitis, 2 minor bleedings and 3 small perforations. No deaths or emergency surgery occurred.

Summary during the second (prospective) period, the percentage of needle knife papillotomy has doubled, but the complication rate halved and the success rate increased.

Conclusion needle knife papillotomy (without pancreatic duct stenting) is a safe and useful method, but has an improvement curve even in experienced hands. Liver and bile ducts, 2: Gallstones, formation, treatmentEndoscopy, general: Instrumentation, therapyEndoscopy, specific: Biliary }" "Needle Knife Papillotomy, A Prospective Study"

"P PP0 0276"PP0 0276 **Extracorporeal Shock-Wave Lithotripsy (ESWL) of Pancreatic Ductal StonesW. Johanns, J. Janssen,**

*L. Greiner

Medical Clinic A, Municipal Hospital Wuppertal, University of Witten-Herdecke, Germany

Introduction Formation of stones in the pancreatic duct can lead to obstruction and maintain obstructive chronic pancreatitis. Endoscopic-operative measures (papillotomy, stone extraction) are of limited use in the case of large or impacted stones or ductal strictures. We used pancreatic ESWL as an alternative to surgical intervention to treat patients with symptomatic pancreatic duct stones, which were not primarily extractable by endoscopy.

Patients/Methods 45 patients (m = 25, f = 20) suffering from chronical calcifying pancreatitis were treated by ultrasound-guided ESWL (500–13500 shock-waves, 14–22 kV). Only 13 patients had solitary stones. The average diameter of the largest stone in each case was 11 (5–25) mm. The mean diameter of the dilated pancreatic duct was 9 (5–28) mm. Endoscopic papillotomy was carried out in 44 patients. Fragments not passed spontaneously after ESWL were extracted endoscopically. 30 patients presented with exocrine pancreatic dysfunction; 6 patients had overt diabetes mellitus and 5 patients presented with impaired glucose tolerance. The average duration of follow up was 23 (3–70) months.

Results Disintegration of the obstructing calculi was possible in all cases. Completely stone-free ducts were achieved in 23 and a significant reduction in the width of the pancreatic duct in 37 cases. 38 patients became asymptomatic or reported a significant reduction in pain. During the follow-up period 23 patients gained weight and pancreatogenic steatorrhoea ceased. In two patients a pathological glucose tolerance test returned to normal. In 3 cases recurrent stones developed. These were again successfully treated. 4 patients had to undergo surgery in the further course. No major complications were observed.

Conclusion Pancreatic ESWL in combination with endoscopy is an effective procedure for non-surgical management of symptomatic pancreaticolithiasis. Removal of the ductal obstruction provides effective pain relief and is frequently accompanied by a reduction in pancreatic exocrine dysfunction. Improvement in endocrine function may even be seen in individual cases.

"P PP0 0279"PP0 0279 **The Feasibility of Upper GI Endoscopy Performed through the Nose Using Thin VideoendoscopeJ.-F. Rey[1], D. Duforest[1], T.A. Marek[2]**

[1] Institut Arnault Tzanck, Saint Laurent-du-Var, France

[2] Silesian Medical Academy, Katowice, Poland

Background and aim Sedation for upper GI endoscopy is inseparably connected with increase in costs and possible adverse effects of the procedure. The attempts to improve the tolerance of upper GI endoscopy without sedation were based mainly on using thinner scope and very recently on change of the traditional oral to the nasal route of insertion. The aim of the study was to assess the tolerance of diagnostic upper GI endoscopy performed with very thin prototype of electronic videoendoscope, Olympus XGIF-N200H.

Patients and methods The first part of the study, made on 10 volunteers, comprised the comparison of the tolerance of endoscopy performed through the nose versus standard oral route. The assessment was made by means of questionnaire, filled-in by volunteers directly after the procedure, in 0–10 scale. Examinations were videotaped for further confirmation of the endoscopic correctness of the procedure, done by independent endoscopist.In the second part, the nose-gastroscopy was performed on the series of consecutive patients, who refused the sedation. Failure of scope insertion, failure of completing the procedure and patients' recommendations for further examinations were noted.

Results – part I In one patient the insertion through the nose failed; she was excluded from the further analysis. The overall tolerance of the procedure did not differ for both routes of insertion (median score: 7 for oral as well as for nasal introduction; $p = 0.612$), but the gagging occurred much less frequently during endoscopies performed by nose (1/9 vs. 6/9; $p = 0.050$).

Results – part II The attempts of nose-gastroscopy were made in 283 patients. In 19 (6.7%) insertion was impossible. In additional 6 (2.1%) patients marked discomfort was the reason for continuing the procedure under sedation. In remaining 256 (91.2%) endoscopy was successfully completed. Out of them, 237 (91.8%) patients accepted the new route of insertion for (possible) follow-up endoscopies. The gagging, which is the main cause of intolerance of unsedated oral gastroscopy, occurred only in 15 (5.7%) patients.

Conclusions The technological progress (very thin endoscope) and the psychological breakthrough (new route of scope insertion) could open the new possibility of decreasing costs of examination while maintaining its tolerance — the thin-scope nose-panendoscopy. Endoscopy, general: Instrumentation, diagnosis }" "The Feasibility of Upper GI Endoscopy Performed through the Nose Using Thin Videoendoscope"

"P PP0 0280"PP0 0280 **The Role of Balloon Catheter Dilatation in the Management of Benign Gastric Outlet Stenosis**

*J. Solt, Zs. Papp[1], M. Moizs, A. G\'e1rdosa

Department of Medicine, of Baranya County Hospital, P\'e9cs, Hungary

[1] Department of Radiology of Baranya County Hospital, P\'e9cs, Hungary

Purpose For long time, gastric outlet obstruction was managed surgically. Since 1981, we have performed 106 dilatations in 46 patients with gastric outlet obstruction of various origins. In the present paper we discuss the results and the effectiveness of this form of therapy.

Methods Dilatation was performed with either double or single lumen (TTS) balloon catheter. For insertion of the double lumen balloon catheter, a guide wire was passed through the stenosis. The single lumen balloon catheter was introduced through the gastroscope. Recently, a big channel gastroscope and high pressure TTS balloon catheter was used. In post vagotomy obstructions, we used a special 20–25 mm diameter balloon catheter. Dilatations were performed under endoscopic or x ray control or both.

Results 106 balloon catheter dilatations were done in 46 patients. Out of these, dilatation was a final solution in 25 patients, while 21 patients required surgery after dilatation. Dilatation was most effective in cases of gastric outlet stenosis complicating Billroth I, Billroth II, modified Whipple surgery or vagotomy. Complications: temporary arterial bleeding in one case and perforation in two cases. The effectiveness of dilatation therapy is presented in table below: Causes of obstruction Balloon dilatation Surgery TotalPost Billroth I or Billroth II 9 0 9Corrosive ingestion 3 10 13Pyloric or duodenal ulcer 5 5 10Postvagotomy 4 1 5Modified Whipple operation 3 3Malignancy 1 (stent implanted) 5 6Total number of patients: 25 21 46

Conclusions Our results suggest that balloon catheter dilatation in gastric outlet obstruction has both diagnostic and therapeutic value. The dilatation therapy in many cases proved alternative to surgery. "P PP0 0281"PP0 0281 **Preliminary Results of Endoscopic MR Imaging for Assessment of Esophageal and Rectal Cancer**

*D. Kulling, D. Feldman, C. Kay, K. Spicer, R. Hawes

Digestive Disease Center, Medical University of South Carolina, SC

Background In contrast to the endorectal surface coil used to assess pelvic tumors, the new magnetic resonance (MR) endoscope has the appearance and all the features of a standard endoscope. We are currently performing a prospective trial on patients with esophageal and rectal cancer, comparing this instrument to endoscopic ultrasound (EUS) in local disease staging. This report presents our preliminary results.

Methods After placement of the MR-endoscope (XGIF MR 30, Olympus, Tokyo, Japan) under direct visualization next to the tumor in patients with esophageal (n = 3) or rectal (n = 1) cancer, imaging was conducted on a 1.5 Tesla scanner. Sequences performed were T1-weighted spin echo (SE), T2-weighted fast spin echo and T1-weighted SE after gadolinium injection. The radiologists reading the endoscopic MR images were blinded for any other staging examination. Assessment of T- and N-stages was compared to EUS.

Results The procedure was well tolerated with no complication. In one patient with esophageal cancer, due to misinterpretation of the localizer image, the area scanned was beyond the range of the MR-endoscope coil, resulting in insufficient image quality. In the other cases, endoscopic MR and EUS revealed identical tumor expansion (1 {\'b4} T2, 2 {\'b4} T3) and peritumorous lymph node metastases (3 {\'b4} N1). In two patients EUS showed additional pathologic lymph nodes beyond the range of the MR-endoscope coil.

Conclusions These preliminary results on endoscopic MR imaging showed high quality images of anatomic details and local cancer depiction in patients with esophageal and rectal tumors. Considering current advantages (three dimensional reconstruction, combination with body coil imaging for M-staging) and awaited technical improvements (real time imaging, open gantry system) of MR imaging, the MR-endoscope is a promising tool for staging of esophageal and rectal cancer. "P P 13 0331"P 13 0331**H. Pylori Infection and Basal Gastrin Levels in Duodenal Ulcer Patients and in Subjects with Normal Endoscopy**

*J.P. Gisbert, D. Boixeda, T. Vila, R. Cant\'f3n, I. Baleriola Alvarez, V. Moreira, Mart\'edn C. de Argila

""Ram\'f3n y Cajal"" Hospital, Madrid, Spain

Purpose To study basal gastrin levels in duodenal ulcer (DU) patients and those with normal endoscopy, according to

H. pylori status.

Methods Eighty-four DU patients and 164 with normal endoscopy were studied. Biopsy specimens were taken from both gastric antrum and body, and investigated for microbiology (Gram stain and culture) and histology (H&E stain). Serum basal gastrin levels were measured (RIA; Becton-Dickinson).

Results In DU patients the percentage of chronic gastritis was higher ($p < 0.001$) than in

H. pylori{ -} patients with normal endoscopy, and similar to

H. pylori+} patients. In patients with normal endoscopy, those infected with *H. pylori* had higher ($p = 0.02$) gastrin levels (m – SD) than non-infected (64 – 34 vs 51 – 14 pg/ml) and similar to DU patients (62 – 20 pg/ml). In the multiple regression model analysis *H. pylori* infection was the only variable which correlated with gastrin levels (regression coef.: 9.48 [SE = 4.59]; multiple correlation coef.: 0.22 [$p = 0.008$]). Additional variables (age, sex, presence of DU lesion) were not correlated with gastrin levels. Patients with chronic gastritis had higher gastrin levels ($p < 0.01$) than those with normal histologic mucosa.*Conclusion* *In patients with normal endoscopy, those infected with {*

H. pylori had significantly higher basal gastrin levels than non-infected subjects, and similar to DU patients (all of them *H. pylori*+). Therefore, hypergastrinaemia seems to be associated with *H. pylori* infection and is not a distinctive feature of DU disease. "P P 13 0332"P 13 0332**Basal Pepsinogen I Levels and *H. Pylori* Infection in Duodenal Ulcer Patients and in Subjects with Normal EndoscopyD. Boixeda,**

*J.P. Gisbert, T. Vila, L. De Rafael, C. Redondo, Mart\'edn C. de Argila, C. Arocena

""Ram\'f3n y Cajal"" Hospital, Madrid, Spain

Purpose To study basal pepsinogen I (PGI) levels in patients with duodenal ulcer (DU) and with normal endoscopy, according to

H. pylori status.

Methods Seventy-nine DU patients and 120 with normal endoscopy were studied. Mean age and sex distribution was: 45 – 15 vs 48 – 13 years; and 75% vs 64% males, respectively. In DU patients biopsy specimens were taken from both gastric antrum and body and investigated for microbiology (Gram stain and culture) and histology (H&E stain). In patients with normal endoscopy, samples were obtained only for microbiologic study. Serum basal PGI levels were measured (RIA; Sorin-Biomedica).

Results In patients with normal endoscopy, those infected with

H. pylori had higher ($p < 0.001$) PGI levels (m – SD) than non-infected patients (81 – 22 vs 54 – 11 ng/ml). PGI levels in DU patients were 106 – 35 ng/ml, which represents a higher value ($p < 0.001$) than in normal endoscopy group (both in

H. pylori+} and *H. pylori{* -} patients). In the multiple regression model analysis PGI levels were correlated with *H. pylori* infection (*r = 27;* EE = 6), presence of DU lesion (*r = 26;* EE = 4) and smoking (*r = 9;* EE = 4).*Conclusion* *Basal PGI levels were significantly higher in DU patients than in {*

H. pylori infected patients with normal endoscopy. Non-infected patients had the lowest PGI values. Therefore, an additional factor seems to exist (besides *H. pylori*) to explain the classically described hyperpepsinogenaemia in DU patients. "P P 13 0334"P 13 0334**Prevalence of Duodenal Bulb Gastric Metaplasia and Helicobacter Pylori in Turkey**

*\'dc.B. Dogan[1], C. Tun\'e7er[1], A. Dursun[2], U. Kandilci[1]

[1] Gazi University, Faculty of Medicine, Department of Gastroenterology, Ankara, Turkey

[2] Gazi University, Faculty of Medicine, Department of Pathology, Ankara, TurkeyHelicobacter pylori (H. pylori) infection causes chronic-active gastritis and is associated with peptic ulceration. However, the link between gastric H. pylori colonization and duodenal ulcers is not well understood. It has been proposed that H. pylori can adhere to the duodenal mucosa where there is gastric metaplasia, survive, and cause focal duodenitis and ulceration. But, duodenal bulb gastric metaplasia and helicobacter pylori are not consistently present in patients with duodenal ulcer, and their frequency have been reported to vary widely from 8% to 92%, and 16% to 83% of patients with duodenal ulcer, respectively. The aim of this study was to investigate the prevalence of duodenal bulb gastric metaplasia and H. pylori in Turkey. 216 patients with duodenal ulcer and 103 with non-ulcer dyspepsia (NUD) were included. Endoscopic mucosal biopsies were done at corpus, antrum, and duodenum, and, if present, ulcer margin. The specimens were stained with periodic acid-Schiff, hematoxylin-eosin, and warthin-starry to examine for gastric metaplasia, mucosal inflammation, and H. pylori, respectively. Prevalence of H. pylori in gastric mucosa was higher in patients with duodenal ulcers (97.6%) than in patients with NUD (57.3%) ($p < 0.001$). Also in the duodenal mucosa of non-ulcer sites, and the ulcer margin of patients with duodenal ulcers, the detection rates (16.8% and 39.20%) were higher than those in the duodenal mucosa of patients with NUD (2.9%) ($p < 0.001$). Gastric metaplasia was present 36.8% and 81.60% in the non-ulcer sites and the ulcer margin of patients with duodenal ulcers, and 13.59% in the duodenal mucosa of patients with NUD ($p < 0.001$). These data suggest that H. pylori is a possible pathogen for duodenal ulcer by duodenal colonization probably via gastric metaplasia in Turkey. "P P 13 0337"P 13 0337**Effect of Chronic Acid Inhibition on Duodenal Bulb Gastric Metaplasia and Helicobacter Pylori**

*\'dc.B. Dogan[1], C. Tun\'e7er[1], A. Dursun[2], U. Kandilci[1]

[1] Gazi University, Faculty of Medicine, Department of Gastroenterology, Ankara, Turkey

[2] Gazi University, Faculty of Medicine, Department of Pathology, Ankara, TurkeyGastric metaplasia (GM) has been demonstrated in the duodenal bulb in patients with duodenal ulcer (DU), representing the result of severe inflammation at the ulcer site. These changes have been shown to be related to acid secretion and may regress on acid reduction by highly selective vagotomy. It has also been found that DU patients on continuous pharmacological acid suppression exhibit a lower prevalence of GM in comparison with intermittently treated patients, although not supported by some. The aim of this study was to evaluate the effect of H2 receptor antagonists on GM in patients with DU. We studied 216 DU patients (130 M, 86 F; 39.7 – 13.4 yrs, m – SD) and 103 healthy controls (35 M, 68 F; 39.4 – 13.7 yrs). DU patients included: 168 patients with active DU (group 1); 26 with healed DU, continuously treated with famotidine (20 mg/nocte), for 3 to 12 months (group 2) and 22 for 2 to 10 years (group 3). Multiple endoscopic biopsies were obtained from the gastric corpus, antrum and the duodenal bulb of each subject. Sections of biopsy tissue were stained with periodic acid-Schiff, hematoxylin-eosin, and warthin-starry to examine for GM, mucosal inflammation, and H. pylori, respectively. Prevalence of gastric and bulber H. pylori, and GM were 85.7%, 31.5%, 71.4% in group 1; 80.8%, 26.9%, 65.4% in group 2; 81.8%, 13.6%, 50% in group 3; and 57.3%, 2.9%, and 13.6% in healthy controls, respectively. Prevalence of GM and bulber H. pylori in group 3 was lower than group 1 ($p < 0.05$). However, there was a lack of correlation between the duration of drug use and both of them. We concluded that chronic continuous inhibition of gastric asid secretion by H2 receptor antagonists decreases of prevalence of GM and bulber H. pylori in DU patients. "P P 14 0388"P 14 0388**Randomised Controlled Trial of Pre Endoscopy Screening for H. Pylori in the Management of Dyspepsia**

*M.A. Asante, P. Patel, M. Thomas, L. Ballam, M. Mendall, T.C. Northfield

Dept. of Medicine, St. George's Hospital Medical School, London, UK

Background It remains unclear whether endoscopy is necessary in the management of H. pylori negative dyspepsia in young patients. In this randomised controlled trial we have tested a hypothesis that endoscopy is does not influence the management outcomes of H. pylori seronegative patients under the age of 45 presenting with dyspepsia. The strategy of not endoscoping young H. pylori seronegative dyspeptic subjects will be considered viable if following management by their General practitioners (GPs), no difference is detected at 6 months in symptoms, disability, GP visits and use of medications when an endoscopy group is compared with a group who are endoscoped.

Design 417 patients under the age of 45 years referred to a direct access endoscopy service were screened with a validated questionnaire and H. pylori serology (Helico-G ELISA). A cut off level of 6.3 u/ml had been previously determined to be suitable for screening. 154 patients (56% male) had serology titres below 6.3 u/ml and were randomised to have either endoscopy or no endoscopy. All patients were returned to their GPs for further management. Patients with a history of weight loss of more than 1/2 stone in 6 months, dysphagia, anaemia or persistent vomiting or on regular NSAIDs were excluded. Six month assessment was by postal questionnaire.

Results Of the 119 due for six month review, 94 (79%) have returned their questionnaires. Endoscopy (50) No endoscopy (44) PSymptom score 1.6 – 0.08 1.5 – 0.08 0.67Disability score 0.8 – 0.13 0.8 – 0.17 0.64Days off work 4.3 – 2.24 2.3 – 1.49 0.78GP visit 1.9 – 0.58 1.9 – 0.61 0.88GP prescriptions 13/38 (34%) 17/39 (44%) 0.54Self medications 19/45 (42%) 27/44 (61%) 0.11Referral to specialist 5/41 (11%) 14/44 (32%) 0.03Referral for endoscopy 2

Summary There was no difference in symptoms, disability, GP visits, and prescriptions between the two groups. There was trend for the endoscoped group to take more days off work, however the non endoscoped group were referred more often for specialist consultations.

Conclusions It is safe to manage young H. pylori negative dyspeptic patients without endoscopy. Clinical practice: Management strategyOesophageal gastric duodenal disorders: Helicobacter Pylori }" "Randomised Controlled Trial of Pre Endoscopy Screening for H. Pylori in the Management of Dyspepsia"

"P P 16 0408"P 16 0408**Chronic Atrophic Gastritis in Children & Adolescents with Upper Dyspeptic Syndrome**

*M.D. Georgieva-Shakola, I. Krasnaliev[1], G.P. Varbanov[2]

Dept. of Pediatrics, Medical University, Varna, Bulgaria

[1] Dept. of Pathology, Medical University, Varna, Bulgaria

[2] Clin. of Gastroenterol., Medical University, Varna, BulgariaThe aim of this study was to evaluate clinical, endoscopic & histological findings of chronic atrophic gastritis in children & adolescents. In 1993–1995, 138 pts (63 girls & 75 boys), aged 6–18, were investigated for upper dyspeptic syndrome. Upper endoscopy with forceps biopsy from antrum for histological investigation, (hematoxylin/eosin & Giemsa for detection of Helicobacter pylori – H.p.) was applied in these pts. In 24 pts was investigated corpus biopsy. Gastritis were graduated by Sidney system. Gastritis was established in 123/138 (89.13 + 5.3%) antral biopsy & in 16/24 corpus biopsy (66.67 + 18.86%). In 33/138 of these biopsy partial atrophy was found. Clinical features of these pts were non specific. Endoscopic findings were: eritematousexudative gastritis in 93.94% & only in 6.06% – atrophic gastritis. Associated pathology was chronic duodenitis in – 81.82%, chronic esophagitis – in 66.67%, duodenogastric reflux – 22.27%, gastroesophageal reflux & duodenal ulcer – in 15.15% ($p > 0.05$). Histopathologically atrophic gastritis was partial & antral. H.p. was detected in 42.42% of these pts ($p > 0.05$). It be concluded that chronic atrophic gastritis is not rare in upper dyspeptic children & adolescents. It is a histopathological diagnosis. Atrophic gastritis is minimal, antral often associated with H.p. in childhood.

"P P 16 0414"P 16 0414**Pediatric Biopsies; Morphology and Gene Expression Compared along the Duodenum during Development**

*E.H. Van Beers, E.H.H.M. Rings, A.W.C. Einerhand, J.A.J.M. Taminiau, H.S.A. Heymans, J. Dekker, H.A. B\'fcller

Pediatric Gastroenterology and Nutrition, Academic Medical Center, Amsterdam, The Netherlands

Purpose To compare mucosal morphology as well as gene expression in pediatric duodenal biopsies from sites proximal and distal to the papilla of Vater during development in patients with upper gastrointestinal complaints.

Methods Duodenal biopsies were obtained from 85 pediatric patients (aged 3 months–18 yrs) with informed consent and permission of the medical ethical committee. Complaints or symptoms included, diarrhea, celiac disease, oesophageal reflux, H. pylori, and G. lamblia. The two locations from which biopsies were taken were proximally and distally from the papilla of Vater and at least 15 cm apart along the duodenum. The study group included white-Caucasian (68) and non white-Caucasian (17) individuals. We used four categories to allocate crypt-villus morphology. Lactase (L) and sucrase-isomaltase (SI) gene expression was measured quantitatively at the mRNA level using Northern analysis and semi-quantitatively at the protein level on paraformaldehyde-fixed tissue using specific monoclonal antibodies [1] and the PAP-technique [2]. Results were assessed double blind using light microscopy.

Summary We report a wide inter-individual variability for all the characteristics studied. However, when biopsies from two locations along the duodenum of a single individual are compared with respect to each of the above criteria (morphology, L and SI gene expression amounts and patterns), similarity for each single trait was at least 93%.

Conclusion Duodenal biopsies taken distally or proximally relative to the papilla of Vater yield very similar results for morphology and L and SI gene expression if taken from a single individual. This appeared to be independent from age, race, and disease. However, there was considerable variation between individuals for each of the measured characteristics. These findings indicate that the mucosa along the duodenum is rather similar within, but not among, individuals. This would imply that the diagnostic value of proximal and distal biopsies from the duodenum are comparable.

"P P 17 0425"P 17 0425**Macroscopic and Histopathologic Extent of Disease in Patients with Ulcerative Colitis at Diagnosis and Follow-Up****Bj\'f8rn Moum[1], Anders Ekbom[2], Morten H. Vatn[3]**

[1] Dept Med, Fredrikstad, Oslo, Norway

[3] Dept Med, Rikshospitalet, Oslo, Norway

[2] Dept Cancer Epidemiol Uppsala, Sweden

Background Colonoscopy has replaced barium enemae as the mean to determine extent of disease in patients with ulcerative colitis (UC). Normally, the extent of disease is determined by direct visualisation of the mucosa, but biopsises are also used with an increased frequency. Very little is known to what extent these two ways to assess extent of disease correlates and if the correlation differs with time of diagnosis and during follow-up.

Aim To determine the changes in extent of disease assessed both by direct visualisation and by histopathological changes in the mucosa at the time of diagnosis and after one year follow-up in a cohort of incident cases of UC patients.

Material and methods All new cases of UC in a defined population were identified during a four year period (496 patients). 384 patients (78%) were available for follow-up and subjected to a second colonoscopy with representative biopsies taken both from normal and affected mucosa.

Results After one year there was macroscopical signs of progression in 14%, 22% showed regression and additionally 30% had a normal colonoscopy. The histopathological changes from diagnosis until follow-up showed progression in 20%, 24% showed regression and in addition 24% had normal histopathologic findings. Histopathologic examination entailed a more extensive disease compared to direct visualisation in 4% at diagnosis and in 28% at follow-up, while direct visualisation entailed a more extensive disease than histopathologic examination in 18% at diagnosis and 12% at follow-up. Best correlation at both diagnosis and follow-up was seen in pancolitis (99% and 88% respectively).

Conclusion From our results it is obvious that there is an increasing difference between macroscopic and histopathological involvement in UC patients at follow-up one year after diagnosis. It remains to be evaluated in further studies to what extent histopathological involvement is a better marker than macroscopic changes for the long-time prognosis. "P P 17 0432"P 17 0432**Measurement of Mucosal Blood Flow in Ulcerative Colitis by Means of Endoscopic Laser Doppler Flowmetry**

*M. Cianci, G. Gizzi, V. Villani, K. Jadallah, G. Elia, A. Ferri, R. Corinaldesi

Department of Internal Medicine and Gastroenterology, University of Bologna, ItalyThe aim of our study was to evaluate colonic mucosal blood flow in patients with ulcerative colitis (UC), using endoscopic laser-doppler flowmetry (ELDF).We studied 20 UC patients (14 M, 6 F: 36 – 8 yrs; mean age – SD) and 18 healthy controls (HC) (10 M, 8 F: 38 – 5 yrs). The Laser-doppler flowmeter used was the Laserflow BPM-403, Vasamedics USA. Four ELDF measurements were taken from the rectosigmoidal mucosa and expressed in flux units (FU) (ml/min in 100 cc of tissue). Finally, skin blood flow was measured at the forearm for 5 minutes. The mucosal/skin flow ratio (MUSK index) was calculated. Results were expressed as mean values – SD and analyzed by ANOVA test.The average of mucosal blood flow (MBF) and MUSK index (MI) was significantly increased in UC patients compared to HC (MBF: 38.1 – 11.2 vs 15.5 – 2.7, $p < 0.02$; MI: 20.1 – 6.8 vs 9.1 – 2.9, $p < 0.05$). The following table illustrates the ELDF measurements and MUSK index related to the mucosal inflammatory activity in UC. Inflammatory mucosal No. Mucosal MUSKactivity Pts Blood Flow (FU) indexRemission 5 24.6 – 3.1* 12.8 – 1.7*Mild 7 35.2 – 6.1* 18.3 – 2.6*Moderate–severe 8 53.9 – 8.8** 28.1 – 3.9***p < 0.05 vs following value of MBF and MI. **P < 0.05 vs all other values of MBF and MI.Our results show a significant increase of mucosal blood flow in UC patients compared to HC. The increase of mucosal blood flow in UC patients is directly related to the mucosal inflammatory activity. The MUSK index seems to be reliable in distinguishing between normal and abnormal mucosa in different degrees of inflammatory activity. "P P 19 0486"P 19 0486**Comparison of Ultrasound-Secretin Test and Sphincter of ODDI Manometry in Patients with Acute Recurrent Pancreatitis**

*M.P. Brunori, V. Di Francesco, L. Rigo, G. Angelini, P. Bovo, M. Filippini, B. Vaona, L. Frulloni, M. Tebaldi, P.C. Farris, T. Grasso, G. Cavallini

Gastroenterology Unit, University of Verona, ItalySphincter of Oddi manometry (SOM) is considered the gold standard for evaluating sphincter of Oddi dysfunction (SOD). It has recently been demonstrated that the Ultrasound-Secretin test (US-S), proposed as a non-invasive test for the study of SOD, yields an high percentages of pathological findings in ARP patients. The aim of this study was to compare the results of the US-S test with SOM findings in a consecutive series of patients with ARP. Twenty-three patients admitted to our GI unit (12 M, 11 F; mean age 41 – 13 years) suffering from ARP underwent US measurement of the main pancreatic duct in the baseline situation and at one-min intervals for 60 min after maximal stimulation with secretin 1 UI/Kg. The test was considered pathological when the duct was still dilated at 20 min. Within one week interval the same patients were submitted to SOM. The procedure was performed endoscopically by using a perfused three or two lumen catheter connected to a computerised system (Polygram Synectis, Sweden). Intraduodenal pressure was taken as a zero reference. In 12 patients Caerulein 0.05 \'b5g/Kg i.v. bolus was administrated during SOM. A stenosis was defined in the presence of > 40 mmHg basal pressure, dyskinesia when paradoxical response to Caerulein or abnormal phasic contraction amplitude (> 300 mmHg), frequency (> 7/min) or propagation (> 50% retrograde) were present. Compared to SOM findings US-S sensitivity and specificity for SOD were 87.5% and 71.4% respectively. SOMUS-S Normal Stenosis DyskinesiaNormal 5 1 1 7 (30.4%)Abnormal 2 10 4 16 (69.6%) 7 (30.4%) 11 (47.8%) 5 (21.7%)

Conclusions 1) most patients with ARP present a documentable SOD both at US-S and SOM; 2) results at US-S are strongly concordant with the SOM findings, therefore US-S may offer a valid alternative to the more expensive and invasive manometric procedure for assessing SOD.

GB-LondonA prospective, randomized, stratified, open and controlled study was performed in 19 centres in 9 European countries. Patients suffering from an endoscopically verified gastroduodenal ulcer bleeding (spurting/oozing/visible vessel) (Forrest IA, IB, IIA) were randomly allocated to receive either single sclerotherapy (polidocanol 1%) or single injection therapy with fibrin sealant (FS) or repeated therapy with FS. A daily endoscopic control was performed until the ulcer base was hematin covered or clean (Forrest IIC or III). A minimum in patient observation period of 5 days and a safety follow-up of one month were required. The primary objective was the comparison of repeated application of FS v.s. sclerotherapy with polidocanol in terms of rebleeding rates after initial hemostasis. Rebleeding was defined as visually (endoscopically) verified bleeding from the same source. Per protocol analysis was performed on 737 patients. The overall incidences of rebleeding were for polidocanol 21.3%, FG single 17.2% and FG repeated 12.1%. This result was statistically significant in favour of repeated therapy with FS in comparison to polidocanol (2-sided p-value 0.020). Safety analysis

as well as evaluation of laboratory parameters and clinical variables revealed no specific risk for either treatment group. As approximately 50% of all rebleedings occurred within 24 hours after initial hemostasis, elective early re-endoscopy with prophylactic retreatment might be beneficial. [2] Dpt of Gastro-Enterology, Erasme Hospital, Brussels, Belgium

[3] Dpt of Gastro-Enterology, Edouard Herriot Hospital, Lyon, Belgium

[4] Dpt of Gastro-Enterology, Beaujon Hospital, Clichy, FranceIPMT of the pancreas are rare and few data are available about the accuracy of preoperative imaging and long term outcome after surgery.

Aims To assess: 1. the accuracies of preoperative findings by Computed Tomodensitometry (CT), Endoscopic Retrograde Pancreatography (ERP) and Endoscopic Ultrasonography (EUS) related invasive malignancy and pancreatic extension of the disease, by comparison to resected specimens. 2. the long term outcome after supposed curative surgery.

Patients and Methods Fourty seven patients (34 M, 13 F, mean age: 63 (35–81), operated between 1980 and 1995, with a definite pathological diagnosis of IPMT were included in this retrospective study. CT (n = 25), ERP (n = 29) and EUS (n = 21) available examinations were each reviewed by 2 physicians unaware of the patients to assess invasive malignancy and pancreatic extension. Surgical resected specimens were reviewed by 2 experimented pathologists. Postoperative follow-up was analysed using the Kaplan-Meier method.

Results Tumors were diffuse or overlaped resection margin in 51% (24/47) cases. IPMT showed histological features with invasive carcinoma in 43% (20/47) patients, with severe dysplasia in 21% (10/47) and with non severe dysplasia in 36% (17/47). The overall accuracies, for the distinction between invasive and non invasive tumors by CT, ERP and EUS, were respectively 76% (19/25), 79% (23/29) and 76% (16/21). The extension of IPMT were correctly assessed by CT, ERP and EUS in respectively 67%, 57% and 62% cases. The overall 3 years free disease survival was 79%, but only 21% in the group of patients operated with features of invasive carcinoma ($p < 0.001$). In these latter 20 patients, 12 malignant recurrences and 7 deaths related tumors occurred.

Conclusions This study underlines the need for an early surgical ressection in patients with suspected IPMT of the pancreas, because: – the high rate of invasive carcinoma, – the insufficiency of preoperative imaging to correctly assess malignancy and – the poor outcome of patients operated with features of invasive carcinoma. OT24 0563**Small Pancreatic Cysts Are Clinical Precancerous Condition? — Analysis of K-Ras Gene Mutation in the Pancreatic Juice-**

*A. Nakaizumi, H. Uehara, K. Sugano, S. Okada, M. Tatsuta, T. Kitamra, H. Ohigashi, O. Ishikawa, S. Ishiguro

Osaka Medical Center for Cancer and Cardiovascular Diseases, Osaka, Japan

National Cancer Center Hospital, Tokyo, JapanThe mutations of K-*ras* codon 12 (MR) was found in the majority of pancreatic adenocarcinomas (PC), and has also been identified in the pancreatic duct with hyperplasia in association with chronic pancreatitis (CP). Therefore some of these CP may be considered to be early precursors of PC. Recently we sometimes found MR in pancreatic juice (PJ) in patients with small pancreatic cyst. Therefore in the present study, we evaluate whether small pancreatic cysts are precancerous condition by the view point of MR in PJ. From November 1994 to December 1995, endoscopic aspiration cytology of PJ was performed in 52 consecutive patients suggested pancreatic diseases. PJ was collected through a endoscopic canulation into the pancreatic duct. Analysis of the MR was performed using the enriched polymerase chain reaction—single-strand conformation polymorphysm technique and confirmed by direct sequencing. MR were detected in 13 of 15 patients with PC, and in 7 of 13 patients with CP. In 16 patients with benign small pancreatic cyst, MR were also detected in 11. None of the 8 normal control had MR. Main mutational patterns in patients with benign small pancreatic cyst included GTT, GAT, and CGT, which were the same as those found in the cases of PC. MR occurred frequently in PJ of patients with benign small pancreatic cysts. Their mutational rate was higher than that of CP cases. We have already detected several cases of *in situ* PC in patients with small pancreatic cysts. These results suggested that patients with benign small cysts may be at high risk for the development of PC. Oncology, general: Molecular biology, geneticsOncology, specific: PancreasEndoscopy, specific: Pancreatic }" "Small Pancreatic Cysts Are Clinical Precancerous Condition? / Analysis of K-Ras Gene Mutation in the Pancreatic Juice-"

OT26 0569**Microlithiasis of Common Bile Duct in Patients with Acute Biliary Pancreatitis (ABP) — An Indication for Endoscopic TreatmentA. Nowak, M. Kohut, E. Nowakowska-Dulawa, R. Kaczor, T.A. Marek**

Department of Gastroenterology, Silesian Medical Academy, Katowice, Poland

Aim The use of endoscopic sphincterotomy in the treatment of ABP patients with no common bile duct stones (CBDS) is not generally accepted. The aim of this study was to investigate the presence of CBD microlithiasis in patients with AP of biliary origin and no CBDS.

Material and methods 117 consecutive patients with ABP and no CBDS on ERCP, performed as an urgent (< 24 hours of admission) procedure, (70 – gallbladder stones, 47 post-cholecystectomy), treated between January 1994 and May 1996 were included to the study. 67 consecutive patients with no CBDS found in ERCP and no AP served as controls. The presence of CBD microlithiasis (CBDM) was calculated according to Juniper and Benson, in CBD bile collected during ERCP.

Results The frequency of CBD microlithiasis in ABP and controls: ABP – acute biliary pancreatitis, GBS – gallbladder stones, PC – post-cholecystectomy, A – acute episode of ABP, H – history of ABP, T-total. GBS PC ABP no ABP no A H T ABP A H T ABPCBDM (+) 58 5 63 8 28 8 36 22 (90%) (40%) (77%) (37%)CBDM ({ -}) 6 1 7 12 4 7 11 37 p < 0.001 p < 0.001

Conclusions 1. In patients with ABP and no CBDS on ERCP, CBD microlithiasis is observed in the vast majority of patients, especially during the acute attack of the disease. 2. Microscopic examination of CBD bile taken during ERCP in an useful diagnostic tool. 3. The presence of CBD microlithiasis in the majority of ABP patients suggests the necessity of endoscopic treatment in every case of acute biliary pancreatitis, also with no CBDS present on ERCP.

"P P 21 0595"P 21 0595**Endoscopic Ultrasound (EUS) Staging of Adenocarcinomas (A) Developed on Barrett's Esophagus (BE)**

*P. Ruszniewski, M.H. Sayegh, P. Dahan, A. Sauvanet, J.F. Fl\'e9jou[1], V. Vilgrain[2], J. Belghiti, P. Bernades

[1] Federation of Hepato-Gastroenterology, Departments of Anatomopathology, 92118 Clichy Cedex, France

[2] Radiology, Hospital Beaujon, 92118 Clichy Cedex, FranceEUS is an accurate procedure for the staging of epidermoid esophageal cancer. The presence of Barrett's epithelium, lymph-node and cardial involvement may account for differencies in EUS performance in the staging of ABE.

Aim of the study to determine the sensitivity of EUS for the assessment of parietal and lymph-node involvement, and for tumoral staging (UICC classification) in patients with ABE.

Patients (pts) and Methods 43 pts with ABE operated on between January 1987 and December 1994 in one center; EUS performed before surgery. Results of EUS were compared to anatomical findings in surgical specimen.

Results staging was complete in 33 pts, but intraversable stenosis was encountered in 10 pts. 1 – Traversable tumors: a) T-stage accuracy: 17 of 19 T1, 4 of 5 T2, 5 of 8 T3 and 1/1 T4 tumors were correctly assessed by EUS, i.e. an accuracy of 81%. Among T1 lesions (accuracy: 90%), EUS was unable to distinguish those limited to the mucosa from those involving the submucosa. b) N staging: 22 of 25 No, 5 of 8 N+ were correctly assessed, i.e. EUS sensitivity and specificity were 75 and 80%, respectively. Tumoral staging according to the UICC classification was correctly determined in 72% of the pts (stage I: 16 of 19; stage IIa: 3 of 5; stage IIb: 1 of 2; stage III: 3 of 7). 2-Intraversable stenoses (10 pts): EUS accuracy decreased dramatically to 20% for T staging. Sensitivity and specificity of EUS for N staging were 57 and 100%, respectively; tumoral UICC staging was correct in 30% of the pts. *Conclusion.* EUS is a useful for preoperative staging of traversable ABE. It is an accurate procedure to assess parietal and lymph-node involvement. EUS accuracy decreases in pts with intraversable tumors, most of which are at T3 or T4 stage. "P P 21 0597"P 21 0597**Barret's Patients Developing Gastric Polyps during Acid Suppression are at Greater Risk for Esophageal DysplasiaA. Svoboda, S. Tillisch-Svoboda**

Sansum Medical Clinic, Santa Barbara, CA, USAEndoscopic surveillance of patients with specialized columnar epithelium and intestinal metatplasia in the tubular esophagus is indicated because of the rapidly increasing incidence of adenocarcinoma of the esophagus (and cardioesophageal junction). The development of large (over 1 cm) gastric hyperplastic polyps in such patients on long-term omeprazole therapy, and their disappearance or reduction in size and number associated with stopping or decreasing the dosage of omeprazole, prompted a retrospective and prospective review of Barrett's patients followed by the author. 121 patients with short segment Barrett's (less than 3 cm) were further compared with 82 patients with long segment classical Barrett's (over 3 cm). The increased occurrence of non-neoplastic gastric polyps was statistically significant in Barrett's patients (17.4%, p = 0.0001), and this was especially true in those treated with proton pump inhibitors. All moderate and high-grade dysplasia (nine) and most low-grade dysplasia (twenty-six of forty seven) occurred with long segment Barrett's. A majority of gastric polyps (59%) occurred with long segment Barrett's. A finding of gastric polyps is associated with a greater risk of esophageal dysplasia (36% versus 19%, p = 0.032). The development of gastric polyps during acid suppression therapy appears to be a side effect of therapy and possibly helps select a group at greater need for careful surveillance. "P P 23 0624"P 23 0624**Dilation of Benign Oesophageal Strictures with Savary-Guilliard Bougies in OutpatientsA. Konstantinide,**

*K. Paraskeva, V. Vamvakousis, A. Germanopouls, N. Scandalis

Gastroenterology department, General Hospital of Athens, Greece

Aim To show that endoscopic dilation of benign esophageal strictures is effective and safe for outpatients.

Patients During the last 2.5 years, 27 patients, 15 male and 12 female, aged 29–84 with benign oesophageal strictures underwent endoscopic dilation. The cause of the stricture was: reflux oesophagitis in 16 patients, sclerotherapy in 7, caustic injury in 3 and surgery in 1 patient. The site of the stricture was: in the upper oesophagus 3, in the middle 2 and in the distal 22 cases.

Method Endoscopic evaluation of the nature, site and extent of the stricture, plus biopsies in all patients and barium radiology in 4 patients. Savary-Guilliard bougies were used over guidewire. After the procedure, the patients were kept under observation for 1–2 hours and then discharged with instructions about liquid food 5 hours later, omeprazole 40 mg\day and keeping in touch in case of adverse events.

Results Each time 4–6 S-G bougies were used, gradually increased in size. The procedure was repeated 2–4 times with 3 weeks intervals in between, to be continued in case of dysphagia. All dilation procedures were 117 (4.3 per patient). There were no complications or adverse events.

Conclusion Endoscopic dilation of benign oesophageal strictures with S-G bougies is effective and safe and patients' hospitalization is not necessary. "P P 24 0626"P 24 0626**Oesophageal Dilatation for Caustic Stenosis in Childhood: Study of 19 Patients**

*M.F. Lopes, A. Reis, M.R. Cunha, A.G. Brand\'e3o, A.M. Ant\'f3nio

Endoscopy Unit of Pediatric Hospital of Coimbra, Coimbra, Portugal

Introduction After the ingestion of a strong caustic agent, oesophageal stenosis remains relatively frequent. Oesophageal repetitive dilatation is usually regarded as an effective therapy but, because large paediatric series are infrequent, there are many doubts about the periodicity of sessions, efficacy and duration of the treatment and rate of complications. We present our results of dilatation therapy for corrosive oesophageal stenosis.

Methods We reviewed rectrospectively our experience (January 1986–May 1996). The dilatations were performed, under sedation or under general anesthesia, in a regimen of day care. The dilatator guide was introduced under endoscopic control. Two different materials were used: until 1987 methalic bougies and since 1987 Savary bougies.

Results One hundred and forty children with accidental ingestion of caustic, were endoscopicaly evaluated for the suspect of oesophageal burn: One of them developed severe complications — oesophageal and gastric necrosis requiring oesophageal replacement — and 19 patients developed oesophageal stenosis. To treat stenosis, 265 sessions of dilatation were performed (median: 10, with SD: 8.35, min.: 2 max: 33). Nine of the 19 children achieved cure with mechanical dilatation: the duration of the treatment was 5 months (median, with SD: 5, min.: 2, max: 16) and the number of dilatations was 9 (median, with SD: 6.95, min.: 2 max: 27). Four of 19 children were operated on because oesophageal dilatations were unsuccessful: the duration of the treatment was 8.5 months (median, with SD: 4.9, min.: 1 max: 13) and the number of dilatations was 18 (median, with SD: 8.81, min.: 4 max: 23). Six children are currently under dilatation therapy: 4 of those children, are on a regular program, with a monthly periodicity; the duration of treatment was respectively 4 months, in 2 cases and 15 months in the other case. The other two children are treated when dysphagia occurs; the duration of the treatment/number of sessions was respectively 18 months/19 dilatations and 48 months/33 dilatations. Oesophageal perforation occurred in 1.13% of the dilatations. All were treated with gastric aspiration, nothing by mouth and antibiotics, and all survived.

Conclusion Dilatation therapy for oesophageal caustic stenosis achieved a 50% cure rate. When performed by an experient team it is safe, but is also time consuming because, to achieve cure, repetitive dilatations are necessary and duration of treatment is long. "P P 24 0627"P 24 0627**Caustic Injuries of Upper Gastrointestinal Tract (UGIT) in Patients Admitted to an ICU**

*E. Pires, A. Valente, J. Lopes, L. Correia, P. Alexandrino, M.C. Moura

University Hospital of Santa Maria, Gastroenterology Intensive Care Unit, Lisbon, PortugalIngestion of caustic agents can cause severe injury to the esophagus and stomach which continues to be a medical and surgical management problem.

Purpose To evaluate patients admitted to an ICU with caustic injuries and correlate the severity of endoscopic lesions with complications developed.

Methods We retrospectively reviewed 23 patients admitted to an ICU, (11 women and 12 men with a mean age of 45 years), during a 4 year period (February 1992–February 1996), with caustic injuries of the UGIT. Statistical analyses were done using the chi-square test.

Results Caustic ingestion was accidental in 12 patients (52%) and suicide attempt in 11 (48%). The type of agent was acid – 9, alkali – 11, medicament – 1 and unknow – 2. The most frequent symptoms were: odynophagia – 82%, hematemesis and epigastric pain – 43%, chest pain – 26%. In 14 patients occurred oropharyngeal lesions independent the UGIT lesions ($p = 0.8$). Endoscopy reveled: caustic esophagitis grade I-2, II A-7, II B-10 e III-4; gastritis grade I-4, II-10, III-9 (Zargar Classification). The mean hospitalization time was 11 days. Infection developed in 8 patients (sepsis in 4) with no significant correlation with the burn grades. All patients were treated with omeprazol and sucralphate, 17 did antibiotics, 5 corticosteroids and 12 needed parenteral nutrition. 100% of grade III and 40% of grade II B injuries developed esophageal stenosis ($p = 0.02$), and 2 patients (1 grade III and 1 II B gastric burns) developed pyloric stenosis ($p = 0.27$). Therapeutic endoscopy were done successfully in 5 patients. Of the 3 patients who needed surgery (total esophagectomy – 2; esophagectomy and gastrectomy – 1) all died.

Conclusions (1) Oropharyngeal lesions had no significant correlation with UGIT injuries; (2) Infection was the most frequent immediate complication, not correlated with the severity of injuries; (3) Only patients with grade IIB and III developed stenosis; (4) Therapeutic endoscopy were successful in 62%; (5) Caustic injuries can be potentially fatal. "P P 28 0671"P 28 0671**Endoscopic Diagnosis of Esophageal Varices Using an Endoscopic Image Processor (EVIP-230)**

*S. Okamura, N. Muguruma, A. Tsutsui, T. Fukuda, S. Hayashi, T. Okahisa, H. Shibata, S. Ito

Second Department of Internal Medicine, School of Medicine, The University of Tokushima, Tokushima, Japan

Purpose Following recent advances in the treatment of esophageal varices, these varices assume diverse morphological features after treatment or upon recurrence. For this reason, detailed endoscopic assessment of varices is now more important than ever. We recently assessed the usefulness of an endoscopic image processor (OLYMPUS Endoprocessor EVIP-230) as a means of endoscopic diagnosis of esophageal varices.

Subjects and Methods The subjects of this study were 45 patients with esophageal varices who underwent endoscopy at our department after October 1995. By the time of endoscopic assessment, 15 cases had received no treatment and 14 cases had undergone treatment, in other 16 cases, endoscopy was performed both before and after treatment. The endoscopic image were subjected to adaptive structure enhancement or IHb color enhancement or both on a real time basis or some time later after the data was stored on optomagnetic disc.

Results Image processing was very useful in assessing the efficacy of treatment and the post treatment morphology of varices, especially in examining the presence/absence and location of small vessels. During the follow-up period, varices recurred in 2 cases. in both cases, the morphology of recurrent varices could be predicted in advance, by processing produced difficulties in making a judgment of Red color sign or to follow the time course of varices.

Conclusion The Endoprocessor EVIP-230 was very useful as a means of endoscopic diagnosis of esophageal varices. However, so that the time course of varices could be followed and the data could be compared among patients treated at different facilities, it seems necessary to process images after assessing the raw images and to standardize the color of processed images.

"P P 28 0672"P 28 0672**Endoscopic Evaluation of Solitary and Scattered Varices and Analysis of Clinical Features**

*T. Fukuda, S. Okamura, A. Tsutsui, S. Taoka, M. Sogabe, H. Matunaga, Y. Ohkita, N. Muguruma, S. Hayashi, T. Okahisa, H. Shibata, S. Ito

Second Department of Internal Medicine, School of Medicine, The University of Tokushima, Tokushima, Japan

Purpose The pathogenesis and clinical significance of solitary or scattered varices of the upper or middle esophagus, not contiguous to any varix of the lower esophagus, have not yet been fully clarified. We recently carried out endoscopic assessment of these varices and analyzed the clinical features of patients with these varices.

Subjects and Methods Between 1991 and 1995, routine endoscopic examinations of the upper gastrointestinal tract were carried out on 6128 individuals. Of these individuals, 31 cases (18 males and 13 females, and 61.3 years old on average) were found to have solitary or scattered varices (53 lesions in total). The clinical features and endoscopic findings of these cases were analyzed. 12 cases (25 lesions) were followed up.

Results Varices were more often solitary (20 cases, 64.5%) than scattered (11 cases, 35.5%). Blue varices were seen in 19 cases (61.3%), and white varices in 11 cases (35.5%). One case (3.2%) had both blue and white varices. Varices were dome-shaped in 23 cases (74.2%) and ""Quonset hut""-shaped in 8 cases (25.8%). Of all cases studied, only 8 cases (25.8%) had underlying disease which could cause ordinary esophageal varices (e.g. portal hypertension, congestive heart failure and SVC obstruction). 4 cases had chronic hepatitis and another 4 cases had liver cirrhosis. Disease of the upper gastrointestinal tract, which accompanied varices, include chronic gastritis (13 cases) and gastric polyps (6 cases). When 12 cases were followed up for 10.4 months on average, 10 cases showed no change in the size or number of varices, one case showed a size reduction, and another one case had disappeared.

Conclusion On the basis of the results we obtained, we think it is unlikely that the factors known to cause ordinary esophageal varices are responsible for the onset of solitary or scattered varices. These varices seem to be attributable to: (1) dilatation of submucosal vessels due to local fragility or compression, or (2) increase in local blood flow. "P P 28 0673"P 28 0673**The Use of Endoscopic Ultrasonography in the Study of the Azygos Vein in Patients with Esogastric Varices**

*Z.A. Salama[1], A.M. Kassem[1], M. Giovannini[2], M.S. Hunter[1]

[1] Tropical Medicine and Gastrintestinal Endoscopy Departments, Faculty of Medicine, Cairo, Egypt

[2] Digestive Oncology Unit. Paoli-Calmettes Institute, 232 bd St-Marguerite, 13273 Marseilles Cedex 9-FranceIn the course of portal hypertension portosystemic collaterals develop, which may lead to the formation of esophagogastric varices (EGV). The most important collateral system is the coronary-gastroesophageal-azygos system. Thus, the azygos vein may be used for quantification of variceal blood flow. In this study the azygos vein was examined by endoscopic ultrasound (EUS) including Color-Doppler EUS. Eighteen patients having esophageal varices due to chronic liver disease were included. Eleven of them had no history of variceal bleeding while 7 had at least one attack of variceal bleeding. They were subjected to EUS examination using the Pentax FG-UA echoendoscope with a Hitachi EUB display unit; a system allowing the performance of duplex Doppler and colour flow mapping in vascular structures. Further 13 cases not suffering from chronic liver disease or varices were used as a control group and were subjected to the same examination. In all patients and controls subjects the azygos vein was sought; its diameter and the velocity inside were measured. Both the diameter and the maximal velocity in the azygos vein were found to be higher among portal hypertensive patients than control subjects ($p < 0.01$). These two parameters were also found to be higher among non-treated portal hypertensive patients than those who have been subjected to injection sclerotherapy (4 patients) without reaching statistical significance. "P P 28 0674"P 28 0674**Prognostic Determinants of Endoscopic Treatment of Esophageal Varices**

*P.K. Kupcsulik, Zs. \'c9les, L. D\'f6ng\'f6lo″, P. Kokas, K. Pinkola

1st Dept of Surgery, Semmelweis Univ. of Medicine, Budapest, Hungary3210 patients with esophageal varices and portal hypertension due to liver cirrhosis underwent endoscopic sclerotherapy between 1980–95. In a prospective nonrandomised trial standardized protocol for treatment of esophageal varices was applied consecutively. Lethality of elective treatment of 1734 patients bleed previously was 0.07 percent. The small number of lethal cases excludes relevant analysis of risk factors for this group of patients. 16.2 percent of 1476 cases admitted for acute variceal bleeding dead.Analysis of independent variables for acute lethal outcome showed patient related and treatment related risk factors of different significance. Child-Pugh status, jaundice, rapid formation or progression of ascitic fluid during bleeding, onset, blood requirement in the first 24 hours, bleeding phase, hemorrhoids are the most characteristic patient related factors influencing early survival. Despite of standardized technique, skill in endoscopy, training of ICU personal play defining role in outcome. Failure of immediate control of rebleeding, optimal timing of repeated sclerotherapy, hesitation for urgent surgery, hypoxia have a significant negative prognostic value.For long term survival regular endoscopic control, lack of rebleeding, stop with alcohol consumption, continuous Propranolol therapy are of significant value. 2 year survival of patient regularly controlled is 92 percent, while that of patients without is 41 percent respectively. At 5 year actuarial survival of patients treated with Propranolol after sclerotherapy (73 percent) is significantly better than that of controls (58 percent) Managed care of patients treated by endoscopic sclerotherapy offers clinically acceptable results. [2] Department of Investigation Unit, La Paz Hospital, Madrid, Spain

Objectives To determine if ultrasonography (U.S.) Duplex Doppler color can help us establish the patients with higher risk of gastrointestinal (GI) bleeding amont those with cirrhosis and oesophageal varices (O.V.) grade III–IV.

Material and Methods

Patients 46 patients with cirrhosis and O.V. grade III–IV. 34 males and 12 females, with ages ranging from 38 to 73 years (average 59). 23 alcoholic, 18 HVC+, 5 alcoholic plus HVC+.We evaluated mean velocities, maximum velocity, flow pattern and flow direction in the portal, splenic veins and their collaterals. We also measured the Congestion Index (C.I.) in the portal vein and the resistivity index in the hepatic artery.Patients were followed up for a period of 14 months (2–18). U.S. Duplex Dopler color was performed at the beginning of the follow up. U.S. findings were evaluated at the end of the trial and comparison was established between two different groups. Group 1 included patients with no episodes of GI bleeding and group 2 included patients with GI bleeding from O.V.

Results 9 patients (19.5%) presented with GI bleeding from O.V. during the follow up. There were no differences between the two groups in terms of mean velocity, maximum velocity and flow pattern found in the portal vein, splenic vein and their collaterals. Patients with previous episodes of bleeding from O.V. had a higher Congestion Index (0.09 vs. 0.05) ($p < 0.05$) and a significant lower mean velocity in the portal vein (10 vs. 14) ($p < 0.05$).

Conclusions The measurement of the C.I. and the mean velocity in the portal vein using U.S. Duplex Doppler color is of great value to differentiated which patients among those with O.V. grade III–IV at greater propensity for variceal haemorrhage. "P P 28 0676"P 28 0676**MR Angiography to Evaluate Patients with Esophago-Gastric Varices before and after Endoscopic Sclerotherapy**

*S. Katsushima, T. Inokuma, H. Oi, M. Matsushita, T. Kimura[1], T. Higashi, J. Konishi[2]

[1] Department of Medicine and Radiology, Osaka Teishin Hospital, Osaka, Japan

[2] Department of Radiology and Nuclear medicine, Kyoto University Faculty of Medicine, Kyoto, Japan

Purpose To evaluate the usefulness of MR angiography (MRA) in the evaluation of patients with esophageal varices (EV) and/or gastric varices (GV) before and after endoscopic injection sclerotherapy (EIS). In particular, we sought 1) to determine whether MRA was useful in detecting both varicose lesions and portal collaterals, and 2) to evaluate therapeutic response to EIS.

Methods MRA was performed in 15 patients with EV and/or GV before and after EIS. For each patient 25–35 axial images were obtained during a single breath-holding using a fast spoiled GRASS pulse sequence. Data were reconstructed by using a two-dimension time-of-flight (TOF) algorithm.

Results MRA detected varicose lesions in all 6 patients with GV and in 9 of 10 patients with EV of grade F2 or higher. However, MRA detected EV of grade F1 in only 1 of 5 patients. There were no false-positive diagnose when compared with standard endoscopic findings. MRA revealed left gastric vein in 5 patients. The sensitivity of MRA for the depiction of left gastric vein was 80% (4 of 5 patients) when compared with findings during the portal phase of superior mesenteric arteriography. In 6 patients with persistent MR evidence of EV after EIS, EV recurred on follow-up endoscopy, although in 1 of 6 patients EIS showed complete eradication of varices endoscopically. EV recurred in 2 of 4 patients with no varices detected with both MRA and endoscopy after EIS; this recurrence correlated with the persistence of left gastric vein. MRA has a better predictor of the prognosis of GV than endoscopy, because EIS causes GV to swell for a few weeks after the procedure.

Conclusion MRA is a non-invasive technique that appears to be useful for detection of varices and other portal collaterals in patients undergoing EIS. "P P 28 0677"P 28 0677**Gastric Varices: Predictors for Bleeding**

*P.N. Cheng, C.Y. Chen, B.S. Sheu, T.T. Chang, X.Z. Lin

Division of Gastroenterology, National Cheng Kung University, Tainan, Taiwan

Background and Aim Gastric varix is an important cause of death in patients with liver cirrhosis and portal hypertension. No conclusive factors were identified as predictors for bleeding. In order to discover the factors which are suggestive of impending or possible gastric variceal bleeding, we conducted this retrospective study.

Patients and Methods From May 1989 to August 1995, two hundred and forty patients were diagnosed to have gastric varices in our endoscopic unit. Eighty-four patients were excluded due to suboptimal image quality for reviewing or lack of follow-up information. The gastric varices were described as form, location, and red color sign according to the classification of Hashizume

et al. Bleeding group was defined as (1) active bleeding or presence of blood clot over varices during endoscopic examination, and (2) lack of other bleeding sources. Non-bleeding group was defined as no bleeding episode occurred one month before and after endoscopic examination. The endoscopic characteristic and demographic data were collected for analysis.

Results The study included 156 patients. They were divided into bleeding and non-bleeding groups. Bleeding Non bleeding *P* valuePatient number (M:F) 31 (20:11) 125 (93:32)Age (yr) 50.6 – 17.8 50.6 – 17.3Etiology(cirrhosis:HCC:others) 22:6:3 89:29:7Location anterior (%) 4 (14%) 19 (17%) NSposterior (%) 6 (22%) 6 (5%) NSgreater curvature (%) 13 (46%) 72 (65%) NSlesser curvature (%) 5 (18%) 14 (13%) NSForm: Form 1 (%) 6 (21%) 72 (60%) < 0.001Form 2 (%) 11 (38%) 35 (29%)Form 3 (%) 12 (41%) 13 (11%)Red color sign (%) 17 (55%) 12 (10%) < 0.001*Conclusion* The form and the red color sign are significantly predictors for gastric variceal bleeding in our patients. "P P 28 0678"P 28 0678**Assessment of Variceal Hemorrhage in Cirrhotic Patients: A Comparison of Doppler Flowmetry, Endoscopy and Clinical Parameters**

*C.H. Wang, L.R. Mo, R.C. Lin, J.Y. Kuo, K.K. Chang

Department of Internal Medicine, Tainan Municipal Hospital, Tainan, Taiwan, R.O.C.

Background Esophageal varices are part of the system of spontaneous portosystemic collaterals that develop in portal hypertensive states. The risk of esophageal hemorrhage was thought to be closely associated with variceal size and other clinical features. However, no firm data are yet available. The aim of this study was to find more parameters to establish a causal relationship with variceal hemorrhage.

Methods We collected 47 cirrhotic patients (29 males, 18 females, mean age: 56.5 – 12.7 yrs) with (n = 17) and without (n = 30) variceal hemorrhage. The assessment parameters were evaluated as followings: (1) age, (2) modified Child's classification (an index of liver dysfunction based on serum albumin and bilirubin levels, prothrombin time, ascites, and encephalopathy), (3) characteristics of varices which were classified endoscopically as suggested by the Japanese Research Society for Portal Hypertension (e.g. color, red color sign, location and form) which were further devised as a simple scoring system, (4) number of varices which were also observed by endoscopy, (5) ""congestion index"" of portal vein (the ratio between the cross-sectional area and the blood flow velocity which was performed by abdominal Doppler examinations).

Results ""Congestion index"" of portal vein was significantly associated with characteristics of varices ($r = 0.53$, $p < 0.0001$), and numbers of varices ($r = 0.41$, $p = 0.006$). The points of variceal scoring system in hemorrhage group (n = 17) were significantly more than non-hemorrhage group (n = 30) ($p < 0.0001$). Also, numbers of varices in hemorrhage group were significantly more than non-hemorrhage group ($p = 0.009$). Logistic regression analysis revealed that characteristics of varices was the independent predictor of variceal hemorrhage.

Conclusions ""Congestion index"" obtained via Doppler ultrasonography have a clinical role in noninvasive detection of severity and numbers of varices. Endoscopic appearances of varices have a predictive value of variceal hemorrhage. "P P 28 0680"P 28 0680**Portal Hemodynamics after Long-Term Endoscopic Sclerotherapy of Esophageal Varices in Advanced Liver CirrhosisK. Boulanov**

Institute of Clinical and Experimental Surgery, Kiev, UkraineEndoscopic sclerotherapy (ES) of bleeding esophageal varices proved to be the treatment of choice in patients with advanced liver cirrhosis. Changes of portal hemodynamics caused by ES were studied in 30 cirrhotic patients (Child-Pugh class B – 14, C – 16), who had bled from large (> 5 mm) esophageal varices. All of them were assigned to elective long-term ES, which consisted of combined intra- and paravariceal injections of 3% sodium tetradecylsulfate using free-hand technique. Sessions of ES included 3–5 injections performed every other day and were repeated every 6 month. Complications were of minor importance. Portal venous flow (PVF) was measured using duplex Doppler system before and after sessions. Patients' follow-up ranged from 12 to 36 months. Mean values of PVF showed evidence of significant increase after ES from 437.0 to 580.2 ml/min ($P < 0.05$), but demonstrated a tendency to reduction before the next session. Complete obliteration of esophageal varices was observed after 4 sessions of ES in 18 patients (60%). At the end of the follow-up, PVF in this group was higher compared with that in patients with persistent varices (591.0 versus 476.6 ml/min). Considerable decrease of blood ammonia nitrogen level confirmed effective interruption of gastroesophageal collateral pathways.Thus, long-term ES in patients with advanced liver cirrhosis produces significant stable rise in PVF, providing that complete eradication of esophageal varices is achieved. "P P 28 0689"P 28 0689**Correlation between Endoscopic Findings and Histology in Portal Hypertensive Gastropathy**

*C. Gheorghe, G. Aposteanu, L. Gheorghe, Al. Oproiu

Center of Gastroenterology, Fundeni, Bucharest, RomaniaThe aims of this prospective longitudinal study were: to evaluate the relation between classic histology on endobioptic specimens and endoscopic patterns of portal hypertensive gastropathy (PHG); to investigate the histology as predictor of PHG evolution, from mild (mPHG) to severe (sPHG) and overt bleeding. Between 1989–1996, 225 pts with hepatic cirrhosis (CH) were evaluated for the study. We used endoscopic inclusion criteria for mPHG/sPHG allocation. We detected 137 PHG pts, of whom 98 pts completed the study (19 pts lost; 20 pts. excluded by means of exclusion criteria). The follow-up program comprised endoscopy-endobiopsies using a standard protocol; the specimens were processed routinely, stained with haematoxylin-eosin and blindly examined; examinations were performed at 6/12 mo. interval (small/large varices) till the end of the study or patient's death. The mean follow-up period was 42 – 24 mo. mPHG was found initially in 86 pts (87.7%) and sPHG in 12 pts (12.2%). During the follow-up, 18 mPHG pts developed sPHG. On admission, there were 41 pts (41.8%) with positive histological criteria for PHG (vascular ectasia) and 57 (58.2%) pts with negative histology. Positive histology correlated with endoscopic pattern of sPHG (cherry red spots) ($p = 0.009$). In the group of mPHG, the positive histology correlated with evolution from mPHG to sPHG: there were 12 positive and 6 negative histology pts in the group of evolving mPHG to sPHG ($p = 0.005$). Overt bleeding occurred in 12/98 and correlated with positive histology: 10 positive vs 2 negative histology pts ($p = 0.03$). Cumulative bleeding probability at 42 mo. was 48% vs 93% in severe/mild PHG (Kaplan-Meier method). The correlation between histology and PHG evolution from mild to severe and overt bleeding may imply the progression of vascular ectasia from the submucosa to mucosa (endobioptically intercepted) in the natural history of PHG. We may conclude that, especially in mPHG, endobiopsies are necessarily in prediction of the natural course of PHG. Endoscopy, specific: Stomach, duodenumLiver and bile ducts, 1: Cirrhosis: portal hypertension }"

"P P 28 0692"P 28 0692**Endoscopic Doppler Flow Ultrasonography in Portal Hypertension — First Results**

*J. Janssen, W. Johanns, C. Jakobeit, L. Greiner

Medical Clinic A, Municipal Hospital Wuppertal, University of Witten-Herdecke, Germany*Introduction.* This pilot study was performed to explore the facilities of endoscopic ultrasound (EUS) including Doppler flow measurement with regard to patients at risk of bleeding from portal hypertension.*Methods.* 20 patients with known portal hypertension were examined by upper gastrointestinal endoscopy and EUS with a 7.5 MHz curved array transducer (Pentax FG 32 UA/Picker CS 192). 10 patients had no prior bleeding episode (group A), 10 patients had undergone sclerotherapy after variceal hemorrhage (group B) and two patients of the latter group could be examined before and after transjugular intrahepatic portosystemic shunting. Variceal size and mean values of three Doppler flow measurements of representative varices were recorded.*Results.* Subepithelial esophageal varices could be detected in 18 patients by endoscopy and in 13 patients by EUS, whereas gastric varices were found in 6 patients by EUS versus two patients in endoscopy. Paraesophageal varices (n = 14) and paragastric varices (n = 6) were seen by EUS only. Distribution pattern of varices was unsystematic between the two groups. Mean flow values and flow range hardly differed between the two groups in paraesophageal, gastric and paragastric varices. Mean velocity tended to be higher in subepithelial varices in group B but could not be measured reliably in 5 of 13 patients because of small vessel diameter. In two patients mean velocity fell by about 10 cm/s after transjugular intrahepatic portosystemic shunting.*Conclusion.* In comparison with endoscopy, EUS is superior in detecting intramural gastric varices but inferior in diagnosing subepithelial esophageal varices. Paraesophageal and paragastric varices can be demonstrated by EUS only. Doppler flow measurement in subepithelial varices cannot reliably be done in vessels of less than 1.5 mm in size. The similar velocity range in both groups reveals that flow does neither necessarily reflect intravascular pressure nor indicate patients at risk of bleeding. Nevertheless the impressive fall in flow after transjugular intrahepatic portosystemic shunting in two patients is the result of lowering portal hypertension. Further systematic research is mandatory. "P P 28 0694"P 28 0694**Modification of Mucosal Blood Flow in Portal Hypertensive Gastropathy. A Laser-Doppler Flowmetry Study**

*M. Cianci, G. Gizzi, K. Jadallah, V. Villani, G. Elia, M. Migliori, A. Ferri, R. Corinaldesi

Department of Internal Medicine and Gastroenterology, University of Bologna, ItalyThe aim of our study was to estimate quantitative variations of gastric mucosal blood flow in patients affected by portal hypertensive gastropathy (PHG), using endoscopic laser-doppler flowmetry (ELDF).We performed ELDF in 11 patients (8 M: 56 – 12 yrs; 3 F: 60 – 9 yrs; mean age – SD) with PHG related to post-hepatitis cirrhosis and in 10 healthy controls (HC) (6 F: 48 – 4 yrs; 4 M: 50 – 9 yrs). All patients had PHG localized in the corpus and antrum (6 mild; 5 severe); 5 had esophageal varices (F1–F2) never undergone sclerotherapy. There was no history of { b}-blockers treatment. The laser-doppler flowmeter (Laserflow BPM-403, Vasamedics, USA) was connected to a perendoscopic laser probe and placed perpendicularly toward the mucosal surface. Two measurements were taken from the greater and lesser curvature of the corpus and antrum and expressed in flux units (ml/min in 100 cc of tissue). Finally, skin blood flow was measured at the forearm for 5 minutes. The mucosal/skin flow ratio (MUSK index) was calculated. Results were expressed as mean values – SD and analyzed by student's *t* test.The results showed a significant increase of the mucosal blood flow (MBF) and MUSK index (MI) in patients with PHG compared to HC (MBF: 30.53 – 4.18 vs 16.41 – 1.23, $p < 0.02$; MI: 9.3 – 0.5 vs 5.49 – 0.86, $p < 0.05$) and in severe PHG compared to the mild form (MBF: 35.84 – 3.3 vs 26.51 – 5.4, $p < 0.05$; MI: 11.08 – 1.6 vs 7.8 – 1.4, $p < 0.05$).We conclude that both MBF and MI are significantly increased in PHG. The increase of these haemodynamic parameters seems to be directly related to the severity of PHG. "P P 28 0695"P 28 0695**Evaluation of Changes in Portal Hypertensive Gastropathy (PHG) Following Endoscopic Treatment of Varices with Endoscopic Sclerotherapy (ES) or Band Ligation (EL)**

*M. Primignani, M. Materia, M. Bianchi, P. Preatoni, R. de Franchis

Cattedra di Gastroenterologia, Istituto di Medicina Interna, University of Milan, Italy

IRCCS Ospedale Policlinico, Milan, ItalyConflicting data exist on the evolution of PHG-related lesions in patients undergoing ES, and little is known about the relationship between PHG and EL.

Aim to evaluate the initial prevalence and severity of PHG in patients undergoing ES or EL, the evolution of gastric mucosal lesions during the course of these therapies, together with PHG-related bleeding events during follow-up.

Methods 55 patients with portal hypertension, mostly cirrhotics with previous variceal bleeding, underwent ES or EL. PHG was assessed by recording the 4 elementary signs of the NIEC classification (mosaic pattern, red points, cherry-red spots, black-brown spots). PHG was classified as mild, (mosaic pattern alone), or severe, (red signs or black-brown spots).

Results 27 patients received ES, 28 EL. Baseline clinical and demographic data were similar in the 2 groups. Initial prevalence of PHG was 55% (mild 44%, severe 11%) in ES, and 68% (mild 39%, severe 29%) in EL patients (P = N.S.). Varices were eradicated in 18 ES patients (67%) with a mean of 6.1 – 3.1 sessions, and in 18 (64.2%) EL patients, with a mean of 2.9 – 1.1 sessions. Worsening of PHG occurred in 9/27 (33.3%) ES and 7/28 (25.0%) EL patients (P = N.S.). Regression from severe to mild PHG was found in 2 (7%) ES and 3 (11%) EL patients (P = N.S.). The rates of progression and of regression of PHG lesions were uniform throughout follow-up in both groups. Rebleeding occurred in 10/27 (37%) ES, and in 11/28 (39%) EL patients (P = N.S.). PHG was the cause of bleeding in 2 (7%) EL patients only.

Conclusions In patients undergoing ES or EL, worsening of PHG-related mucosal lesions occurs in 25–35% of cases, while improvement occurs in 5–10% of cases. The effect of the two treatments on PHG is virtually identical, and uniform throughout follow-up. Bleeding related to PHG lesions is relatively uncommon. "P P 29 0704"P 29 0704**Role of ERCP before and after Laparoscopic Cholecystectomy**

*F. Sbeih, H. Khan, M. Al Johani, I. Al Traif

King Fahad National Guard Hospital, Riyadh, Saudi Arabia

Purpose To evaluate the usefulness of ERCP and endoscopic sphincterotomy (EST) in patients undergoing laparoscopic cholecystectomy (LC) with suspicion of choledocholithiasis and in the management of complications resulting from LC.

Methods This is a retrospective analysis of our experience at King Fahad National Guard Hospital, a tertiary care and referral center for hepatobiliary disease. Between January 1992 and December 1995 a total of 717 ERCP and 1221 LC were performed. 257 ERCP were performed on 225 patients who underwent LC, 230 were done before LC and 27 after LC. Age range was 10–85 years (mean 43.5 years). There were 77 (34%) males with mean age of 51.7 years and 148 (66%) females with mean age of 39 years.

Results Over all success rate for ERCP was 92% (96% for diagnostic and 88% for therapeutic outcome). Choledocholithiasis was found in 79 patients (40%). Prediction of choledocholithiasis based on abnormal liver chemistries was accurate in 28%, in 47% of cases when based on ultrasound criteria and it reached 70% when based on both. From 40 cases of acute biliary pancreatitis, choledocholithiasis was found in 8 (20%). Indications for ERCP post LC included 8 retained stones, 8 cases of bile leaks, (7 of which treated endoscopically) and 4 major duct injuries which required surgical repair. Complications encountered were two cases of significant bleeding post EST and 3 cases of mild pancreatitis.

Conclusion ERCP and EST are effective and safe in the diagnosis and management of choledocholithiasis and facilitate the role of LC. The procedures are also valuable in the diagnosis and management of most complications resulting from LC. "P P 29 0708"P 29 0708**Endoscopic Papillary Dilatation and Nasobiliary Drainage for Bile Leak after Laparoscopic Cholecystectomy**

*M. Ito[1], T. Ooyama, S. Sezai, T. Abe, Y. Sakurai, F. Ikegami, K. Kamisaka, K. Ito[2], S. Agawa, Y. Ishihara

[1] Dept. of Gastroenterology, The Kanto Teishin Hospital, Tokyo 141, Japan

[2] Dept. of Surgery, The Kanto Teishin Hospital, Tokyo 141, JapanLaparoscopic cholecystectomy carries an increased risk for bile duct injury than open cholecystectomy does. Most frequent complications are minor bile leaks such as cystic duct leak which have been usually treated with papillotomy and/or stent insertion for several weeks. Recently papillary balloon dilatation has received attention and replaced papillotomy in some cases. We investigated the usefulness of papillary balloon dilatation and nasobiliary drainage in patients of bile leak after laparoscopic cholecystectomy.*Patients and Methods.* During four-year period, 450 patients underwent laparoscopic cholecystectomy. Bile duct injuries recognized after the operation were reviewed. When bile leak was noted at postoperative ERCP, we preferred to perform papillary balloon dilatation and nasobiliary drainage for a week.*Results.* Five patients of bile leaks from cystic duct stump and one patient of right hepatic duct leak were diagnosed by ERCP and successfully treated with papillary balloon dilatation and nasobiliary drain. The drainage tube was withdrawn about a week later when no leak was shown by nasobiliary tube cholangiography. The remaining one patient was noted to have transection of the common bile duct and treated with hepaticojejunostomy.*Conclusions.* Endoscopic papillary dilatation and nasobiliary drainage is another safe and useful treatment for bile leakage after laparoscopic cholecystectomy.

"P P 30 0723"P 30 0723**Evaluation of 12 Cases of Anomalous Arrangement of Pancreaticobiliary Ductal System (AAPBDS)**

*Kamiya Ryoichi[1], Seki Hidemasa[1], Suzuki Akihiko[1], Oikawa Masataka[1], Saito Juniti[2], Kato Norihiro[2], Sugimura Yoshihiko[2], Monma Nobuhiro[3], Kakuhara Noriyoshi[4], Abe Chihiro[4]

[1] Department of Gastroenterology, Morioka Red Cross Hospital

[2] Department of Surgery, Morioka Red Cross Hospital

[3] Department of Pathology, Morioka Red Cross Hospital

[4] Department of Radiology, Morioka Red Cross Hospital

Aim This study was carried out in order to demonstrate that Anomalous Arrangement of Pancreaticobiliary Ductal System (AAPBDS) was closely associated with carcinoma in the biliary tract.

Methods and Results Between January 1988 and April 1994, Endoscopic-Retrograde-Cholangio-Pancreatography (ERCP) was performed in our hospital for 935 cases, of which 12 cases were diagnosed as AAPBDS. The ages of these cases ranged from 40 to 70 years; 4 cases of age in the 40s, 4 in the 50s, 3 in the 60s and one in the 70s.Ultrasonography (US), Endoscopic Ultrasonography (EUS), Computed Tomography (CT) and Angiography were performed for these 12 patients, 4 of whom had a carcinoma in the biliary tract. Patients consisted of 3 females aged 44–68 years and one male 40-year-old: an average age of 50 years.On the other hand, operation could be carried out in 9 of 12 patients diagnosed as AAPBDS by ERCP and EUS. The value of amylase in the bile of the 9 patients was extremely elevated. From these findings, the presence of AAPBDS in these patients could be confirmed.

Conclusions It should be noted that the average age, in the case having biliary tract carcinoma with AAPBDS, was 20 years younger than those who had the carcinoma without AAPBDS. Concerning the fact that 4 cases (33%) with complicated carcinoma in the biliary tract, minute examination of AAPBDS by ERCP and EUS should be required before surgery. "P P 32 0746"P 32 0746**Association of Melanosis Coli and Colorectal Neoplasms?G. Nusko, B. Schneider, Ch. Wittekind, E.G. Hahn**

Depts. of Medicine I & Pathology, University of Erlangen and Inst. of Biometrics, Medical School of Hannover, GermanyMelanosis coli has been considered for a long time as a harmless pigmentation of the colorectum associated with the use of anthranoid laxatives. Recent experimental and clinical studies (Gut 1993; 34: 1099–1101) showed the evidence of a possible association of melanosis coli and colorectal neoplasms.

Methods A total of 2229 consecutive patients underwent total colonoscopy at the Dept. of Medicine I of the University of Erlangen. The findings of the initial colonoscopic examination were analysed. The median of age of patients was 55 years. 1213 (54%) patients were male and 1016 (46%) female. The association of melanosis coli, laxative use and colorectal neoplasms was analysed retrospectively and statistically assessed using the Mantel-Haenszel test for linear association.

Results Melanosis coli was found in 102 (4.6%) patients. Hyperplastic polyps were found in 198 (8.9%), adenomas in 441 (19.8%) and carcinomas in 60 (2.7%) patients. Colorectal polyps were significantly associated with melanosis coli (p = 0.0002). The relative risk of melanosis coli for tubular adenomas was 1.8 (95% CI: 1.3–2.6), for tubulovillous adenomas 2.03 (95% CI: 1.1–3.8). An association of melanosis coli and villous adenomas was not found, and the association with carcinoma was not significant (RR 1.1; 95% CI: 0.4–3.4). Melanosis coli was significantly associated with anthranoid laxative use (p = 0.00004). The relative risk of laxative use for tubular adenomas was 1.6 (95% CI: 1.3–2.1). Laxative use and tubulovillous or villous adenomas or carcinomas were not significantly associated. Colorectal adenomas found in patients with melanosis coli were predominantly located in the proximal colon (p = 0.0002) and were significantly smaller (p = 0.00001) than in patients without melanosis coli. No significant differences were found in the grade of dysplasia between patients showing melanosis coli and those without. Colorectal carcinoma was not associated with melanosis coli or laxative use.

Conclusions Melanosis coli and anthranoid laxative use can not be considered as a significant risk factor in the development of colorectal carcinomas. Colorectal adenomas associated with melanosis coli are small and proximal located polyps. Polyps do not contain the melanin-like piment. The association of colorectal adenomas and melanosis coli can be explained by the easiness of detecting even smaller polyps as a white point within a dark coloured colonic mucosa. Oncology, specific: Colon, rectumOncology, general: Screening, prevention }"

"P P 35 0790"P 35 0790**Endoscopic Treatment for Anal FissureJ. Mat\'e9,**

*A. G\'f3mez, M. P\'e9rez, P. Robledo, J.A. Correa, J.M. Pajares

Gastroenterology Department, Hospital de la Princesa, Madrid, Spain

Aim To compare the results of endoscopic anal dilatation (EAD) with those of lateral internal sphincterotomy (LIS) for the treatment of fissure-in-ano.

Patients and Methods 62 patients, 35 F (mean age 43 yrs, range 20–72) and 27 M (mean age 42 yrs, range 16–82) were referred to our Department for treatment of fissure-in-ano. Anal dilatation was performed with a two-valved anoscope (RichardWolf 884900) under local anesthesia in an ambulatory setting. A complete dilatation is achieved when anoscope's valves are parallel, reaching a distance of 4.5 cm., and is maintained for 4 minutes. Patients follow-up was at 30 days and at 12–24 months. There was therapeutic response when the symptoms completely dissapeared, another treatment procedures were not necessary or fissure epithelization could be demonstrated at anoscopy.

Results At 30 days 55 patients (95.2%) were free of symptoms and the treatment was considered successful. 4 patients did not come to the visit and other three shew a persistent fissure at anoscopy. All of them were excluded from the study. After a mean interval of 19 months (range 12–24), we contacted one more time with our patients. 47 of them replied: 46 were asymptomatic (97.8%). The other one recurred and underwent surgical treatment. At last, 4 were considered failures, in three of them EAD was not effective (4.8%), and the other one had a late recurrence (2.2%). No complications (incontinence, bleeding or discharge) were described.

Conclusions We compared our results with those of LIS reported and we verified that EAD is equivalent to LIS for anal fissure treatment and, furthermore, it is associated with fewer complications. So we think: 1) EAD is the choice procedure for patients with anal fissure, and so more in elder people in which LIS carries a higher complication rate and 2) Indications for LIS should be reserved for those patients with persistent or recurred fissure, and patients in which a proper dilatation can not be accomplished because of a fibrous anal stenosis. "P P 35 0791"P 35 0791**High Frequency Endosonography of the Female Perineum**

*A. Frudinger, C. Bartram

St Mark's Hospital, London, UK

Purpose of the study Recent technical improvements in anal endosonography, notably a 10 MHz transducer, have increased resolution requiring re-assessment of the normal anatomy.

Patients and methods 50 consecutive nulliparous females of median age 31.5 (range 19–65 yrs) were investigated. Anal endosonography was performed using a B&K Medical 3535 ultrasound scanner with 1850 endoprobe and 10 MHz transducer (focal length 1.5–4 cm).

Results A significant correlation with age was found only with the subepithelial thickness high in the canal (r^2 0.113, p 0.0179), and internal sphincter in the high (r^2 0.3024, $p < 0.0001$) and mid canal levels (r^2 0.2543, p 0.0002). The longitudinal muscle (95% CI 2.2–2.5 mms) could be distinguished as a distinct layer in all the females, and formed part of the anterior muscle ring in 42/50 (84%). The superficial transverse perineal muscles were demonstrated in 39 (78%). Aberrant muscle slips from the external anal sphincter, simulating defects, in 4/50 (8%). The 95% CI thickness of the anterior muscle ring was 4.4–5.2 mms.

Conclusion Improved sonographic resolution has allowed for the first time all the layers of the anal canal to be visualised in the female. Normal parameters have been established for a baseline for comparison to patients with damaged sphincters. "P P 35 0792"P 35 0792**Vaginal Endosonography in the Diagnosis of Anorectal Disease**

*A.C. Poen, R.J.F. Felt-Bersma, M. Koorevaar, M.A. Cuesta, S.G.M. Meuwissen

Depts. of Surgery and Gastroenterology, University Hospital ""Vrije Universiteit"", Amsterdam, the NetherlandsAnal endosonography is an established procedure in the evaluation of anorectal disease. However, vaginal endosonography (VE) is able to image the anal sphincters without distortion by the probe and can serve as an alternative if anal endosonography (AE) is not possible. In this study we described the pelvic floor anatomy with VE and we evaluated the additive value of VE in diagnosing anorectal disease.Between October 1994 and August 1995 AE as well as VE was performed in 81 women (26 fecal incontinence, 21 perianal abscess/fistula, 5 constipation, 6 IBD, 2 proctalgia, 21 other). In 23 cases, both with VE and AE the thickness was assessed of the internal (IST) and external anal sphincter (EST), the puborectal muscle (PRT) and the submucosa (SMT). Diagnostic improvement after vaginal endosonography was defined as obtaining more information due to clearer images with VE or due to limiting factors regarding anal endosonography (for example pain or anal stenosis)VE visualised the anal sphincters clearly in 67 of 81 cases. The dorsolateral part of the external anal sphincter was most difficult to image. IST (2.9 vs. 1.7 mm, $p < 0.001$), PRT (8.7 vs. 7.6 mm, $p = 0.001$) and SMT (5.8 vs. 2.4 mm, $p < 0.001$) were significantly increased compared to AE, while EST (5.7 vs. 7.5, $p < 0.001$) was significantly decreased. Anal and vaginal sphincter measurements correlated significantly. Differences existed by measuring the anal sphincters in an undistorted fashion and under a different angle with VE. Diagnostic improvement was seen in 18 (22%) of 81 cases. This was achieved especially in disorders of the rectovaginal septum, such as anterior sphincter defects and anovaginal sepsis.

In conclusion Vaginal endosonography is capable of imaging the anal sphincters in an undistorted fashion and has the potential of adding to the diagnosis of anorectal disease.

"P P 38 0869"P 38 0869**Mucosal Tissue Activated Oxygen-Producing Capacity in Endoscopic Redness of Gastric Mucosa by Chemiluminescence Assay****Kouichi Furukawa, Terasu Honma, Hirotaka Motoyama, Hiroyuki Enomoto, Yoshihisa Tsukada, Toru Takahashi, Hitoshi Asakura**

3rd Department of Internal Medicine, School of Medicine, Niigata Univ.

Objective Redness of the gastric mucosa noted by endoscopy is thought to reflect circulatory dynamics and inflammation at the affected areas. It is felt worthwhile therefore to study the degree of severity of mucosal inflammation in redness with or without erosion, superficial reddening and congestive gastropathy.

Methods Biopsy specimens taken from gastric mucosal lesions of 13, 12 and 13 patients, with endoscopically proven erosion, superficial reddening and congestive gastropathy (redness group) respectively and from the normal appearing gastric mucosa of 21 subjects for a non-redness (control) group (gastric body in 15 and pyloric region in 6) were used in the study. Mucosal tissue activated oxygen-producing capacity (ChL) was measured by luminol-dependent chemiluminescence method. Furthermore, histological changes of biopsy specimens categorized according to the Sydney system of gastritis classification were compared in ChL and polymorphonuclear leukocyte infiltration assessed by Erik et al.'s index among these lesions.

Results As to mucosal lesions, ChL was found to be significantly increased in erosive mucosa, but not significantly different in mucosal areas exhibiting superficial reddening or congestive gastropathy from the control. Assessed by the Sydney system of gastritis classification, ChL had a correlation with the degree of severity of inflammation but no significant association with any of the degree of inflammatory cell infiltration, atrophy, intestinal metaplasia and Helicobacter pylori (HP) infection. ChL, when assessed by Erik et al.'s index, was demonstrated to have a positive trend with increasing severity of mucosal infiltration by inflammatory cells, predominantly neutrophils.

Conclusion This study showed that superficial reddening of the gastric mucosa and congestive gastropathy unlike redness with or without erosion were not accompanied by inflammatory changes, suggesting participation of other factors than inflammation in the pathogenesis of the mucosal lesions. It seems that the presence of HP in the affected gastric mucosa does not always accompany by inflammation. Measurement of ChL by luminol-dependent chemiluminescence method was considered to be useful for evaluating the degree of severity of mucosal inflammatory cell infiltration, mainly by neutrophils, because it can be expressed numerically.

"P P 39 0888"P 39 0888**Long-Term Outcome of Enteral Nutrition by Percutaneous Endoscopic Gastrostomy (PEG)A. Jordan, A. Emde, A. Markus, W.F. Caspary, H. Seifert, J. Stein**

II Department of Internal Medicine, Div. of Gastroenterology, J.W. Goethe-University, 60590 Frankfurt/Main, GermanySince percutaneous endoscopic gastrostomy (PEG) was first described in 1980 it has gained wide acceptance and is now the preferred method for providing long-term enteral nutrition. However, most published studies describe only short-term outcome follow-up in any detail. The objective of this retrospective study was to evaluate the complications and course of long-term enteral nutrition by percutaneous endoscopic gastrostomy.

Subjects and methods A retrospective analysis was performed on 80 patients (21 F, 59 M; mean age 57.9 – 11.5 years, range 21–86) treated by PEG between 1992 and 1995. Complications has been devised into minor (requiring local care) and major (requiring laparotomy or life threatening).

Results PEG insertion was technically successful in all cases, no procedure related mortality was observed. Mean duration of PEG was 132 – 121 days (12–731). Severe complications occurred in 5% (1 aspiration induced pneumonia, 2 PEG tube-dislocation, 1 ileus). Most common minor complications were peristomal wound infection (31.3%) and brief periods of abdominal pain (37.5%). Typical side effects specific to nutrition were gastrointestinal symptoms (45%) like diarrhoea (12%), vomiting (13%), obstipation (11%).

Conclusion Long-term enteral feeding by PEG was safe, cost-effective, and had a low complication rate. Our patients were managed by a specialist nutrition team, which may reduce the complication rate and hospital visits for patients being fed at home. }" "Long-Term Outcome of Enteral Nutrition by Percutaneous Endoscopic Gastrostomy (PEG)"

"P P 39 0889"P 39 0889**Gastric Volvulus Managed by Endoscopic Decompression and Nonsurgical Gastropexia Via a Percutaneous Endoscopic Gastrostomy (PEG)**

*A. Schulte-Bockholt, U. Rosenstock, S. Clemens, A. Hofmann, B. Pleger, M. Keymling

II. Med. Klinik, Klinikum Meiningen, GermanyGastric volvulus, clinically characterized by Borchardts trias of pain, violent retching and inability to pass a nasogastric tube, occurs when the stomach twists on itself. We here describe a case of recurrent gastric Volvulus managed by endoscopic decompression and nonsurgical endoscopic gastropexia.

Material and Methods A 53 y male who was curatively treated with a resection of the cardia and fundus for an adenocarcinoma 6 years earlier, was hospitalized several times for pain and postprandial vomiting; a work up showed esophagitis grade III, but no obstruction. When admitted to our hospital with hematemesis, we again found esophagitis but this time were unable to visualize the pylorus and an organoaxial volvulus along the incisure was suspected. This condition resolved and reoccurred spontaneously twice over the next 5 days, and the patient was diagnosed endoscopically and radiologically of having a recurrent organoaxial gastric volvulus. When the volvulus reoccurred and a third time, we did a endoscopic decompression by advancing the scope past the point of torsion, turning and locking the tip and rotating the endoscope by 180 degrees, as described elsewhere.After decompression, as an alternative to a surgical gastropexia, the antrum of the stomach was attached to the abdominal wall by a 15 Fr. standard gastric pull through percutaneous endoscopic gastrostomy (PEG standard gastral; Fresenius, Germany). Our initial plan to attach the stomach to the abdominal wall by two PEG's instead of one, as described in the only other available case report, was not feasible. Because of resection of the cardia and fundus in our patient resulting in a small residual stomach, a second PEG could not be inserted.

Results After PEG placement the patients was without symptoms and the esophagitis resolved. The PEG was removed 4 month later, and after removal of the PEG the gastric volvulus did not reoccur within the last 6 month.

Discussion We describe here, to our knowledge, the second case of a gastric volvulus managed by endoscopic gastropexia via a percutaneous endoscopic gastrostomy. The assumed mechanism by which the stomach is fixed and stays attached to the abdominal wall are adhesions as seen with long standing PEG placement. While acute gastric volvulus with blood supply compromisation is often a dramatic illness, that requires fast surgical intervention, endoscopic gastropexia by PEG is a reasonable minimal invasive alternative treatment for recurrent and chronic volvulus. "P P 39 0890"P 39 0890**Transnasal Percutaneous Endoscopic Gastrostomy in Head and Neck Cancer Patients**

*A. Taller, E. Horv\'e1th, L. Hars\'e1nyi[1], L. Ili\'e1s

Uzsoki Teaching Hospital, Budapest, Hungary

[1] 1st Dept. of Surgery, Semmelweis Med. Univ., Budapest, Hungary

The purpose of the study Percutaneous endoscopic gastrostomy (PEG) feeding tubes are widely used for enteral feeding of undernourished cancer patients. PEG is frequently unsuccessful in head and neck malignancies. The purpose of the present study was to develop new endoscopic techniques for enhancing the success rate.

The methods used 32 consecutive patients with head and neck malignancies underwent 33 PEG placements between 01. 07. 95.–01. 05. 96. The ""pull-through"" method was used. There were three patients with partial trismus who were unable to open their mouths in a satisfactory degree for the introduction of the gastroscope. The gastroscope (Fujinon EG7–FP3) was inserted through the nostril and the esophagus was reached via the naso- and oropharyngx. After carrying out the upper gastro-intestinal endoscopy a PEG was placed on the an-terior wall of the stomach.

Summary of the results Transnasal introduction of the gastroscope and the placement of a PEG was successful in all patients. The procedure was well tolerated and was accomplished without any complications.

Conclusions Transnasal upper gastrointestinal tract endoscopy can be used for diagnostic and therapeutic reasons. This modification of the standard technique could be used in those cases when the oral route is unaccessible.The method is presented on video film. "P P 39 0891"P 39 0891**A Prospective Study of Enteral Long-Term Nutrition Via Percutaneous Endoscopic Gastrostomy (PEG) in 220 PatientsChr. L\'f6ser, S. Wolters, U.R. F\'f6lsch**

I. Medical Department, Christian-Albrechts-University of Kiel, GermanyAim of the present prospective study was to evaluate over a four-year observation period the long-term results, complication rates, subjective and general behaviour and nutritional problems in 220 patients with PEG.

Methods Between 1991 and 1995 a PEG was placed in 220 patients (130 ♂, 74 ♀; age 61.4 – 15.5 years) and the patients were prospectively controlled and followed up for an average of 134 – 182 (1–1498) days. 41% had malignant, 59% benign diseases. All patients received a single antibiotic prophylaxis (2 g cephalosporine i.v.). Indication, early and late complications, mortality, nutritional status, course of body weight and disease, individual behaviour and management as well as nutritional long-term problems were prospectively studied.

Results Indication: internal medicine 30%, ENT 28%, neurological diseases 42%. Duration of PEG procedure: 13.3 – 4.2 min. Mortality: 0%. Early complications (< 30 days): perforation = 0.5%, peritonitis 0.5%, aspiration 0.5%, mild local wound infection 10.3%. Late complications (> 30 days): local wound infections 1.5%, tube fracture 0.5%. In 6 patients the PEG had to be removed due to severe complications. In 39 patients with benign diseases the PEG could be removed without complication after sufficient oral food intake was reachieved. Concomitant patients' care: special hospitals 17%, nursing home 20%, at home by relatives 29%, by themselves 6%, by home-care services 21%. Drop of body weight in 3 months before PEG (x&bar; = { -}11.4 – 1.5 kg); gain of body weight during 1 year after PEG placement (all: +3.5 – 1.7 kg; malignant: +2.3 – 2.2 kg). Subjective acceptance: well 83%; sufficient 15%; bad 2%. Nutritional status was obviously improved.

Conclusions In this prospective study long-term enteral feeding via PEG proved to be a safe, effective, easy to practise and highly acceptable method with few complications and excellent long-term results. Early PEG placement significantly improves nutritional status and increases quality of life in all patients studied. "P P 39 0892"P 39 0892**Percutaneous Endoscopic Gastrostomy — Experiences of 775 Procedures**

*M. Gawenda, B. Wolfgarten, H. Sch\'e4fer, M. Walter

Department of Surgery, Medical Center, University of Cologne, D-50924 Cologne, GermanyPercutaneous endoscopic gastrostomy (PEG) was introduced in 1980 as an alternative to traditional operative methods for creation of a feeding gastrostomy. The simple procedure involves a shorter hospitalization, lower risk and reduced costs.The aim of this retrospective study was to determine the indications, success rate, the procedure-related mortality, and major and minor complication rates.

Results In our experience from 1st January 1987 to 15 March 1996 775 patients underwent placement of a percutaneous endoscopic gastrostomy (PEG) tube using a single endoscopic technique and a polyurethane gastrostomy tube; material costs amount below 100,— DM.Most patients (95%) received intravenous sedatives with topical anesthesia.575 males and 200 females with mean age of 57.8 years (SEM – 0.5, range: 2–96) were supplied with PEG tubes for the purpose of enteral feeding. In 67.3% carcinoma disease indicated PEG tube. The most common indications for placement of the gastrostomy tube were otorhino-laryngeal disorders (52%) and carcinoma of the maxillo-facial region (15.9%). Neurologically based dyphagia indicated PEG-tube placement in 12.6%.The overall complication rate was 10.0%, with a major complication rate of 1.2%. Three method correlated death occurred.

Conclusion We conclude that PEG is the procedure of choice to achieve long-term enteral nutrition. Furthermore PEG is an efficient, rapid method with minimal morbidity, low costs and insignificant mortality that made placement possible without general anesthesia. "P P 39 0893"P 39 0893**Single Shot Antibiotics in Percutaneous Endoscopic Gastrostomy (PEG) — A Prospective Randomized Study**

*M. Gawenda, H. Sch\'e4fer, B. Wolfgarten, M. Walter

Department of Surgery, Medical Center, University of Cologne, D-50924 Cologne, GermanyPercutaneous endoscopic gastrostomy (PEG) was introduced in 1980 as an alternative to traditional operative methods for creation of a feeding gastrostomy. The simple procedure involves a shorter hospitalization, lower risk and reduced costs.To literature tube infection is the most common complication with a frequency of 10 to 30%.In a prospective randomized study we want to find out if single shot antibiotic at the time of tube insertion can reduce the rate of early local infections.

Method All patients that receive percutaneous endoscopic gastrosomy were randomized to two groups. Group I receive Cefazolin (2 gr.) as single shot antibiotic before starting the endsocopic procedure. The other patients (Group II) received PEG tube without antibiotics.

Results 100 patients underwent placement of a percutaneous endoscopic gastrostomy (PEG) tube using a single endoscopic technique and a polyurethane gastrostomy tube; material costs amount below 100,— DM. Most patients (97%) received intravenous sedatives with topical anesthesia. The procedure was technically successful in all patients. The mean age was 57.8 years (SEM – 0.5, range: 2–96). In both groups 5 patients developed local skin infections at the tube insertion. Therefore the overall complication rate was 10.0%, without major complications. No method correlated death occurred.

Conclusion We conclude that PEG is the procedure of choice to achieve long-term enteral nutrition. Furthermore PEG is an efficient, rapid method with minimal morbidity, low costs and insignificant mortality that made placement possible without general anesthesia. Single shot antibiotic cannot reduced the early skin infection rate. Endoscopy, general: ComplicationsEndoscopy, specific: Stomach, duodenumNutrition: Techniques of nutrition }"

"P P 39 0894"P 39 0894**Percutaneous Endoscopic Gastrostomy Feeding: Scintigraphic Detection of Gastrooesophageal Reflux**

*K.K. Balan, J. Bennett[1], P. Maltby, S. Woods, S. Vinjamuri, J.R. Playfer[2], M. Critchley

Department of Nuclear Medicine, Royal Liverpool & Broadgreen University Hospital Trust, Liverpool, L7 8XP, England

[1] Department of Gastroenterology, Royal Liverpool & Broadgreen University Hospital Trust, Liverpool, L7 8XP, England

[2] Department of Geriatrics, Royal Liverpool & Broadgreen University Hospital Trust, Liverpool, L7 8XP, EnglandPercutaneous endoscopic gastrostomy (PEG) is the method of choice for feeding patients who are unable to eat adequately and yet have a functional GI tract. PEG eliminates the need for surgery or nasogastric tubes, is easily performed with few demands on health service resources. Aspiration pneumonia may complicate PEG insertion but there are few studies on gastrooesophageal reflux (GOR) in PEG patients.

Methods 19 patients (12 M, 7 F, age 43–83 years, median 72) with PEG underwent radionuclide GOR studies. 12 patients had neurological and 7 had mechanical dysphagia. They received 100 ml of orange juice containing 25 MBq of Tc^{99m}-tin colloid followed by 250 ml of normal saline, through the PEG tube. Patients lay supine under the gamma camera linked to a digital computer system. 4 minute and 4 hour images over stomach, oesophagus and lungs were examined for GOR and lung aspiration.

Results 8 patients, 6 of whom with neurological dysphagia and 2 of whom with mechanical dysphagia, had severe GOR. 2 other patients with neurological dysphagia had mild GOR. One patient with severe GOR also had lung aspiration at 4 hours. 9 patients had normal studies.

Conclusions 1) Radionuclide imaging can assess GOR in PEG patients 2) GOR appears to be a significant problem in patients with PEG and 3) PEG patients with neurological dysphagia appear to be at greater risk for GOR than those with mechanical dysphagia. Further studies are in progress. Nutrition: Nutrients and gut function }" "Percutaneous Endoscopic Gastrostomy Feeding: Scintigraphic Detection of Gastrooesophageal Reflux"

"P P 39 0896"P 39 0896**Efficacy of Endoscopic Resection of Intramucosal Gastric Cancer after Five Pointed Laser Marking**

*K. Fukase, T. Matsuda, M. Terashita, I. Aoyama, Y. Okuyama, J. Sakai, H. Saito, S. Sato

Dept. of Internal Medicine, Yamagata Prefectural Central Hospital, Yamagata-city, Japan

Purpose The result of endoscopic resection (ER) of intramucosal gastric cancer without marking was not satisfactory. For the purpose of accomplishing higher rate of complete resection (CR), ER was performed after marking.

Patients and methods From July 1978 to April 1996, 384 cases, 410 lesions of intramucosal gastric cancer were resected endoscopically. The laser marking was started in August 1990 and 86 cases, 89 lesions were treated with this method. Firstly 5 points (2 points in the oral and 1 point in the anal, anterior and posterior side) are marked endoscopically, about 2 mm distant from the border of the lesion, using a Nd-YAG laser. Secondly the lesions were resected including these markings. If 5 markings are detected, the lesion is considered to be completely resected. If the 2 oral markings are detected in the resected specimen, it is possible to find the orientation. And if there is a remnant lesion, the remaining markings make it easier to perform re-ER or additional laser treatment.

Result Out of 321 lesions without marking, 134 lesions were resected completely and the rate of CR was 41.7%. Out of 89 lesions with markings, 63 lesions were resected completely and the rate of CR was 70.8%. The rate of CR using laser markings was higher than the one without ($p < 0.01$).

Conclusion This method is effective because it improves the rate of CR, it enables recognition of the orientation and greater ease of additional endoscopic treatment. "P P 39 0897"P 39 0897**The Value of Endoscopic Ultrasonography (EUS) in Diagnosis and Staging of Primary Gastric LymphomaS. Tarazis,**

*C. Markoglou, E. Tsohataridis, M.Z. Trivizakis, N. Kalantzis

Department of Gastroenterology, NIMTS Hospital; Athens, Greece

Purpose The diagnosis of primary gastric lymphoma cannot always be established by endoscopic biopsies, because the lesion arises from the lymphatic tissue, which may not be reached with a biopsy forceps. Moreover, the lack of specific gross abnormalities does not allow the establishment of diagnosis during endoscopy. In our study we report our experience concerning the value of EUS in detecting and staging gastric Non-Hodgkin's lymphoma.

Materials and methods Between 1993 and 1996 EUS was performed in 550 patients in our department. Among the patients with non specific gross abnormalities, abnormal EUS findings, which would be compatible with primary gastric lymphoma, were shown in 55 patients. In 18 of them the final diagnosis established by surgery was primary gastric lymphoma. T_1–T_3 patients were subjected to total or subtotal gastrectomy, while T_4 patients were followed-up by means of EUS after chemotherapy. In 13/18 patients the diagnosis was revealed by endoscopic biopsies. The other 5 patients required exploratory laparotomy to prove the diagnosis.

Results The results of EUS were compared with those obtained by endoscopy, CT scan, surgical exploration and the detailed histological examination of the resected specimens. One T_3 patient according to the EUS findings was finally T_2. In 4 patients EUS failed in the N staging. One patient was overstaged and three were understaged.We *conclude* that EUS can clearly visualize the abnormalities of the layer structure of the gastric wall, and could be used together with other diagnostic procedures such as US and CT to determine the extent of a tumor and to decide whether to operate or to administer chemotherapy. "P P 39 0898"P 39 0898**Diagnosis of Early Gastric Cancers by an Endoscopic Autofluorescence Imaging System**

*H. Yano[1], H. Iishi, M. Tatsuta[2]

[1] Yukawa Gastrointestinal Hosp., Osaka, Japan

[2] Dept. of Gastrointestinal Oncology Osaka Medical Center for Cancer and Cardiovascular Diseases, Osaka, JapanCancer and precancerous lesions in many organs generates attenuated autofluorescence in green spectrum band compared to that from normal tissues when irradiated by blue light. In the present study, we examined the clinical value of a new endoscopic autofluorescence imaging system for diagnosis of early gastoric cancers. This endoscopic system, LIFE-GI (Light Induced Fluorescence Endoscopy), was joint developed by Olympus (Japan) and Xillix (Canada). LIFE-GI consists of a mercury light source with blue light pass filter, a camera equipped with two high sensitivity image sensors for detection of green and red autofluorescence, and imaging processor for displaying auto fluorescence image. We applied this system to 30 patients with gastric cancer or suspicious of gastric cancer. In 23 of 25 early gastric cancers the lesions could be observed as a dark reddish-colored area by this system. Histological examinations of the resected specimens showed that the tumors corresponded well with the dark reddish-colored area. By this auto fluorescence endoscopy, we could detect a small early gastric cancer which could not be observed by conventional endoscopy. Neither hyperplastic polyps nor gastric ulcer scars showed autofluorescence. In conclusion, autofluorescence endoscopy is useful for diagnosis of early gastric cancers. Oncology, specific: StomachEndoscopy, specific: Stomach, duodenum }" "Diagnosis of Early Gastric Cancers by an Endoscopic Autofluorescence Imaging System"

"P P 39 0899"P 39 0899**Endoscopic Ultrasonography (EUS) for Evaluating Early Gastric Cancer before Endoscopic Mucosal Resection (EMR)M. Kida, Y. Yamada, T. Sakaguchi, H. Imaizumi, S. Tanabe, W. Koizumi, K. Saigenji, H. Shimao[1]**

Dept. of Internal Medicine, Kitasato Univ. East Hospital, Sagamihara, Kanagawa, 228 Japan

[1] Dept. of Surgery, Kitasato Univ. East Hospital, Sagamihara, Kanagawa, 228 Japan

Introduction Endoscopic mucosal resection (EMR) has been attempted in patient with small cancer ({\'a3} 2 cm) suspected to be mucosal invasion. We have already reported that EUS is the most accurate method presently available to determine the depth of cancer invasion and report the role of EUS for evaluating the indication of EMR.

Method We have already performed EUS in over 1300 patients with gastric cancer, and 1135 lesion were resected and studied histologically. And 56 lesions were removed by EMR in this group. EUS examination were performed with conventional EUS (GF-UM3, UM20, 34 lesions) and ultrasonic probe (USP, UM-3R, 2R, 22 lesions).

Result The diagnostic accuracy of USP vs EUS is 94.8% (93/98) vs 89.5% (274/306) in m-cancer, 68.1% (32/47) vs 69.3% (151/218) in sm-cancer, 54.5% (6/11) vs 72.8% (67/92) in pm-cancer, 75.0% (15/20) vs 89.8% (308/343) in ss-s-cancer, respectively. And totally 83.0% (146/176) vs 83.4% (800/959). Fathermore the accuracy of USP vs EUS for small lesion ({\'a3} 2 cm) is 85.7% (54/63) vs 86.1% (180/209). In the group of lesions resected by EMR, the accuracy is 90.9% (20/22) vs 94.1% (32/34). It is sometimes difficult to detect the small and flat lesion by conventional EUS, however there was no cases that could not be detected by USP.

Conclusions EUS is useful for evaluating the indication of EMR and USP is helpfull to evaluate the cases with small and flat lesions. }" "Endoscopic Ultrasonography (EUS) for Evaluating Early Gastric Cancer before Endoscopic Mucosal Resection (EMR)"

"P P 39 0900"P 39 0900**A Role of Endoscopic Mucosal Resection (EMR) and Laser Irradiation for Early Gastric Cancer**

*M. Morise, H. Shimao, Y. Arai, S. Kikuchi, N. Kobayashi, H. Mieno, Y. Sakakibara, Y. Hiki, A. Kakita, Y. Yokoyama, H. Imaizumi, S. Tanabe

Department of Surgery and Gastroenterology, Kitasato University, Sagamihara, JapanEndoscopic therapy, laparoscopic surgery, and minimally invasive surgery have been developed to as therapeutic procedures in patients with early gastric cancer. Presently, the procedure of choice for the endoscopic therapy of early gastric cancer is EMR because it permits histopathological evaluation. At our hospital we have performed EMR in 161 cases and laser therapy in 131 cases (total 292 cases) of early gastric cancer during 1981 to March 1995.The success rate for EMR, including absolute and relative indications, is about 50%. Various techniques are employed to treat remnant lesions. In inoperable cases, we use laser irradiation since there is no other satisfactory therapy. In operable cases, laser irradiation is performed in a limited number of indications because surgery has been established as radical therapy. Laser irradiation for remnant tumor after EMR in cases absolute indicated has been shown to be effective, with a cancer eradication rate of 93.1%. In cases relatively indicated for EMR, the rate for laser irradiation was 83.3%, which is rather good compared with that of 5.6% for EMR. Laser irradiation can thus be expected to provide a good outcome in the treatment of early gastric cancer, provided it is performed for the proper indications and objectives. "P P 39 0902"P 39 0902**Endoscopic Opening of Totally Laparoscopic Gastrointestinal Anastomosis with Previous Suture (EA)**

*K. Hashiba, A.L. Paula, S. Wada, W.R. Freitas, J.A. Delai, D. Moribe, A.F. Silva, D. Birolini

D. Dept. of Surgery, S. Paulo University Medical School, Dept. of Surgery Hospital and Mat. Atibaia, S. Paulo BrazilThis study introduces a new idea for the performance of totally laparoscopic gastrointestinal anastomosis in which the lumen is opened after the suture to prevent contact of gastrointestinal contents with the peritoneal cavity. The opening was done through endoscopic procedure.A metal stitch is introduced through the walls of the organs to bring them together as in a ""U"" suture. The ends of this metal stitch are taken by an endoscope and pulled to the mouth. Then a suture with non-absorbable stitch is made around the area that was brought together in order to tie the walls. Next, the ends of metal stitch were pulled against a plastic tube and, like a polypectomy snare, the walls were cut with a cautery under endoscopic control. The anastomosis is thus opened.Under general anesthesia, 4 pigs underwent gastrojejunal derivation and an other 4 pigs, gastrectomy. There were no complications in any procedures. Histology of the anastomoses did not reveal significant changes on the fifteenth day. One patient with small advanced gastric cancer underwent gastrectomy with EA. In the postoperative course this patient showed an abdominal wall hematoma.The results suggest that EA is a safe, easy and cheap procedure which opens a new path in the field of endoscopic procedures. Endoscopy, specific: Stomach, duodenumLaparoscopic surgery: Therapy }"

"P P 39 0903"P 39 0903**New Endoscopic Evaluation of the Healing Process of Gastric Ulcer**

*H. Imaizumi, M. Ohida, S. Noguchi, K. Hibi, S. Sugano, I. Kondou, Y. Kida, S. Tanabe, M. Kida, W. Koizumi, T. Mitsuhashi, K. Saigenji

Department of Gastroenterology, Kitasato University East Hospital, Sagamihara, Kanagawa, JapanTo clarify the healing process of gastric ulcers, we studied the usefulness of the pharmacoendoscopy (PE) method using epinephrine (Ep) spray.

Patient and Method Sixty five scar lesions were selected for this purpose. After color of scar lesions were classified red and white by conventional endoscopy, 0.02% Ep (10 ml) were sprayed endoscopially. After 3 minits spraying, the changes in color of scar lesions were classified to P_R (persistent reddish) and Pw (whitish). We also investigated the blood volume of the ulcer scar lesions using computer image analysis both before and after Ep spray. Then, cumulative recurrent rates in each group was calculated.

Result The mean blood volume of the P_R scar group was about 1.5 times higher than that of the surrounding normal mucosa. In contrast, the mean blood volume of the P_W scar group was almost same as that of normal mucosa. Cumulative recurrent rate in each 4 groups was studied dualing 24 months. Twenty four months cumulative recurrent rate in red scar group was 45%, while 35% in white scar group. These rates in P_R and P_W scar group were 43% and 10% respectively. P_W group showed the lowest 24 month cumulative recurrent rate among all groups. Biopsied specimens were examined histologically. The P_W scar group was showed more matured regenerating epithelium than the P_R scar group.

Conclusion These findings suggested that PE is useful for estimating the grade of ulcer healing especially for in scar stage. From the viewpoint of intra mucosal vessel function, ulcer scar showing P_W seemed to be healed completely. "P P 39 0905"P 39 0905**Diagnostic Accuracy of Salivary IgG Anti-Helicobacter Pylori in Dyspeptic Patients Referred to First Upper Digestive Endoscopy**

*F. Costa, S. Marchi, M.R. Romano, G. Amato, C. Belcari, E. Tumino, M. Bellini, M. Manghetti, M. Spataro, G. Maltinti

U.O. Gastroenterologia, I Clinica Medica, Universit\'e0 di Pisa, Pisa, Italia

Introduction and aim Salivary specific IgG anti-Helicobacter pylori (Hp) could be a simple and suitable tool for the diagnosis of Hp infection particularly in paediatric patients. The aim of the study was to evaluate the diagnostic accuracy of salivary IgG anti-Hp measurement by a new commercially available kit (Helisal-Cortecs Ltd. UK).

Patients and Methods Thirty consecutive dyspeptic patients (17 females, mean age 41 years) referred to first upper digestive endoscopy (UDE) entered the study. No patient had been treated before for Hp infection and had assumed non steroidal anti-inflammatory drugs, antisecretory drugs, antibiotics or bismuth compounds in the previous 3 months. Hp status was assessed by Cp-test, histology and serology (IgG Helori test Eurospital, Italy). Patients were defined as Hp positive if Cp-test and histology gave a positive result and negative if both tests resulted negative. Serum and unstimulated saliva were collected before UDE and stored at { -}20 \'b0C and 4\'b0C respectively until assayed.

Results UDE revealed duodenal ulcer (DU) in 5 patients and no gastroduodenal lesions (NUD) in 25 patients. Sixteen (53%) patients were diagnosed as Hp positive (5/5 DU and 11/25 NUD). Serum IgG anti-Hp gave 3 false positive and 0 false negative results; the sensitivity was 100%, the specificity 79%, the positive and negative predictive value (PPV and NPV) 84% and 100% respectively. Salivary IgG anti-Hp gave 5 false positive and 4 false negative results with a diagnostic sensitivity of 75%, a specificity of 64% and a PPV and a NPV of 71% and 44% respectively, the accuracy rate as a whole resulted of 70%. Salivary and serum IgG anti-Hp showed concordant results in 24 out of 30 patients.

Conclusion IgG anti-Hp are present in the saliva of Hp infected patients and their measurement can represent a simple and rapid method for the diagnosis of Hp infection. Our preliminary results, nevertheless, show a lower sensitivity, specificity and diagnostic accuracy if compared with serology and require further investigation. "P P 39 0907"P 39 0907**Prediction of Diagnosis of Dyspepsia in the Era of Open Access Endoscopy**

*C.R. Ramsay, M.K. Campbell, M. Lopez[1], S.A. Naji, F.E. Murray[1]

Health Services Research Unit, Foresterhill, Aberdeen AB25 2ZD

[1] Dept of Clinical Pharmacology, Ninewells Hospital, Dundee DD1 9SYThe investigation of dyspepsia has altered in much of the UK consequent to the wide spread of open access endoscopy. The benefit of a normal diagnosis remains to be confirmed.

Aim To evaluate factors which may be predictive of an endoscopy (1) in terms of impact on patient management and (2) in terms of patients with important clinical diagnoses, at a newly established open access endoscopy service.

Methods During a 1-year period, 1028 patients endoscoped within this service were evaluated. All patients were asked to complete a dyspepsia questionnaire, and referring doctors also completed a referral questionnaire for each patient. Follow-up questionnaires were sent to the referring doctors and patients one month after the endoscopy. The dataset was randomly split into two groups, one group (the Model group) was used to develop predictive models using logistic discriminant analysis and the second group (the Test group) to test the robustness of the developed models.

Results The accuracy of the referring doctor's provisional diagnosis ranged from 1% for ulcers and 5% for cancers to 39% for reflux oesophagitis. Two factors were predictive of 57% of significant diagnosis — smoking and sex of patient and six factors were found to be predictive of 57% of the reflux oesophagitis cases. No factors were identified which could predict a change in the patients management following endscopy. The Test group patients showed a similar prediction level.

Conclusion Clinical diagnosis of dyspepsia based on symptoms alone remains imprecise and emphasises the need in clinical practice for access to diagnostic facilities in such patients. }"

"P P 40 0908"P 40 0908**Gastric Mass Survey by Photofluorography on 122,666 Subjects**

*T. Kanai, A. Kashiwagi, T. Idesawa, I. Takayama, F. Kitahara, Y. Yoda, K. Kobayashi, M.A. Fujino

Health Care Center, Yamanashi, Prefectural Welfare Federation of Agricultural Cooperatives and Dept. Medicine, Yamanashi Medical University, Yamanashi, JapanGastric carcinoma has been a frequent form of cancer in Japan. Mass survey has been widely performed to detect this cancer since 1960s. It has succeeded in detecting gastric cancers at an early stage. Furthermore, it has contributed to a remarkable improvement in the postoperative 5-year survival rate of gastric carcinoma.Our gastric mass survey, performed as a part of the general medical check-up, has been done for the past 6 years. In an itinerant check-up program for rural participants, we have used modified buses installed with photofluorographic apparatus. Among 122,666 subjects (50,659 males and 72,007 females) 21,883 (17.8%) were pointed out to have abnormal findings on photofluorography, requiring further diagnostic procedures. Two-hundred forty-five cases (0.20%) were ultimately diagnosed as gastric carcinoma. The expense for screening photofluorography was 3,500 Japanese yen per person and diagnostic endoscopy 22,000 Japanese yen per examination. The participants paid only 10 to 30% of the expense and the rest was covered by the governmental aid, however.As for the detected gastric cancer, 160 cases were detected at an early stage (65.0%) and 85 were advanced; early cancer ratio has been increasing year by year, from 59.0% in 1989 to 69.2% in 1994. Thirteen cases were curable by endoscopic resection in total. Itinerant mass survey by photofluorography is quite useful for early detection of gastric carcinoma. "P P 42 0939"P 42 0939**Endoscopic Healing with cA2 Anti-TNF Antibodies in Crohn's Disease: A European Multicenter Trial**

*G.R. D'Haens, S.J.H. van Deventer, R. Van Hogezand, D.M. Chalmers, T.A.J. Braakman, H. Bijl, P.J. Rutgeerts

The European cA2 study group in Leuven, Belgium; Amsterdam, Leiden, The Netherlands; Leeds, UKSeveral trials have demonstrated clinical efficacy of chimeric monoclonal anti-TNF-{ a} antibody (cA2) therapy for active Crohn's disease (CD). Initial open-label experience revealed that this effect was accompanied by a fast endoscopic healing of colonic lesions. Endoscopic response to cA2 was further investigated in a multicenter randomized double-blind, placebo controlled trial including 108 pts with active CD (CDAI 220–400), 30 of whom were enrolled in Europe and underwent an ileocolonoscopy before and 4 weeks after IV administration of 5 mg/kg (n = 8), 10 mg/kg (n = 7), 20 mg/kg (n = 7) of cA2 or placebo (n = 8) as a single 2 hour IV infusion. Concomitant therapy was kept stable throughout the trial. Video-endoscopic examination was performed at baseline and 4 week later after standard bowel preparation by the same endoscopist. Lesions were scored by means of the CD Endoscopic Index of Severity (CDEIS), which was previously validated by the French GETAID. This score includes the presence of deep/superficial ulceration, ulcerated/non-ulcerated stenosis, and the segments and the proportion of mucosal surface involved by CD.Significant endoscopic improvement was observed in all cA2-treated patients, with a drop in mean CDEIS from 15.1 – 6.9 to 6.4 – 5.1 in the 5 mg/kg group (p = 0.006), from 10.6 – 7.8 to 4.3 – 5.4 in the 10 mg/kg group (p = 0.009), and from 13.3 – 6.9 to 5.2 – 2.8 in the 20 mg/kg group (p = 0.006). For all cA2-treated pts, the CDEIS dropped from 13.0 – 7.1 to 5.3 – 4.4 (p < 0.001), without a significant dose-response. There was no endoscopic improvement in the placebo group (CDEIS from 8.4 – 6.3 to 7.5 – 5.4). The changes in the endoscopic index CDEIS correlated highly with those in the clinical index CDAI (r = 0.56, p = 0.002). We conclude that the clinical improvement after cA2-therapy in active CD is accompanied by significant healing of endoscopically viewed ileocolonic lesions.

"P P 43 0974"P 43 0974**The Role of Small Bowel Biopsy in the Endoscopic Evaluation of Adults with Iron Deficiency Anemia**

*Z. Ackerman, R. Eliakim, R. Stalnikowicz, D. Rachmilewitz

Department of Medicine, Hadassah University Hospital, Mount Scopus, Jerusalem, IsraelThe recommended evaluation of adult patients presenting with iron deficiency anemia (IDA) includes the performance of colonoscopy and esophagogastroduodenoscopy (EGD). IDA is a common feature in patients with celiac disease and, in several, may be the only presenting sign. The performance of small bowel biopsy (SBB) for the evaluation of celiac disease as the cause of IDA is not routinely recommended. The aim of the present study was to determine the yield of SBB performed during routine endoscopy of adults with IDA.We prospectively studied 93 patient with IDA. Three control groups were included: 23 patients with steatorrhea, 37 patients with idiopathic diarrhea and nine patients in whom SBB was performed for miscellaneous indications.Eleven patients with IDA and two patients with steatorrhea had SBB compatible with celiac disease. None of the patients from the other two groups had similar findings. Two patients with IDA, who were later diagnosed to suffer from celiac disease, presented — one with occult blood in the stool and the other with rectal bleeding. Subgroup analysis of patients with IDA revealed that patients with celiac disease were younger, had significantly more episodes of diarrhea, lower mean hemoglobin level and longer duration of anemia than those without celiac disease. Other mucosal abnormalities were found in a substantial number of patients with celiac disease: esophagitis, gastritis, duodenitis, hemorrhoids and colitis.A substantial number of adult Israeli patients who present with IDA are found, on SBB, to have mucosal abnormalities compatible with the diagnosis of celiac disease. The presence of esophagitis, gastritis or duodenitis on EGD, or other abnormalities on colonoscopy, do not exclude the coexistence of celiac disease. Celiac disease should be included and routinely looked for in the differential diagnosis of adult patients with IDA. II Div. Ped. Osp. DI Crisina Palermo, Italy

Anat. Patol. USL 6 Palermo, Italy

INSERM U315 Marsiglia, Italy and FrancePAP is a stress protein expressed in human pancreas during pancreatitis but also in the small intestine. We evaluated its expression in patients with celiac disease (CD). Serum PAP concentration were determined in 54 patients with CD on a free-diet (Group A), in 47 patients with CD on a gluten-free diet (Group B) and in 22 patients with other intestinal pathologies but with normal intestinal mucosa (Group C). Serum PAP levels (ng/ml) were significantly higher in Group A (127 – 57) than in the other groups (B: 47 – 20; C: 51 – 32). In Group A a positive correlation was observed between serum PAP values and anti-gluten antibody levels (vs AGA IgG $r = 0.58$, $p < 0.001$; vs AGA IgA $r = 0.66$ $p < 0.001$). In addition 12 patients were followed before and after 10–12 months of gluten-free diet and in all serum PAP values decreased after the diet (mean – SD before the diet: 122 – 36, after the diet: 49 – 13 ng/ml, p <; 0001). An immunocytochemical study localized PAP in the intestinal mucosa to the Paneth cells and to globet cells, in patients with mucosal atrophy as well as in those with normal mucosa with no obvious quantitative difference. We concluded that in patients with CD the active phase of the disease was accompanied by an increased serum concentration of PAP, and PAP levels could be a marker of histological damage of the intestinal mucosa. Intestinal disorders, absorption: Gluten enteropathyIntestinal disorders, absorption: Malabsorption: children }" "Pancreatitis Associated Protein in Patients with Coeliac Disease. "P P 45 1010"P 45 1010**Long-Term Ultrasound Observation of Pancreatic Pseudocysts Spontaneous Course and Influence of Interventional Sonography****W. Johanns, J. Janssen, S. Kahl,**

*L. Greiner

Medical Clinic A, Municipal Hospital Wuppertal, University of Witten-Herdecke, Germany

Introduction Performance of repeated ultrasound scans at short intervals can provide a detailed insight into the natural history of pancreatic pseudocysts. This information is an important prerequisite for assessment of the prognostic significance of these cysts and for the decision as to whether and what form of treatment is indicated. We therefore conducted a retrospective study of the spontaneous course of pancreatic pseudocysts and the influence of interventional sonography.

Patients/Methods 69 patients (13 women, 56 men; average age 48.9 years) with pancreatic pseudocysts were monitored by ultrasound without operative intervention. The length of follow-up was between 3 and 136 months. The aetiologies were alcoholic (47), biliary (10), idiopathic (8), and malignant (4). There were 44 pseudocysts measuring {\'a3} 4 cm, 15 measuring {\'a3} 6 cm and 10 measuring > 6 cm. Diagnostic aspiration was performed in 32 patients, therapeutic aspiration in 7 patients and percutaneous drainage in 3 patients.

Results 49 pseudocysts (71%) disappeared spontaneously, 2 became smaller spontaneously, 6 remained unchanged. The age and size of the pseudocysts and the aetiology of the pancreatitis had no influence on the rate of spontaneous regression. The success rate of therapeutic aspiration was 57.1%, that of drainage 100%.

Conclusion The study refutes the conventional wisdom that spontaneous regression only occurs during the first 6–12 weeks after development of the pseudocysts, is rare in patients with chronic pancreatitis and occurs mainly in small pseudocysts. The high success rate of interventional sonography reported in other studies is confirmed. In the light of these findings the recommendation of elective surgery for pseudocysts which show no signs of spontaneous regression after 6–12 weeks should be questioned. On the contrary, if there are no complications, pancreatic pseudocysts should be monitored by ultrasound in anticipation of their spontaneous regression. Pancreas: Pancreatitis, acutePancreas: Pancreatitis, chronic }" "Long-Term Ultrasound Observation of Pancreatic Pseudocysts Spontaneous Course and Influence of Interventional Sonography"

"P P 45 1027"P 45 1027**Endoscopic Pancreatic Sphincterotomy (EPS): Results of 150 Procedures****G. Costamagna, M. Mutignani,**

*A. Gabbrielli, V. Perri, M. Pandolfi, G.M. Colombo, A. Bruni, F. Crucitti

Istituto di Clinica Chirurgica, Catholic University of Rome, ItalyFew published reports have deemed with indications, technical issues and results of EPS. This endoscopic procedure has gained popularity only recently, because of the increasing interest in the non-surgical approach to chronic pancreatitis (CP). Aim of this work is to report our clinical experience with EPS performed according to a standardized technique.*Patients and Technique.* Between June '88 and April '96, 150 EPS (132 at major papilla, 18 minor papilla) were attempted in 147 patients (112 M, 35 F, mean age 51.9 years, range 3–89 years). Indications included primary CP (n = 114), neoplastic obstructive CP (n = 19), benign obstructive CP (n = 6), external pancreatic fistula (n = 3), post-necrotic pseudocyst (n = 3), diagnostic aim (n = 1) and attempt at deep cannulation of the bile duct (n = 1). Technically a biliary sphincterotomy (EBS) is performed as the first step to get an easier access to the pancreatic office. After deep cannulation of the pancreatic duct with a guide wire, EPS is performed over the wire with a long-nose proximal papillotome having a 20 mm. cutting wire. Eighty watts of pure cut current are generally applied. EPS is accomplished under direct visual control with the sphincterotome oriented along the axis of the pancreatic duct at 12–2 o'clock direction. The length of the cut is mostly depending on the anatomy of the individual patient, averaging 5 to 10 mm. Minor papilla EPS is performed according to the same technique. In case of incomplete EPS, edema or obstruction of the distal pancreatic duct, it is always advisable to obtain a good drainage of the main pancreatic duct (naso-pancreatic drainage, extraction of stones, insertion of large bore 10 Fr pancreatic stent) to avoid septic complications or duct hypertension.*Results:* EPS was successful in all but 3 patients (2%). In 3 cases (2%) a needle-knife pre-cut was utilized. One 73 years old patient with fluid collection after acute pancreatitis, died within 30 days from septic complications. Specific complications of EPS in patients with primary CP, included one patient with a severe acute pancreatitis and pancreatic abscess who underwent surgery and one patient with overt bleeding who underwent endoscopic hemostasis (1.7%). Both patients eventually recovered.*Conclusions:* EPS is a safe and effective procedure. It is often the first step in the pancreatic operative endoscopy like EBS in the biliary tract. The technique deserves more critical review and prospective studies about his efficacy in various disease states. Pancreas: Pancreatitis, chronicEndoscopy, specific: Pancreatic }" "Endoscopic Pancreatic Sphincterotomy (EPS): Results of 150 Procedures"

"P P 45 1028"P 45 1028**Painful Chronic Pancreatitis without Dilated Duct: Effect of Endoscopic Treatment**

*C. Renou, R. Laugier

Service d'H\'e9pato-Gastroent\'e9rologie et Inserm U-260, Hospital de la Conception, Marseille, FranceSurgery might be necessary to treat severe pain during chronic pancreatitis when medical attitudes have failed. Decompressive surgery is only feasible when the main pancreatic duct (MPD) is dilated over sufficient length; in other cases, resection becomes mandatory. Our aim was to evaluate in such special cases the results of endoscopic stent drainage. *Methods:* Out of our chronic pancreatitis (CP) patients, 16 were included in this study: 13 men, 3 women, 46.3 – 4.2 years. They presented a mean of 5.3 episodes of pain in the 6 months before treatment. Decompressive surgery was not possible because of a mean MPD diameter of 5.8 mm. CP was alcoholic in 11 cases, hereditary in one and idiopathic in 4 cases. Four patients had a pancreas divisum and 7 were also complicated by a cyst. Stents were 7 F in diameter in 8 patients and 12 F in the 8 others. They were left in the duct after endoscopic dilatation for 9.5 – 1.0 months (6 to 17), each stent being systematically changed every 4 months. In 5 patients, cysto gastrostomy (3) or duodenostomy (2) was associated. *Results:* During stenting we observed 2 early obstructions (one month) and 7 episodes of pain in 6 patients. Three episodes of mild acute pancreatitis were noted after stenting in one patient. At the end of treatment, all cysts disappeared and stenosis of MPD disappeared anatomically in 5 cases while it persisted in 4. Endoscopic treatment was stopped after 8 months in one patient. During follow up (22.2 months – 5.7) only 2 episodes of mild pain were noted (treated in outpatients). No cyst reappeared. Finally the mean diameter of MPD did not change after treatment. Complete disappearance of stenosis was only observed with 12 F stents and not with 7 F one ($p < 0.05$). *Conclusion:* Endoscopic stenting treatment in selected cases of CP unsuitable for decompressive surgery appears to be safe efficient on clinical stand point. Perfect anatomical results are only obtained if large stents are used. Pancreas: Pancreatitis, chronic }" "Painful Chronic Pancreatitis without Dilated Duct: Effect of Endoscopic Treatment"

"P P 45 1029"P 45 1029**Ultrasonographic Imaging of the Pancreatic Duct before and after Secretin Stimulation**

*R. Alekse, J. Pokrotnieks

P. Stradins Clinical Hospital Riga, LatviaWe have measured the caliber of the ultrasonographically visualized pancreatic duct in 42 patients with chronic pancreatitis and 20 practically healthy persons before and after secretin stimulation. The patients with marked duct dilatation and intraductal stones were excluded. The pancreatic duct diameter was measured in the region of corpus before and several times during the first 30 min. after intravenous injection of 1 CU secretin per kilogram body weight.In the group of 20 healthy persons we found an average duct diameter of 1.3 – 0.3 mm. After intravenous injection of secretin a duct enlargement was observed in all healthy persons to a mean of 3.1 – 0.3 mm. The maximal diameter was measured around 4–5 min. after injection. In the group of 42 patients with chronic pancreatitis the average duct diameter before secretin injection was 2.9 – 0.4 mm. In 33 of these patients no duct dilatation was observed after secretin injection. Only 9 patients showed a small duct dilatation on average only 0.8 mm.We conclude the use of ultrasonographic secretin test may be helpful in the diagnosis of chronic pancreatitis. Pancreas: Pancreatitis, chronicRadiology and ultrasound: Diagnosis }" "Ultrasonographic Imaging of the Pancreatic Duct before and after Secretin Stimulation"

"P P 45 1030"P 45 1030**Endoscopic Pancreatic Stenting in Patients with Pain Due to Chronic Pancreatitis**

*J.F. Pellicer, J.F. Fern\'e1ndez, J.M. Mart\'edn, H. Pallar\'e9s, R. Romero, M. Hassan, R. Sa\'e9nz, P. Hergueta, J.M. Herrer\'edas

Servicio de Aparato Digestivo Hospital Universitario Virgen Macarena, Sevilla 41008 Espa\'f1a*Introduction:* Chronic pancreatitis is a progressive disease that implies loss of acinar parenchyma and fibrosis of the gland. Consequences are exocrine and endocrine disfunction and chronic pain. Pain is supposed to depend on two different mechanisms: A) intraglandular neural affection and B) pancreatic duct drainage obstruction with an increase in intraductal pressure. To achieve pain relief surgical and endoscopic stenting have been used.*Aim:* The aim of the study was to evaluate the efficacy of pancreatic duct stenting in patients with a narcotic-dependent pain due to chronic pancreatitis.*Patients and Methods:* From May 1994 to May 1996 we treated six male patients. Age ranged from 39 to 59 (mean: 47.5). Etiology of chronic pancreatitis was alcohol abuse in all cases. ERCP showed single or multiple strictures in Wirsung's duct. When intraductal lithiasis was present Fogarty-type balloon or Dormia's basket was used to remove them. Pancreatic duct strictures were negotiated with a 0.025-inch guide wire advancing a 7-F dilating catheter over the guide to dilate the stricture. Prothesis calibre was 7-F in all cases and variable length (5–10 cm) depending on the anatomical location of the stricture. Stents were removed when patients complained pain again. Stent survival time was defined as the patient's pain-free time.*Results:* Patient Wirsung's ERCP image Stents # Prothesis length Stent survival time (cm) (days)1 Proximal stenosis 1 10 902 Proximal stenosis 2 5; 5 45; 873 Multiple stenosis without lithiasis 3 10; 5; 10 300; 30; 404 Proximal stenosis 1 5 1805 Multiple stenosis and lithiasis 2 10; 10 105; 2706 Multiple stenosis and lithiasis 1 10 95Mean time to achieve pain relief was 3 days (mean: 1–5). No complications due to the procedure were observed. Mean stent survival was 136 days (first stent) and 197 days (second stent).*Conclusions:*1. Endoscopic pancreatic stent drainage seems to be effective in pain relief due to chronic pancreatitis with ductal stenosis. 2. It is a safe procedure without complications in our series. 3. When the stent is placed through the stricture pain relief is achieved. "P P 45 1033"P 45 1033**Thirteen-Year Experience with Ultrasound-Guided Drainage of Pancreatic Pseudocysts**

*G. Di Candio, U. Boggi, P.C. Giulianotti, F. Sbrana, R. Bellini, F. Mosca

Istituto di Chirurgia Generale e Sperimentale, Universit\'e0 di Pisa, ItalyThe purpose of this retrospective study is the evaluation of our 13-year experience with ultrasound-guided (US-G) percutaneous drainage (PD) of pancreatic pseudocysts (PSCs). A statistical analysis of the factors influencing therapeutic outcome is also provided.The records of 70 pt.s (48 m. and 22 f., mean age: 56.4 years, range: 26–80) were reviewed. Based on D'Egidio's classification and on recommendations from the Consensus Conference on acute pancreatitis held in Atlanta in 1992, PSCs were classified into six groups: immature acute PSCs (n = 3) mature acute PSCs (n = 29), post-necrotic chronic PSCs (n = 9), retention chronic PSCs (n = 5), postoperative abscesses (n = 10) and pancreatic abscesses of infected PSCs (n = 14). After removal of the catheter, all pt.s were entered into a combined clinico-ultrasonographic follow-up. A total of 15 variables, potentially conditioning the therapeutic outcome, were statistically evaluated.In all pt.s PD achieved PSC detention with evident pain relief and sharp reduction of serum amylase. Sepsis promptly resolved in all infected collections. Four pt.s died: 3 from sequelae of severe pancreatitis and 1 from acute myocardial infarction. Procedure related morbidity was 17.6%. High amylase concentration in the cystic fluid ($p = 0.02$) and delayed removal of the catheter ($p = 0.02$) were statistically related to morbidity. Sixty-six pt.s were followed-up for a mean of 41 months (range 12–132). Eleven pt.s (15.7%) required repeated PDs. Long-term PD success rate was 85.7%. Factors influencing therapeutic outcome were: age ($p = 0.01$), type of PSC (0.04) and dilation of the main pancreatic duct (0.002)In conclusion, US-G PD of PSCs seems to be a safe and effective alternative to surgical management. In acute PSCs and postoperative abscesses PD this treatment should be considered as the initial therapy. In selected instances, after careful imaging of the pancreas, a small subset of chronic PSCs may also benefit from a PD. OT40 1037**Nd:YAG Laser Combined with Omeprazole as a Treatment of Barrett's Esophagus. Preliminary Results of a Prospective Multicenter StudyV. Meyer, J. Boyer, S. Naveau, G. Cadiot, A. Rotenberg, O. Bouch\'e9, M. Robaszkiewicz, M. Le Rhun, Barrett's Esophagus Study Group**

Angers, Paris, Dreux, Reims, Brest, Nantes, INSERM Clinical Research Network*Aim:* to determine whether Nd:YAG laser therapy combined with omeprazole is able to destroy Barrett's mucosa and to regenerate normal esophageal squamous cell mucosa.*Methods:* 19 patients with Barrett's esophagus (BE), mean age 55 years, were included by 6 centers in the study; the initial mean surface area was 1679 mm^2 (range 50–4900 mm^2). Nd:YAG laser therapy was applied in combination with omeprazole 40 mg/day. On average, laser treatment was repeated every 2 weeks until endoscopic ablation of at least 80% of the initial BE surface (maximum 6 sessions). Endoscopic and histopathologic assessment was realized at 1 and 3 months. After 6 sessions of laser therapy, the persistence of more than 20% of the initial BE surface area was considered as a failure. The response was complete (CR) if no Barrett's mucosa was found on biopsies. If the response was incomplete at 1 or 3 months, supplementary Nd:YAG laser session was applied on the macroscopic or histological remnants.*Results:* More than 80% of BE was replaced with squamous cell mucosa in 18 of the 19 cases, after 1 to 6 sessions. In one patient who presented extensive phlebitis requiring anti-thrombotic treatment, laser therapy was stopped and he was considered as failure. At 1 month, 8 patients had a CR (42%) and 10 patients an incomplete response (mean remaining surface area 4.7%). At 3 months, the rate of CR was 53%. The tolerance of the treatment was good and no severe complication was noted.*Conclusion:* Nd:YAG laser photoablation combined with omeprazole is able to make BE to be replaced with a squamous cell mucosa. These results justify pursuing the study up to the inclusion of final number of patients. Oesophageal gastric duodenal disorders: EG RefluxEndoscopy, general: Instrumentation, therapyEndoscopy, specific: Oesophagus }" "Nd:YAG Laser Combined with Omeprazole as a Treatment of Barrett's Esophagus. OT40 1038**Does the Macroscopic Disappearance of Barrett's Oesophagus after Endoscopic Thermal Ablation Preclude Its Dysplastic Potential?**

*S. Michopoulos, H. Bouzakis, I. Vougadiotis, M. Sotiropoulou[1], P. Tsibouris, N. Kralios

[1] Gastroenterology Unit, ""Alexandra"" University Hospital, Athens, Greece

[1] Pathology Unit, ""Alexandra"" University Hospital, Athens, GreeceBarrett's esophagus is considered as a premalignant condition. The possibility of eradicating the metaplastic epithelium by application of thermal methods combined with antisecretory agents has been recently reported. Islets of residual specialised type glandular tissue beneath regenerative squamous epithelium is rarely mentioned after Barrett ablation. The *aim of our study* was to evaluate the possibility of Barrett's ablation by means of heater probe and examine if residual glandular mucosa remains beneath the restored epithelium. *Patients and Methods:* 10 patients (6 men, 4 women) with Barrett esophagus (length: 2.5–6 cm) and type III enteric metaplasia were enrolled in the study. Endoscopic application of thermal energy was applied by means of Heater Probe (Shirakawa Olympus Co. LTD Japan). All sessions started from the upper limit of Barrett mucosa progressing distally and causing injury by delivering pulses of 5–10 joules. They were repeated monthly until complete ablation was considered. Four-quadrant biopsies were obtained at one cm intervals, 1–3 months after the last session and stained with Alcian blue (AB) pH 2.5/PAS and AB pH1/HID. All patients were on 40 mg/day of omeprazole continuously. *Results:* Macroscopic ablation of Barrett mucosa, endoscopically evaluated, was achieved in all patients after 1–4 sessions. No complication was observed. Histological examination did not reveal superficial islet of enteric metaplasia in any of the biopsies obtained, but in 2 out of 10 patients, 3 specimens (3/24 biopsies in those 2 patients) showed residual enteric metaplasia beneath the restored mucosa.. *Conclusions:* 1) Heater probe is an effective method for macroscopic Barrett's mucosa ablation but in some patients, islets of residual intestinal metaplasia were found beneath restored mucosa. 2) The malignant potential of this ""covered"" residual intestinal metaplasia has to be evaluated by prospective studies but until a final report comes out, a surveillance of ablated Barrett mucosa (possibly marked before) in our opinion should be continued. Clinical practice: Management strategyOesophageal gastric duodenal disorders: EG RefluxEndoscopy, specific: Oesophagus }" "Does the Macroscopic Disappearance of Barrett's Oesophagus after Endoscopic Thermal Ablation Preclude Its Dysplastic Potential?"

OT44 1043**Impact of Lymph Nodes Endoscopic Ultrasound-Guided Biopsy in the Decision Making for Esophageal Carcinoma**

*M. Giovannini, J.F. Seitz, G. Monges

Digestiv Oncology Unit, Paoli-Calmettes Institute, 232 bd St-Marguerite, 13273 Marseilles Cedex 9-France*The aim* of this study was to evaluate the impact of EUS guided biopsy of lymph nodes in the therapeutic decision making for patients with esophageal carcinoma.*Patients and methods:* From january 1994 to april 1996, 150 patients (132 men and 17 women) with a mean age of 66 years (range: 42–76 years) underwent EUS for the local staging of a squamous cell carcinoma of the esophagus in 113 cases and an adenocarcinoma of the esophagus in 37 cases before treatment. 23/150 patients (15.3%) underwent EUS-lymph node guided biopsy. The indication of the EUS guided biopsy of lymph node were: tumor localized in the middle or inferior part of the mediastinum with cervical lymph nodes (16 cases), tumor localized in the superior part of the mediastinum with celiac lymph nodes (7 cases). The EUS endoscop used are the FG 32UA and the EG 36-30U manufactured by Pentax.*Results.* Patient tolerance was excellent and the insertion of the needle into the lesion to be biopsed was always successful. An adequate specimen could not be obtained in 1 case. The sensitivity and specificity of the diagnosis of lymph node malignancy were 95.4% and 100. The results of EUS guided biopsy of lymph nodes modified the stage of the tumor in 21/23 cases, these esophageal tumors with cervical or celiac lymph node involvement were considered like metastastic. The therapeutic decision making was modified by the results of the lymph node EUS guided biopsy in 15/23 patients (65%). These 15 patients were treated by a concomitant radiotherapy and chemotherapy and surgery was no indicated.*Conclusion:* in this prospective study of EUS for esophageal carcinoma, a EUS guided biopsy of lymph node was indicated in 15% of cases and the results of this biopsy modified the stage and the decision making in 91% and 65% of cases respectively. OT44 1045**Villous Adenomous Tissue in Colorectal Polyps**

*P. Netzer, N. Gries, A. Schmassmann, F. Halter

Gastrointestinal Unit, Inselspital, Univ. of Berne, Switzerland*Background:* > 95% of colon cancers seem to develop from adenomatous polyps especially if villous adenomatous tissue is present. However, most (> 80%) polyps have been reported to be of the tubular type.*Methods:* Epidemiologic data from all patients (pts) in whom a lower endoscopy has been performed during 1980–1994, were analyzed. Pts with familiar adenomatous polyposis or inflammatory bowel disease were excluded from the study. 61 pts with multiple (> 10) polyps were analyzed separately.*Results:* During the 15 years time period, lower endoscopy was performed in 12{\'a2}565 pts (mean age: 66; range: 4–97; m:f = 1.7:1). Non-malignant adenomatous and malignant polyps were detected in 13% and 0.9%, respectively. In pts with polyps, synchronous or previous resected colon cancer were found in 8.5% and 4.9%, respectively. Polyp localization: Rectum: 19%; sigmoid colon: 46%; descending colon: 10%; transverse colon: 9%; ascending colon: 10%; caecum: 6%.Histological data in relation to size (1689 polyps). Size N Tubular Tubulo-villous Villous < 0.5 cm 22% 16% 5% 0.6%< 1 cm 37% 21% 16% 0.5%1–2 cm 23% 8% 15% 0.6%> 2 cm 17% 6% 11% 2.3%Total 100% 49% 47% 4%Multiple colon polyps: 4% of pts had multiple (> 10) polyps. Polyp size: 51% < 0.5 cm, 44% = 0.5–1 cm, 5% > 1 cm. Localization: Rectum: 17%, sigmoid c.: 31%, descending c.: 13%, transverse c.: 16%, ascending c.: 13%, caecum: 9%.*Conclusion:* Careful histological analysis showed villous adenomous tissue in approximately 50% of all polyps. Presence of villous tissue in polyps was closely correlated with polyp size. Approximately 2/3 of all polyps were in the rectum or sigma. OT45 1048**Effectiveness of Long-Term Colonoscopic Screening in Families with Hereditary Nonpolyposis Colorectal Cancer**

*M. Jablonsk\'e1, A. Chlumsk\'e1

IVth Medical Clinic, Charles University, Prague, Czech Republic*Background.* Identification of families with hereditary nonpolyposis colorectal cancer (HNPCC-Lynch-syndrome) provides an opportunity of early detection or even prevention of colorectal cancer (CRC). *The aim of this study* was to evaluate the effectiveness of long-term screening of such cases during a 15 year period. *Methods:* 364 asymptomatic HNPCC family members entered periodic colonoscopic surveillance at 1–1.5 year intervals; results and survival rates were compared with 237 symptomatic unscreened HNPCC members. *Results:* In the first group initial total colonoscopy revealed CRC in 16.7% and adenomas in 33.5%; on the whole — periodic colonoscopies included — CRC in 21% and adenomas in 43.5%. In the second group CRC was found in 61.5% and adenomas in 30.5%. In the first group CRC was classified as DUKES A in 53%, B in 29%, C in 18% and D in 0%; in the second group A in 21%, B in 46%, C in 18% and D in 15%. In the first group no death from CRC occurred during the follow-up; in the second group survival rates were 65% after 5, 52% after 10 and 30% after 15 years. *Summary:* Colonoscopic results and survival rates in CRC in HNPCC were clearly more favorable in an asymptomatic screened than in a symptomatic unscreened group. *Conclusions:* As long as genetic testing is not available colonoscopic surveillance of HNPCC members appears fully justified to achieve improved CRC control including longer survival rates. Oncology, general: Screening, preventionOncology, specific: Colon, rectum }" "Effectiveness of Long-Term Colonoscopic Screening in Families with Hereditary Nonpolyposis Colorectal Cancer"

OT45 1050**Incidence and Recurrence Rates of Colorectal Adenomas in First-Degree Relatives of Colon Cancer Patients**

*F. Bazzoli, S. Fossi, R.M. Zagari, S. Sottili, P. Pozzato, C. Mwangemi, L. Ricciardiello, E. Roda

Cattedra di Gastroenterologia, Universit\'e0 di Bologna, Italy*Background:* we have shown that asymptomatic patients with one first-degree relative with colorectal cancer have an increased risk of developing adenomatous polyps, a significantly higher frequency of a proximal polyp location and a greater frequency of severely dysplastic lesions (Gastroenterology 1995; 109: 783–788). *Purpose:* the aim of the study was to compare the recurrence rate and the incidence rate of colorectal adenomas in patients with only one first-degree relative with colorectal cancer, and patients without such a family history. *Methods:* we evaluated 157 patients who underwent follow-up colonoscopy 3 years after the first examination. Patients were grouped on having either a positive family history defined by the presence of only one first-degree relative with colon cancer (no. 68; 42 males; mean age – SE: 59.7 – 1.4) or on having completely negative cancer family history (no. 89; 58 males; mean age – SE: 57.5 – 1.2). Both groups were composed of subjects with one or more adenomatous polyps at the first examination (evaluable for the recurrence rate) and subjects with a normal first examination (evaluable for the incidence rate). *Results:* three year follow-up colonoscopy showed no difference in the recurrence rate of adenomas, 28.6% (12/42) in the group with positive family history and 33.8% (26/77) in the group without family history (Chi-square test: p = ns). As regarding the incidence rate, 26.9% (7/26) of patients with positive family history who had no adenomas at the first examination developed a new lesion, while in the group with no family history, the incidence rate was 0% (0/12) (Fisher exact test 1 tail: p = 0.05). *Conclusions:* over a three year period, the recurrence rate of adenomatous polyps is similar in persons with and without positive family history of colorectal cancer; differently, the presence of such a history determines a significant increase in the incidence of new adenomas. OT46 1052**Photodynamic Therapy of Stage IV Cholangiocellular Carcinoma**

*M. Ortner, S. Schreiber, J. Liebetruth, H.P. Berlin[1], U. Wruck, H. Lochs

4th Med Dep., Charit\'e9 University, Berlin, Germany

[1] Lasercenter Steglitz, Berlin, Germany*Background:* Short term prognosis for palliative interventions in advanced cholangiocellular carcinoma (CCC) is very poor. The *Aim* of this study was to evaluate the efficacy of photodynamic therapy in stage IV, Bismuth III–IV CCC. Primary outcome parameter was reduction of cholestasis, secondary parameters were Quality of Life (Karnofsky index) and survival time. *Methods:* Thirteen patients (age: median 54 (40–74), 8 female, 5 male) with stage IV CCC (Bismuth III–IV) underwent biliary drainage by endoscopic double-endoprostheses (left/right hepatic biliary duct). If cholestasis was not reduced effectively (bilirubin decrease > 50% within 7 days), patients underwent photodynamic therapy (PDT). Photofrin' (Quadra-Logica, Amsterdam, Holland) was infused intravenously (2 mg/kg bodyweight) and intraluminal photoactivation was performed by Argon dye laser via cholangioscopy (wavelength 630 nm, 400–500 mWatt/cm^2). 3 Patients with remaining macroscopic tumor by control-cholangioscopy (after 8 weeks) received retreatment. *Results:* Endoprostheses were implanted in all patients without technical problems. Bilirubin decreased sufficiently in 4 patients (31%) after stenting (from 433 – 99 to 144 – 42, p = 0.03), however Karnofsky index remained unchanged (52.5 – 2.5 and 42.5 – 11, p = 0.69). In these patients 30 day survival was 25% and 11 month survival 0%. In the remaining 9 patients with unsuccessful biliary drainage, PDT reduced bilirubin serum levels (Table) with no significant increase during monthly follow ups. Before stent After stent After PDT PBilirubin (mmol/l) 313 – 66.6 317 – 72.1 108 – 34.5 0.004Karnofsky index 41.1 – 8.4 32.2 – 8.1 68.8 – 6.1 0.008In contrast to stenting Karnofsky index improved significantly after PDT (Table). The 30 day survival after PDT was 100% and 11 month survival 78%. *Conclusion:* In patients with unsuccessful endoscopic biliary drainage due to disseminated CCC, photodynamic therapy results in a dramatic reduction of cholestasis and an increase in life quality. Survival in patients treated with photodynamic therapy appears to be prolonged in comparison with patients successfully stented.

OT46 1053**Is the Preoperative Diagnosis of a Benign Ampulloma Safe?**

*A. Sauvanet, O. Chapuis, Ph. Ponsot, P. Hammel, P. Bernades, J. Belghiti

F\'e9d\'e9ration d'H\'e9patogastroent\'e9rologie M\'e9dico-Chirurgicale, Hospital Beaujon, University Paris VII, Clichy, FranceMalignant ampullomas can be curatively treated by pancreaticoduodenectomy (PD). A local excision can be proposed in case of benign ampulloma. The aim of this study was to evaluate the value of side-viewing duodenoscopy (SVD) with biopsies, endoscopic sphincterotomy (ES), and endoscopic ultrasonography (EUS) for preoperative diagnosis of benign and malignant ampullomas.*Material et methods:* From October 1989 to September 1995, 26 patients with ampulloma were explored preoperatively by SVD — including ES in 9 cases — and EUS. The papilla of Vater was always explored at SVD and forceps biopsies were performed in all patients except one with a typical malignant tumour. EUS evaluated the T stage of the TNM classification in all patients except six because of a previous ES (n = 5) and difficulty to localize the papilla (n = 1). The N stage of the TNM classification was evaluated by EUS in all cases. A curative resection was always performed: 2 local excisions of the ampulla (one adenoma with low-grade dysplasia and one xanthoma), and 24 PD for 20 carcinomas (including 9 (45%) N1) and 4 benign lesions.*Results:* At SVD, papilla was both ulcerated and protruding into the duodenal lumen in 10 cases, prominent and smooth in 15 cases, and normal in one case. Histologic examination of the 25 biopsies revealed malignancy in 10 cases (always confirmed by pathological examination of the resected specimen) and a benign lesion in 15 cases (resected specimen: 6 benign lesions and 9 carcinomas), among the 9 biopsies performed after ES, two only revealed a carcinoma (resected specimen: 4 benign lesions and 5 carcinomas) with an accuracy rate of 64% globally and 66% after ES. At EUS, 13 lesions were presumed limited to ampulla (benign lesion or stages T in situ and T1) but 4 out of these 13 were classified T2 or more histologically; among the 7 tumours classified T2 or more by EUS, one was histologically limited to ampulla. The accuracy rate of EUS for the T stage was 75%. At EUS, lymph nodes were presumed benign (N0) in 21 cases (histology: N0 in 15 cases and N1 in 6 cases) and metastatic (N1) in 5 cases (histology: N0 in 2 cases and N1 in 3 cases), with an accuracy rate of 69%. All endoscopic explorations were compatible with a benign lesion in 11 patients; histologically, 6 patients out of these 11 had a carcinoma including one with a T1N1 and two with a T2N0 tumour.*Conclusions:* In patients with ampulloma tumour, SVD with biopsies even after ES, and EUS are not accurate enough to make sure preoperatively that the tumour is benign. Therefore a local resection cannot be safely indicated. Oncology, specific: Liver, biliary }" "Is the Preoperative Diagnosis of a Benign Ampulloma Safe?"

[3] Inserm U45, Hospital Edouard Herriot, Lyon, France

[2] Molecular Biology Laboratory, Hospital Edouard Herriot, Lyon, FranceGastrin releasing peptide is expressed in about 30% of cell lines established from colon carcinoma and is potentially involved in the stimulation of neoplastic growth. *Aim:* To compare the expression of the bombesin/GRP-receptor (GRP-R) in clone E2, with low metastatic potential, and clone C5, rapidly metastasising in new-born immunodeficient rats [1], from the human colon adenocarcinoma Lovo cell line, and in Caco-2 cells. *Methods:* Pharmacological characterisation of cell surface receptors was achieved by measuring the specific binding of ^{125}I-Tyr^{4} bombesin (BBS). Activation of Phospholipase C by BBS was checked by (H3) inositol phosphate production. The level of GRP-R mRNA was compared by competitive amplification of a 570 bp sequence of the GRP-R cDNA (30 cycles, annealing temp. 53\'b0). A competitive template consisting of this PCR product with a 110 bp deletion was constructed after cloning in Bluescript vector. After reverse-transcription, the GRP-R cDNA was co-amplified with several dilutions of the competitive template. The PCR product was analysed on agarose gel and after Southern blotting. Whether BBS at least at high concentration (10 nM) stimulated cell proliferation was tested by cell count and ^{3}H-Thymidine incorporation. *Results:* Binding studies showed a single high affinity receptor (Kd = 0.45 nM) on clones E2 and C5 of the Lovo cell line, that however differed as to the estimated number of receptors (E2: 2600, C5: 560 per cell). As tested on E2 cells this receptor was a GRP-preferring (Ki = 0.49 nM for BBS, versus 250 nM for neuromedin B), and BBS had a weak but significant effect on (H3) inositol phosphate production (30% at 10 nM BBS). Caco-2 cells, whether undifferentiated or differentiated, did not bind ^{125}I-Tyr^{4} BBS to any detectable extent. At competitive RT-PCR, the GRP-R mRNA levels in E2 cells were more than 10 fold higher than in C5 cells, and 100 times higher than in Caco 2 cells. The tested dose of BBS did not increase the growth rate of clone E2 nor of clone C5. *Conclusion:* The present study confirms that the bombesin receptor is expressed in Lovo cell line. We showed that this receptor is a GRP-preferring one. There is a fair consistency in Lovo and Caco-2 cells between GRP-R mRNA levels and the number of receptors per cell. However, the signification of a different GRP-R expression in the two Lovo clones in regard to their respective metastasising capacities remains to be elucidated.

OT51 1066**Octereotide Infusion Plus Emergency Sclerotherapy Versus Sclerotherapy Alone for the Control of Bleeding Oesophageal Varices: A Prospective Randomized Clinical Trial**

*G. Shiha, S. Sayed, M. Hamid, M. Farag, F> Azzam, H. Assalany

Internal Medicine Department, Almansoura Faculty of Medicine, EgyptSclerotherapy is the gold standard for treatment of bleeding varices. Octereotide infusion is found to be effective in control of actively bleeding oesophageal varices. *The aim* of this work is to evaluate the use of the combination of emergent sclerotherapy and octereotide infusion in the control of bleeding from oesaphageal varices in comparison to sclerotherapy alone.*Methods:* Cirrhotic patients presented to our unit with acute variceal bleeding for a period of six months (189 patients) were randomly allocated to recieve either emergency sclerotherapy alone (Group I; 96 patients) or emergency sclerotherapy plus continuous infusion of octereotide 257 \'b5g/hr for 48 hrs (Group II; 93 patients).*Results:* No statistically significant difference between the 2 groups as regard age, sex, etiology of cirrhosis and modified Child's scoring. Rebleeding was significantly less in group II (4.1%) when compared to group I (25%) $P < 0.001$; and the transfusion requirments was significantly less in group II ($P < 0.001$); but there was no significant difference in mortality due to bleeding ($P > 0.05$). No major side effects were reported due to octereotide infusion.*Conclusion:* This study provides a support for the use of a continuous infusion of octereotide (25 \'b5g/hr) in combination with emergency sclerotherapy for a better control of bleeding oesophageal varices. Endoscopy, general: GI bleedingLiver and bile ducts, 1: Cirrhosis: portal hypertension }" "Octereotide Infusion Plus Emergency Sclerotherapy Versus Sclerotherapy Alone for the Control of Bleeding Oesophageal Varices: A Prospective Randomized Clinical Trial"

OT51 1067**Comparison of Ring Elasticity and Ligation Volume of Different Variceal Single and Multiple Band Ligators Using a Multicylindrical Stretching Apparatus in a Porcine Esophagus Model in vitro**

*H. Reh, J. Hochberger, F. H\'f6rning, A. Brather[1], P. Martus[2], E.G. Hahn

Dep. of Medicine I., Friedrich-Alexander-University, Erlangen, Germany

[1] Inst. of Material Technology, Friedrich-Alexander-University, Erlangen, Germany

[2] Inst. of Biomed, Statistics, Friedrich-Alexander-University, Erlangen, GermanyRecently a new multiple-band ligator (""Speedband""; *SpB;* Microvasive, USA) was introduced which allows the consecutive application of up to 5 bands. In our first clinical experiences many of the Speedband bands were lost within 24 hours despite correct initial positioning (DDW'96#186). We therefore compared band elasticity and ligation volume of three esophageal and one hemorrhoidal ligator in material tests and on specially prepared porcine esophagi in vitro. *Mat & Meth:* The Bard Stiegman & Goff set (*BA;* USA), the Pauldrach OVL set (*PD;* Germany), the SpB Multiligator and a conventional hemorrhoidal set (R. Wolf, Germany) plus standard O-bands (*HE;* Hemolastic, Switzerland) were investigated. For elasticity measurements the different bands were mounted on a special apparatus composed of two hemi-cylinder shells with an o.a transversal diam. of 3/4/5/6/7/8/9/10 mm. The min. force [N] required to widen the bands at the choosen diameter was determined electronically for 5 bands/setting. To simulate the ligation situation ""in vivo"" 8 slaughterhouse-fresh porcine esophagi (1–2.5 h sacr. time) were opened longitudinally and submucosal depots of 2–3 ml saline were injected in order to lift the mucosa layer. This permitted suction of the mucosa and underlying fluid into the ligation cylinder (0.6 bars evac.). The volume of the thus created ""ligation mushrooms"" (n = 5/set) was determ. by means of water displacement (princ. of Archimedes; – 0.05 ml). *Results:* The vol. achieved with PD (m 0.61 – 0.07 ml) were sign. smaller ($p < 0.01$) than those of HE, SpB and BA (m HE = 0.88 – 0.03 ml; SpB = 0.94 – 0.07, BA = 0.91 – 0.07). The vol. for HE, SpB and BA were not sign. different. The mean inner \'f8 of the unstretched bands were 1.81 mm (PD), 1.82 mm (BA), 2.50 mm (SpB) and 2.35 mm (HE), respectively, dir. after release. The radial force of the bands was: HE > PD > BA {\'b3} SpB. ANOVA variance analysis showed sign. differences for HE and PA bands ($p > 0.001$; $p < 0.05$) compared to the SpB and BA bands (SpB to BA overall n.s.). The median stretching force [N] determined for a 3/6/9 mm inner band \'d8 was: PD 1.40/3.62/5.05; HE 2.38/5.34/7.5; SpB 0.57/2.38/3.71; BA 0.86/2.43/3.56). The ligation volume of PD (m 0.60 – 0.07 ml) was sign. smaller ($p < 0.01$) to HE, SpB and BA (median HE 0.90, SpB 0.95, BA 0.95 ml; n.s.) *Conclusions:* Ligation devices can differ substantially in band characteristics and cylinder vol.. A larger inner \'d8 plus a low radial retraction force may be the cause of an early loss of part of the SpB bands. However to date no negative influence of this phenomenon on acute complications or eradication rate could be observed. To optimize band and cylinder characteristics systematic investigations in animal models appear desirable and are presently in prep. OT51 1069**Randomized, Prospective Comparison of Sclerotherapy Vs. Cyanoacrylate for Esophageal Variceal Bleeding in Child-Pugh C Cirrhotic Patients**

*F. Maluf Filho, P. Sakai, S. Ishioka, E.G.H. Moura, S. Matuguma

Department of Gastrointestinal Endoscopy, Hospital das Cl\'ednicas, University of S\'e3o Paulo, S\'e3o Paulo, Brasil*Purpose:* Variceal bleeding is a high-mortality condition in Child-Pugh C, non-alcoholic cirrhotic patients. The tissue adhesive, n-butyl-2-cyanoacrylate, promotes immediate obliteration of esophageal varix, independently of coagulation or healing capabilities. Its higher performance when compared to sclerotherapy could decrease in-hospital mortality.*Method:* Thirty non-alcoholic cirrhotic Child-Pugh C patients were admitted with a first episode of variceal hemorrhage. They were randomized to receive sclerotherapy with 3% ethanolamin oleate (Group I-16 pts) or injection with n-butyl-2-cyanocrylate (Group II-14 pts). After bleeding interruption, all patients were submitted to weekly sessions of conventional sclero until variceal erradication. The recidives of variceal bleeding were managed following the randomization: sclero for Group I and cyanoacrylate for Group II pts. Pts were managed by ICU MDs who were blinded to endoscopic therapy.*Results:* The groups were homogeneous in entry criteria: mean age of 49.4 years, 67% viral liver disease, mean Child-Pugh score of 11.4. 83.3% of the pts. presented with moderate or severe hemorrhage and received a mean of 3.1 URBC. Group I Group II p valueRebleeding (%) 50 14.3 0.047Rebleeding (episode/pt) 0.81 – 1.11 0.14 – 0.36 0.03Esophageal ulcer (%) 37.5 0 0.02Balloon tamponade (%) 31.2 0 0.04In-hospital mortality (%) 75 35.7 0.040*Conclusions:* The treatment with tissue adhesive changed the in-hospital course of variceal bleeding in Child-Pugh C non-alcoholic Cirrhotic patients when compared to conventional sclerpotherapy. OT56 1081**Post-Operative Bile Duct Strictures (BDS): Long-Term Results after Endoscopic Treatment**

*J.-M. Dumonceau, J. Deviére, A. Schmit, M. Delhaye, M. Cremer

Department of Gastroenterology, Erasme University Hospital, University Libre de Bruxelles, BrusselsThe endoscopic treatment of BDS is safe and can provide good immediate drainage.*Aim:* To assess long-term results after endoscopic treatment of post operative BDS.*Patients and methods:* Follow-up data (biliary symptoms, Alk Phosphatases and bilirubin serum levels) were obtained in all of 35 consecutive cases of post operative BDS (male: 20, age: 57 – 16 years) where the absence of further endoscopic treatment had been recommended because of a calibration of the BDS estimated to be sufficient. BDS, mainly attributable to cholecystectomy (N = 22) and OLTX (N = 6) were located in the main bile duct (N = 32), hilum (N = 1), left bile duct (N = 1) and hepaticojejunostomy (N = 1). The management had consisted of dilation, alone (N = 2), as well as associated with insertion of Wallstent (N = 6) or plastic stents (N = 29, for a period of 6.9 – 5.1 months). All patients with abnormal follow-up data underwent ERCP in order to confirm a recurrent BDS.*Results:* Probability of remaining free of BDS (%)

Compared to plastic stents, Wallstents were associated with a higher incidence of BDS recurrence 6 months after insertion of Wallstent or plastic stent removal ($p < 0.01$). In this group, stenoses eventually recurred in all but 1 patient (83% of cases) and required hepaticojejunostomy (N = 2), continuous plastic stenting (N = 2) or repeated diathermic cleaning (N = 1). In contrast, recurrences after treatment with dilation alone or plastic stents were detected in 5 cases (17%) only and were successfully managed by a repeated calibration with plastic stents.*Conclusion:* These results show that dilation and plastic stenting are safe and efficient treatments of BDS on a long-term basis. Wallstents are followed by rapid restenosis and should be considered as contraindicated in this indication. If a striciture recurs after a first calibration procedure with plastic stents, a second similar procedure is indicated. }" "Post-Operative Bile Duct Strictures (BDS): Long-Term Results after Endoscopic Treatment"

OT56 1082**Endoscopic Palliation of Malignant Biliary Strictures: Results of a Prospective Randomized Study**

*F. Prat, O. Chapat, T. Ponchon, J. Fritsch, A.D. Choury, G. Pelletier, C. Buffet

Bic\'eatre and Lyon, FranceThe endoscopic approach to palliation of inoperable malignant biliary strictures has proven to be the option of choice. Although self-expanding metallic stents remain patent for a longer period than plastic stents, the optimal strategy is still controversial because of the high cost of metallic stents and the short life expectancy of candidates to palliation.101 patients (mean age 72.5 – 12.9), OMS > 3, with a common bile duct stricture were included (pancreatic head cancer = 65 cases, cholangiocarcinoma = 21, ampulloma = 3, metastatic lymph nodes = 12). After randomization, patients received either an 11.5 F polyethylene stent, to be exchanged only in case of dysfunction (group 1, 33 patients), an 11.5 F stent to be exchanged every 3 months (group 2, 34 patients) or a metallic Wallstent' prosthesis (group 3, 34 patients).The three groups were comparable. Endoscopic procedures succeeded in 100% of cases. Procedure-related morbidity was 11.9% and mortality 2.9%. Complete relief of jaundice was obtained in all cases Bilirubinemia after 48 hours (37.2 – 21.7% decrease) did not differ between groups. The patients were followed for a mean of 166 days (median 143; range 0–596 days); at the present time, 80 patients (80.2%) are dead. The global survivals were not different between groups 1, 2 and 3. However, the complication-free survival of groups 2 (systematic exchange) and 3 (metallic stents) was longer than that of group 1 (p {\'a3} 0.07 and 0.06 respectively), but groups 2 and 3 were not different (p = 0.61). Cumulated hospital stays were 7.5 – 1.7, 13.1 – 3, and 6.4 – 1.7 days (groups 1, 2 and 3 respectively) — p {\'a3} 0.05 —. The cost-effectiveness analysis shows that metallic stents are cost-effective in patients surviving more than 6 months. In patients surviving 6 months or less, a plastic stent with one systematic exchange is cost-effective.*Conclusions:* The systematic quarterly exchange of plastic stents and the insertion of self-expandable metallic stents are two valuable alternatives to increase the complication-free survival of patients with inoperable malignant biliary strictures. The latter is cost-effective only in patients with the longest life expectancy. OT56 1083**Placement of Stents above or across the Sphincter of Oddi — A Randomised Controlled Trial**

*F.M. Pedersen, A.T. Lassen, O.B. Schaffalitzky de Muckadell

The Department of Medical Gastroenterology, S, Odense University Hospital, Denmark*Background:* Stents placed above the sphincter of Oddi (SO) in dogs seem to have a longer patency than stents placed across (ref. 1).*Aim:* To compare stent survival time in human patients with malignant biliary obstruction for stents placed across versus above the SO.*Methods:* 36 patients (13 male) with malignant biliary obstruction were randomised to have the stent placed endoscopically either across the SO (group A) or above the SO (group B). No sphinterotomy was performed. Straight 10 FG stents were used. In group B 9 patients had the distal flap of the stent removed before placement. The patients were evaluated clinically and biochemically every month till malfunction of the stent or death.*Results:* Across SO (A) Above SO (B)Total number (male) 20 (5) 16 (8)50% patient survival, Kaplan-Meier. 88 days 139 days(25–75% percentiles) (41–283) (71–347)50% stent survival, Kaplan-Meier. 89 days 139 days(25–75% percentiles) (53–126) (61–320)Number of patients with stent exchange 8 9(dislocated/occluded) (5/3) (8/1)Median time for stent exchange 71 days 91 days(25–75% percentiles) (21–119) (27–230)*Conclusion:* We found no significant differences in survival time or complication rate between the groups. Stents placed above the SO might survive longer than stents placed across the SO, if the tendency of stent dislocation could be resolved.

OT56 1084**Clinical Laserlithotripsy of Difficult Bile Duct Stones by Means of a Rhodamin-6 G Dye Laser with an Automatic Optical Stone/Tissue Detection System (oSTDS) — Results in 49 Patients**

*J. Hochberger, A. May, J. Bayer, S. M\'fchldorfer, R. Stein, W.E. Fleig, E.G. Hahn, C. Ell

Department of Medicine I, Friedrich-Alexander-University, Erlangen, GermanyLaserlithotripsy of difficult common bile duct stons (CBDS) has become a commonly accepted endoscopic treatment modality. The procedure is usually carried out under direct endoscopic vision due to the potential risk of bile duct injury in ""blind"" RX-guided laser application. In the following we report on our clinical results using a new lasertriptor with integrated optical automat. stone/tissue detection system (oSTDS). *Patients, Mat. & Methods:* From 1st Sept. 1991 to 1st Jan. 1996 49 pts [33 = f, 16 = m; age: 71 – 13 y (39–96 y)] with giant or impacted CBDS [n stones > 1 cm: 3.0 – 1.0 (1–5 stones) with a size 2.2 – 1.0 cm (1.0–6.0 cm);] were treated on the endoscopic retrograde route using a rhodamine (Rh-6G) dye laser (595 nm, 2.5 \'b5s, 250 \'b5m fiber, Telemit Corp./C. Baasel Lasertech., D) with integrated oSTDS. In case of tissue contact oSTDS cuts off the laser pulse 190 ns after its beginning ({\'a3} 8% of the total pulse energy delivered). The first 10 pts. (20%) were treated under cholangioscopic vision (M&B-scope), 28 pts. (57%) merely under oSTDS/intermitt. RX control via standard duodenoscopes and 7F catheters, 8 pts. (16%) using both techniques. *Results:* Laser-induced fragmentation could be achieved in all pts. (100%). 42/49 pts. (86%) became completely free of stones at the end of the treatment. 1.8 – 1.0 (1–4) laserlithotripsy sessions per pat. were performed. In one fully anticoagulated pat. a relevant hemobilia (Hb 13.5 g% {’} 11.0 g%) and transient cholangitis occured as well as 2 episodes of cholangitis in two further pats. as only relevant complications. They were successfully treated conservatively. *Conclusion:* Laserlithotripsy using the described Rh-6G dye laser with automatic optical stone/tissue detection system appears safe and effective and allows ""blind"" fragmentation of difficult CBDS via standard duodenoscopes and catheters.

OT66 1096**A New Technic for Endoscopic Ultrasound-Guided Biopsy Using the Biopsy Needle – Vilmann Type. Results in 115 PatientsM. Giovannini, G. Monges, J.F. Seitz**

Digestiv Oncology Unit, Paoli-Calmettes Institute, 232 bd St-Marguerite, 13273 Marseilles Cedex 9-France*The aim* of this study was to evaluate 1) a new type of needle (Vilmann type) for endoscopic ulrasound (EUS) guided biopsy, 2) a new technic of EUS biopsy using a continuous vacuum applied to the needle using a 20 ml syringe with an auto-locked system and to compare the results of cytology and micro-histology performed for each lesion punctured. *Patients and Methods:* From august 1994 to april 1996, 115 patients (88 men and 27 women) with a mean age of 62 years (range: 24–82 years) underwent EUS with guided biopsy at our institution. The indications were: diagnosis of a pancreatic mass in 40 cases, mediastinal lymph nodes or masses in 23 cases, cervical lymph nodes in 14 cases, celiac lymph nodes in 17 cases, retropancreatic lymph nodes in 11 cases and peri-rectal lymph nodes in 10 cases. The EUS endoscop used are the FG 32UA and the EG 36-30U manufactured by Pentax. The biopsy needle (GIP-Medizin) consist of a biopsy handle with a needle with stylet and spiral sheath. The needle is a 170 cm long steel needle and 0.8 mm outer diameter. Two needle pass were necessary to obtain 1 adequate specimen for cytology and 1 adequate specimen for histologic examination. For the cytology, the material was smared onto a glass slide and stained according the MGG method. For the histologic examination, the core was placed in formaldehyde and fixed in paraffin. *Results.* Neither hemmorrhage nor any other complication was observed during this study. Patient tolerance was excellent and the insertion of the needle into the lesion to be biopsed was always successful. An adequate specimen could not be obtained in 6 cases (5.1%). The sensitivity and specificity of the diagnosis of malignancy were for the cytology 70.0% and 100%, for the micro-histology 81.4% ($p < 0.05$) and 100% and for the combination cytology + histology 87.6% and 100%. For the pancreatic tumor, the sensitivity and specificity of the diagnosis of cancer were for the cytology 65.0% and 100%, for the micro-histology 77.5%) and 100% and for the combination cytology + histology 82.5% ($p < 0.05$) and 100%. For the lymph nodes, the sensitivity and specificity of the diagnosis of malignancy were for the cytology 72.6% and 100%, for the micro-histology 83.5%) and 100% and for the combination cytology + histology 90.4% ($p < 0.05$) and 100%. *Conclusion:* the results of EUS biopsy using the new Vilmann-needle with continuous vacuum system are superior than these obtained with the first prototype of needle. The results of this study suggest that it was necessary to combine cytologic and histologic examination for obtain a sensitivity about 87%. OT66 1097**Accuracy of Endoscopic Ultrasonography (EUS) in the Staging of Gastric Malt Lymphoma**

*Ph. Jacob, B. Pujol, B. Napoleon, O. Keriven-Souquet, J.C. Souquet

Department of Digestive Diseases, Hospital E. Herriot, Lyon, FranceEUS has been considered as an useful investigation for the preoperative staging of gastric lymphoma. Primary gastric lymphoma of the Mucosa-Associated-Lymphoid-Tissue (MALT), when associated with Helicobacter pylori (Hp) could be treated with anti-Hp therapy. However, this treatment is often limited to low grade lymphoma and its efficacy is unknown in case of transmural gastric invasion and/or lymph node extension. Therefore, the aim of this study was to compare the results of EUS to the pathology of resection specimens after gastrectomy in the specific subgroup of gastric MALT lymphoma.*Methods:* From 1990 to 1995, EUS was performed with an Olympus echoendoscope in 16 patients (8 men, 8 women; mean age, 54 years; range, 37–86 years) with confirmed gastric MALT lymphoma. In 15 cases, the diagnosis was made by endoscopic biopsies with immunohistopathologic studies before EUS. In the last case, lymphoma was only suspected before EUS. The findings at endoscopy showed large or multiple small ulcers in 10 cases and enlarged gastric folds in 6 cases. Gastrectomy was total in 10 patients and subtotal in 6. The mean interval between EUS and surgery was 32 days (range: 2–137 days).*Results:* EUS in evaluating the gastric wall was normal in 4 cases, found a thickening of the second layer and the third submucosal layer respectively in 8 and 3 cases, a transmural infiltration with complete disappearance of the layer structure in 1 case. Histopathologic examination of resection specimens showed: 4 cases with serosal involvement by MALT lymphoma with low (n = 3) and high grade malignancy (n = 1) and 12 cases with only mucosa and submucosa involvement. The depth of tumor infiltration was correctly assessed by EUS in 81.3% of cases. EUS underestimated tumor infiltration in 3 patients with serosal involvement by low grade gastric lymphoma but its staging was accurate for the high grade lymphoma. Histopathologic examination showed involved lymph nodes located in the perigastric area in 5 cases. EUS was 85% accurate in detecting lymph nodes invasion, but 2 false negatives were encountered.*Conclusions:* EUS had a good efficacy in staging gastric MALT lymphoma (more than 80% for parietal invasion and lymph node involvement). However, patients with low grade gastric MALT lymphoma, can present a transmural gastric infiltration with lymph nodes involvement. In this form, EUS can understage the lymphoma. Thus, EUS improves lymphoma evaluation, but careful follow-up will remain mandatory. OT66 1098**Transrectal Ultrasound in the Diagnosis and Management of Inflammatory Bowel Disease**

*\'dc. Dagli, H. \'d6ver, A. Tezel, \'c7. Baysal, A. \'dclker, G. Temu\'e7in

Y\'fcksek Ihtisas Hospital, Ankara-TurkeyThe value of transrectal ultrasonography (TRUS) in the assessment of IBD was determined. TRUS was found to be useful for estimation of the histological changes of IBD.TRUS examinations were performed to study 30 healthy individual and 84 patients with IBD, including 60 ulcerative colitis (UC), 24 Crohn's disease (CD). A rigid linear endorectal probe was used to examine the rectal wall.In healthy individuals, the rectal wall showed five layers with a total diameter of maximum 3 mm (mean: 2.6, range: 2.2–3). The patients with quiescent UC, active UC and healthy control subjects revealed significant differences in total rectal wall thickness, submucosal and mucosal thicknesses. In active UC, the average rectal wall thickness was found 6.17 mm (range 5.1–7.5). In quiescent UC, it was 4.02 mm (range 2.4–5.5). Besides these findings in cases with active UC irregularity of the submucosa and an increase in the vascularity diagnosed by doppler US, was observed. The cases with CD localized to ileum revealed normal TRUS findings. But all our cases with ileocolitis and colitis (including the cases with normal rectoscopic findings) showed transmural inflammation findings.5 of these cases during the follow-up period had undergone colectomy. Mucosal inflammation was noticed in 4 cases and transmural inflammation in 1 case. The histological examination of the colectomy specimens was in accordance with our TRUS findings.As a conclusion; TRUS can be used as an additional method in the differantial diagnosis of UC and CD as well as the evaluation of the active UC. OT66 1099**3-Dimensional Endoscopic Ultrasonography (3D-EUS) for Upper Gastrointestinal DiseasesM. Kida, M. Watanabe, S. Sugano, Y. Yamada, T. Sakaguchi, M. Noto, M. Oh-Ida, K. Saigenji**

Dept. of Int. Med., Kitasato University East Hospital, Sagamihara, Kanagawa, 228 Japan*Introduction:* EUS has opened up a new era and played an important role in gastro-enterological imaging diagnosis. Now we have performed new prototype 3D-EUS made by Olympus in evaluating UGI diseases and report the usefulness of 3D-EUS.*Methods:* From November 1994 to now, we have performed 3D-EUS in 33 patients with 13 early gastric cancer, 8 advanced gastric cancer, 5 submucosal tumor (SMT), 4 post endoscopic resection (EMR), 2 esophageal cancer, and others respectively. The specification of 3D-EUS (UM-3R3D, 2R3D) are as follows; the maximum size is 3.4 mm in diameter, the frequency is 20 (3R3D) or 12 (2R3D) MHz, automatic mechanical spiral scanning is longitudinally carried out within 40 or 20 or 8 mm like helical CT.*Result:* After scanning, both radial and linear cross sectional image can be obtained at the same time by computer. The image quality of 3D-EUS is nearly of the same to ultrasonic probe (UM-3R, 2R). Three dimensional presentation that is reconstructed by the optinal radial and linear cross sectional image with the surface image of GI tract like normal endoscopy can be possible. It is also possible to calculate the volume of lesion by tracing the lesion on each radial image. The diagnostic accuracy of 3D-EUS for evaluating the depth of gastric cancer invasion is 86.7% (13/15 resected cases).*Conclusions:* Using 3D-EUS, the most important image can be evaluated after scanning, therefore it seems that 3D-EUS can become more accurate and easy, compare to EUS. And 3D-EUS will become the interface between endoscopist and endosonographist. OT66 1100**Modalities for Three-Dimensional Endoscopic and Laparoscopic Ultrasonography: In vitro and in vivo Evaluation**

*S.-O. Molin[1], L.B. Nesje, O.H. Gilja, T. Hausken, S. \'d8degaard

[1] Dep. of Surgery, Eastern Hospital, University of Gothenburg, Gothenburg, Sweden

Dep. of Medicine A, Haukeland Hospital, University of Bergen, Bergen, Norway*Purpose:* To evaluate different modalities for three-dimensional (3D) reconstructions based on ultrasound (US) images obtained during endoscopic (EUS) or laparoscopic (LUS) ultrasonography.*Methods:* We used cardiac transesophageal multiplane (MP) or biplane (BP) echo-probes (Vingmed, Acuson), radial scanning 7.5/12 MHz echo-endoscopes, (Olympus EU-M20/M30), 8 Fr miniature 12 MHz (UM-2R) and 20 MHz (UM-3R) US probes (Olympus) and a guidewire-fitted 8 Fr 20 Mhz US catheter (CVIS) for volume estimation (0–12 ml) and tissue visualisation (0.5–2 cm in size) in vitro, as well as for investigation of healthy subjects and patients with upper GI lesions. MP, BP, UM-2R, UM-3R and CVIS were also adopted for laparoscopic examinations. A computer-controlled stepping motor device was used for the acquisition of 2D-images, and 3D image processing was performed with a Tomtec Echo-scan work-station or locally developed PC-based prototype system (CMR – Chr. Michelsen Research, Bergen, Norway).*Results:* UM-2/3R, EU-M20/M30 and BP were most accurate for visualization and volume estimation in vitro, error 0.6–7 percent. In vivo 3D reconstructions was best done with EU-M20/M30. Post processing with Tomtec or CMR were equal for volume estimations, error 2.3 percent. Inter observer error was low. Post-processed images could be edited for optimized performance, and orthogonal slicing helped visualizing reconstructed volumes.*Conclusions:* 3D images can easily and accurately be obtained from EUS or LUS recordings, facilitating the visualization and volume estimation of lesions. Better guidance for interventions may also be achieved. OT66 1101**EUS-Guided Injection of Botulinum Toxin for Achalasia**

*B. Hoffman, W. Knapple, M. Bhutani, L. Aabakken, N. Verne, R. Hawes

Digestive Disease Center, Medical University of South Carolina*Purpose:* Preliminary data has suggested that EUS-guided injection of Botox for treatment of achalasia may have an improved long term success rate compared to blind endoscopic injection. Here, we update our results from a previous report with a larger number of patients (pts) and longer follow-up.*Methods:* The study population consists of 7 pts with manometrically confirmed achalasia. All patients underwent questioning in regard to symptoms of regurgitation, chest pain, and dysphagia before treatment and every 3 months after. They were scored based upon the following scale: 0, none; 1, occasionally; 2, daily; 3, with every meal. The maximum possible symptom score was nine; failure of treatment was considered a score of 3 or more. EUS was performed using the Pentax FG32UA linear array echoendoscope. A 4 cm long, 23 gauge needle was passed through the echoendoscope and advanced into the muscularis propria at the level of the LES under real-time EUS guidance. Four injections of Botox (20 u/cc) were made into the LES in different quadrants. An enlarging hypoechoic zone around the needle was seen as the Botox was injected.*Results:* Six of seven patients were tolerating a regular diet within 48 hours. Follow-up has ranged from 1 to 13 months with six of seven patients reporting no dysphagia, chest pain, or regurgitation (symptoms scores of 0 of 9). Two of the seven patients had prior balloon dilatation. The seventh patient had undergone two prior Botox injections with blind endoscopic injection that failed; he also did not respond to EUS-guided injection.*Conclusion:* EUS-guided Botox injection may have a better long term success (87% versus 66%) than endoscopic blind injection. In patients who have received two prior endoscopic injections of Botox, antibodies may form thus making EUS-guidance of no further benefit. Botox injection is recommended in those who have failed balloon dilatation. Echoendosonography: EchoendoscopyOesophageal gastric duodenal disorders: Oesophageal disorders, non refluxEndoscopy, specific: Oesophagus }" "EUS-Guided Injection of Botulinum Toxin for Achalasia"

"P P 46 1106"P 46 1106**Esophageal Clearance and Gastro-Esophageal Reflux Examined by Ultrasound**

*L. M\'e1di-Szab\'f3, Gy. Kocsis, J. Penyige

Dept. of Gastro., Budagy\'f6ngye k\'f3rh\'e1z, Budapest, Hungary*Purpose of the study:* Ultrasound is able to visualize the upper and lower quarters of the esophagus: it is without any interference with the normal conditions and displays the events in motion.*Method:* 25 patients were selected on the endoscopic signs of esophagitis (Group I) and 25 ones on initial abdominal ultrasonography (Group II). The patients starved for 3–6 hours prior to ultrasonography. Ultrasonography was performed for 15–20 minutes, in that the patients drank 1–2 mouthful of water, or tea. The events were recorded on VTR. Endoscopy was carried out in all cases; in 46 cases (21 and 25) gastric acidity was subsequently examined (test meal). Manometry was not carried out, pH measurements were done in 12 patients.*Results:* In 32 patients of 46 GERD (gastro-esophageal reflux disease) a special kind of reflux was demonstrated by ultrasonography: a slow, trickling reflux of the gastric content was seen. Several episodes were followed by a fast clearing movement only after 1–2 minutes. On the opposite, in healthy people only a fast reflux and immediate clearance were observed. Ultrasound Endoscopy pH-monitoringGERD Trickling form Esophagitis in Slow decrease(46) of reflux 70% in 9No GERD Only fast reflux Esophagitis in No events(4) 25% in 3*Conclusion:* The observation above seems to refer to a special form of gastro-esophageal reflux, a slow, trickling form, that can be responsible for the development of GERD. This special form was observed only in GERD patients. This can explain a number of often contradictory measurements and the effect of cisapride. Acidic form requires aggressive treatment (omeprasol). Oesophageal gastric duodenal disorders: EG Reflux }" "Esophageal Clearance and Gastro-Esophageal Reflux Examined by Ultrasound"

"P P 46 1120"P 46 1120**Transcutaneous Ultrasonography of the Esophagogastric Junction**

*J. Janssen, W. Johanns, M. Lehnhardt, L. Greiner

Medical Clinic A, Municipal Hospital Wuppertal, University of Witten, Herdecke*Purpose.* We performed a prospective trial in order to evaluate the diagnostic facilities of transcutaneous ultrasonography (TUS) of the esophagogastric junction in comparison with endoscopic results.*Methods.* 211 patients without prior endoscopy or X-ray of the upper gastrointestinal tract were consecutively examined by TUS and endoscopy. Examinations were independently done by two experienced investigators who always inquired the patient's history. Diagnostic findings and values for length and width of the terminal esophagus were registrated.*Results.* In all 211 patients the terminal esophagus or hiatal hernia could be seen by TUS. 27 times examination conditions were impaired by ascites, meteorism, enlarged liver or thoracic abnormities. 78 patients with normal results in TUS and endoscopy showed a mean length of 3.4 cm (1.7–5.4 cm) and a mean width of 4.5 mm (2.3–6.6 mm) of the abdominal esophagus. Eight patients had a hypoechoic thickening of the wall (8–27 mm) with underlying carcinoma (n = 6, T2–T4), lymphoma (n = 1) or Crohn's disease (n = 1). There were no malignant lesions missed by TUS. 64 out of 77 hiatal hernias (85.3%) and three out of eight cases with esophageal varices were correctly diagnosed by TUS. In one patient achalasia was found in TUS and endoscopy as well. Four times normal status was misinterpreted as hiatal hernia.*Conclusion.* TUS of the esophagogastric junction can successfully be done in nearly every patient. Our data show that it is a confident means in detecting hiatal hernia and malignant lesions of the terminal esophagus or cardia at least in advanced stages. Differentiation between benign and malignant disease is not possible by TUS. Decompensated achalasia presents with a characteristic calyx like ultrasonographic pattern. We suggest that TUS of the esophagogastric junction should be used as screening method more often, because TUS is the first technical examination applied to most patients with gastroenterologic problems. Further diagnostic procedures can be selected more precisely, but may seldom become avoidable by TUS. "P P 47 1130"P 47 1130**Assessment of Esophageal Wall in Patients with the Nutcracker Esophagus (NE) by Endoscopic Ultrasonography (EUS)**

*E. Melzer[1], Y. Ron[2], E. Tiomni[3], S. Bar Meir[1]

[1] Dept. Gastroenterology, Sheba, Medical Center

[2] Dept. Gastroenterology, Wolfson, Medical Center

[3] Dept. Gastroenterology, Ichilov, Medical Center

Dept. Gastroenterology, Sackler School of Medicine, Tel Aviv University*Purpose:* The NE is diagnosed when high pressure is recorded in the esophagus. It may be assumed that in NE patients the muscularis propria (MP) may be wider than normal. *Methods:* Eighteen patients with manometric features of NE and six controls were examined for assessment of the esophageal width of muscularis propria by EUS (360\'b0 Rotatable Echoendoscope JF-UM20, Olympus, Japan). Total and MP diameters were measured at the gastroesophageal junction (GEJ), 5 cm (lower esophagus), 10 cm (middle) and 15 cm (upper) above the GEJ. In patients with NE the width of MP was correlated with symptoms and esophageal pressure. *Results:* Mean MP diameter – SD (mm) at various levels of the esophagus are presented in the table. GEJ LE ME UEPatients 1.8 – 1.4* 1.5 – 1.2 1.5 – 0.8 1.2 – 0.4*Control 1.2 – 0.3 1.2 – 0.3 1.1 – 0.3 0.9 – 0.1*p < 0.05A wide MP was found in six NE patients (33%). The width of the MP was 3, 4, and 6 mm in 3, 2 and 1 patients, respectively. The site of the wide MP had no correlation with the esophageal segment where high pressure was recorded, except for one patient in whom an extraordinarily high pressure (> 800 mm Hg) was recorded in the same segment in which a 6 mm MP was measured by EUS. There was no correlation of MP width and factors, such as length of disease, frequency of symptoms and the length of each symptomatic period. *Conclusion:* Hypertrophy of MP is demonstrated by EUS in one third of patients with the NE. This anatomic finding is in no correlation with the site of manometric abnormality or with the clinical presentation. "P P 47 1143"P 47 1143**Risk Factors of Early Complication after Progressive Pneumatic Dilation for Achalasia**

*E.H. Metman, J.P. Lagasse, L. Picon, L. d'Alteroche, B. Scotto, J.P. Barbieux

Gastroenterology CHU Trousseau Tours-FranceEsophageal perforation is the most serious complication after dilation for achalasia. The aim of this study was to determine factors associated with increased risk of perforation or other immediate complications after progressive pneumatic dilation (PPD) for achalasia.*Methods:* Between 1979 to 1994, 504 dilations with our own design Sippy balloons until 1989 then Rigiflex balloons (3 to 4 cm), were performed in 237 achalasic patients (pts). The first dilation was usually performed with a balloon of 30 or 35 mm diameter for women and 35 mm for men, inflated at 6 psi. X-ray esophageal transit were performed 24 h after each dilation. We observed 15 complications (6% of pts): 7 perforations (3% of pts), 3 asymptomatic esophageal mucosal tears, 4 esophageal hematomas and 1 fever. We compared the clinical, radiographic, endoscopic, manometric and technical data of the 15 pts with complications and the 7 pts with perforation to the data of pts without complications.*Results:* six of 7 perforations occured in women (NS). There were no perforations in pts with hiatal hernia (27 pts), epiphrenic diverticulum (13 pts), vigourous achalasia (21 pts). Esophagitis did not increase the risk of perforation (4.6% vs 2.6%, NS). Six of 7 perforations occured during the first dilation. In women, the use of a balloon larger than 3 cm during the first dilation tended to increase the risk of perforation (8.5% vs 1.7%, NS). Difficulty to keep the balloon in the correct position during dilation significantly increased the risk of early complications (12.7% vs 4.3%, $p < 0.05$).*Conclusion:* Pts with hiatal hernia, esophageal diverticulum or vigourous achalasia may safely undergo PPD. There was no predictive pre-therapeutic factor of perforation, but the role of the gender remains questionable. Difficulty to keep the balloon in the correct position increased the risk of early complications. "P P 47 1144"P 47 1144**Endoscopic Balloon Dilation of Vigorous Achalasia**

*F.J. Jim\'e9nez, A. Arin, I. Mart\'edn-Granizo, F. Borda

Hospital de Navarra, Pamplona, SpainVigorous achalasia is a variant of idiopathic achalasia characterized by the appearance of both simultaneous and high amplitude contractions in the oesophageal body. From a therapeutic viewpoint vigorous achalasia has been thought to have a poorer response to dilation than the classical variety and it has been considered an indication for surgery. The aim of this study is to analyse both clinical and manometric results after endoscopic dilation.*Material and Methods:* From January 1.990 to December 1.995, 46 patients were diagnosed of achalasia in our Motility Unit. 17 out of them (36.9%) were considered to have vigorous achalasia (8 males/9 females; mean age 51.2 – 17.3). Endoscopic treatment was proposed and 16 of them accepted to undergo balloon dilation. 35 mm Rigiflex balloon dilators were used. The balloon was inflated to generate a pressure of 250 mmHg and kept in place during one minute for three times under endoscopic control. Post-dilation endoscopic examination was performed to discharge complications. X-ray films were taken 4 hours after the procedure for identical reasons. Follow up (6–62 months) was both manometric and clinical.*Results:* Successful dilation was achieved in all patients and no major complications were observed. Patients initiated a virtually normal diet 48 hours after dilation. LOS resting pressure dropped after dilation (35.7 – 14.8 vs 10.3 – 6.5 mmHg) with statistical significance ($p < 0.01$). 3 patients required a second dilation 29/36/26 months after the first procedure.*Conclusions:* 1. Endoscopic balloon dilation is an effective treatment for vigorous achalasia. 2. Motor disorders of the oesophageal body seem to play a secondary role in this entity. 3. Surgery might be questioned as first choice therapy. Motility, specific: OesophagusEndoscopy, general: Instrumentation, therapyEndoscopy, specific: Oesophagus }"

"P P 47 1146"P 47 1146**Progressive Pneumatic Dilation in Achalasia. Long Term Results in 237 Patients**

*E.H. Metman, L. d'Alteroche, J.P. Lagasse, L. Picon, J.P. Barbieux, E.D. Dorval

Gastroenterology CHU Trousseau, Tours-FranceSingle dilation with large balloon and high pressure in achalasia are associated with high rate of perforation. Progressive pneumatic dilation (PPD) minimize this risk. The aim of our study was to evaluate the long term results of PPD.*Methods:* Between 1979–1994, 237 consecutive achalasic patients (pts) (124 males; mean age at time of PPD 57 years) were treated by PPD using our own designed balloons until 1989 then Rigiflex balloons. A serie of PPD was composed of 1 to 4 dilations performed every other day with balloons of progressively increasing diameter, according to radiological and manometric controls performed the day after each dilation. The serie could be repeated some months later according to the clinical evolution. After the first serie, 227 pts were evaluated (4 lost to follow up, 6 died before 6 months). Forty six pts had 2 or more series and 43 of them were evaluated (3 lost to follow up). After the final treatment, 222 pts were evaluated. Long term results were assessed according to Vantrappen's classification (fair and poor results: relapses; good and excellent results: remissions). The probability of remission was calculated using the Kaplan Meier estimator.*Results:* The probability of remission after the first serie (64%) was constant over 3 years. Repetition of series increased the probability of remission from 64% to 75%. 1st serie 2nd serie Final treatmentMean follow up (months) 44 39 50Remission probability (3 years) 64% 47% 75%*Conclusion:* PPD was an efficient treatment of achalasia in 2 of 3 pts after 1 serie and again in 1 of 2 pts after a second serie. Final long term probability of remission was 75%. Relapses were rarely observed after 3 years (after 1 as well more series). "P P 47 1147"P 47 1147**Polyethylane Balloons for Pneumatic Dilation in Achalasia**

*V. Balatsos, V. Delis, K. Kastanas, A. Goundopoulos, A. Pantes, N. Skandalis

Gastroenterology Department, District General Hospital of Athens “George Gennimatas”. Athens, GreeceThe purpose of the present study was to evaluate the efficacy and safety of the Microvasive Rigiflex Balloon Dilator in patients with achalasia.Twenty one patients, 13 men and 8 women, age 20–85 years, were included in this prospective study. Their symptoms were: dysphagia 21, regurgitation 14, weight loss 9 and chest pain 2. Barium esophagograms were compatible with achalasia and manometry revealed absent or incomplete relaxation of the lower esophageal sphincter. Pre-treatment endoscopy revealed dilated and/or tortuous esophagus, aperistalsis or minimal peristalsis. In all patients this was the first dilation therapy for achalasia.A floppy-tipped quide wire was passed through the biopsy channel of the gastroscopy into the stomach. The Microvasive Rigiflex Balloon Dilator was inserted over the quide wire under fluoroscopic control and was positioned across the distal segment of the esophagus. The balloon was inflated to pressure ranging from 10 to 15 psi for 60 sec. Chest x-rays and gastrograffin esophagogram was performed after dilation's. The patients hospitalized for a day.A total of 21 patients underwent 26 procedures (1–2 procedures per patient) with 30, 35 or 40 mm balloons. Patients in 4 of 26 procedures complained of post-dilation chest pain which disappeared in ten minutes. There was not any complication.The patients were followed up for 6–46 months. 17/21 (81%) patients are ingesting liquid and solid food with no difficulty and 3/21 (14%) with mild difficulty. One patient (5%) did not have any improvement.We conclude that pneumatic balloon dilation for achalasia is highly efficacious, safe and cost effective. Clinical practice: Management strategyOesophageal gastric duodenal disorders: Oesophageal disorders, non refluxEndoscopy, general: Instrumentation, therapy }" "Polyethylane Balloons for Pneumatic Dilation in Achalasia"

"P P 47 1150"P 47 1150**Botulinum Toxin (Botox) for Achalasia**

*P. Souto, D. Gomes, J. Baranda, H. Lopes, C. Greg\'f3rio, H. Gouveia, Diniz de Freitas

Dept. of Gastroenterology, Coimbra University Hospital, Coimbra, Portugal*Aim:* To determine the efficacy and adverse effects of intrasphincteric Botox injection in patients with achalasia.*Methods:* Prospectively, 16 symptomatic patients with achalasia, underwent endoscopy with Botox injection (20 U/ml, 4 {\'b4} 1 ml) at the lower esophageal sphincter (LES). Manometry was done pre-treatment and after treatment (at 1 and 6 months). Symptoms were assessed by scores: dysphagia (D), chest pain (CP), regurgitation (R), each on a 0–3 scale (occasional = 1, daily = 2, every meal = 3), and total symptoms, on a 9 point scale total (TS = D + CP + R). Weight loss score (W) was also assessed (1–5 kg = 1, 5–10 kg = 2, > 10 kg = 3). Stages (St II or St III) were used either as inclusion criteria or as failure criteria (St = TS + W; I = 2–3, II = 4–5 and III = > 6). Statistical analysis was done by t-Student, Wilcoxon and correlation tests.*Results:* From the 16 patients (age: 18–85 years; 9 female and 7 male), half had symptoms for more than 2 years and only 5 had never received prior treatment. A mild transient chest pain, immediately after injection, was frequent (10 of 16). The mean follow-up was 5 – 1.4 (3–7) months. At the first month, there was only 1 failure (1 of 16). TS (from ""5.9 – 1.6"" to ""2.4 – 2.2""; p < 0.003) and individual scores improved, except for chest pain. LES pressure decreased from 29 – 10.5 to 16.5 – 9 mmHg (p < 0.001). After initial improvement, 3 of 5 patients return to St II at the 6 month examination, and other 2, of the remaining 10, relapsed 3 and 5 month after treatment. Good response was not related to age, sex, duration of illness, previous treatments, prior LES pressure or initial symptomatic scores (p = NS). A better response was seen in patients with higher esophageal body wave mean amplitude.*Conclusion:* Botox injection is safe, simple and effective at short-term, even in patients with prior balloon dilation.

"P P 48 1153"P 48 1153**Sedation Is Not Needed for Diagnostic Upper Gastrointestinal EndoscopyG. Gatto, V. Peri[1], M. Amuso,**

*M. Traina

Divisione di Medicina Interna, Az. Ospedaliera V. Cervello

[1] Istituto di Clinica Medica R, Universit\'e0 degli Studi, Palermo, Italy*Aim:* Cardiopulmonary complications of upper gastrointestinal (GI) endoscopy have been related to sedation. Pharyngeal anaesthesia reduces patient's discomfort during the procedure. Aim of the present study was to assess safety, efficiency and acceptability of upper GI endoscopy performed without conscious sedation in patients presenting for their first examination.*Methods:* Retrospective review of all new endoscopies performed in a 100 days-period, in a regional hospital in Palermo, Italy. Main measures were: number of upper GI endoscopies performed without sedation in a diagnostic or emergency/operative setting; number of endoscopies interrupted because of patient's intollerance or judged unsatisfactory for diagnosis by endoscopist; number of procedure-related adverse outcomes.*Results:* Four hundreds records of all new endoscopies performed in a 100-days period were reviewed: 312 diagnostic, 75 emergency/operative, 13 jejunoscopies. A total of 52 (13%) endoscopies were performed under sedation: 15/312 diagnostic (5%), 31/75 emergency/operative (41%) and 6/13 jejunoscopies (50%). The use of sedation was not related to sex, age and to the indication to procedure. Seven procedures were interrupted: 3 among sedated (6%) and 4 among non sedated patients (1%). Eight procedures were judged unsatisfactory by the endoscopist, 3 among sedated (4%) and 5 among non sedated patients (1.4%). No adverse outcome occurred.*Conclusions:* Up to 95% diagnostic and up to 60% emergency/operative procedures in this series were successfully performed without sedation. Avoidance of sedation did not increase the number of procedures interrupted or judged technically unsatisfactory. Upper GI endoscopy can be safely and efficiently performed without sedation. Endoscopy, general: Preparation, managementEndoscopy, general: Complications }" "Sedation Is Not Needed for Diagnostic Upper Gastrointestinal Endoscopy"

"P P 48 1154"P 48 1154**Changes in Haemodynamic Parameters during Upper Endoscopy**

*P. P\'e9rez-Rojo, M. Mu\'f1oz-Navas, M.T. Bet\'e9s, J.C. Subtil

University Clinic of Navarra, Pamplona, SpainKnowledge of changes in vital variables during upper endoscopy, according to different medication, can help to improve nursing and medical care of patients undergoing upper endoscopy.We present the preliminary results of an on-going prospective study to assess the influence of medication, supplemental oxygen and maneuvering the endoscope on oxygen saturation, heart rate and blood pressure controlled by monitoring system.All endoscopic procedures and data collection (recorded at 1–2 minutes intervals before, during and after the endoscopy) were performed by the same doctor and nurse.One hundred and twelve unselected patients were randomly divided into three groups receive to different medication: without medication (group I); with midazolam-pethidine (group II) and with propofol-atropine administered by an anesthetist (group III).Continuous supplemental oxygen via nasal or oral route was provided in a predetermined number of cases.No significant differences between groups were recorded with regard to age, sex, body mass index, smoking, previous endoscopy, procedure duration and basal data.An increase in heart rate was recorded during upper endoscopy in all groups. Changes were significantly greater in group I or II, than in group III (patients with propofol-atropine) ($p < 0.001$). No significant differences were observed between groups I and II.Mean arterial pressure significantly increased in group I and II but not in group III ($p < 0.001$). No significant differences were observed between groups I and II.After endoscopic procedure no significant differences in haemodynamic parameters were recorded according to different medication or without medication ($p > 0.05$).No patient with oxygen supplementation via nasal route presented desaturation episodes ($SatO2 < 90\%$). When no oxygen supplementation was provided, 2 patients in group I and 3 patients in group II presented desaturation episodes. Endoscopy, general: Preparation, managementEndoscopy, specific: Stomach, duodenum }" "Changes in Haemodynamic Parameters during Upper Endoscopy"

"P P 48 1156"P 48 1156**A Randomized, Double-Blind Study Comparing Intravenous and Oral Administrated Sedatives for Diagnostic Upper Gastrointestinal Endoscopy — Preliminary Results**

*R.R.O. Castro, A.P. Ferrari, A.N. Atallah, S. Geocze, M.R.S. Rohr, C.Q. Brant, E.D. Libera

Digestive Endoscopy Section of the UNIFESP, S\'e3o Paulo, BrazilEvidence is needed regarding the degree of improvement in patient satisfaction and comfort when intravenous (IV) as opposed to oral (PO) sedation is used during endoscopic procedures. Diazepam, one of the standardly-used drugs, requires a sedation period that largely exceeds the duration of the examination. In addition to the desired effects, significant respiratory depression and localized effects due to IV administration may occur. For this study, we assessed patient satisfaction when undergoing diagnostic upper gastrointestinal endoscopy (UGE) using diazepam IV as compared to midazolam, PO, and analyzed the cost/benefit relationship of each administration route and working conditions after the examination.We conducted a randomized, double-blind study comprised of 143 patients (ages 18–65) submitted to UGE. Sixty eight patients received midazolam, 7.5 mg, PO and 75 received diazepam, 10 mg, IV. The endoscopist evaluated the satisfaction of the patients immediately after the procedures; and 24 hours later the patients answered a telephone survey.There was no statistically significant difference between IV and PO groups degree of satisfaction ($x^2 = 1.92$, $p = 0.16$) and same day working conditions ($x^2 = 0.30$, $p = 0.55$). However, the variables amnesia ($x^2 = 13.03$, $p = 0.0003$) and afternoon drowsiness ($x^2 = 14.76$, $p = 0.0001$) yielded results showing statistical significance with the IV group predominating. The IV group costs were twice as high as the PO group.To be able to have 90% statistical power, with 95% confidence interval is necessary to double the sample size. "P P 48 1157"P 48 1157**Patient Stress and Patient Satisfaction When Allowed Presence of an Accompanying Person during Endoscopy**

*J. Lachter, H. Wiseman, Y. Lavee

Seker Medical Center and Faculties of Education and of Social Work, Haifa University, Haifa, Israel*Introduction:* We hypothesized that it may be possible to decrease patient stress and anxiety, thereby possibly making procedures safer, and also possibly increasing patient satisfaction, by allowing an accompanying person (AP) to be present in the endoscopy suite during gastroscopy (EGD).*Patients and methods:* Forty one patients were randomly divided into two groups who would either be offered to have an AP with them during endoscopy, or not to be so offered. Spielberg's well-validated state anxiety evaluation was administered before and after EGD. The benefit was significant for persons with higher levels of state anxiety before the EGD ($p < 0.04$). APs completed questionnaires as to their reactions after EGD.*Results:* 58.8% of patients so offered chose to have APs in the endoscopy suite with them. After the procedures, 83% of the APs recommended the accompaniment of patients. The patients who underwent EGD with an AP showed a trend ($p < 0.06$) to have a lessening in measurable anxiety compared to the patients to whom having an AP was not offered. Patients undergoing EGD for the first time had more anxiety than those with previous EGD experience ($p < 0.034$). The benefit of having an AP was significant for persons with higher levels of state anxiety before the EGD ($p < 0.04$).*Discussion and Conclusions:* Offering to permit the presence of an accompanying person during EGD was shown to often have such benefits as improving patient satisfaction and reducing anxiety. "P P 48 1158"P 48 1158**Evaluation of Bacteriological Contamination of Gastrointestinal and Pulmonary Endoscopes after Cleaning and Disinfection Procedures**

*D. Luu Duc, J. Shum Cheong Sing, M.R. Mallaret, H. Soule, C. Arnaud, J. Croiz\'e9, J. Calop

University Hospital, Grenoble, FranceThe increasing number of endoscopic interventions as well as the risk of patient transfer of microorganisms contributed to put maintenance procedures of endoscopic instruments forward.We evaluated the quality of the procedures applied in our hospital during 2 years: a manuel and a automated disinfection with Olympus ETD, 14 bronchoscopes, 20 coloscopes and 22 gastroscopes were studied. The manual procedure included channels brushing and cleaning with a detergent and a desinfection for 15 mn in glutaraldehyde 2%.The internal channels were sampled by injecting a mixture inhibiting of the glutaraldehyde effect containing 3% (v/v) tween 80, 0.3% (w/v) lecithin, 0.1% (w/v) L-histidin.They were shown to be more contaminated than the other sampled sites (moving extremity part, valves). The operator channel was shown to be more often contaminated in case of coloscopes (85%) in comparison with the results for the gastroscopes (72.3%) and bronchoscopes (57.1%); however the contamination was lower after an automated maintenance instead of a manual maintenance ($p = 0.05$). Concerning storage, a period superior to 12 hours was shown to increase the level of contamination of the operator channel, and it was all the more contaminted since the drying was not well performed.The most encountered bacteria are: negative coagulase *Staphylococcus, Pseudomonas aeruginosa, Bacillus* and *Pseudomonas species.* Clinical practice: Quality assurance }" "Evaluation of Bacteriological Contamination of Gastrointestinal and Pulmonary Endoscopes after Cleaning and Disinfection Procedures"

"P P 48 1159"P 48 1159**Systematic Hepatitis C Virus (HCV) Screening in Patients Submitted to Ambulatory Endoscopic Procedures**

*J.L. Gaudin, R. Bobichon, O. Dumont, J.C. Souquet

Hepatogastroenterology, Hospital de la Croix-Rousse, Lyon, FranceHCV transmission is usually due to blood transfusions or intravenous drug injections. Such an etiology can not be found in about 30% of contamined patients. Endoscopy has been considered as a potential contamination source, although no definite case has been reported in the literature. The aim of our study was to determine systematically the VHC status of patients admitted to our ambulatory unit and to compare the frequency of positive tests in patients with and without previous endoscopic examinations.*Methods:* From December 95 and on, all patients admitted for endoscopic examinations in the ambulatory unit, had an Elisa III test for HCV with their agreement. They were asked about their past history of GI diseases and their files were searched for previous endoscopy. Most patients with previous examinations had their procedures performed in our division. All examinations under sedation are performed in the same endoscopic room. All liver diseases, including chronic hepatitis C, are treated. Moreover the hospital includes a large liver surgery unit (with liver transplantation) and an infectious diseases unit with HIV patients (drug abusers). So HCV positive patients are regularly referred for endoscopy but usually seen as non-ambulatory patients. Disinfection protocols have evolved with time according to the scientific recommendations. So far all procedures have been performed by the nurses without washing-machine. Autoclave for endoscopic material has been systematically used since 1995.*Results:* So far 302 patients have been included. Mean age was 50 yrs (range 17–85), with a slight male predominance (54.4%). Most examinations (91%) consisted in gastroscopy and colonoscopy. 172 patients (57%) had no previous endoscopic procedures, while 130 (43%) had at least one procedure more than 6 months before inclusion. In this last group, median year for the 1st endoscopic examination was 1993 (range 1983–1995) and median number of procedures was 3 (range 1–15). Only 8 patients had no biopsy or polypectomy during these previous examinations. Results of VHC screening was available in 289 patients (95.7%). Missing data were observed respectively in 3% and 8% of patients with and without previous examinations. Only 2 patients had a positive test for HCV, one in each group. The patient with previous endoscopic examinations, was referred for HCV cirrhosis before his 1st endoscopic procedure. Thus of the 130 patients with previous endoscopy studied so far, none had hepatitis C related to endoscopy.*Conclusions:* this ongoing study does not show a high risk of HCV transmission by endoscopic procedure, even with the previous less careful decontamination procedures. Endoscopy, general: Preparation, managementEndoscopy, general: ComplicationsLiver and bile ducts, 1: Hepatitis viral, diagnosis }" "Systematic Hepatitis C Virus (HCV) Screening in Patients Submitted to Ambulatory Endoscopic Procedures"

"P P 48 1160"P 48 1160**Development of a Filing System for Endoscopy Fullfilling the Guidelines of the Minimal Standards Committee of Esge**

*A. Grassi, V. Casale, M. Crespi

National Cancer Institute Regina Elena, Rome, ItalyA multimedia filing system for endoscopic reports, enabling the management of the clinical and research activities has recently been developed for our Endoscopy Units. This system, called ELENA, is built on a database including clinical records of patients and endoscopic pictures taken directly from the videoendoscopes during the procedure. Considering the importance that computerized systems be homogenous, we considered the guidelines of the ""Minimal Standards Committee"" of the ESGE, introducing in our filing system the full recommendations for the structure of the endoscopic record, the ""reasons for performing endoscopy"", as well as the terms for describing the endoscopic findings and the diagnosis. Considering that this new multimedia system will be the third edition of the existing software for the management of our Endoscopy Service, we didn't find substantial problems to fullfill the Minimal Standards recommendations. We are convinced that the possibility to equalise the clinical records in endoscopy must be taken today into consideration for the development of new softwares and the updating of the old ones. Clinical practice: Management strategyClinical practice: Quality assurance }" "Development of a Filing System for Endoscopy Fullfilling the Guidelines of the Minimal Standards Committee of Esge"

"P P 48 1161"P 48 1161**How Long Does It Takes to Form a Good Biliary Endoscopist?**

*M. Tantau, M. Prelipceanu, O. Pascu, M. Chiorean

University of Medicine and Pharmacy Cluj-Napoca, RomaniaThere is no agreement about the duration of the training period for endoscopic retrograde cholangiopancreatography (ERCP) and endoscopic sphincterotomy (ES), and there are few endoscopists publishing their early results.*Objectives:* To study prospectively the impact of the accumulating experience on the results of diagnostic and therapeutic biliary endoscopy in an attempt to define the minimum required to perform competitively ERCP and ES.*Methods:* We studied prospectively the results of the first 271 ERCPs and 100 ESs performed by a young endoscopist between December 1994 and May 1996, in the university medical center of Cluj-Napoca, Romania, after having a one year biliary endoscopy training in a good gastroenterological center in France. Two groups of patients were formed: one group included the first 50 ES and the other group the remaining 50 ES both with the period corresponding diagnostic ERCPs. Success rate of diagnostic ERCP, ES and stone extraction, the number of sessions per procedure and the rate of complications in the two groups of patients were followed.*Results:* ERCP was succesfull in 89% of patients in the first group, compared with 94% in the second group; we noted 3 and respectively one failure of ES, 7 and respectively 2 impossibilities of removing choledocal stones after sphincterotomy in the both groups. Overall success of treatment was 80% in the first group and 92% in the second group. 5 (10%) complications were noted for the first 50 sphincterotomies: 3 hemorrhages, and 2 acute pancreatities; in the second group only one (2%) acute pancreatitis was noted. Mortality was null in both groups. 1.38 sessions were needed per procedure in the first group, versus 1.12 in the second group.*Conclusions:* Although one year of education for diagnostic and therapeutic biliary endoscopy could be enough, two years, in which minimum 300 diagnostic ERCPs and 50 ESs are needed to form a competitive biliary endoscopist. Liver and bile ducts, 2: Gallstones, formation, treatmentEndoscopy, general: Instrumentation, therapy }" "How Long Does It Takes to Form a Good Biliary Endoscopist?"

"P P 48 1162"P 48 1162**Effect of Different Upper Gastrointestinal Tract Diseases (UGITD) and Endoscopy on Quality of Life (QOL): Results from the Herqules Project**

*F. Arpinelli, A. Olivieri, L. Gandolfi[1], L. Norberto[1], F. Pacini[1], C. Surrenti[1], G.F. De Carli, S.H. Irvine[2], F. Bamfi, G. Recchia, A.I.G.O.[2], S.I.E.D.[2], S.I.G.E.[2]

[1] Glaxo Wellcome S.p.A. Research and Development, Verona, Italy

[2] Italy

University of Plymouth, UKQoL has become widely accepted as a major outcome in the healthcare process, particularly in pharmacological therapy. QoL in UGITD has been assessed with different general questionnaires, while experience with specific instrument for peptic ulcer and/or GORD is limited. A specific questionnaire for UGITD, called QPD32 (Quality of life in Patients with Dyspepsia-32 items) has been developed and validated in Italy and now it is submitted to validation in some countries. It consists of 32 items exploring pain, symptoms and physical domains. To detect differences in individual QoL due to psychological characteristics a Personality Inventory Scale is included.In order to verify if different UGITD have different impact on QoL and if administration of a questionnaire before or after endoscopy may result in different score, a transversal, observational survey was performed with the three major Italian gastroenterological societies.QPD32 and the general tool SF36 were administered to patients (pts) suffering from gastric (GU) or duodenal (DU) ulcer, oesophagitis (OE), other upper gastrointestinal complaints (O).32 gastroenterologists administered both questionnaires to 305 pts (61.1% males, mean age 45.9 y) who suffered from GU (8%), DU (46%), OE (29%) and O (15%). The mean total scores of QPD32 in GU, DU, OE and O were respectively 62.9, 61.9, 62.8 and 61.6; score was similar when QPD32 was administered before (61.25), just after (60.0) or few days after endoscopy (60.5). SF36 scores showed a not significant better QoL in OE and DU pts and after endoscopy.In conclusion, pts with different UGITD have the same perception of their illness when QoL is measured with a specific tool. Moreover, thanks to its specificity, QPD32 could be administered indifferently before or after an UGIT endoscopy. "P P 48 1163"P 48 1163**Diagnostic Jejunoscopy with the Pentax VSB-P2900 EnteroscopeN. Skandalis,**

*K. Paraskeva, A. Dalianas, A. Konstantinidis, V. Balatsos, V. Ntelis

Gastroenterology department, General Hospital of Athens, Greece*Objective:* To evaluate the efficacy of the VSB-P2900 enteroscope in small bowel diseases.*Patients:* 84 patients, 43 female and 41 male, mean age of 51.5 years range 14–83, underwent small bowel enteroscopy during the last 3 years, in our department. Indications for the examination included: occult G1 bleeding (37 patients), diarrhea (30 patients), abdominal pain (6 patients), abnormal barium studies of the small bowel (4 patients) secondary malignancy (2 patients), possible upper involvment of Crohn's disease (5 patients). Previous diagnostic studies included gastroscopy (79 patients), colonoscopy (80 patients) and radiografic barium studies (10 patients).*Method:* The Pentax VSB-P 2900 enterscope, which has a working length of 250 cm was used. Midazolame (1–5 mg) was given as sedation. The instrument passed through the oesophagus towards the second part of the duodenum (as in routine upper endoscopy) and was then inserted to maximum depth. Final depth of small bowel intubation was estimated by straightening the instrument to remove the gastric loop and subtracting 80, cm from the ligament of Treitz. Forcep biopsies were obtained when nesessary.*Results:* Visualization of the small bowel was excellent in all patients. Mean depth of insertion was 50 cm past the ligament of Treitz (range 5–100 cm) Duration of the examination was 15–40 min. Tolerance of the procedure was good (similar to the upper endoscopy) for all patients. There were no complications or post procedure symptom complaints. Findings included: Arteriovenous Malformations (7 patients), adenocarcinoma (2 patients), leiomyoma (2 patients), hamartomas (1 patient), celiac sprue (3 patients), eosinophilic gastroenteritis (1 patient), Crohn's disease (5 patients) and long efferent loop in BILL II (1 patient). Findings proximal to the ligament of Treitz included duodenal ulcer (3 patients), Mallory-Weiss tear (1 patient) and polyp of Vater papilla (1 patient).*Conclusion:* Enteroscopy using the VSB-P2900 is simple, safe and efficacious in the diagnosis of small bowel diseases. Endoscopy, specific: EnteroscopyEndoscopy, general: Instrumentation, diagnosis }" "Diagnostic Jejunoscopy with the Pentax VSB-P2900 Enteroscope"

"P P 48 1164"P 48 1164**Diagnostic Efficiency of Push Type Enteroscopy**

*B. Landi[1], M. Gaudric[2], C. Cellier[1], M. Tkoub[1], R. Guimbaud[2], J.-P. Cervoni[1], J. Auroux[1], S. Chaussade[2], D. Couturier[2], J.-P.H. Barbier[1]

Department of Gastroenterology, La\'ebnnec Hospital, Paris, France

Department of Gastroenterology, Cochin Hospital, Paris, FrancePush-type enteroscopy (PE) is still being assessed. The aim of this study was to report the diagnostic efficiency of this procedure according to the indication.*Patients and Methods:* From march 1994 to march 1996, 173 patients (mean age: 34 years) underwent PE using an Olympus SIF 100 videoenteroscope (upper GI tract PE: n = 105, lower GI tract PE: n = 17; double way PE: n = 51). The indications were: unexplained iron-deficiency anemia (n = 41) or gastro-intestinal macroscopic bleeding (n = 45), radiological suspicion of small bowel lesion (small bowel follow through: n = 23; CT scan: n = 2), unexplained diarrhea and/or malabsorption (n = 15), abdominal pain of obscure origin (n = 13), various indications (n = 34). Each patient had negative upper and lower GI tract endoscopies prior to PE.*Results:* The mean length of jejunal and ileal insertion was respectively 120 cm (30–160) and 60 cm (20–120) (failure of ileoscopy: 15/68). A small bowel lesion potentially responsible for bleeding was detected in 2 patients (5%) with iron-deficiency anemia and in 8 patients (18%) with macroscopic gastrointestinal bleeding. An upper or lower GI tract lesion previously not shown by gastroscopy or colonoscopy was found in 12 of these patients (14%). PE provided a diagnosis or modified the radiological interpretation in 19 cases out of 25 (76%) of suspected small bowel lesion. In the exploration of unexplained diarrhea and/or malabsorption, PE provided a diagnosis in 4 cases (26%). PE was normal in all patients with abdominal pain.*Conclusion:* PE was very efficient for the diagnosis of small bowel radiological abnormalities. It provided a diagnosis in 26% of patients with unexplained chronic diarrhea, in 15% of patients with macroscopic gastrointestinal bleeding, in 5% only of those with iron-deficiency anemia and was negative in all cases of abdominal pain. Endoscopy, specific: EnteroscopyEndoscopy, general: GI bleeding }" "Diagnostic Efficiency of Push Type Enteroscopy"

"P P 48 1165"P 48 1165**Comparison between Push Type Enteroscopy and Radiological Examination of the Small Bowel in Patients with Gastrointestinal Bleeding of Obscure Origin**

*B. Landi[1], M. Gaudric[2], C. Cellier[1], M. Tkoub[1], R. Guimbaud[2], J.-P. Cervoni[1], J. Auroux[1], S. Chaussade[2], D. Couturier[2], J.-P.H. Barbier[1]

[1] Department of Gastroenterology, La\'ebnnec Hospital, Paris, France

[2] Department of Gastroenterology, Cochin Hospital, Paris, FranceA radiological examination of the small bowel is often performed in case of gastrointestinal bleeding of obscure origin. More recently, push type enteroscopy (PE) has been reported as a valuable tool in this indication. The purpose of this study was to compare the diagnosis efficiency of this two procedures.*Methods:* From February 1994 to June 1995, 34 patients (mean age: 51 years) with obscure gastrointestinal bleeding (iron-deficiency anemia without obvious cause of blood loss or malabsorption: n = 15; macroscopic gastrointestinal bleeding: n = 19) were examined by small bowel follow through (SBFT) and PE (jejunoscopy n = 17; double way examination n = 17). An Olympus SIF 100 videoenteroscope was used. Each patient had negative upper and lower GI tract endoscopies prior to small bowel examinations.*Results:* SBFT revealed only one lesion potentially responsible for blood loss, corresponding to a jejunal leiomyoma. PE detected small bowel lesions potentially responsible for blood loss in 5 patients (15%). The lesions were always located in the jejunum (arteriovenous malformations: n = 3; metastasis: n = 1; leiomyoma: n = 1). The efficiency of PE for the detection of a small bowel lesion was of 21% in case of macroscopic bleeding and of 6% in case of iron-deficiency anemia. PE also revealed lesions previously not detected by gastroscopy or colonoscopy in 6 patients (18%).*Conclusion:* PE was more effective than SBFT to detect the origin of obscure gastrointestinal bleeding. Nevertheless, its efficiency for the diagnosis of a small bowel lesion was limited, in particular in case of iron-deficiency anemia without macroscopic bleeding. Endoscopy, specific: EnteroscopyEndoscopy, general: GI bleeding }" "Comparison between Push Type Enteroscopy and Radiological Examination of the Small Bowel in Patients with Gastrointestinal Bleeding of Obscure Origin"

"P P 48 1166"P 48 1166**Evaluation of a Near-Infrared Electronic Endoscope in the Alcoholics with and without Cirrhosis**

*E. Borotto, S. Naveau, V. Giraud, J.C. Chaput

Service d'H\'e9pato-gastro-ent\'e9rologie, Hospital Antoine B\'e9clére, F-92141 Clamart, FranceNew vascular signs identified only with a near-infrared electronic endoscopy would be predictive of esophageal varices (EV) bleeding.*The aim of the study* was to describe vascular signs with a near-infrared light in alcoholics.*Method.* Twelve alcoholics without cirrhosis and 16 alcoholics with histologically proven cirrhosis were included prospectively. The patients (pts) were examined with a near-infrared electronic endoscope (Scop Olympus, Rungis) in white light and in near-infrared light – injection of 2 mg/kg of indocyanine green (ICG) which absorbed this infrared light. With near-infrared light and injection of ICG, a dark lines on pink background was interpreted as the opacification of a vessel.*Results.* 1. The near-infrared endoscopy without injection of ICG was less performant than the white light endoscopy. 2. With near-infrared light and injection of ICG: esophageal non variceal vessels invisible in white light were observed in 4/16 pts with cirrhosis and in 1/12 pts without cirrhosis (p = NS). Ten pts with cirrhosis had EV. Opacification of EV was observed in 2 pts and had not bleeded. Conversely, 2 other pts had bleeded and had large varices with red signs predictive of EV bleeding in white light. Gastric vessels invisible in white light were observed in 7/12 pts without cirrhosis and in 4/16 pts with cirrhosis (p = NS). In the pts with cirrhosis, gastric vessels were observed in 2/11 pts with congestive gastropathy and in 2/5 pts without congestive gastropathy (p = NS).*Conclusion.* Vascular signs invisible in white light are identified both in the pts with and without cirrhosis. Further studies are needed to know the significance and the interest of these signs. Moreover, the improvement of the picture contrast is necessary. [2] service d'H\'e9pato-gastro-ent\'e9rologie, Hospital Antoine B\'e9clére, Clamart, France

[3] service de Physiologie, UFR Paris XI, Kremlin Bic\'eatre, FranceIndocyanine green (ICG) is fluorescent in the near-infrared light. This property is used for high resolution choroidal fluorescence angiography. The observation of fluorescent gastrointestinal vessels by an endoscope could be useful in case of portal hypertension or bleeding ulcer.*The aim of the study* was to observe fluorescent gastrointestinal vessels with a near-infrared camera.*Method.* The near-infrared source was a 100 mW, 808 nm laser diode. The fluorescence was selected by two 830 nm band-pass filters. A computer allowed image capture and treatment. Eleven Wistar rats were anesthetized and a catheter was inserted in the femoral vein. A laparotomy was performed. Before and after injection of ICG and both with white and near-infrared lights, we made pictures of the vessels of the stomach, the small intestine or the colon.*Results.* Some serous vessels larger than one mm were visible with white light. None vessels were observable with near-infrared light without injection of ICG. Conversely, with near-infrared light and after injection of ICG, we observed numerous white lines on dark background corresponding to a transient and bright fluorescence of vessels larger than 1/10 mm. Thanks to high resolution, we could distinguish arterial and venous fluorescence. The fluorescence reappeared after each new injection of ICG but a background white noise from the parenchymatous growed.*Conclusion.* This animal pattern allows to display gastrointestinal vessels flow. It could help to develop a near-infrared endoscope and be useful in surgery to test the vitality of the gut. Endoscopy, general: Instrumentation, diagnosis }" "In vivo Observation with a Near-Infrared Camera of Fluorescent Gastrointestinal Vessels in Rats"

*N. Marcon[2]

[1] The Ontario Cancer Institute, Toronto, Canada

[2] The Wellesley Hospital, Toronto, Canada*Purpose:* Demonstrate the effect of different light delivery-detector geometries on Laser Induced Fluorescence Spectroscopy (LIFS) in the gastrointestinal tract following 437 nm excitation.*Methods:* 122 patients (61 colonoscopies and 61 esophagogastroduodenoscopies, EGD) undergoing endoscopy consented to LIFS examination. Abnormalities, identified during white light endoscopy, and their surrounding normal appearing mucosa were additionally examined by LIFS, using 437 nm as excitation wavelength and optical fibers for light delivery and detection. The fluorescence light detection fiber was in contact with the mucosa for all patients, while the excitation light delivery was either via a fiber adjacent to the detector fiber (50 patients), or via the endoscope illumination bundle (72 patients). Fluorescence spectra were collected with an optical multi channel analyzer. Tissue samples of the abnormalities and the surrounding normal tissue were retrieved. In a blinded fashion, all samples were assessed by a single pathologist. A specific numerical diagnostic code (1–4 denoting non-neoplastic changes, 6 to 9 neoplastic, and 5 atypia of undetermined significance) was assigned to each sample.*Results:* A total of 158/347 colonoscopies and 124/275 EGD evaluable spectra were obtained for excitation light delivery via fiber/endoscope illumination channel respectively. Spectra were normalized and grouped according to their anatomical site and the observed pathological state. The average spectra with the corresponding standard deviation were derived for each group. Using MVLR either two or three spectral bandwidth providing maximum sensitivity to differentiate non-neoplastic from neoplastic mucosa were identified. For both excitation light delivery geometries 510 and 670 nm proved most effective for 2 spectral bandwidth, while 510, 600 and 670 nm proved best for 3 spectral bandwidth. Sensitivity and specificity of the differentiation was in the 75% to 88% range for both excitation light delivery modalities and all investigated sites. Theoretical modeling of the data indicates that macroscopic morphological changes in the mucosa causes most of the spectral differences observed.*Conclusion:* LIFS for the gastrointestinal tract is a feasible tool to identify histologically significant lesions from histologically insignificant lesions with an acceptable sensitivity and specificity if a repetitive light delivery detection geometry is selected.

"P P 48 1169"P 48 1169**Detection of Dysplasia Using Fluorescence in vivo Using the XILLIX-Life-GE-System**

*M.L. van Ierland-van Leeuwen, G.N.J. Tytgat

Academic Medical Center Meibergdreef 9, 1105 AZ Amsterdam, The NetherlandsThere is increasing interest in the exploration of the usefulness of tissue autofluorescence (FL) in the detection of dysplasia and malignancy. In a pilot study 38 patients (pts) were screened between february and may 1996 for dysplasia using the XILLIX-life gastrointestinal FL system in ""in vivo"" endoscopy. Olympus Tokyo and the XILLIX Technologies corp. developed an endoscope in which the use of regular endoscopy and FL, using a blue light source and a sensitive camera to detect an FL pattern were combined. All pts were screened with regular endoscopy and with FL. FL of normal mucosa is seen as a blue image on the screen. If however dysplasia is present either as mild, moderate, severe or (in situ) carcinoma (ca) the reflected light is altered and a reddish brown to red FL pattern is seen. Thus a distinction can be made which could lead to better targeted biopsies of suspicious lesions using FL. For the analysis all lesions were judged to be either normal or suspicious using both techniques, the diagnosis was appropriately confirmed with histology. Colonoscopy was performed in 23 pts, gastroscopy in 15 pts. In the colon 17 pts were screened for polyps or earlier ca, three for ulcerative colitis (UC), one had a pneumatosis coli in the past, one mucosal prolaps and one ileo-anal pouch for UC. In 15 gastroscopies: 6 Barrett's oesophagus, 3 oesophagusca, 1 hiatal hernia, one Billroth-II stomach resection, three prior stomach cancers and one duodenal villous adenoma were examined. Three FL investigations failed, two because of a blue light source failure during colonoscopy, one because of poor visualisation in the stomach. Matching FL images and histology, the sensitivity and specificity of FL could be calculated, as shown in the table: Colonoscopy Gastroscopy TotalTrue positive 5 7 12True negative 13 6 19False positive 3 1 4False negative 0 0 0Failed 2 1 3Sensitivity 100% 100% 100%Specificity 76.9% 83.3% 78.9%*Conclusions:* in this pilot study no false negative results were obtained, leading to a high sensitivity. The false positive results may be due to biopsy sampling error in this early learning stage with the new technique, because visualisation of the biopsy forceps using blue light is occasionally difficult. The false positive results can also occur due to interference of mucus, stool or blood, which all give an intense FL signal. In two pts a carcinoma in a Barrett's segment, which was not clearly identified during regular endoscopy, was diagnosed using FL. Both pts had a curative oesophageal resection in this early stage of their disease. The technique of in vivo FL for earlier dysplasia detection in combination with a regular endoscopy looks promising, especially in diseases known to predispose for malignancy. }" "Detection of Dysplasia Using Fluorescence in vivo Using the XILLIX-Life-GE-System"

"P P 48 1170"P 48 1170**Laser Induced Fluorescence (LIF) Endoscopy (E): A Pilot Study of a Real-Time (RT) Autofluorescence Imaging System for Early Detection of Dysplasia and Carcinoma in the Gastrointestinal (GI) Tract**

G.A. DuVall[1], J. Kost[2], D. Scheider[1], L. Lilge[2], M. Cirocco[1], S. Hassaram[1], G. Kandel[1], P. Kortan[1], G. Haber[1], T. Mang[2], R. DaCosta[2], B. Wilson[2],

*N. Marcon[1]

[1] The Wellesley Hospital, Toronto, Canada

[2] The Ontario Cancer Institute, Toronto, Canada*Purpose:* RT LIF bronchoscopy (Xillix, Vancouver) has been established as a sensitive screening tool for dysplasia/carcinoma in the bronchial tree. The purpose of this study was to demonstrate the feasibility of RT LIFE in the GI tract for differentiating normal mucosa from dysplasia/carcinoma.*Methods:* 102 patients (59 male, mean age 65) consented to have RT LIFE imaging performed during routine colonoscopy, 59; esphagogastroduodeno-scopies (EGD), 43. All procedures were documented with video and still images. In addition to routine white light endoscopy, all mucosal abnormalities were examined with RT LIFE using an excitation wavelength of 437 nm. Tissue from the lesions and adjacent normal mucosa was obtained. In a blinded fashion, all samples were assessed by a single pathologist. A specific numerical diagnostic code (1 to 4 denoting non-neoplastic changes, 6 to 9 neoplastic, and 5 atypia of undetermined significance) was assigned to each sample.*Results:* All lesions noted on routine endoscopy were seen on RT LIFE. The still LIFE images were reviewed by a single gastroenterologist familiar with the RT LIFE system. The lesions were classified as LIFE positive (""red"" fluorescence) or LIFE negative (""no red"" fluorescence) when compared with normal (""green"" fluorescence) mucosa. The sensitivity and specificity of the LIFE system was calculated by correlating the positive and negative LIFE findings to the pathology codes. The sensitivity and specificity for colonic disease were 89.6% and 86.8%. In esophageal disease, excluding Barrett's without obvious carcinoma (as it universally produced false positive LIF findings) the sensitivity and specificity were 93.3% and 86.9%, respectively.*Conclusion:* The RT LIFE imaging system in the GI tract can differentiate normal mucosa from dysplasia/carcinoma with a combined sensitivity and specificity of 90.5% and 86.8%, if Barrett's esophagus is excluded. Given that Barrett's esophagus produces a false positive fluorescent signal (due to intrinsic differences in fluorescent properties of gastric and squamous mucosa), it is difficult to identify dysplasia/carcinoma within the gastric metaplasia, as compared to identifying dysplasia/carcinoma in the setting of squamous epithelium. Further investigation is needed to better define the role of RT LIFE imaging in the surveillance of Barrett's esophagus. "P P 48 1171"P 48 1171**Endo-Loop in the Prevention of Post-Polypectomy Bleeding — Preliminary ResultsJ.-F. Rey[1], T.A. Marek[2]**

[1] Institut Arnault Tzanck, Saint-Laurent-du-Var, France

[2] Silesian Medical Academy, Katowice, Poland*Introduction:* Bleeding is the most frequent complication of endoscopic polypectomy, occurring in up to 4% of cases. The risk of post-polypectomy bleeding is especially increased in large, thick-stalked polyps. The risk of bleeding is also higher in patients on anti-coagulant/NSAID treatment. The injection of adrenaline or adrenaline and sclerosant is recommended for such cases, but the injection of adrenaline alone may not prevent the delayed bleeding, while sclerosant injection may increase the risk of bowel perforation. The development of mechanical devices, i.e. endo-loop, and clips, opened the new possibility in the prevention of post-polypectomy hemorrhage. Both tools could be placed on polyp's stalk before snaring, compressing mechanically stalk's vessels and preventing early, as well as, by being left on the stalk remnant, delayed bleeding. We herein report our preliminary results of use of endo-loop in the prevention of bleeding after colonic polypectomy.*Methods and patients:* The prototype endo-loop (Olympus Optical Co.) is made from teflon, with length of 50 mm and width of 35 mm when completely opened. The closing of the loop is performed by sliding the stopper. After visualization of the polyp endo-loop is placed on the stalk and closed. The polypectomy is then performed in the standard manner, cutting the stalk between endo-loop and polyp's head. After the polypectomy the loop is left on place to spontaneous fall off, what occurs about 7 days after the procedure. During the period between July 1994 and November 1995, endo-loops were used prophylactically in 15 patients with colonic polyps.*Results:* Endo-loops were placed correctly in 14 out 15 attempts. In one patient the placement failed, due to size of the polyp (> 25 mm). The significant change of the color of the polyp's head caused by ischaemia was noted. In all 14 patients with correctly placed endo-loop it was possible to perform cutting between endo-loop and the head of the polyp. No blood flow from the stalk was observed after polypectomy. No delayed bleeding occurred in one month after the procedure.*Conclusions:* 1. Endo-loop seems to be efficient tool in the prevention of post-polypectomy bleeding. 2. The placement of endo-loop before polypectomy is technically easy. 3. The endo-loop prevention may be of value in patients with increased risk of bleeding, i.e. patients with big, thick-stalked polyps, clotting disorders, low platelet count and being on anti-coagulant/NSAID treatment. }" "Endo-Loop in the Prevention of Post-Polypectomy Bleeding / Preliminary Results"

"P P 48 1172"P 48 1172**Use of Argon Beamer Electrocoagulation in a UK Endoscopy Unit**

S. Elhasani, R.M. Hodson, H.H. Tsai, G.S. Duthie

*K.R. Wedgwood

Castle Hill Hospital, Cottingham, East Yorkshire, England, HU16 5JQThe argon beamer is a new device that delivers controlled electrocoagulation. This device can be introduced via an endoscope and may aid in haemostasis and tumour debulking in the GI tract. We have evaluated its usefulness in a GI endoscopy unit.*Methods:* A prospective audit of the use of the argon beamer (ERBE ICC200) over an 8 month period (1.10.95–21.5.96) in a busy endoscopy unit.*Results:* A total of 28 therapeutic procedures were carried out using the argon beamer in 18 patients. The therapeutic procedures were for haemostasis (11), tumour debulking (8), angiodysplasia (6), inflammatory polyps (2) and tumour ablation (1). Of those patients whom underwent argon beam coagulation for haemostasis, 2 were for bleeding from oesophageal ulcers (1 malignant), 6 patients had coagulation of the polyp base after snare polypectomy, 1 patient was treated for bleeding after biopsy of a gastric ulcer, 1 patient for bleeding after a papillotomy and 1 patient had a bleeding ampullary cancer. All patients had a successful arrest of bleeding after 1 treatment. 4 patients had treatment for tumour debulking (1 previously stented oesophageal cancer, 1 cardia lesion, 1 rectal, 1 ampullary), requiring a mean of 2 sessions to achieve adequate tumour debulking. 3 patients were successfully treated for angiodysplastic lesions (2 stomach, 1 colonic) after a mean of 2 sessions. 1 patient had a villous tumour of the caecum which was successfully ablated after 1 treatment and 1 patient underwent 2 treatments to successfully eradicate inflammatory polyps in the oesophagus. All operators found the argon beamer easy to use and there were no complications.*Conclusions:* Argon beamer electrocoagulation therapy appears to be a safe, effective and versatile tool for the endoscopist. It is valuable as a therapeutic modality for bleeding, tumour debulking and obliteration of angiodysplasia. Endoscopy, general: Instrumentation, therapyEndoscopy, general: GI bleeding }"

"P P 48 1173"P 48 1173**Argon Plasma Coagulation (APC) in Flexible Endoscopy of the Gastrointestinal Tract: In vitro StudiesW. Johanns, J. Janssen, C. Jakobeit,**

*L Greiner

Medical Clinic A, Municipal Hospital Wuppertal, University of Witten Herdecke, Germany*Introduction:* Diathermy procedures are indispensable in interventional endoscopy. Argon plasma coagulation (APC) is an innovative no-touch electrocoagulation technique in which high-frequency alternating current is delivered to the tissue by ionised argon gas without contact. Before clinical application of the technique, we studied the effect of APC to the tissue under defined in-vitro conditions in order to obtain data on the diameter and depth of necrosis and thus assess the risk of perforation.*Methods:* The coagulation current was applied to a total of 20 fresh operative specimens, 4 from the stomach, 6 from the small intestine and 10 from the colon. Five different power/gas flow settings between 40 and 155 W and 2 and 7 l/min were used. The impact time (1 s–10 s) and the incident angle of the probe (45\'b0 and 90\'b0) were also varied. The treated specimens were fixed in 4% formalin solution and examined microscopically.*Results:* We evaluated a total of 640 lesions. The histological examinations showed an onion-skin-type pattern with a layer of vesicular necrosis (desiccation zone), followed by a dense homogenised layer (coagulation zone), then by increasing occurrence of fibrous structures and pyknotic nuclei (devitalisation zone). The depth and diameter of the coagulation zone increased with increasing impact times and energy settings. Depending on the energy setting and impact time the diameter of the coagulation zone was 0.1–1.1 cm and the depth of penetration 0.1–2.4 mm. Variation of the incident angle of the probe only produced a more oval-shaped coagulation zone but did not reduce the depth of penetration. No perforation of the intestinal wall occurred in any of the constellations investigated.*Conclusion:* APC is an effective and relatively low-cost alternative to laser therapy in gastrointestinal endoscopy. Endoscopy, general: Instrumentation, diagnosisEndoscopy, general: Instrumentation, therapy }" "Argon Plasma Coagulation (APC) in Flexible Endoscopy of the Gastrointestinal Tract: In vitro Studies"

"P P 48 1174"P 48 1174**Argon Plasma Coagulation (APC) in Flexible Endoscopy of the Gastrointestinal Tract: Initial Clinical ExperiencesW. Johanns, J. Janssen, C. Jakobeit,**

*L. Greiner

Medical Clinic A, Municipal Hospital Wuppertal, University of Witten Herdecke, Germany*Introduction:* Interventional endoscopy would be inconceivable without the use of high-frequency diathermy techniques, e.g. for polypectomy and papillotomy. In addition to the conventional unipolar and bipolar coagulation techniques, the argon plasma coagulation (APC) provides us with a new method of electrocoagulation in which high-frequency alternating current can be delivered to the tissue by a no-touch technique.*Patients/Methods:* APC was used in the upper and lower gastrointestinal tract in 66 consecutive patients with a mean age of 68 (47–86) years. The indications for treatment were bleeding from angiodysplastic lesions or polypectomy sites, oozing of blood from erosions or ulcers, bleeding due to vascular penetration by tumours, residual sessile adenoma tissue after snare adenomectomy and palliative treatment of stenosing tumours to restore patency before stent implantation. The maximum intensity of bleeding was Forrest Ib. The treatment was performed under combined sedation and analgesia. Two power/gas flow settings of 40 and 70 W and 2 and 3 l/min, respectively, were used. The impact time and incident angle were varied individually.*Results:* In 49 of the 50 patients with gastrointestinal hemorrhage definitive haemostasis was achieved in one to two sessions. In all of the 11 patients with residual sessile adenoma tissue complete removal was possible. Oesophageal patency was restored in all 5 patients with stenosing tumours. In one patient with angiodysplasia of the caecal pole an asymptomatic accumulation of gas in the submucosa was observed which resolved spontaneously. In two patients with extensive oesophageal carcinoma there was a transitory — also asymptomatic — accumulation of gas in the mediastinum and peritoneal cavity but no evidence of perforation.*Conclusion:* APC is an useful and non expensive alternative to laser therapy in the endoscopic management of gastrointestinal hemorrhage and flat or stenosing tumors. *P. Springer, A. Dessl, S.M. Giacomuzzi, W. Buchberger, A. St\'f6ger, M. Oberwalder, W. Jaschke

Univ.-Hospital Innsbruck, Dept. Radiology, Anichstrasse 35, A-6020 Innsbruck, AustriaThe purpose was to evaluate different techniques of virtual CT-gastroscopy in correlation to fiberoptic endoscopy.3 mm helical CT-scans of a pig stomach were obtained with air insufflation, instillation of diluted contrast (amidotrizoat) and with double contrast. Afterwards virtual endoscopy images were calculated on a Sun Sparc 20 workstation (128 MB RAM, 4 GB Festplatte) by using dedicated Software (Navigator, General Electrics Medical Sytems Company). The endoscopy sequences were compared to fiberoptic endoscopy.Virtual endoscopy with diluted contrast and with double contrast showed artifacts simulating polyps, erosions or flat ulcers. Monocontrast air insufflation sequences showed excellent correlation to real endoscopy and anatomical specimen with no artifacts except slice artifacts (partial voluming).As our preliminary results show virtual CT-gastroscopy is able to produce insights into the upper gastrointestinal tract similar to fiberoptic endoscopy, but it is, as spatial resolution of CT is limited, not competitive to fiberoptic gastroscopy. Radiology and ultrasound: DiagnosisEndoscopy, specific: Stomach, duodenumEndoscopy, general: Instrumentation, diagnosis }" "Virtual CT-Gastroscopy / A New Technique"

"P P 48 1179"P 48 1179**Endoscopic Ultrasound-Guided Histologic Needle Biopsy**

*N. Harada, T. Kouzu, M. Arima, K. Isono

Department of Surgery (II), Chiba University School of Medicine, Chiba, JapanEndoscopic ultrasound (EUS)-guided fine needle aspiration (FNA) is recently under evaluation. However, histologic biopsy may have advantage rather than aspiration cytology in diagnosing e.g., myogenic tumors. We evaluated the role of EUS-guided histologic needle biopsy in those patients with submucosal tomrs and extrinsic lesions of UGI tract.*Methods:* From August 1994 to January 1996, 20 consequtive patients (10 M, 10 F; mean age 61.4 years, range 42–87 years) underwent EUS-guided histologic needle biopsy. Of the 20 lesions, 14 were submucosal (3 esophageal, 11 gastric) and 6 were extrinsic (3 pancreas, 1 retroperitoneal, 1 mediastinal and 1 paraaortic lymph node). EUS-guided histologic needle biopsy was performed using a phased array endoscopic ultrasound transducer Toshiba PEF-703FA. The needle used was the EUS-guided histologic biopsy needle Endo-Sonopsy Needle (21-gauge, 25-mm needle, 1600-mm Teflon catheter embedded stainless steel wire mesh with stylet; Hakko Shoji, Tokyo, Japan).*Results:* In 17 of 20 patients, adequate tissue specimens were obtained (85%). EUS-guided histologic needle biopsy was diagnostic in 15 of 17 patients in whom surgical comfirmation was available or comfirmed by clinical follow-up (88.2%). In the subgroup of patients with myogenic tumors, EUS-guided histologic needle biopsy was diagnostic in 7 of 9 patient (77.8%). There were no complications in this series.*Summary:* 1) EUS-guided histologic needle biopsy is a sensitive technique for establishing a histologic diagnosis. 2) EUS guided histologic needle biopsy permits histologic comfirmation of myogenic lesions.*Conclusion:* EUS-guided histologic needle biopsy should be considered in the evaluation of gastrointestinal and extrinsic lesions. "P P 48 1180"P 48 1180**Endoscopic Ultrasound-Guided Fine Needle Aspiration in the Evaluation of Extrarectal Pelvic Masses**

*B. Hoffman[1], M. Bhutani, L. Aabakken, P. Baron, D. Cole, R. Hawes

Division of Gastroenterology and Section of Surgical Oncology, Medical University of South Carolina, Charleston, South Carolina

[1] Digestive Disease Center, Medical University of South Carolina, Charleston, South Carolina*Introduction:* The role of endoscopic ultrasound (EUS) in staging rectal cancer is well established but its role in the evaluation of peri-rectal processes is less well defined. The development of the linear array echoendoscope (EE) now allows guided fine needle aspiration (FNA) cytology. We performed this study to determine the role of EUS-guided FNA in the evaluation of pelvic masses.*Patients/Methods:* Between June 1994 and October 1995, 8 patients were referred for EUS evaluation of pelvic masses. A 360\'b0 radial scanning EE was first used to identify the abnormality and establish overall orientation. Next, the linear array EE (Pentax FG 32-UA) was used to perform guided FNA. Pulsed and/or color Doppler were used to distinguish vascular structures. A Teflon catheter with a 23 gauge needle was advanced thru the working channel of the EE and the needle guided into the mass using real time ultrasound imaging.*Results:* In 5/8 (63%), a definitive diagnosis of malignancy was made. These included adenocarcinoma (2), ovarian carcinoma (1), cervical carcinoma (1), and lymphoma (1). In two patients the EUS image and FNA were consistent with abscesses; both were treated accordingly with resolution of symptoms. The EUS images and FNA from the sample of the remaining patient suggested an inflammatory reaction felt to be related to prior radiation therapy. The total cost excluding cytopathology ranged from $1046–1252 for EUS compared to $1323–1823 for a CT-guided aspiration. The diagnostic yield of EUS + FNA was 100% as determined by positive FNA and/or clinical follow-up. The procedures were completed in 45 minutes on average, required no sedation, and there were no biopsy related complications.*Conclusions:* EUS is able to detect pelvic abnormalities; fine needle aspiration is a useful adjunct for suspected neoplasms and EUS-guided FNA may be a cost-saving diagnostic method in these pts.

"P P 48 1181"P 48 1181**Ultrasonically Guided Percutaneous Therapy of Postoperative Complications in Gastrointestinal Surgery**

*M. Opacic, N. Rustemovic, R. Pulanic, B. Vucelic, R. Ostojic, Z. Krznaric, T. Brkic

Division of Gastroenterology, Department of Internal Medicine, University Hospital Rebro, Zagreb, Croatia*Purpose:* To evaluate percutaneous drainage as a method of choice in therapy of intraperitoneal collections after abdominal surgery.*Method:* 31 intraperitoneal fluid collections with diffferent intraperitoneal localisation (22 abscesses, 6 hematomas and 3 bilomas) in 30 patients with recent intraabdominal surgical intervention were found and verified by aspiration under ultrasonographic guidance. Some of the patients had high risk for surgical therapy of complications.Modified Seldinger and trocar technique were used in drainage procedure. Drainage was performed with various ""Angiomed"" and ""Cook"" catethers, 10 to 16 Fr in diameter and ""Aloka 680 SSD"" ultrasound unit with 3.5 MHz convex probe. Puncture was guided by free hand technique. Therapeutic procedure was effective in 28 collections (90%). Average duration of drainage was 14 days. There were no serious complications during the drainage procedure. In three patients additional surgical procedure was necessary to complete the evacuation of collections.*Conclusion:* Drainage was successful in 90% of our patients, without serious complications. Our experience confirmed the value of ultrasonically guided percutaneous drainage in previously surgicaly treated patients with intraperitoneal abscesses and liquid collections, especially in patients with high risk for surgical treatment of such complications.

"P P 48 1182"P 48 1182**Development of a High Intensity Focused Ultrasound (HIFU) Transducer Suitable for Endoscopic Applications**

*F. Prat, J.Y. Chapelon, A. Arefiev, Y. Theilliére, D. Cathignol

INSERM U281, Lyon, FranceThe potentialities of HIFU for selective and non-invasive tissue destruction have been demonstrated experimentally and clinically. Until now, only large transducers for extracorporeal applications had been evaluated. We have developed small HIFU transducers for endoscopic (GI and laparoscopic) purposes.The therapeutic element used was a semi-spherical piezocomposite transducer, 50 {\'b4} 22 mm, mounted on a handpiece, with a focal distance of 45 mm and a working frequency of 3 MHz. Targeting was achieved with a 2-dimenional ultrasound sector scan probe. 16 new Zealand hybrid rabbits were used for preliminary experiments designed for therapeutic parameter determination. The beam was directed transcutaneously to the liver parenchyma at depths of 20–25 mm from the adominal wall. Pulses were adjusted to respiratory motion in order to achieve destruction of 1 cm^3 tissue volumes. In a second series of 3 animals bearing a percutaneous gastrostomy, volumes of liver parenchyma were targeted through the gastric wall. Autopsies were performed 24 hours after treatment.1.2 – 0.2 cm^3 volumes of coagulation necrosis were reproducibly obtained in the liver at the desired site with twenty, 4 sec pulses delivered at a power output of 13 W.cm{ -2}. The mean treatment duration required to generate one such lesion in the liver was 17 – 3 minutes. In the rabbits treated through the gastric wall, 1.1 – 0.2 cm^3 lesion volumes were obtained. Neither skin nor gastric wall burns were observed with the treatment parameters defined.HIFU can be applied successfully with small transducers readily adaptable to the tip of an endoscope, thus opening a new perspective for endotherapy. "P P 48 1184"P 48 1184**The 3D Surface Image of the Ultrasonic Probe; Comparison of the Reconstructed Image with the Macroscopic Findings of Gastrointestinal Lesions**

*Y. Niwa, H. Goto, T. Arisawa, S. Hase, K. Nishimura, Y. Hirooka, H. Kameyama, M. Matsui, T. Hayakawa

2nd Department of Internal Medicine, Nagoya University School of Medicine, Nagoya, Japan*Purpose:* The aim of this study is to clarify the usefulness of three-dimensional (3D) ultrasonic surface images obtained with the endoscopic ultrasonic probe. *Methods:* Eighteen formalin-fixed resected specimens of gastrointestinal (GI) lesions (2 esophageal cancers, 11 gastric cancers, 2 gastric ulcers, 1 duodenal ulcer, and 2 colonoic cancers) and 20 patients with GI tract lesions (6 esophageal lesions, 3 gastric lesions, and 11 rectal lesions) were examined with the ultrasonic probe. The probe was passed over the specimens in vitro and withdrawn via the biopsy channel in vitro at a constant speed. The images were recorded on video and, following the examination, 3D displays of the lesions were reconstructed by computer (DEC station 3000/300) and compared with the gross pathological findings. We used the ultrasound probe (MP-PN series, 15 MHz, SSD-550, Aloka Co. Ltd.) to obtain ultrasound images. We compared 3D surface images with the macroscopic findings of the resected specimens and the lesions in vivo. We evaluated quality in three grades: good, fair, and poor. *Results:* In vitro study, the reconstructed surface image was consistent with the macroscopic findings. According to our evaluation, 13 cases were judged good, 4 fair, and 1 poor. In vivo study, 2 cases in the upper GI were evaluated good, 6 fair, and 1 poor. On the other hand, 7 cases of rectal lesions were evaluated good, 3 fair, and 1 poor. The surface image of flat and non-demarcated lesions didn't correlate well with the macroscopic findings. We could not obtain good images of upper GI lesions compared with rectal lesions because of breathing and circulatory pulsations. However, we could obtain the reconstructed surface image of lesions behind a fold or from the view opposite that of the conventional viewpoint by scanning with the probe. *Conclusions:* Using the endoscopic ultrasound probe, we can obtain both cross-sectional images and surface image of GI lesions. "P P 48 1185"P 48 1185**Identification and Histologic Correlation of Gastrointestinal Wall Layers Imaged with a MR-Endoscope**

*D. Kulling, D. Bohning, C. Kay, K. Spicer, R. Hawes

Digestive Disease Center, Medical University of South Carolina, Charleston, SC*Purpose:* To define the anatomic correlates to the gastrointestinal wall layers imaged in vitro with the new magnetic resonance (MR) endoscope.*Methods:* Using a MR-endoscope (XGIF MR30, Olympus, Tokyo, Japan) in a 1.5 Tesla scanner, 22 porcine tissue specimens (4 esophageal, 6 gastric, 6 duodenal, 6 rectal) were imaged. We performed T1- and T2-weighted spin echo, T2-weighted fast spin echo and FSPGR sequences. Serving as a marker, 0.1 ml cyanoacrylate was injected into the tissue strips. 18 specimens were imaged in a fresh state, 6 were reexamined after fixation in 10% formalin and 4 specimens were scanned in a fixed state only. Tissue sections representing the area previously scanned were stained with hematoxylin and eosin.*Results:* T1-weighted spin echo images (TR 600, TE 30, FOV 4 {\'b4} 4 cm, 256 {\'b4} 224 matrix, 3 mm slice, 1.5 mm spacing, 2 NEX) revealed the best layer discrimination. The use of a cyanoacrylate drop injected into the tissue strip provided an accurate mechanism to correlate histologic layers with the MR images. In T1 images, in general, the mucosa shows high signal intensity, the submucosa shows low intensity and the muscularis propria has an intermediate signal intensity. In the proximal duodenum and distal rectum however, the submucosa is densely infiltrated by glands, resulting in high signal intensity of the submucosa. In the esophagus and rectum the muscularis propria can be visualized as 3 layers consisting of circular and longitudinal muscle and intervening connective tissue, which appears with low signal intensity. Imaging after fixation of the tissue showed significantly reduced contrast between different layers.*Conclusions:* In vitro imaging with the new MR-endoscope shows 3 to 5 wall layers of the porcine gastrointestinal tract depending on the segment scanned. This detail in gut wall imaging opens promising prospects for T-staging of gastrointestinal tumors. Endoscopy, general: Instrumentation, diagnosis }"

"P P 50 1197"P 50 1197**Efficacy and Longterm Follow-Up of Endoscopic Variceal Ligation in Esophageal Varix Bleeding**

*D.H. Lee, K.K. Lee, H.C. Jung, H.S. Lee, Y.B. Yoon, I.S. Song, C.Y. Kim

Department of Internal Medicine and Liver Research Institute, Seoul National University, College of Medicine, Seoul, KoreaHemorrhage from esophageal varices is a catastrophic complication of portal hypertension. Endoscopic variceal ligation (EVL) has been proven to be a viable substitute for endoscopic injection sclerotherapy (EIS). But rebleeding after EVL treatment is not infrequent and has been a problem of longterm management of esophageal varix bleeding. *Aim:* The aim of this study was to evaluate longterm outcome of EVL, rebleeding rate of esophageal varices and longterm survival rate. *Methods:* Total 52 patients who had received EVL because of esophageal varix bleeding were followed-up and analysed during three years period. *Results:* Total 689 ligations were performed during 117 separate EVL sessions. Control rate of acute bleeding was 90.5% (38 of 42 patients). Four patient who were failed in control of bleeding were taken EIS with successful bleeding control. The eradication rate of esophageal varix was 76.2% (32 of 42 patients) and the mean session for eradication of varix was 3.0 (2–6), the mean number of bands per person was 16.0 (5–41), and the mean number of bands per session was 6.0 (4–11). Rebleeding after initiation of EVL occurred in 11 of 42 patient (26.2%); Rebleeding occurred after 1–27 months (mean 11.7 months) since EVL was done. 81.8% of rebleeding occurred after 6 months since EVL was done. The mortality rate and survival rate after varix eradication during follow-up period (6–45 months, mean: 15.5 months) was each 14.3% (6/42) and 85.7% (36/42). The causes of death were hepatic failure (3/6), esophageal variceal bleeding (2/6) and hepatic encephalopathy (1/6). After EVL, there were no serious treatment-related complications; except mild complications of mild chest pain in 5 patient (12.0%) and mild substernal pain in 7 patients (16.6%). *Conclusion:* 1) These results suggested that although EVL is a safe and effective method for treatment of variceal bleeding control and eradication of esophageal varices with least serious complication, rebleeding of varices after EVL treatment occurred in about one forth and about 80% of rebleeding occurred after 6 months since EVL was done. 2) Regular periodic examination for early detection of recurrence of esophageal varix (esophagogastroscopy) and repeat EVL should be required because of high risk of rebleeding especially after 6 months since EVL was done. "P P 50 1198"P 50 1198**Endoscopic Ligation in Acute Esophageal Variceal Bleeding Will Exacerbate Concomitant Gastric Variceal Bleeding?**

*C.Y. Chen[1], C.Y. Chen, T.T. Chang, X.Z. Lin

[1] Department of Internal Medicine, Chia-Yi Christian Hospital, Taiwan

National Cheng Kung University Hospital, TaiwanEndoscopic variceal ligation (EVL) has been developed to provide a safe and effective alternative for treatment of bleeding esophageal varices. However, in bleeding esophageal varices (EV) with concomitant gastric varices (GV), EVL may be relatively contraindicated for fear of the exacerbation of GV bleeding. Histoacryl injection of gastric varices had shown excellent effect.*Material and Method:* We initiate this randomized, controlled study to evaluate the hemostatic effect of EVL and the GV status. Forty-five patients were included because of bleeding EV with concomitant GV at index endoscopy. Twenty-two patients were treated with histoacryl injection of GV followed with EVL for bleeding EV (Group A), and 23 patients with EVL for bleeding EV alone (Group B). EVL was according to Stiegmann method. Histoacryl was injected intra-variceally into concomitant nonbleeding gastric varices only during the first session in patients of the Group A with lipiodol (1:1).*Result:* Active EV bleeding at the first treatment was controlled in 40 of 45 patients (88.8%): 19/22 (86.3%) in Group A and 21/23 (91.3%) in Group B, $P > 0.05$. Five episodes of early EV rebleeding were controlled by the second EVL. No evidence of early GV bleeding was found in both group. Variceal eradication was achieved in 35 of 45 patients (77.7%): 18/22 (81.8%) in Group A and 17/23 (73.9%) in Group B, $P > 0.05$. Recurrent bleeding occurred in 22.7% (5/22) in Group A compared to 30.4% (4/23) in Group B ($P > 0.05$). However, one fatal rebleeding from GV in Group B was found 183 days after initial treatment.*Conclusion:* EVL can be safely performed in bleeding EV with concomitant GV. There was no significant benefit in variceal eradication and prevention of second gastric variceal bleeding if further histoacryl injection of concomitant gastric varix was done. However, prophylactic histoacryl injection of GV may prevent further fatal GV bleeding after esophageal variceal eradication. "P P 50 1199"P 50 1199**The ""Six-Shooter"" — A New Technique for Endoscopic Variceal Ligation**

*U. Seitz, S. Bohnacker, K.F. Binmoeller, F. Thonke, B. Brand, N. Soehendra

Department of Endoscopic Surgery, University Hospital Eppendorf, Hamburg, GermanyLigation therapy of varices is an established procedure. The major drawback is the multiple introduction of the endoscope, that necessitates an overtube. We report our experience with the new Multishooter-Rubberband-Ligation-Set ""Six-Shooter"" (Wilson-Cook Co.). Six ligations can be placed before the endoscope has to be reloaded. There is no need for an overtube.*Methods:* Time for application, misshooting rate, and efficacy of treatment were determined. 45 patients (Child A: 26 pts/B: 15 pts/C: 4 pts) with non-bleeding varices (I\'b0 6 pts/II\'b0 21 pts/III\'b0 18 pts) were treated in 122 sessions with 132 ""Six-shooter""-sets. Patients were divided in 2 groups: untreated varices (UTR, 19 pts) and prior treated with sclerotherapy and/or Histoacryl'-obliteration (SKL, 26 pts). Hemostasis of acute variceal bleedings was achieved by Histoacryl'-injection before ligation was started. When ligation showed no further effect on the size of varices in 2 subsequent sessions treatment was changed to sclerotherapy.*Results:* Median follow-up was 7 weeks (1–39). Median 6 rubberbands/session (2–14) were applied in median 2 minutes (0.5–9.0). Eradication of the varices was possible in 94% of the UTR-pts (median 2 sessions; 1–4) and in 70% of the SKL-patients (median 2 sessions; 1–4). Recurrence of varices had to be noted 58% of the UTR-pts within 4 weeks. There was no severe complication like perforation, stricture or procedure related bleeding.*Conclusions:* The handling of the Six-Shooter is safe. Application of rubberbands is easy and fast. Eradication of prior untreated varices is possible within few sessions, but recurrence of varices occurs frequently. A majority of recurrent varices after sclerotherapy may be successfully treated by the ""Six-shooter"". "P P 50 1200"P 50 1200**Combination of Ligation and Sclerotherapy Versus Ligation Alone in Eradication of Bleeding Esophageal Varices****B.D. Djurdjevic**

Zvezdara University Hospital, Belgrade, Dimitrija Tucovica 161*Aim:* A prospective, randomized trial was performed in order to assess whether faster eradication of bleeding esophageal varices was achieved with a combination of ligation and sclerotherapy than with ligation alone.*Patients and methods:* Thirty-six patients with esophageal varices that were actively bleeding or had bled recently were randomly assigned to a combination of ligation and sclerotherapy with a smaller volume of sclerosing agent (1 ml of 1% Aethoxysclerol). Ligation was done as described by Stiegmann. Endoscopic treatment was repeated a week later after initial procedure and than at 14-day intervals until variceal obliteration was achieved or varices were reduced to grade I. Thereafter, endoscopic examination was done at three-month intervals or whenever rebleeding occurred. Mean follow-up was 5.5 months.*Results:* No significant differences were found between combined therapy and ligation alone in respect to the number of sessions, required for achieving of variceal eradication (2.3 – 0.2 vs. 2.5 – 0.3), rebleeding (8% vs 9%) complications (11% vs 8.5%), or deaths (10% vs 12%).*Conclusions:* We conclude that a combination of ligation and sclerotherapy is not superior to ligation alone in regard to rapidity of eradication of esophageal varices and decreasing the rate of complications and therefore we do not recommend this combining therapy for the treatment of esophageal varices. Endoscopy, general: GI bleedingEndoscopy, specific: Oesophagus }" "Combination of Ligation and Sclerotherapy Versus Ligation Alone in Eradication of Bleeding Esophageal Varices"

"P P 50 1201"P 50 1201**Audit of Combined Band Ligation and Injection Sclerotherapy Following Octreotide Infusion in Grade IV Bleeding Esophageal VaricesGun Tayyab**

Cons. Gastroenterologist, Jinnah Hospital, Lahore, PakistanBleeding varices is one of the common emergencies in our hospitals due to high prevalence of the post infectious chronic liver disease. Hemostasis is in particularly difficult to achieve when the varices are big and tortuous with the hemocystic areas on the overlying mucosa. Band ligation alone may not be sufficient in these patients. In February 1996 a policy was adopted to keep all the patients with the h/o upper GI bleed on octreotide infusion (50 ug stat and 50 ug/h) till endoscopic intervention. At the time of endoscopy patients with grade IV varices were separated out and dealt by band ligation followed by injection sclerotherapy with absolute. alcohol at the O.G jn and 5 cm proximal. Octreotide infusion was continued for another 48 hr. following the sclerotherapy. An upper GI endoscopy was repeated in all these patients every week till the time of complete obliteration of varices.Till 15th May, 70 patients had presented to us with variceal bleeding and 25 of these patients were found to have grade IV varices at the time of endoscopy. Their subsequent management was carried out according to the above mentioned routine. Mean age of these patients is 37 yrs (range 17–65 yr.) with a male to female ratio of 15:10, 7, 13 and 5 patients were in Child–Pugh stage A, B, and C respectively. One patient in first 24 hr. (4%) and two patients in the first 48 hr rebled (8%) which were managed successfully with esophageal transaction and stapling. None of the other patients rebled. A marked reduction of variceal size was observed in all the patients except for two on the endoscopy carried out on 7th day (21/23) and all the patients received another set of sclerosant injections on 14th day. The varices were well settled by third week. Two patients complained of transient dysphagia and pleuritic type of chest pain each. This audit is strongly in favor of using a combined approach (band ligation + injection sclerotherapy) along with octreotide infusion and there is a need of running a controlled trial to confirm these observations. Liver and bile ducts, 1: Cirrhosis: portal hypertensionEndoscopy, general: GI bleedingEndoscopy, general: Instrumentation, therapy }"

"P P 50 1202"P 50 1202**Multiple-Fire Versus One-Shot Ligator in Endoscopic Elastic Band Ligation of Esophageal VaricesF. Garc\'eda Dur\'e1n, P. Mench\'e9n, C. Senent, R. Alvarez, P. Jimenez, J.A. Carneros, R. Ba\'f1ares[1], M. Romero, J.L. Velo, E. Cos**

[1] Gastrointestinal Departament, Endoscopic Unit, Haemorragic Unit

General Universitary Hospital ""Gregorio Mara\'f1\'f3n""*Introduction:* The endoscopic elastic band ligation is a technique that it has been demonstrated efficient in the treatment of the esophageal varices. The appearance of multiple-fire ligators is permitting a better variceal management. *Aim:* Compare the endoscopic elastic band ligation with multiple-fire ligator versus one-shot ligator in two groups of patients, analyzing eradication rate, number of sessions for the variceal disappearance and cost of the treatment. *Methods:* Endoscopic elastic band ligation was used to prevent recurrence of variceal hemorrhage in 26 cirrhotic patients who had previously bled from esophageal varices. 13 patients were treated with one-shot ligator (Bard) and 13 with multiple-fire ligator (SpeedBand). There were no difference between the two groups concerning Child-Pugh score or variceal size at the beginning of the treatment. *Results:* The variceal eradication rate was similar in the two groups (0.92 vs 0.85 ($p = 0.5$), multiple-fire vs one-shot ligator, respectively). Also, the number of strips applied by patient, was similar in the two groups (8.07 vs 10.15, $p = 0.2$). The better patient tolerance permitted to apply more strips by session in the multiple-fire ligator group (5.01) that in the one-shot group (2.8). On the other hand, less sessions by patient were need in the multiple-fire ligator group for variceal eradication (1.6 vs 3.6 ($p < 0.001$)). The cost medium of the treatment by patient to achieve the variceal eradication was similar in both groups. *Conclusions:* 1. Both treatments have a similar efficiency for variceal eradication. 2. The multiple-shot ligator permits to put more strips by session than one-shot ligator, due to a better patient allowance. 3. The multiple-fire ligator permits the variceal eradication in a minor number of sessions and with a similar cost than one-shot ligator. Liver and bile ducts, 1: Cirrhosis: portal hypertensionEndoscopy, general: Instrumentation, therapyEndoscopy, general: GI bleeding }" "Multiple-Fire Versus One-Shot Ligator in Endoscopic Elastic Band Ligation of Esophageal Varices"

"P P 50 1203"P 50 1203**Ligation of Esophageal Varices with Endo-Loop — an Alternative for Rubber BandingJ.F. REY[1], T. MAREK[2]**

[1] Institut Arnault Tzanck, St. Laurent-Du-Var, France

[2] Silesian Medical Academy, Katowice, Poland*Background and aim:* The results of treatment of esophageal varices by rubber banding are comparable to sclerotherapy, with significantly fewer complications. Variceal ligation with endo-loop is, like rubber banding, a new method based on mechanical compression of the varix. Study was undertaken to assess the safety and efficiency of endo-loop ligation in the treatment of esophageal varices.*Material and methods:* 34 patients with either recent history (22) or acute variceal bleeding (12) were treated by endo-loop ligation. Endo-loops were placed in sessions in ten days intervals, with average number of 2.7 loops per session and 4.2 sessions per patient.*Results:* Hemostasis was obtained in 11 out of 12 patients with acute bleeding; the remaining patient died. Early rebleeding was observed in additional 2 patients (6%); both underwent successful repeated treatment. The only early complication was fever observed in in 2 (6%) cases. Complete eradication of varices was obtained in 27 (79%) patients; in 7 cases ligation was supported with sclerotherapy and in 2 with the placement of clips. After average 6 months of follow-up 27 patients are still alive, 5 died from hepatic encephalopathy and 1 from the next episode of bleeding.*Conclusions:* 1. Ligation of esophageal varices with endo-loop appears to be safe and easy method. 2. The eradication rate after endo-loop placement does not differ significantly from results obtained by sclerotherapy or rubber banding. Endoscopy, general: GI bleeding }" "Ligation of Esophageal Varices with Endo-Loop / an Alternative for Rubber Banding"

"P P 50 1204"P 50 1204**Role of Endoscopic Ligation in Active Variceal Bleeding under Emergency Conditions**

*W. Veltzke, A. Adler, R.E. Hintze

Depts. of Gastroenterology, Central Interdisciplinary Endoscopy, Virchow-Klinikum, Humboldt-University of Berlin*Introduction:* Ligature of esophageal varices was introduced by Stiegmann and Goff as method of choice for eradication of esophageal varices. The role of banding therapy in the management of active varicel hemorrhage remains controversial. We conducted a prospective trial to assess the use of endoscopic banding (EB) under emergency conditions.*Patients and methods:* From 7/94–10/95 we tried to control active variceal bleeding in n = 54 patients (male n = 38, female n = 16, average age 49.2) in the first line with banding therapy.*Results:* In only n = 13 patients (24.1%) out of n = 54 patients EB was successful in stopping haemorrhage. In n = 41 patients (75.1%) we had to treat by sclerotherapy (ST) in the same endoscopic course. This procedure was efficient in n = 34 patients (82.9%). Only n = 7 (13%) patients underwent Sengstacken-Blackmore tube.*Discussion:* In comparison to sclerotherapy EB is less effective in active variceal hemorrhage under emergency conditions. Main reason for failure is the reduced endoscopic view caused by the commercial ligature instrument. Only 30% of the video screen is available in a situation where also blood reduces sight. Definition of the bleeding source and placement of the ligature is therefore difficult. We are looking foreward to better results with a new constructed ligature instrument for emergency conditions. "P P 50 1205"P 50 1205**Emergency Sclerotherapy Vs. Banding Ligation for Arresting of Actively Bleeding Esophageal Varices**

*G.H. Lo, K.H. Lai, J.S. Huang

Division of Gastroenterology, Department of Medicine, Veterans General Hospital-Kaohsiung, Kaohsiung, Taiwan*Purpose:* The efficacy of endoscopic variceal ligation (EVL) and endoscopic injection sclerotherapy (EIS) in the management of actively bleeding esophageal varices is still undetermined. This study was conducted to compare the efficacy and complications of both methods in the arresting of actively bleeding esophageal varices.*Methods:* Patients with actively bleeding esophageal varices on endoscopy, without malignancy, or gastric varices, were enrolled. Seventy-one elgible patients were randomized to receive EVL (37 patients) or EIS (34 patients) immediately after endoscopic examinations.*Results:* Initial success rate (bleeding stopped for 48 hours) was 95% in the EVL group and 76% in the EIS ($p = 0.009$). The efficacy of EVL was similar to EIS in the control of oozing varices (100% vs. 89%, $p > 0.05$), whereas EVL was superior to EIS in the control of spurting varices (94% vs. 62%, $p = 0.012$). Definite control of hemorrhage at one month was 92% in the EVL group vs. 70% in the EIS group ($p = 0.02$). Blood transfusion requirement was significantly lower in the EVL group than in the EIS group (3.2 – 1.2 vs. 4.5 – 1.8 units, $p < 0.01$). Rebleeding rate at one month was 17% in the EVL group and 33% in the EIS group ($p = 0.09$). Significant complications were encountered in 5% of the EVL group and 29% of the EIS group ($p < 0.03$). Mortality rates at one month was 19% in the EVL group and 38% in the EIS group ($p > 0.05$).*Conclusions:* EVL was superior to EIS in the control of actively bleeding esophageal varices, with greater effectiveness, lower requirement of blood transfusion and less complications. "P P 50 1206"P 50 1206**Injection Sclerotherapy for Non-Variceal Bleeding of Stomach and DuodenumM. Bulajic,**

*N. Popovic, M. Glisic, P. Popovic, T. Milosavljevic, M. Ugljesic, L. Pandey, R. Krstic, D. Popovic, P. Dugalic, D. Tomic, S. \'d0uranovic, N. Mijalkovic, O. Matejic, K. Todorovic

Clinic for Gastroenterology and Hepatology, Clinical Center, Belgrade, YugoslaviaIn the period between 1992–96, 645 (44 males, 205 females, age 17–91) consecutively admitted patients with active non-variceal upper GI bleeding were treated by endoscopic injection sclerotherapy of combined epinephrine/polydocanol, within 1–6 hours of admission. Control endoscopy was performed in 24–72 hours. Bleeding lesions were graded according to Forrest classification: active arterial bleeding – F Ia 57 (8.83%), active venous or capillary bleeding – F Ib 381 (59.06%), visible blood vessel – F IIa, 107 (16.58%) and adhering clot – F IIb 100 (15.50%). Initial hemostasis was achieved in 638 (98.91%), and definitive hemostasis in 600 (93.02%), respectively: in F Ia – 51 (89.47%), in F Ib – 361 (94.75%), in F IIa – 95 (88.78%), in F IIb – 96 (96.00%). Definitive hemostasis was achieved in 88.92% of gastric and in 94.86% of duodenal ulcers. The gastric ulcers had 12.24% of recidives and duodenal ulcers had 5.50% of recidives. Thirty six (5.58%) patients underwent surgery, and 1 (0.15%) patient underwent arterial embolization. There were 7 (1.08%) lethal outcomes, in patients with additional heart and renal diseases. There were three cases of perforation (0.46%) of resclerozated duodenal ulcers.*Conclusion:* Injection endoscopic sclerotherapy is an efficient and safe procedure for definitive hemostasis of non-variceal bleeding in stomach and duodenum, with minimal complications. "P P 50 1208"P 50 1208**Results of Injection Sclerotherapy for Esophageal Varices in Noncirrhotic Portal Hypertension**

*G. Boztas, Z. Mungan, S. \'d6zdil, O. Yegins\'fc, Y. \'c7akaloglu, S. Kaymakoglu, F. Besisik, A. \'d6kten, N. Erol, R. Sezer

Dept. of Gastroenterohepatology, Istanbul Medical Faculty, Istanbul T\'fcrkiyePorto-systemic shunts and non-shunting procedures have been used for the management of bleeding esophageal varices (EV) in noncirrhotic portal hypertensive (NCPH) patients. Endoscopic injection sclerotherapy (EIS) may be an effective alternative procedure in these patients.From January 1988 to December 1995, 32 consecutive NCPH patients (20 males; mean age 39 – 15) with a history of EV bleeding were admitted for EIS. The mean number of bleeding episodes before admission to EIS were 3.48 – 2.93/patient. The underlying causes of portal hypertension were portal vein thrombosis (37.5%), congenital hepatic fibrosis (12.5%), splenic vein thrombosis (6.25%), portal vein hypoplasia (6.25%) and idiopathic portal hypertension (37.5%). Earlier surgical procedures were done in 20 patients (splenectomy alone in 12 patients, shunt operation in 6 patients, devascularization in 2 patients). Six patients were excluded from study because of they refused further therapy so 26 patients were evaluated at the end of study. EIS was unsuccessful in two patients (7.7%), in these patients surgical procedures were done successfully. We were able to obliterate EV in 24 patients (92.3%). The mean therapy session number were 4.87 – 2.09/patient. The mean total volume of sclerosant solution (sodium tetradecyl sulfate, 2%) used until complete variceal obliteration were 45 – 17.4 ml/patient. Complications related to the EIS were developed in 21 patients (superficial ulcers 62.5%, deep ulcers 16.7%, esophageal stenosis 8.3%) and all of them were resolved by medical therapy.The average follow-up period of 24 patients after variceal obliteration were 38.88 – 20.37 months (7–66 months); during this period recurrent EV was noted in 41.7% and rebleeding in 8.3%. EIS was performed in all these patients. There was no bleeding related mortality.*Conclusion:* EIS may be an alternative to surgical therapeutic approaches for the secondary prophylaxis of variceal bleeding in NCPH patients. "P P 50 1209"P 50 1209**Endosonographic Evaluation of the Venous Changes Around the Gastro-Esophageal Junction during Band Ligation and Injection Sclerotherapy of Varices**

*G. Choudhuri, A. Srivastava, D.K. Agarwal, R.K. Dhiman

Sanjay Gandhi Postgraduate Institute of Medical Sciences, Lucknow, IndiaIn this prospective longitudinal study using endoscopic ultrasound (EUS) we tried to see if the changes in the venous anatomy around the GE junction that accompany successful variceal ligation (EVL) of large esophageal varices differ from those that follow injection sclerotherapy (EST).Eleven cirrhotic portal hypertensive patients (m: B, age 38.2 yrs) with large esophageal varices on endoscopy were found on initial evaluation with EUS to have 3.45 + 1.21 submucosal veins/varices (SMV) measuring 4.27 + 1.00 mm in diameter and 4.63 + 1.20 paraesophageal veins (PEV) measuring 3.90 + 1.64 mm in diameter lying adjacent to the esophageal wall before starting therapy.EUS was repeated after variceal obliteration. In 4 of the 6 patients (6 men, mean age 45 years) who achieved variceal sclerosis after EST (mean of 6.8 sessions), obliteration of SMV was accompanied by a reduction in number (3.5 vs 1.25) and size (5.0 mm vs 2.75 mm) of PEVs. However in all the 5 patients (5 men, mean age 28.6 years) who achieved immediate collapse and thrombosis of varices following EVL, there was no change in the number (3.8 vs 3.2) and size (4.2 vs 4.6 mm) of PEVS.Our initial observations show that successful obliteration of esophageal varices by injection sclerotherapy is accompanied by obliteration of paraesophageal collateral veins. These PEVs seems to remain unaffected after EVL. Persistence of dilated paraesophageal veins after successful initial EVL could lead to early recurrence of varices. "P P 50 1210"P 50 1210**Long-Term Follow-Up of Gastric Variceal Sclerotherapy: An 11 Year ExperienceS.K. Sarin**

Department of Gastroenterology, G.B. Pant Hospital, New Delhi, India*Background:* Bleeding from gastric varices (GV) is often a serious medical emergency. The role of endoscopy in the management of GV bleeding is still controversial. The type of GV and the management strategies for different types of GV have not been identified. *Materials and Methods:* GV were observed in 209 of the 939 (22.3%) patients with portal hypertension. Seventy one patients (mean age 33.9 – 18.2 yr, M:F::46:25) underwent GV sclerotherapy; 53 (75%) for a GV bleed. Portal hypertension was due to cirrhosis in 33 (46.5%) and non-cirrhotic causes in the remaining. Using a previously described classification (Hepatology 1992: 102: 994), GV were divided into Gastroesophageal varices type 1 (GOV1) (n = 21) and type II (GOV2) (n = 34); and Isolated GV (IGV1) (n = 16). GV sclerotherapy was done every week, using a combination of para- and intravariceal technique and absolute alcohol as a sclerosant. *Results:* GV sclerotherapy could arrest acute bleed in 12 (66.7%) of 18 patients. Variceal obliteration could be achieved in 45 of the 60 (75%) patients. While the success of GV sclerotherapy in different types of GV was comparable in acute bleed, variceal obliteration wash higher in patients with GOV1 (94.4%) than GOV2 (70.4%) and IGV1 (41%). Rebleed after elective GV sclerotherapy was 5.5%, 19% and 40% respectively in the three types of GV. There was no recurrence as GV during a mean follow-up of 24.2 – 22.9 mo. Seventeen (24%) patients died; nearly equally due to rebleeding and liver failure. *Conclusions:* (i) GV sclerotherapy can successfully arrest acute GV bleed (66%) and achieve GV obliteration (75%) (ii) GV sclerotherapy is more effective in patients with gastroesophageal varices. (iii) Alternative therapies need to be evaluated for patients with IGV1. "P P 50 1214"P 50 1214**Emergency Medical Treatment of Bleeding Esophageal Varices**

*S.S. Elsyed, M.F. Farag, F. Azzam, M. Hamid, G. Shiha, H. Askalani, A. Meneesy

Mansoura Faculty of Medicine, Mansoura, EgyptThe aim of this study is a trial to find the most effective emergency medical modality treatment of bleeding esophageal varices which provide acute hemostasis and prevent early rebleeding with less side effects and complications.This research comprised 2442 patients presented with upper gastrointestinal bleeding. Patients with variceal bleeding (70%) were divided into groups according to the line of therapy (drugs eg. sndostattin and glypressin, balloon tamonade, band ligation, and sclerotherapr either alone or in combination), besides conservative treatment. They followed up fore 12 months after treatment. Evaluation of treatment depending on: Overall control of bleeding, early rebleeding, units of blood transfused, mortality and number of sclerotherapy needed on follow up.From the results it was found that: The best line of treatment was sandostatin plus sclerotherapy. Sandostatin was effective as sclerotherapy. Sandostatin was more effective than glypressin. Band ligation was effective as sclerotherapy with less side effects. Adding sandostatin infusion to balloon tamponade markdly decrease the mortality and morbidity. Sandostatin infusion decrease the number of blood units transfused and the number of sclerotherapy on follow upIn a conclusion: Fore medical treatment of acute variceal bleeding, sandostatin infusion must be given to all patients fore the first 48 hours. Sandostatin infusion plus sclerotherapy is the ideal medical modality treatment. Combined sandostatin infusion and balloon tamponade is advisable in hospitals not equibed with endoscop services. Sandostatin infusion decrease the number of blood units needed and also decrease the numbers of sclerotherap needed on follow up. "P P 50 1215"P 50 1215**Octreotide Use in Acute Variceal Haemorrage: A Prospective Randomized Study**

*S.H.A. Shah, S.M.W. Jafri, A. Ahmed, S.S. Hamid, A.H. Khan

Department of Medicine, Aga Khan University Hospital, Karachi, PakistanSclerotherapy of bleeding oesophageal varices is considered the most effective treatment to arrest haemorrhage. However, the risk of rebleeding and mortality is high. There is a need to have adjunctive treatment to prevent early rebleeding and risk of death.In a prospective study we evaluated the role of octreotide (50 \'b5g/hr for 36 hrs) along with sclerotherapy in 105 adult cirrhotic patients who were actively bleeding from varices or had a recent bleed. Patients were assigned to receive octreotide plus sclerotherapy or sclerotherapy alone.Initial control of bleeding was achieved in 46/51 (90.2%) patients who received combined treatment compared to 41/51 (80.4%) patients (p = 0.05) in sclerotherapy alone group. Rebleeding after the first 24 hrs was less in the octreotide treated patients, 2/46 vs 8/41 patients (p = 0.003). The octreotide treated patients had a better short term (5 days) survival 44/51 vs 33/54 (p = 0.003) and shorter hospital stay, 5.314 – 3.87 days vs 6.63 – 3.86, p = 0.008 as compared to sclerotherapy alone group. The blood transfusion requirement was also less in the combined treatment group 3.882 – 2.805 vs 5.37 – 3.152 (p = 0.002).We conclude, 1) The combination of sclerotherapy and octreotide is more effective than sclerotherapy alone in the treatment of acute variceal bleeding. 2) Although early mortality is improved, there is no difference in the overall inpatient mortality between the two treatment modalities. "P P 51 1226"P 51 1226**Conventional Surgical Treatment for Cholecystolithiasis and Choledocholithiasis with and without Preoperative Endoscopic Papillotomy**

*A. Figueira, E.J. Lobo, L.F.R. Gatto, A.N. Dias, NETO R. Colleoni, F.° B. Herani, J.R. Ferraro, A. Goldenberg, T. Trivi\'f1o

Universidade Federal De S\'e3o Paulo, Brasil

Escola Paulista De Medicina, S\'e3o Paulo, BrasilTo study the risks of postoperative complications and death and technical failure to remove stones from common bile duct, 101 patients with symptomatic cholecystolithiasis and choledocholithiasis and papillary obstruction due to stone or inflammatory process were considered in two groups: Group I (n = 50) underwent preoperative endoscopic papillotomy and open cholecystectomy in the same hospitalization; Group II (n = 51) underwent open cholecystectomy, common bile duct exploration, T-tube drainage and transduodenal papillotomy. Patients with intermediate operative risk (ASA III – American Society of Anesthesiology) were present in 33.3% (Group I) and 36.0% (Group II). Patients with poor risk (ASA IV and V) were excluded. The common bile duct was free of stones in 75% (Group I) and 90% (Group II). Multivariate analysis showed that surgical team (p = 0.032) was related to postoperative complications and greater hospitalization in the conventional surgery (Group II); surgical risk (p = 0.53) was related to systemic postoperative complications in the conventional surgery (Group II); distal choledochal stenosis (p = 0.014) was related to technical failure, complications and death in the preoperative endoscopic procedures (Group I); choledochal stenosis was found to be more influent factor for complications than the number and size of stones. The conclusion is that the preoperative endoscopic papillotomy should remain the procedure of choice for common bile duct stones in patients with comorbid illnesses and cholecystectomy and common bile duct exploration is the procedure of choice in no risk patients.

"P P 51 1227"P 51 1227**The Application of Endoscopic Papillosphinctero-Manometry (EPSM) for Prevention of the Retro-Duodenal Perforation (RDP) on Papillary Stenosis**

*Orlov S. Yu, V.I. Sidorenko, S.A. Tchernyakevich, E.D. Fedorov

Department of Abdominal Surgery, Gastroenterology & Digestive Endoscopy, Russia State Medical University, Moscow, RussiaThe purpose: is to determine the frequency of the development of RDP and the opportunities of its prevention on the patients (pts.) with isolated papillary stenosis (PS). The pts. to the trial were selected according to 11 criteria: the absence of peripapillary diverticula, operations on PDM, bilio-digestive anastomoses, gastric resections, acute pancreato-biliary diseases at the moment of investigation, etc. Such a selection was necessary for the objective evaluation of the complications, depending only on the character and volume of operation. Firstly the retrospective analysis of the results of EPST was made out on 38 pts. with CBD stones less than 15 mm – control group – without pathological changes of PDM (m-4, f-34; mean age 66.4 yrs.) and on 36 pts. with isolated PS (m-3, f-33; mean age 63.3 yrs.). The length of EPST was defined on the basis of the preoperative ERCP and endoscopical landmarks. There was no RDP after EPST on the control group of pts. with CBD stones. Opposite to it there was 3 (8.3%) cases of RDP in pts. with PS. Thus, we came to the conclusion, that after EPST, carried out for PS, the frequency of RDP is higher, than on choledocholithiasis ($p < 0.025$). Then 37 pts. with isolated PS (m-1, f-36; mean age 58.4 yrs.) were examined prospectively. They underwent EPSM, – modified in our clinic method of standard sphincter of Oddy (SO) manometry, – before EPST. This method allowed us in each case to define precisely the length of SO, the localization and the stretch of stenotic segment of Oddi zone, on the basis of pathologically high pressure borders in SO (the major sign of PS – the basal pressure in SO is more than 35 mm Hg). The optimal length of EPST in all the cases was defined on the basis of EPSM, as the middle of the distance between the proximal margin of stenosis and the total length of SO. There was no RDP in this group of pts. Consequently EPSM gives the opportunity to estimate objectively the optimal volume of EPST in pts. with PS and to avoid RDP during this endoscopic intervention. "P P 51 1228"P 51 1228**Endoscopic Sphincterotomy for Common Bile Duct Stones in Patients under 60 Years of Age**

*F.M. Pedersen, A.T. Lassen, O.B. Schaffalitzky de Muckadell

Department of medical gastroenterology S, Odense University Hospital, Denmark*Background:* In the era of LC and the absence of prospective controlled studies concerning treatment of young patients with CBD, considerable controversy exists about the management of these patients.*Methods:* This study reports the results of a medium-term follow-up study of 86 (68 women) consecutive patients under 60 years of age who underwent endoscopic sphincterotomy (ES) for common bile duct stones. The median observation time after ES was 27.1 months. Complete follow-up was accomplished in 80 patients.*Results:* Sixty-one patients were discharged after ES with gallbladder left in situ. At the time of ES subsequent cholecystectomy was planned in 18 patients. Acute cholecystectomy was undertaken in seven patients due to acute cholecystitis (n = 4) or biliary colic (n = 3). Recurrent attacks of biliary colic required elective cholecystectomy in another nine patients. Cholecystectomy was not needed in 27 patients, of which 23 had gallbladder stones. One hundred ninety days after ES the probability of still having a gallbladder in situ was 50%. Most surgery was undertaken within half a year after ES.*Conclusion:* Young patients manage well without any need of cholecystectomy after ES for common bile duct stones. This group represented nearly half of those discharged after ES with gallbladder left in situ. "P P 51 1229"P 51 1229**Endoscopic Sphincteroclasy for Choledocholithiasis**

*F. Prat, J. Boyer, G. Pelletier, J. Fritsch, A.D. Choury, B. Person, J.F. Bretagne, C. Buffet

Hepatogastroenterology, Bic\'eatre, Angers and Rennes hospitals, FranceThe hydrostatic dilatation of the sphincter of Oddi (endoscopic sphincteroclasy – ESpcl –) is a recently proposed alternative to sphincterotomy for common bile duct stones (CBDL). Our aim was to assess the results and feasibility of the technique.30 patients (12 men, 18 women, mean age 64.2 – 16.4 years) with suspected CBDL were enrolled with the following criteria: signs and symptoms of biliary obstruction, presence on retrograde opacification of not more than 4 stones, not exceeding 10 mm in diameter. Two patients had an impaired coagulation; 6 had a gastrojejunal anastomosis duodenal diverticulae. Cannulation was performed with an indwelling guidewire, the papilla was dilated with a 2 cm-long Maxforce' balloon catheter (diameter 8 mm) inflated at 12 atmospheres durin60 seconds. Patients were followed prospectively during one month.In 3 patients, cannulation with a guidewire failed and a papillotomy was needed. Of the other 27, 24 had CBDL (1.4 – 0.8 stones; range 0–3; largesstone diameter: 5.1 – 2.9 mm) and no stone was found in 3 patients. Complete stone extraction was possible in 100% of the cases after ESpcl. Mechanical lithotripsy was never required. A naso-biliary drainage was used in 3 patients. There was no conversion to sphincterotomy. Bile duct clearance was achieved after one session in 22/24 cases (91.6%). Success rate was therefore 90% (27/30). Immediate and 1-month morbidity was 6.6% (one mild pancreatitis; one asymptomatic case of tears of the lower part of the bile duct).Espcl is feasible and suitable for the endoscopic therapy of CBDL when stones are neither too large nor too many; its morbidity seems to be low. Its long term results and effects on the sphincter of Oddi require evaluation. "P P 51 1230"P 51 1230**Severe Stenosis Following Endoscopic SphincterotomyF. Dos Santos,**

*T. Ponchon, R. Lambert, A. Chavaillon, R. Bory, B. Napol\'e9on, F. Hedelius, S. Sidi

Department of Digestive Diseases Hospital E. Herriot, Lyon, FranceLong-term complications following endoscopic sphincterotomy (ES) have still to be classified and analyzed. Recent publications pointed out to a particular complication which consists in a stricture of the biliopancreatic orifice.We reviewed the follow-up of a series of 3.138 consecutive ES done for choledocholithiasis and sphincter of Oddi dysfunction from january 1985 to december 1994 in our unit, to look for such a complication. We found 4 cases of ES stricture and we present here the clinical, fluoroscopic and endoscopic features of these cases and the management we used.*Patients:* Four patients (female: 4, age: 33–50, previous cholecystectomy in all) underwent an endoscopic sphincterotomy for bile duct lithiasis in 2 and for papillary stenosis in 2. No immediate complication was observed. One to 4 months later (mean: 80 days), the patients (pts) presented with acute mild pancreatitis (1 case), cholangitis in (2 cases), and abdominal pain and cholestasis (1 case). Endoscopy showed a punctiform sphincterotomy orifice with retraction of the peripapillary duodenal folds. The orifice was difficult to catheterize and cholangiography revealed a long stricture extending up to 7–15 mm beyond the biliary orifice and a common bile duct dilation. Pancreatic ducts were found normal.*Treatment:* Repeated endoscopic sphincterotomy was attempted in 2 pts but could not relieve the stricture. Plastic stents (Three 10 french stent side to side) were inserted in 2 pts during 6 months and a metallic stent in one. Stenoses recurred when removing the plastic stent, and the metallic stent rapidly occluded due to inflammatory processes. Finally the 4 pts were submitted to a choledochojejunostomy. Two pts then presented 2 and 6 months later a stenosis of the anastomosis and are now treated by a percutaneous prolonged silicone drainage.*Conclusions:* Endoscopic sphincterotomy stricture has a low prevalence of 1 for 1.000 ES. The endoscopic and cholangiographic features are impressive and the management, endoscopic or surgical, is difficult. Papillary stenosis and constitutional problems of scaring could be etiological factors. Endoscopy, specific: Biliary }"

"P P 51 1231"P 51 1231**Endoscopic Therapy of Choledocholithiasis 1973-1995: A Meta-AnalysisW. Sandschin, P. Born, K. Ulm[1], M. Classen**

[1] 2nd Medical Department, Institute for Medical Statistics and Epidemiology, Germany

Klinikum rechts der Isar, Technical University of Munich, Germany*Introduction:* Since its introduction in 1973 endoscopic papillotomy has gained a broad acceptance in the therapy of choledocholithiasis. The continuous improvement of the technical equipment enables endoscopists now to treat nearly all kind of biliary stones. In a Meta-Analysis this development as to success rates and complication rates was evaluated.*Material and Methods:* 31 papers published since 1979 including a total of 10335 patients were evaluated using a meta-analytical approach. Test on homogeneity (95% CI) were performed using the Yussuf-Peto method. Success rates (short and long term) as well as complication rates were investigated. The results of three different periods of time (I = 1973–1980, II = 1980–1990, 1990–1996) were compared.*Results:* Shortterm success rates were in I: 87.2% in II: 90.4% and in III: 94.6%. Complications were seen in 6.5% (I), 9.4% (II) and 6.8% (III) respectively. The increase of the complications (I-II) was significant (CI 95%).Longterm outcome was beneficial in 90% for pat. with gallbladder in situ and 87.4% for cholecystectomized pat. respectively. The in situ of the gallbladder shows no influence with respect to the long term outcome. In pat. with gallbladder in situ success rates were 86.4% compared to 86.5% in pat. after cholecystectomy (95% CI).*Conclusion:* Endoscopic therapy in the treatment of choledocholithiasis is highly effective. Likely due to the development of additional therapeutic systems such as ESWL or laser success rates significantly increased from 1973 to 1995. Despite of growing experience short term complication rates did not significantly improve, a consequence, as we think of the growing proportion of high risk patients. Thus in a time of laparoscopic cholecystectomy with splitting the therapeutic modalities between surgery and endoscopy endoscopic therapy is an important partner of surgery. "P P 51 1232"P 51 1232**The Safety Sphincterotome: An Effective Design to Minimise Risk**

*D.F. Martin, R.E. England

Department of Radiology, South Manchester University Hospitals, Manchester, UKEndoscopic sphincterotomy has become increasingly safe because of an appreciation of technical and clinical factors which lead to complication. There has been little attention to factors in the design of the sphincterotome, which may be associated with risk.We have designed a wire-guided tapered tip long nosed sphincterome, with a partly insulated 3 cm cutting wire. Each component of the design is incorporated specifically to reduce risk of complication based upon previous experience with commercially available devices. The long nose maintains access during sphincterotomy. Wire guidance ensures bile duct placement after deep cannulation with a standard cannula. A long cutting wire maintains axial orientation. Partial insulation of the cutting wire guards against inadvertent contact with endoscope or duodenum when the cutting wire is fully withdrawn from the papilla, in order to maintain high current density for sphincterotomy.We have used two similar devices, one with a mono filament cutting wire and another with a braided cutting wire, whilst assessing the power requirements for sphincterotomy by measuring total cutting time for each sphincterotomy.75 patients with bile duct stones have undergone sphincterotomy with these devices. A complication of sphincterotomy (bleeding requiring transfusion) has occurred in only one patient. No other complication has occurred and sphincterotomy has been successful in all cases. There is no difference in the crudely measured power requirement between mono filament and braided wire sphincterotomes.This device appears to enable safe, certain endoscopic sphincterotomy. "P P 51 1233"P 51 1233**Endoscopic Retrograde Cholangiographic Patterns of Biliary Fasscioliasis**

*M.Y.T. Rashed, T.A. El-Sefi, I. Boghdadi

HPB Unit Alexandria University, Surg. Dept. Liver Institute, and Medical Dept., Faculty of Medicine Menoufiya University, EgyptThe cholangiographic patterns of 14 patients with biliary fascioliasis were reviewed to define its characteristics; The diagnosis was confirmed by retrieval of Fasciola flukes from the biliary tree either endoscopically or/and surgically. In all patients, bile ducts were dilated with one or more of the following cholangiographic patterns (ERC).Endoscopic retrograde cholangiographic patterns:1) Single or multiple leaf shaped filling defects2) whip-worm like filling defects (7/14).3) Irregular changing filling defects on serial films (3/14).4) Jagged irregular bile duct wall (5/14).5) Segmental main bile duct stricture (2/14).In three patients, there were associated bile duct stones.In 9 patients (64 m/m), the gallbladder was infestedThe gallbladder filling patterns included: 1) Dry cracked earth appearance (4/9). 2) Numerous whip worm like filling defects in the fundus or at the neck with beaded cystic duct (2/9). 3) Vague ill defined filling defects with jagged irregular wall (2/9). 4) Contracted small sized gallbladder (1/9). In two patients, there were associated small gallbladder stones. In conclusions, these endoscopic cholangiographic patterns should be considered as specific for the diagnosis of biliary Fascioliasis. }" "Endoscopic Retrograde Cholangiographic Patterns of Biliary Fasscioliasis"

"P P 51 1234"P 51 1234**Endoscopic Treatment of Biliary Fistula: Papillotomy or Stenting?**

*Z. Wajda, M. Dobosz, A. Babicki

II Department of Surgery, Medical University of Gdansk, Gdansk, PolandAuthors present 21 patients with postoperative biliary fistula. The biliary fistula was a consequence of laparoscopic cholecystectomy in 6 patients, open cholecystectomy in 6 patients, T-tube drainage failure in 4 patients. In 3 patients the biliary leakage was recognized after right hemihepatectomy, and in 2 patients following stab or blunt hepatic wound. ERCP examination revealed intrahepatic bile duct leakage in 5 patients, while in 16 patients the bile duct injury involved extrahepatic biliary tree. The patients were divided into three groups. Group A comprised 10 patients in whom endoscopic papillotomy was performed only, and was sufficient for fistulas healing. Group B consisted of 6 patients in whom endoscopic papillotomy did not diminished biliary leakage, and consecutive endoprosthesis impacement was performed. Group C included 5 patientsIn these patients endoscopic papillotomy and endoprosthesis implacement were carried out simultaneously. There were no differences concerning the amount of biliary leakage and the site of the bile duct injury. In all the patients the biliary fistula was healed. No complications were observed following endoscopic treatment. The mean time of fistulas healing was in group A 8.3 days, in group B 14.6 days, and in group C 3.9 days. Since it is difficult to predict in which cases endoscopic papillotomy might be sufficient in biliary fistulas healing, authors suggest than in patients with postoperative biliary leakage primary biliary stenting shorten hospital stay period and should be considered as a procedure of choice. "P P 51 1235"P 51 1235**Peroral Cholangioscopy Using a Dissolving Top Chip without Endoscopic Sphincterotomy**

*Y. Shinohara, K. Takeda, K. Takei, T. Itoi, K. Nakamura, S. Fukuda, S. Ogiwara, T. Horibe, H. Kakutani, T. Saitoh

Department of 4th Internal Medicine, Tokyo Medical College Hospital, Tokyo, Japan*Purpose:* Peroral Cholangioscope with forceps channel and angulation system has been known to require endoscopic sphincterectomy (EST) in order to intubate of biliary duct. We developed a dissolving top chip (DTP) for the purpose of introducing cholangioscope into the bile duct without EST.*Patients and Methods:* Sixteen patients who were examined by the peroral cholangioscopy with DTP were studied. DTP has the shape of cone and is made from polyvinyl alcohol for medical use. DTP can be easily dissolved and disappeared within several hours in the bile duct because of its characteristics. The cholangioscope (FCP-9BP, Pentax) is 3.1 mm in external diameter at the rigid portion of the tip, has a working channel 1.2 mm in diameter and two directional angulation system (up and down).At first step, catheter was inserted into the CBD without EST using standard therapeutic duodenoscope and endoscopic retrograde cholangiography was performed. Each patient was administered with preparation of isosorbide denitrate in the biliary duct in order to relax papillary sphincter. Then, guide-wire was inserted into CBD through the catheter. Cone-shaped DTP was passed over the guide-wire and followed by cholangioscope. Combination of DTP and cholangioscope made it possible to get insertion quite reliably.*Results:* With the help of DTP, the insertion of cholangioscope into CBD without EST was successful in fourteen cases (87.5%). DTP did not prevent us from viewing the bile duct. Observation of papilla immediately after examination showed no bleeding or edema. Complications such as cholangitis and acute pancreatitis did not occur after this examination.*Conclusion:* Using DTP, cholangioscope with forceps channel and angulation system can be readily inserted into CBD without EST. We are convinced that this method would be very useful in improving the diagnostic and therapeutic ability of cholangioscope and could be applied even in the case of youth or the patient who has hemorrhagic diathesis. "P P 51 1236"P 51 1236**Correlation between the Location of Juxtapapillary Diverticula and Choledocholithiasis**

*J.S. Huang, K.H. Lai, G.H. Lo, N.J. Peng[1]

[1] Division of Gastroenterology and Nuclear medicine, Taiwan

Veterans General Hospital-Kaohsiung, Taiwan*Purpose* To evaluate the distribution of Juxtapapillary diverticulum (JPD) and its relationship with choledocholithiasis.*Methods* 1128 consecutive cases underwent ERCP between October 1990 and October 1994. The location of JPD and the papilla of vater was subdivided into six types: type A: the papilla was located at inferior border of JPD, 6 o'clock; type B: the papilla was located at inferior border of JPD, 7 to 9 o'clock; type C: the papilla was located at inferior border of JPD, 3 to 5 o'clock; type D: the papilla was located inside the JPD; type E: the papilla was located at > 1 cm distal to JPD; type F: the papilla was located at the proximal portion of JPD. 141 patients (76 cases with JPD, 65 cases without JPD) with prior cholecystectomy and endoscopic sphincterotomy had received quantitative cholescintigraphy (QC) after complete clearance of stones and normalization of liver function test.*Result* The incidence of JPD in our series was 30% (334/1128) and the incidence increased with age. The incidence of common bile duct (CBD) stones in patients with JPD is higher than patients without JPD (53.5% Vs 27% $P < 0.01$). The incidence of CBD stones in different types of JPD are as followings: type A: 75/152 (49%); type B: 54/84 (64%); type C: 19/26 (73%); type D: 2/9 (22%); type E: 26/54 (48%); type F: 3/9 (33%). (type B Vs A, D, E, F, $P < 0.01$, type C Vs A,. D, E, F, $P < 0.01$). In QC, there was no significant difference in time-activity curves between the patients with JPD and without JPD, but the patients with type B and C JPD had delayed hepatic clearance of isotopes compared with other types and patients without JPD.*Conclusion:* The incidence of choledocholithiasis was higher in patients with JPD, especially type B and C probably due to slower hepatic clearance or biliary emptying.

"P P 51 1237"P 51 1237**Duodenal Diverticula: Relationship with the Function of Sphincter Oddi, Biliary and Pancreatic DiseaseB. Vladimirov**

Clinical Center of Gastroenterology, University Hospital ""Tz. Joanna"", Sofia, BulgariaIn this study we assessed the clinical significance of duodenal diverticula (DD) and function of sphincter Oddi (SO) in patients with biliary and pancreatic diseases. Diverticula were found in 196 of the patients (12.3%), underwent ERCP. The mean age of these patients was 64.9 – 13.9 years. The most frequent diverticula were singles (87%) and with periampullary localization (60%). Selective cannulation of the papilla Vateri in these patients was not more difficult than in nondiverticulum patients – 98.4% and 99% respectively. The significant changes in this group compared to the patients without DD were: 1. The incidence of common bile duct stones after cholecystectomy – 59%; 2. The incidence of pancreatitis was 37%; 3. Fecal type bacterial overgrowth in duodenum and biliary juice; 4. Abnormal SO manometric findings: SO stenosis (elevated basal SO pressure > 40 mmHg) – 16%, SO insufficiency – 8% and SO dysfunction (amplitude > 240 mmHg, frequency > 10 p/min and retrograde sequence > 50%) – 76%. Endoscopic sphincterotomy with/without stone extraction and lithotripsy was performed in 119 patients with DD. The endoscopic methods for treatment were more difficult. The complications (pancreatitis and hemorrhage) were significantly higher, but most of them were not severe and treated nonsurgically. Success rate was the same as in the patients without duodenal diverticula. Endoscopy, general: Instrumentation, therapyEndoscopy, specific: Biliary }" "Duodenal Diverticula: Relationship with the Function of Sphincter Oddi, Biliary and Pancreatic Disease"

"P P 51 1240"P 51 1240**Endoscopic Drainage Treatment of Biliary Fistulas Caused by Gunshot Wounds**

*M. Bulajic, V. Korneti, M. Markovic, M. Ugljesic, R. Krstic, T. Milosavljevic

Institute for Digestive Diseases, University Clinical Center, Belgrade, YugoslaviaThe gunshot biliary fistulas may be very common, especially if obtained in war. Their surgical treatment is very difficult because they are frequently associated with shock and blast injuries of the liver and the adjacent organs. Consequently, complicated biliary fistulas require endoscopic drainage as a preoperative or definite therapeutical procedure.During the period from 1993–1995 we treated endoscopically six patients with war injuries. Three of them had bilio-bronchial fistulas. In those cases, EST was performed, and biliary stents applied. The nasobiliary catheter (NBC) was inserted, also after EST, in two wounded patients with bilio-pancreatico-colic fistulas. The remaining two patients with bilio-biliary fistulas underwent a combination of endoprosthesis-NBC drainage. The endoscopic drainage has been applied as a definite treatment procedure in 3 patients, while 4 patients, after significant recovery, due to endoscopy, underwent surgery. One patients died 1 month after surgery. Endoscopy, general: Instrumentation, therapyEndoscopy, specific: Biliary }" "Endoscopic Drainage Treatment of Biliary Fistulas Caused by Gunshot Wounds"

"P P 51 1241"P 51 1241**Post-ERCP Pancreatitis: Comparison of Two Different Approaches in Patients with CholedocholithiasisS. Wojtun, W. Gietka,**

*M. Gil, J. Gil

Digestive Endoscopy Unit, Central Clinical Hospital, Armed Forces Medical Academy, Warsaw, Poland*Aim:* Diagnostic and therapeutic ERCP are complicated by pancreatitis in 1 to 10% of patients, and evidence suggest that the type of procedure may be here of importance. Our aim was to compare two different ERCP procedures in patients with choledocholithiasis concerning the frequency of pancreatitis after the procedure.*Methods:* 535 patients were retrospectively analysed. Cases where biliary tree cannulation was easily obtained during first approach were excluded from final analysis. The rest of the patients were divided into two groups: A (n = 135), where cannulation finally succeeded using standard fashion ERCP, and B (n = 112) where selective biliary tree visualisation was obtained using wire-guided technique. Following parameters were analysed: blood and serum amylase, transaminases, bilirubin, WBC.*Results:* Among patients in group A 1 case of perforation, 3 cases of bleeding, 4 cases of pancreatitis were noted. In group B these figures were 0, 0, 1, respectively. Statistically significant differences were seen ($p < 0.05$), in the incidence of perforations, bleeding and pancreatitis. Serum amylase elevation in group A was seen 50% more often and lasted longer than in group B.*Conclusions:* In order to decrease the number of post-ERCP pancreatitis wire-guided procedure should in our view be recommended as a standard approach, when biliary tree visualisation cannot be obtained without difficulty. Endoscopy, general: Instrumentation, diagnosisEndoscopy, general: ComplicationsClinical practice: Management strategy }" "Post-ERCP Pancreatitis: Comparison of Two Different Approaches in Patients with Choledocholithiasis"

"P P 51 1242"P 51 1242**Tazobactam-Piperacillin Effectively Prevents Post-ERCP Infections**

*R. Fried, C. Beglinger, G. Stalder

Dept. of Gastroenterology, Univ. of Basel, Switzerland*Introduction:* In patients with cholestasis, post-procedure cholangitis is one of the major complications of therapeutic ERCP. Because of its excellent penetration into bile we used a combination of the broad-spectrum antibiotic piperacillin with the beta-lactamase inhibitor tazobactam (TAZ; Lederle AG, Switzerland) as prophylaxis in patients with cholestasis undergoing ERCP.*Methods:* 84 patients (37 f, 47 m; mean age 64.7 y [22–92]) with elevated parameters of cholestasis or dilatation of bile ducts at risk for procedure-related cholangitis were included in this open-label multicenter study and had antibiotic prophylaxis with TAZ (4.5 g iv) before, and 8 h and 16 h after ERCP. Patients already receiving antibiotics or with an allergy to penicillins were excluded. Patients were followed after ERCP for 1 week.*Results:* Cholangiography was achieved in 79/84 (94%). ERC was normal in 5 cases. Drainage was established during primary ERCP in 66 of the remaining 79 patients (84%). The etiology of cholestasis was choledocholithiasis in 36, a pancreatic tumor or cholangiocarcinoma in 34, and a stricture in 4. Cholangitis after ERCP was suspected in 8 cases. In one of these, endoscopic drainage had not been possible. After three courses of TAZ, antibiotics were continued in 5 cases because of repeat ERCP/PTC, preoperatively in 3, and for other reasons in 2. No side effects of TAZ were noted.*Summary:* Tazobactam-piperacillin (4.5 g iv) before and 8 h and 16 h after ERCP prevented post-procedural infections in 91% of patients at high risk for cholangitis.*Conclusions:* Because of its efficacy and excellent tolerance, tazobactam-piperacillin appears to be a very cost-effective drug for prophylaxis of post-ERCP cholangitis in patients with cholestasis in whom therapeutic ERCP is planned. "P P 51 1243"P 51 1243**Bile Leaks: Minimally Invasive Management?R.E. England, J.P. McLindon, D.F. Martin**

Departments of Radiology & Gastroenterology South Manchester University Hospitals NHS TrustBile leaks are relatively uncommon but associated with significant morbidity and mortality. Early diagnosis is essential and close collaboration between endoscopist, interventional radiologist and surgeon is necessary to optimise patient care.*Aim:* To review our experience of bile leaks — their cause, management and outcome.*Method:* Retrospective review of notes and imaging of all patients with bile leaks between January 1991 and December 1995.*Results:* 27 patients, 11 M 16 F, median age 54.5 (range 28–83). Aetiologies include: post cholecystectomy (16), post-intervention (ERCP + PTC) (9), trauma (1) and spontaneous leak associated with distal bile duct stricture (1). Leaks post cholecystectomy were post laparoscopic surgery in 10 and sites of leak were cystic duct stump (9), ducts of Luschka (2) and along T-tube tracks (5). 15 were managed endoscopically with sphincterotomy (ES) in 9, stents in 5 and ES and stent in 1. 1 patient was managed percutaneously with extraction of retained stones. Post-intervention leaks were clinically significant in 3 of 9 and managed with percutaneous metal stents (2) and endoscopic stenting (1). The spontaneous leak occurred from the GB in the presence of a distal bile duct stricture, and post operatively a persistent leak from the GB fossa was managed with endoscopic stenting. The trauma induced leak was a self-inflicted knife wound transecting the CBD and PD. Although the CBD could be stented the patient succumbed to multi-organ failure.20 of 27 leaks responded to percutaneous or endoscopic techniques, 6 resolved spontaneously and only one failed to respond.*Conclusion:* The majority of bile leaks can be managed safely and effectively using a variety of endoscopic and percutaneous techniques. "P P 51 1245"P 51 1245**Acute Cholecystitis Treated by Transpapillary Endoscopic Retrograde CholecystostomyR. Dumas, J.F. Demarquay, P. Hastier, B. Maes, J.P. Delmont**

Department of Gastroenterology, Cimiez Hospital, Nice, FranceA new approach of the gallbladder is now possible due to recent advances in endoscopic techniques and instruments, allowing selective cannulation of the cystic duct during ERCP. From October 1993, to March 1996, 15 unoperable patients were referred with the diagnosis of acute cholecystitis (male: 9, female: 6, mean age: 72.6, ext.: 34–92). Contraindications for surgery were: recent severe polytraumatism 1, subarachno\'efdal hemorrhage 1, cardiac failure 4, poor general status, in elderly patients 7, cirrhosis with liver failure 1, therapeutic aplasia after chemotherapy for leukemia 1. Indications for endoscopic draingage were: lithiasic acute cholecystitis 14, associated with acute cholangitis in 5 pts, with acute pancreatitis in 2 pts; acalculus cholecystitis (with perforated gallbladder) in 1 pt..Selective cannulation of the cystic duct and gallbladder endoscopic drainage were successfully achieved in 13 (86.6%). Endoscopic procedures were carried out under sedation by pethidine or propofol. An endoscopic sphincterotomy was performed in 13 pts. An hydrophilic atraumatic terumo' guide was used in 12 cases, being driven into the cystic duct through a specific preshaped catheter (""retrogall"" Schneider') in 4 patients. In one patient a miniscope (Pentax FCP9P) appeared to be helpful.Gallblader drainage was carried out through standard naso biliary catheters (10 cases) or specific ""intragall"" Schneider' catheters (3 cases) in association with irrigations, infusion of mucolytic agents, and intravenous antibiotherapy during 7 to 14 days. No complication was observed. In 12 of the 13 patients with successful endoscopic drainage emergency cholecystectomy could be avoided. Absence of clinical and ultrasonographic improvement lead to surgical cholecystectomy in one patient. In the 12 other patients (92.3%) evolution was favorable including the patient with perforated gallbladder. ESWL allowed gallbladder stones clearance in two patients. Cystic duct was stented with a double pig tail endoprosthesis in 4 cases during 6 weeks. The leukemic patient could be cholecystectomised 2 months later, after therapeutic aplasia had disappeared. The follow up of the other patients doesn't suggest high risk of relapse until now. *Conclusion:* our results suggest that in unoperable patients with acute cholecystitis endoscopic transpapillary drainage should be considered as an alternative to emergency cholecystectomy. Endoscopy, general: Instrumentation, therapyEndoscopy, specific: Biliary }" "Acute Cholecystitis Treated by Transpapillary Endoscopic Retrograde Cholecystostomy"

"P P 51 1246"P 51 1246**Basic Investigations Concerning a New Low-Cost Piezo-Acoustic Stone-Tissue-Discrimination-System (paSTDS) for ""Smart"" Laserlithotriptors and ""Blind"" Fragmentation of GallstonesJ. Hochberger, J. Tschepe[1],**

*S. Tex, J. Bayer, R. Stein, C. Ell, J. Helfmann[1], P. Martus[2], E.G. Hahn

Dept. of Medicine I, Friedr.-Alexander-University, Erlangen

[2] I. Biom. Statist., Friedr.-Alexander-University, Erlangen

[1] Laser Medical Technologies Berlin, Berlin, FRGIn animal experiments and clinically we were able to prove the effectiveness of an optical stone-tissue-discrimination-system (oSTDS) in combination with a Rhodamine-6 dye laser (""Lithognost"", Baasel Lasertechnik, FRG). The system provides the possibility of disintegrating biliary concrements in a reliable and safe manner using standard duodenoscopes and catheters without cholangioscopic control. However, the dye laser and the oSTD system represent two expensive components of this sophisticated technology, thus restricting the use of this ""smart laser"" to selected gastroenterologic centers at present. In the following we report on our preliminary results concerning a new low cost *p*iezo *a*coustic STDS (paSTDS), which is currently integrated in a *fre*quency-*d*oubled *d*ouble-pulse Nd:*Y*AG-laser (FREDDY). *Mat. & Methods:* The paSTDS was used in combination with FREDDY (laser double pulse at 532 nm/1064 nm wavelength, 16/79 mJ, 1.4 us, ""Lithon"", Clyxon Corp. Berlin, FRG) and a 280 \'b5m quartz-fiber system. The fundamental concept of paSTDS is the good conductance of quartz for mechanical waves as generated e.g. during plasma expansion, pseudo-cavitation and ""bubble collapse"" in laserlithotripsy. 20 human gallstones, porcine gall bladder ""in vitro"" and 6 rabbit gallbladders in acute animal experiment were exposed to laser pulses at different energy settings (35–95 mJ; 0–16 mJ at 532 nm) in direct stone/tissue contact. The time interval between plasma expansion (1st signal) and collapse of the plasma induced bubble (2nd signal) were detected by a needle-hydrophone as well as by a piezosensor attached to the fiber surface and analyzed optically and electronically (storage oscilloscope/paSTDS). *Results:* Concerning the stones, paSTDS using a 280 \'b5m quartz fiber proved dependable detection of the aquired signals in comparison to the hydrophone measurements (300–700 us). On the porcine gallbladder in vitro no plasma signals were detected even after 10.000 FREDDY laser pulses. In preliminary animal experiments plasma formation on tissue was rare with the lack of plasma formation in up to 1,000 pulses on the gallbladder of the rabbit. Further testings in the animal and first clin. applications are currently under investigation. *Conclusions:* According to our preliminary results paSTDS appears to offer a very promising low-cost alternative stone-tissue-discrimination-system for ""blind"" laserlithotripsy of gallstones allowing the use of standard duodenoscopes and catheters. However, the clinical outcome, realized in FREDDY + paSTDS as a first alternative ""low cost smart laserlithotriptor"" at 1/3 of the prize of established systems has to be awaited. "P P 51 1248"P 51 1248**Intra-Corporeal Lithotripsy in Complex Biliary StonesB. Behjou, F. Prat, J. Fritsch, A.D. Choury, G. Pelletier, C. Buffet**

H\'e9patogastroent\'e9rologie, CHU de Bic\'eatre, le Kremlin-Bic\'eatreIn 2 to 5% of cases of biliary lithiasis, the usual endoscopic techniques fail to make bile ducts free. Intracorporeal lithotripsy (ICL) is a recognized method for the treatment of such cases. Our aims were to compare two different techniques, laser (L-ICL) and electrohydraulic (EH-ICL) lithotripsy, and to assess the long term results of these methods.40 patients (27 women, 13 men, mean age 76 – 14 years) were treated by L-ICL (22 patients), EH-ICL (10 patients) or both techniques successively (8 patients). Stones (mean diameter 23 – 12 mm) were intra-hepatic in 4 cases, choledochal in 31 cases and both intra- and extra-hepatic in 5 cases. Stones were approached via the trans-hepatic route in 3 cases, the endoscopic retrograde route in 35 cases and both routes in 2 cases. The 3 groups were statistically identical.The mean number of ICL sessions was 1.6 – 0.8; complete fragmentation and free bile ducts were obtained in 95% of cases (2 failures: Roux-en-Y anastomosis = 1; conservative treatment = 1). The mean hospital stay was 10.8 – 9.5 days. The global morbidity at 30 days was 32.5% (mostly transitory bouts of hyperthermia) but only one case of major morbidity was noted (bleeding sphincterotomy: 2.5%) and was not directly related to ICL, there was no procedure-related mortality. There was no difference between groups for all of these criteria. Long term information was obtained in 36 patients (90%) with a median follow-up of 17 months (range 4–52). Ten patients died from non-biliary diseases. Two patients developed biliary symptoms 24 and 34 months after ICL (5%), one of whom after a failed ICL.ICL is an effective method for the treatment of the most complex cases of biliary lithiasis. Its morbidity is acceptable. Both techniques (L-ICL and EH-ICL) yield similar results. The long term symptomatic complications of ICL seem to be rare. "P P 51 1249"P 51 1249**Usefulness of Electro Hydrouric Lithotripsy for Common Bile Duct and Intraheptic Bile Duct Stone**

*A. Murakami, A. Kano[1], R. Kamiya[2], Y. Saitoh[3]

[1] Division of Int. Med. of Gastroenterology Iwate Prefectural Central Hospital, Morioka Iwate, Japan

[2] Division of Int. Med. of Gastroenterology Iwate Red Cross Hospital, Morioka Iwate, Japan

[3] Division of Int. Med. of Gastroenterology Iwate Prefectural Miyako Hospital, Morioka Iwate, Japan*Introduction:* Although, Electro Hydrouric Lithotripsy (EHL) is an effective treatment for common bile duct (CBD) stone, EHL is difficult to perform in patients with huge stone or confluence stone. Laser or extracorporeal shock wave lithotripsy (ESWL) would not be cost-effective.*Aim and Method:* We evaluated the usefulness of EHL with peri oral cholangio scopy (POCS) in the treatment of CBD stone. We also examined the effect of EHL on intrahepatic bile duct stone after choledochojejunostomy. EHL was performed using the 4.5 or 3 Fr. probe under POCS with mother scope (TJF M20) and babyscope (CHF B20).*Patients:* EHL with POCS was done in 11 patients (male 6, female 5, mean age 68) and EHL with percutaneous transhepatic cholangiscopy (PTCS) in 4 (male 3, female 1, mean age 61).*Results:* Mean diameter of CBD stones in treated by EHL with POCS was 22 mm (range 18 – 30 mm). Seven demonstrated Bilirubin stone and four demonstrated cholesterol stones. Four patients had confluence stones. EHL was successful in all patients. Lithotripsic time for bilirubin stones was less than one hour in 6 of 7 patients, (mean time 48 min, range 35 – 70 min). While lithotriptic time for cholesterol stones required more than one hour in all four patients, presumably due to the increased hardness (mean time 62 min, range 60 – 70 min). In patients undergoing EHL with POCS, CBD was examined following removal of the stones to investigate the effect of EHL on the mucosa and determine the presence of CBD residual stones. EHL with PTCS was performed for bilirubin stones in patients with stenosis after choledochojejunostomy. Stenosis was successfully dilated by balloon following EHL removal of stones.*Conclusion:* EHL with POCS is an effective treatment for huge CBD stones and confluence stones, although the time required for the procedure is longer. "P P 51 1250"P 51 1250**Transhepatic Cholangioscopy in the Treatment Difficult Choledocholithiasis**

*J. Petrt\'fdl, V. Dufek, R. Brůha, Z. Marecek

Ist Medical Department, Charles University, Prague, Czech RepublicCholedocholithiasis (CDL) is the most common biliary tree disturbance, affecting more than 50% of population in Central and Eastern Europe in the elderly. Endoscopic solution of CDL is, in general, a method of choice, nowadays. However, in about 12% of patients (pts) the endoscopy fails and such a stones are mentioned as difficult ones (DCDL).*Aim:* This study was performed to assess the feasibility of transhepatic cholangioscopy (THCS) in the treatment of DCDL.*Patients and Methods:* Since May 93 to May 96, 20 consecutive pts with DCDL (7 females, 13 males, mean age 66.7 years) were entered into the study. In six of them, gastric resections, periampullary diverticula or CBD stenoses were present, in 14 cases, hepaticolithiasis or large CBD stones were found during ERCP. THCS was performed using a flexible scopes. For the stones removal, an intracorporeal shock waves lithotrypsi (ISWL) was used.*Results:* In all pts, the crushing and removal of DCDL was achieved in 1.5 sessions (range 1–3). Analgosedation by fentanyl and midazolam was the only treatment modality in THCS. CBD strictures of benign origine in 2 cases were treated by metallic endoprostheses before ISWLThe toleration of both THCS and ISWL was excellent. We were not able to demonstrate any weighty side effect, either local or systemic.*Conclusions:* On the basis of the results mentioned is possible to conclude, that THCS in combination with ISWL is, nowadays, the method of choice in the nonsurgical treatment of DCDL. P P 51 1251"P 51 1251**Percutaneous Cholecystostomy in Elderly Patients with Acute Calculous CholecystitisT. Noro, H. Hashimoto, K. Kino, M. Naito, Y. Tanaka, K. Yoshiura, K. Katsuragawa**

Tokyo Metropolitan Geriatric Hospital, Department of Surgery and Internal Medicine, Tokyo, Japan*Purpose:* Efficacy of percutaneous cholecystostostomy as a therapeutic maneuver was evaluated in 70 patients of advanced age with acute cholecystitis.*Method:* 60 patients consisting of 40 men and 30 Women, 61–94 years old (mean age; 78.7 years) with acute cholecystitis underwent percutaneous cholecystostomy. All patients were with one or more medical problems, including respiratory failure, congestive heart failure, renal failure, and cerebrovascular accident. etc. and had a high fever (> 38\'b0C), elevated WBC counts, and evidence of abdominal pain or tenderness in the right upper quadrant on clinical examination. Percutaneous cholecystostomy was performed by using a transhepatic approach with sonographic guidance. Under local anesthesia, the gallbladder was punctuated with a 22-gauge needle. Catheters were then placed in tandem to the needle into the gallbladder.*Results:* In all of 70 patients, significant improvement was shown in the clinical condition within 24 to 48 hr, including disappearance of abdominal pain or tenderness, deferrescence, WBC count returning to normal. No complications related to catheter in sertion occurred.*Conclusion:* Percutaneous cholecystostomy is an effective temporary measwe in elderly patints with acnte cholecystitis and, under close clinical supervision, a safe alternative to surgical intervention Liver and bile ducts, 2: Gallstones, formation, treatmentClinical practice: Management strategy }" "Percutaneous Cholecystostomy in Elderly Patients with Acute Calculous Cholecystitis"

"P P 51 1253"P 51 1253**Endoscopic Stent Placement without Sphincterotomy in Malignant Biliary Tract Obstruction**

*F.J. Jim\'e9nez, R. Aznarez, I. Mart\'edn-Granizo, F. Borda

Hospital de Navarra, Pamplona, SpainEndoscopic stent placement has become accepted therapy for malignant biliary tract obstruction. Endoscopic stenting has less morbidity and mortality in malignant jaundice than surgery or percutaneous stenting. Sphincterotomy is usually performed to facilitate insertion of the stent and to prevent possible occlusion of the pancreatic orifice by the stent and secondary pancreatitis. However, stenting morbidity and mortality rates might be influenced by sphincterotomy complications. We report our experience in endoscopic stenting without previous sphincterotomy in malignant jaundice.*Material and Methods:* 41 patients (22 women/19 men) with ages between 57 and 91 years (mean 74.2) were treated because of malignant jaundice by means of endoscopic stenting without previous sphincterotomy. Diagnosis was pancreatic cancer in 23 patients, cholangiocarcinoma in 12 patients, ampullary cancer in 5 patients and metastatic cancer in 1 patient. Stents were 10 F (n = 35) or 11.5 F (n = 6) slightly curved polyethylene Cotton-Leung stents of different lengths and they were all positioned with an Oasis stent introducer set (Wilson Cook Medical Inc.).*Results:* All stents could be placed endoscopically. Previous dilation of the stenosis was necessary in only 3 patients. Cytologic specimens could be taken using Cytomax cytology brushes (Wilson Cook Medical Inc). Only one patient (2.4%) developed secondary pancreatitis which was managed conservatively.*Conclusions:* 1. Sphincterotomy performance is not necessary for endoscopic stenting. 2. Stenting alone avoids potential complications due to sphincterotomy. 3. Stenting without sphincterotomy does not increase the incidence of pancreatitis. Oncology, specific: Liver, biliaryEndoscopy, general: Instrumentation, therapyEndoscopy, specific: Biliary }"

"P P 51 1254"P 51 1254**Post-Surgical Biliary Stricture. Clinical Outcome of Endoscopic StentingG. Viceconte, E. Di Giulio, F. Fiocca, G. D'Ambra, G. Delle Fave**

Progetto Cooperativo per lo Studio delle Malattie Digestive Universita' degli Studi di Roma ""La Sapienza""*Introduction:* benign strictures of the bile duct following surgery (cholecistectomy, choledocotomy, etc.) are reported in about 1% of operated patients. The criteria for their management remain to be solved. The therapeutical approach: by surgery, radiology or endoscopy has been reported to be successful in about 80% of patients but the small number of patients reported in very few series, still make the question open for studies with larger series of patients. Then we aimed a study to evaluate the clinical outcome of endoscopic biliary stenting in patients with post-surgical benign biliary stricture.*Materials and Methods:* 59 patients (54% male; 32–76 aged), previously operated for cholecistectomy 81% (43.7% laparotomy; 37.5% laparoscopy); 4.1% choledocotomy and 2.8% end to end anastomosis were attempted for endoscopic biliary stenting.Study protocol: during 1 year, 1 to 3 plastic prothesis were positioned per patient and changed every 3–6 months. After 1 year the prothesis were removed in all patients.*Results:* the procedure was successfully attempted in 48 of 59 patients (81%). A 28 months median follow-up were completed in 91% of all patients (4 lost at follow-up). Of the 48 treated patients 65.9 had excellent results (normal liver function and no cholangitis); 13.6% good (1 episode/year of cholangitis); 20.4% had poor results (2 or more episodes of cholangitis/year). The complicances during the treatment year were 9.7% cholangitis and 2.4% acute pancreatitis. Finally the overall evaluation demonstrated that 59.3% (35 out of 59 patients) were successfully treated (excellent + good score) but when the stent/s were successfully positioned the positive results increase to 79.5%.*Conclusion:* the endoscopic biliary stenting appear to be a well tholerated, poorly invasive, a low rate of complicance procedure and then may be considered as first choice for treatment of post-surgical biliary strictures. "P P 51 1255"P 51 1255**Temporary and Long Term Biliary Stenting for Retained Common Bile Duct Stones in an Irish Cohort**

*S. Pathmakanthan, J. Goh, E. Clarke, J. Lennon, P. MacMathuna, J. Crowe

Department of Gastroenterology, Mater Misericordiae Hospital, Dublin, IrelandCommon bile duct (CBD) stones that are not amenable to extraction at ERCP can be managed by temporary biliary stenting. In selected patients, repeated biliary stenting may be an alternative to definitive surgical procedures. The aim of the present study is to evaluate the safety and clinical outcome of temporary and long-term stenting.337 patients underwent ERCP for CBD stones over a 4 year period (1991–1995). 295 (87%) had successful duct clearance after a single ERCP while the remaining 42 (12%; 19 M, 23 F mean age 77.5; range 56–95) underwent temporary biliary stenting for non-extractable stones. The last cohort was followed up for a mean period of 20 months.Of the 42 patients who underwent temporary biliary stenting initially, 4 underwent surgical CBD clearance; 17 patients (40%) underwent successful endoscopic CBD clearance after only one additional ERCP in 65% (range 1–4); the remaining 21 patients (Mean age 77, range 68–95) had unsuccessful stone clearance subsequently and were managed by long-term biliary stenting with stent change performed for stent blockage. In this long-term stenting group, 6 died from non-biliary causes and the remainder have not experienced any biliary-related complications during a mean follow-up period of 20 months.Early complications following stenting included pancreatitis (1), cholangitis (3), oesophageal laceration during stent removal (1) and stent migration (1). Late complications (> 72 hours post ERCP) occurred in 6 and comprised stent migration, cholangitis and hepatic abscess. No mortality was observed.*Conclusion:* Biliary stenting for non-extractable CBD stones at the first attempt is safe and allows further attempts at duct clearance to be performed electively. Long-term biliary stenting with elective stent change is a safe management option in the frail and elderly. "P P 51 1256"P 51 1256**Biliary Stenting with Self-Expandable Nitinol Spring StentJ.F. Rey[1], D. Duforest[1], T.A. Marek[2]**

[1] Institut Arnault Tzanck, Saint Laurent du Var, France

[2] Silesian Medical Academy, Katowice, Poland*Introduction:* Biliary stenting with self-expandable metal stents is gaining increasingly wider acceptance as a palliative treatment of pancreatic and bile duct cancer. Recently, a new kind of metal stent has been developed, which structure could better prevent tumor ingrowth.*Stent description:* The stent (EndoCoil, InStent, USA) is made from a nickel and titanium alloy, in shape of coil spring. The stent is introduced constricted over a 12F catheter, hold by a wire. During three-phase (proximal end, distal end, center) delivery stent shortens (closing spaces between spring coils) and widens rapidly, up to 24F.*Patients:* Between January 1994 and November 1995 stent insertion was attempted in 27 patients (11 M, 16 F; age range: 47–91) with obstructive jaundice due to non-resectable cancer. The tumor was located in the pancreatic head in 20 cases, in 4 cases in the upper CBD, and in 3 in the papilla of Vater.*Insertion:* Stents were correctly placed in 19/27 (70%) patients. In 6 cases we were not able to pass the introduction catheter through the stricture. In 2 cases stents initially did not expand completely, what resulted in the entrapment of the delivery catheter. In both cases stents had to be removed.*Occlusion* of the stent occurred in 12 (6 – overgrowth, 6 – sludge) cases after median time of 213 (range: 145–255) days. This was managed by cleaning with Dormia basket (6), additional stent placement (4) or stent replacement (2 cases). No tumor ingrowth into the tight stenting section was observed.*Removal:* We were able to withdrawn the stent by pulling the distal end using Dormia basket/polypectomy snare in 4 cases (in 2 due to tumor overgrowth, in 2 due to inadequate expansion), with 1 complication.*Complications* occurred in 3 cases (14%) with one fatality (5%). The removal of the stent with entrapped delivery system resulted in perforation of the distal CBD and severe bleeding, leading to death. In additional 2 cases clinically asymptomatic perforation of the CBD occurred, as a consequence of CBD wall pinching between neighboring coils of the stent helix during delivery.*Conclusions:* The new self-expandable stent offers several advantages; the ingrowth prevention and the possibility of removal are the most important. However, the insertion system should be improved, to avoid CBD injury during stent's shortening and the possible entrapment of delivery catheter. The removal of the stent should be carefully monitored endoscopically and radiologically.

"P P 51 1257"P 51 1257**Importance of Hydraulic Dilatation (h.d.) before Biliary Stenting with Endocoil Instent (e.i.) Prostheses, Preliminary Results in 35 PatientsA. Verduron, O. de Loubens, F. Girault**

Clinique Pereire, Levallois, FranceThe new self expandable metallic biliary stent e. i. is supposed to prevent tumor ingrowth, owing to the tight loops of the coil. However when the stenosis is too hard, the radial force of the stent may not be strong enough to allow fast full expansion and therefore easy withdrawal of the delivery catheter and quick loops joining. We propose previous h.d. in order to give the stenosis the diameter of the fully expanded stent. We report our experience with this new prosthese first without, then with, previous h.d.*Patients-methods:* Between November 1994 and April 1996, stent insertion was attempted in 35 patients (19 F-16 M, x&bar; age 73 – 15 years) with obstructive jaundice due to non resectable malignant stenosis of the intra pancreatic common bile duct. The first 13 patients had no h.d. (Group 1), the next 22 (Group 2) had h.d. first with a biliary balloon (Maxforce-microvasive) able to reach a 24 FR diameter with a 12 ATM, pressure. Patients were comparable in term of age, stenosis and cholestasis.*Results:* Stent insertion was successful in all 35 patients. Withdrawal of the delivery catheter was laborious in all Group 1 patients, for 2 of them the catheter got caught in the stenosis during 3 and 4 days, withdrawal was easy and immediate in all Group 2 patients. The average time for full stent expansion was 5.3. days (range 1–12) in Group 1 vs 1.14 (range 0–5) in Group 2 ($p < 0.05$). At the fourth post-operative day there was a total bilirubin decrease of 16% in Group 1 vs 42% in Group 2. Cholecystitis requiring cholecystectomy occurred in 3 Group 1 patients within 2 weeks of insertion, stent clogging by tumor ingrowth happened in 2 Group 1 patients respectively 1 and 2 months after the intervention. There was no complication in Group 2. Median follow up after insertion was 121 days (range 12–341).*Conclusion:* These preliminary results show that previous h.d. in biliary stenting with e.i. is essential to remove immediate technical difficulties. Moreover they suggest that it improves immediate successful drainage and prevents late clogging by tumour ingrowth. "P P 52 1260"P 52 1260**Outcome of Malignant Colo-Rectal Polyps**

*P. Netzer, J. Binek[1], J. Lange[2], B. Hammer[1]

Gastrointestinal Unit, Inselspital, University of Berne, Kantonsspital St. Gallen

[1] Gastrointestinal Unit, Kantonsspital St. Gallen

[2] Surgical Department, Kantonsspital St. Gallen*Background:* Malignant colo-rectal polyps are defined as endoscopically detected polyps which revealed cancer tissue in the histological examination. We studied epidemiologic data and outcome in our patients (pts) with malignant polyps.*Methods:* All pts in whom a endoscopy has been performed during 1986–1995, were analyzed. Outcome was assessed by interview with patients and general practitioners.*Results:* Lower endoscopy was performed in 6605 pts (mean-age: 68, range: 53–83; m: f = 2.5:1) and a malignant polyp was detected in 35 (0.5%) pts. Six pts were treated by primary segmental colonic resection (histological staging see table 1). Staging pT1N0M0 pT2N0M0 pT3N0M0 pT3N1M0 pT4NxMxN = 6 2 3 0 1 0In 29 patients, local polyp resection was performed. In 11 of these 29 patients, a segmental colonic/rectal resection was performed because histological analysis suggested an incomplete tumor resection (histological staging see table 2). Histology Normal Adenoma pT1 pT2 pT3 pTN1 pTNM1N = 11 8 2 1 0 0 0 0Pts who were adequately treated exclusively by polypectomy, showed no local or distance recurrence. Three pts (9%) had an unfavourable outcome. One patient after endoscopic polypectomy who refused surgical resection despite unfavourable histology (G3 and lymphatic vessels – infiltration) developed local recurrence. One patient died postoperatively and one patient died after segmental colon resection because of liver metastasis.*Conclusion:* Malignant polyps were detected in approximately 0.5% of all lower endoscopies or 4% of patients with polyps. Patients remained tumor-free in 91%. Endoscopic polypectomy is the treatment of choice for patients with favorable histology. "P P 52 1261"P 52 1261**What are the Optimal Intervals for the Survey of Patients with Adenomatous Colon Polyps?**

*M. Hart, R.A.M. Damhuis[1], H. Geldof

IJsselland Hospital, Capelle a/d IJssel, The Netherlands

[1] Comprehensive Cancer Centre, Rotterdam, The Netherlands*Aim.* The follow-up of patients with adenomatous colon polyps is an accepted strategy. The surveillance intervals however are subject of discussion. According to the Dutch consensus these are 1 year after polypectomy followed by an interval of 3 years (> 1 polyp) and 5 years (1 polyp). In this study we evaluated the yield of this schedule and tried to identify enrolment risk factors.*Method.* In 315 patients a colonoscopy was performed 1 year after removal of newly diagnosed adenomatous polyps and in 69 of these patients (no relapse after 1 year) again 3 years later. At enrolment and follow-up colonoscopy sex, age, polyp-location, -size, -number, sessile or pedunculated, histological type and grade of dysplasia were recorded.*Results.* After 1 year in 63 patients (20%) polyps were found. In 16 patients (5.1%) these polyps were classified as local relapse, mainly correlated with initial villous sessile (> 1 cm) polyps (15 sessile vs 1 pedunculated; $p < 0.01$). In the remaining 47 patients (14.9%) the polyps were either newly formed or initially missed. Two risk factors were identified: multiple polyps (20% multiple vs 11% single; $p < 0.05$) and age. The relapse rate after 1 year in 126 patients younger than 60 years was 8% against 21% in 189 older patients ($p < 0.01$). Three patients (all > 60 years and > 1 polyp at enrolment) had high-grade dysplasia or invasive cancer.In the 69 patients four years after the initial polipectomy the relapse rate was 17%; no enrolment risk factors and no high-grade dysplasia or invasive cancer were detected in this group.*Conclusions.* The relapse rate after one year seems high, however we are dealing with newly formed polyps and polyps missed at the initial colonoscopy which can be up to 29% according to literature. Our results suggest that colonoscopy after 1 year should only be performed in patients older than 60 years with multiple or sessile (> 1 cm) polyps. Otherwise a three years interval seems acceptable. In this study the number of colonoscopies after 1 year would be reduced with 30%. Clinical practice: Management strategyOncology, general: Screening, preventionOncology, specific: Colon, rectum }" "What are the Optimal Intervals for the Survey of Patients with Adenomatous Colon Polyps?"

"P P 52 1263"P 52 1263**Regression of Small Intestinal and Colonic Polyps after Non-Steroidal Antiinflammatory Drug-Tenoxicam Treatment in Patients with Adenomatous Polyposis**

*M. Tuncer, A. Dobrucali, I. Yurdakul, S. Tuncer, A. \'c7elik, K. Bal, H. Uzanismail, E. Oktay

Gastroenterology Department of Cerrahpasa Medical Faculty of Istanbul University, Istanbul, Turkey*Purpose:* Colonic cancer is the leading cause of death in patients with adenomatous polyposis. The aim of this study was to assess the effect of the non-steroidal antiinflammatory drug-Tenoxicam on duodenal and colonic polyps in patients with adenomatous polyposis.*Method:* Twenty-eight patients with advenced duodenal and colonic polyposis were randomly planned to receive a six months treatment of either 20 mg Tenoxicam (Tenoxicam groub (TG) n = 14) or placebo [Placebo groub (PG), n = 14] twice a day. Duadenoscopy and colonoscopy before and after 6 months was done and dimension and number of polyps in the duodenum and colon region were assessed by a blinded observer. The size of polyps was estimated by comparison with an opened biopsy forceps.*Results:* Both groups were comparable with regard to pretreatment polyp number (TG: 12 – 5, PG: 10 – 5) and dimension (TG: 4.5 – 1.5 mm; PG: 4.7 – 1.4 mm). After six month, more patients in the PG than in the TG have developed new polyps ($p < 0.05$).Polyps with less than 3 mm in size decreased or disappeared in 11 TG patients (79%) but only 3 PG patients (21%) ($p < 0.05$).Polyps with more than 5 mm in size were not significantly changed in both groups.*Conclusion:* These findings suggest that non-steroidal antiinflammatory drug-Tenoxicam induces regression of small intestinal and colonic polyps. Further studies will reveal if Adenomatous polyposis patients with early stage of intestinal and colonic disease could benefit from tenoxicam therapy. "P P 52 1264"P 52 1264**Significance of Colorectal Polyps Found on Sigmoidoscopy in Asymptomatic Patients**

*J. Kim, H.J. Son, H.Y. Lee, P.L. Rhee, K.C. Koh, S.W. Paik, J.C. Rhee, Y.L. Oh[1]

Division of Gastroenterology, Samsung Medical Center, Seoul, Korea

[1] Department of Pathology, Samsung Medical Center, Seoul, Korea*Purpose:* There has been much controversy regarding the significance of the hyperplastic polyps found on sigmoidoscopy as markers for synchronous adenomatous polyps. Therefore, we prospectively performed colonoscopy in asymptomatic individuals with colorectal polyps found on screening sigmoidoscopy to determine the possible association between synchronous polyps with the size or histologic type of colorectal polyps.*Method:* We performed flexible sigmoidoscopy in 2895 persons who wanted sigmoidoscopy out of 10705 healthy persons who visited Samsung Medical Center for health check up from August 1994 to November 1995. Colorectal polyps were found in 590 of 2895 individuals and colonoscopy was performed in 280 of 590 subjects. The size and location of all polyps were noted and biopsied.*Result:* Of 280 subjects, 73 (26.1%) subjects had synchronous polyps and 55 subjects (19.6%) had synchronous adenomatous polyps. 134 polyps were found in colonoscopy including adenomatous polyps (61.3%), hyperplastic polyps (12.9%) and inflammatory polyps (16.1%). The proportion of subjects with adenomatous polyps who had synchronous adenomatous polyps (25%) was significantly greater than the proportion of those with hyperplastic polyps who had synchronous adenomatous polyps (6.8%) ($p < 0.05$). The percentage of subjects with larger polyps (> 0.5 cm) who had synchronous adenomatous polyps (43.2%) was significantly greater than the proportion of those with diminutive polyps ({\'a3} 0.5 cm) who had synchronous adenomatous polyps (16.0%) ($p < 0.05$).*Conclusions:* Adenomatous polyps found during sigmoidoscopy justify colonoscopy for synchronous polyps. However, diminutive hyperplastic polyps are not significant indicators of risk for synchronous adenomatous polyps. Oncology, specific: Colon, rectumEndoscopy, specific: Colon, rectum }"

"P P 52 1267"P 52 1267**Differences in the Risk of Severe Dysplasia between Endoscopically and Surgically Removed Colorectal AdenomasG. Nusko, U. Mansmann, A. Altendorf-Hofmann, Kessler, Ch. Wittekind, C. Ell, E.G. Hahn**

Depts. of Medicine I, Surgery & Pathology, Tumor Registry, University of Erlangen, Germany

Institute of Medical Statistics, Free University of Berlin, GermanyRisk factors for severe dysplasia in colorectal adenomas have been studied in endoscopical removed specimens (Gastroenterology 1990, Scand J Gastroenterol 1993). The aim of this study is to detect differences in variables of risk between endoscopical or surgical removed adenomas.*Methods:* From 1978 to 1993, 6631 consecutive patients of the Medical & Surgical Depts. with colorectal polyps were prospectively documented at the Erlangen Registry of Polyps. A total number of 11380 adenomas were documented according to the WHO classification and statistically analysed by logistic regression.*Results:* At the initial examination 5972 adenomas were removed *endoscopically* in 3343 patients and 3820 adenomas were removed *surgically* in 1749 patients. 313 (9%) endoscopic and 260 (15%) surgical patients had adenomas with severe dysplasia. The strongest discrimination between these groups was given by the size (significant cutpoint at 32 mm). Size of adenomas was the most important risk factor (endoscopic OR 8.2; 95% CI: 5.6–11.9 and surgical OR 13.8; 95% CI: 6.8–28.2). Tubulovillous and villous adenomas were of a higher risk in endoscopic (OR 2.3; 95%CI: 1.7–3.0) and surgical (OR 4.3; 95% CI: 1.4–13.6) specimens. Adenomas located in the right colon showed a lower risk in endoscopic (OR 0.4; 95% CI: 0.3–0.7) and surgical (OR 0.4; 95% CI: 0.2–0.9) resections. The risk factors in *endoscopic* removed adenomas can be described by a model of independent variables. But the risk of severe dysplasia in *surgical* resected adenomas have to be described by an interactive model. Significant interactive effects were found for the size ({\'b3} 10 mm) and villous, structure (OR 0.2; 95% CI: 0.1–0.7), size ({\'b3} 20 mm) and right colon location (OR 2.7; 95% CI: 1.1–6.7), and villous structure and colonic compared with rectal location (OR 2.7; 95% CI: 1.3–5.8).*Conclusions:* Size and villous structure are the most important risk factors for developing severe dysplasia whereas adenomas located in the right colon are of a lower risk in both groups. The difference between endoscopic and surgical removed adenomas is that size, villous structure and location are independent risk factors in endoscopical specimens. The risk of severe dysplasia in surgical removed adenomas has to be described by an interactive model with modifying interactive effects of size, villous component and location. "P P 52 1268"P 52 1268**Polyps Found in Screening Colonoscopy: A Three Year Single Center ExperienceK. Lang,**

*J. Hammer, Ch. Oesterreicher, R. P\'f6tzi, A. Gangl

General Hospital of Vienna, Abt. f. Gastroenterologie und Hepatologie, University of Vienna, AustriaWe evaluated frequency, site, and histologic characteristic of polyps found during colonoscopy of consecutive asymptomatic patients. Between January 1992 and December 1994 complete colonoscopies were performed on 2387 individuals who did not have a history of colonic polyps, inflammatory bowel disease, intestinal resection, or hematochezia, and did not have a contraindication against biopsies. All polyps found were either resected or, if polypectomy was not possible, biopsied. Polyps were found in 822 patients (34% of all individuals, 438 men, 384 women). The table shows number of patients with one or more than one polyps found in the colonic regions and histology of polyps. ""Others"" summarizes hyperplastic polyps, inflammatory polyps, carcinoids (2 cases) and leiomyomas (2 cases). 1 polyp {\'b3} 2 polyps Adenomas Carcinomas OthersRectum 256 96 201 17 134Sigmoid 252 99 258 5 88Descending 109 24 113 3 17Transverse 93 23 94 3 19Ascending 158 59 163 12 42Cecum 78 19 69 5 23As expected, most polyps were found in the distal colon. However, 34% of all polyps found were located in the proximal colon (i.e. transverse colon, ascending colon, and cecum) and 22% of patients only had polyps in the proximal colon. Moreover, the chance that a polyp was an adenoma (or carcinoma) increased proximally: in the rectum 62% of all polyps were adenomas (or carcinomas), 75% in the sigmoid colon, 87% (descending colon), 84% (transverse colon), 81% (ascending colon), and 76% (cecum), respectively. In summary, adenomas and carcinomas are often found in the proximal colon. Our data, we believe, argue for screening colonoscopy (instead of sigmoidoscopy) in primary work up of asymptomatic individuals. }" "Polyps Found in Screening Colonoscopy: A Three Year Single Center Experience"

"P P 53 1269"P 53 1269**A New Tecnique for Endoscopic Crossing Lower Digestive Tract Stenoses**

*L. De Salvo, F.E. Gianiorio, G. Borgonovo, C. Bianchi, A. Arezzo, F.P. Mattioli

Clinica Chirurgica R. University of Genoa, Genoa, ItalyEndoscopic dilatation of the of rectal and sigmoid stenoses are performed more and more frequently, but, despite of the large diameter of the dilator used, it is often impossible to drive the endoscope through the stricture. *Aim of the study* is to test a new tecnique to pass through rectal and sigmoidal stenoses. *Material and methods:* We used a baloon dilator (Meditech Rigiflex Microvasive 18 mm.\'d8) previously modified cutting off and blunting the thin tip of flexible plastic material in order to avoid perforation. This dilator enflated is kept near to the tip of the endoscope and becomes itself an ogival tip of the endoscopic tool. Strictures can be crossed by pushing the dilator and the instrument together. A partial view of the lumen is obtained through the baloon dilator made of transparent material. In this way from 1993 Jan. and 1996 Jan. 43 rectal strictures have been dilated with baloon or bougie dilators and then crossed with the endoscopic tool using the tecnique previously described. We also obtained by using this method an accurate description of the stenotic bowel and its carefully mesurement. Moreover biopsy or brushing of the lesion was performed in almost all the cases. *Results:* In this group of 43 pts. (24 male and 19 female) with an age range from 42 to 86 years we were able to go through the stricture in 37 cases (86%). In six pts. this was not possible for a wide and fixed angulus formed by the bowel proximal to the stricture. Major complications such as perforation or rupture of the stricture was never seen. A mild or moderate pain during the dilatation time was present in 16 pts. and mild self limiting bleeding was observed during the manouvre in. We never used this procedure in pts. with known diverticular disease. *Conclusion:* We can conclude that this method is a safe and acceptable procedure to pass through rectal and lower sigmoid strictures. "P P 53 1270"P 53 1270**Usefulness of a Specially Designed Grasping Forceps in Retrieving the Polypectomized Multiple Polyps of the Colon**

*Y. Uchida, H. Inoue, K. Matsuda, M. Nishioka

Third Department of Internal Medicine, Kagawa Medical School, Kagawa, Japan*Purpose:* Because the histopathological diagnosis of colonic polyps is an integral part of the polypectomy procedure, the resected specimens should be retrieved without destruction. However, in cases with multiple colonic polyps, several insertions of the colonoscope are necessary to retrieve all polypectomized polyps, then it usually becomes very time-consuming and troublesome for patients and also colonoscopists. Therefore, we developed a specially designed grasping forceps to retrieve multiple polyps in only one session.*Methods:* A specially designed grasping forceps which we developed is essentially similar to the basket type grasping forceps FG-16L (Olympus Lab.). However, the tip basket part of our forceps can be detached by manipulating the operation part near at hand. One of different color strings 3–4 cm in length have been tied to each basket. Retrieving multiple polyps, after first polypectomy the specimen is grasped by the basket type forceps, and the basket part grasping the specimen is detached and left temporarily within the colon. Then other polyps are treated in the same way. When all polyps have been polypectomized and grasped, all strings are hold one after another by a standard biopsy forceps. When the entire instrument with some baskets just outside the tip of the scope is withdrawn, the multiple specimens can be retrieved. The identification of each polyp can be confirmed by the color of each string.*Results:* We have used this forceps on 21 patients with multiple colonic polyps. Polyps less than 20 mm in diameter could be grasped with this forceps, and even three specimens could be easily retrieved in one session. We have never experienced any complications.*Conclusion:* The use of a grasping forceps with detachable basket tip allows the colonoscopist to retrieve the polypectomized multiple polyps in one session, and this method is safe in practice. Endoscopy, specific: Colon, rectumEndoscopy, general: Instrumentation, therapy }" "Usefulness of a Specially Designed Grasping Forceps in Retrieving the Polypectomized Multiple Polyps of the Colon"

"P P 53 1271"P 53 1271**Management of Ileus Caused by Cancer in the Left Colon-Colonoscopic Retrograde Bowel Drainage (CRBD)**

*T. Ochiai, M. Sugitani, M. Moriwaki, K. Yasuda, T. Sakakibara, H. Noguchi, T. Okada, T. Toyoda, N. Sakakibara

Department of Surgery East Tokyo Metropolitan Hospital, Tokyo, Japan

The First Department of Surgery, Juntendo University School of Medicine, Tokyo, JapanSince nasal tube insertion was not so effective for the management of ileus caused by cancer in the left colon, emergency operation often has been performed for the ileus. Recently a new preoperative colonoscopic procedure was invented to avoid the emergency operation.The method is colonoscopic retrograde bowel drainage (CRBD). The following is the procedure of CRBD. After confirming the lesion with colonoscopy, the drainage (decompression) tube is inserted beyond the obstructive lesion through the guide-wire and dilator. This method was applied to 12 patients (8 male and 4 female). Average age of the patients was 64.4 (44 – 81 years old).Ten cases were successful (1 case of the descending colon cancer, 5 cases of the sigmoid colon cancer, 2 cases of the rectal cancer and 2 cases of Schnitzler metastasis). It was the 10.5 days before the surgery. In this duration, preoperative examinations and complete preparation of the colon could be performed, and operations were performed satisfactorily. The most important point of CRBD is that obstructive lesion is observed in frontal view with colonoscope. This procedure prevents some complications.CRBD can avoid the emergency operation. We concluded that CRBD should be tried first. Endoscopy, general: Instrumentation, therapyEndoscopy, specific: Colon, rectum }" "Management of Ileus Caused by Cancer in the Left Colon-Colonoscopic Retrograde Bowel Drainage (CRBD)"

"P P 53 1272"P 53 1272**Endoscopic Laser Therapy in Rectal Diseases**

*H. Schmidt, P. Pescatore, B.C. Manegold

Department of Surgical Endoscopy, Klinikum Mannheim, GermanyThe aim of our study was to evaluate the safety and efficacy of laser therapy in rectal diseases.*Methods:* Retrospective review of all 181 patients (100 men, 81 women; age 73 years; 32–97) treated by Nd-YAG laser (MEDILAS 2 MBB) from 01.01.88–31.12.1995. Indications were 137 inoperable rectal cancers, 18 anastomotic strictures, 17 villous adenomas and 9 others.*Results:* The symptoms leading to laser therapy of rectal cancer (obstipation n = 100, bleeding n = 33, mucous discharge n = 4) were successfully relieved in 94% of cases after 4 (1–9) sessions in intervals of 2 days. Restenosis had to be treated again every 4 weeks. All anastomotic strictures were effectively dilated in intervals of 2 days after 1.4 (1–2) sessions. In 55% of cases a supplementary balloon dilation was carried out. Long-term efficacy was obtained in 17/18 patients, 1 anastomosis resection was necessary. All adenomas were completely removed in 3 (1–7) sessions in intervals of 2 days without further recurrence. Complications were: 6 bleedings, 3 perforations and 1 perianal abscess, 3 of which had to be operated upon. The procedure related mortality was 1.1%.*Conclusions:* Laser therapy in rectal diseases is safe and effective. In palliative management of rectal carcinomas repeated sessions in 4 weeks intervals are necessary.

"P P 53 1273"P 53 1273**Long-Term Follow-Up of Patients Treated by Laser for Rectal Villous Adenoma Staged T1N0 at Endoscopic Ultrasound (EUS)**

*M. Angels Gines, B. Napoleon, O. Keriven-Souquet, B. Pujol, F. Descos, J.C. Souquet

Department of Digestive Diseases, Hospital E Herriot, Lyon, FranceA major concern in laser treatment of rectal villous adenoma is the lack of pathologic study of the whole adenoma. Invasion of the muscularis propria, or metastic nodes can be missed with a risk of cancer recurrence. EUS, while unable to detect mucosal cancer, has been shown accurate for the detection of muscularis propria invasion (T2). Its efficacy to detect malignant nodes is unknown, as the surgical series presented only a few number of N1 patients. This retrospective study aimed to define the long-term results of laser treatment in villous adenoma either large (> 3 cm) or with severe dysplasia/carcinoma, and staged uT1N0 before treatment.*Methods:* From 1982 to 1994, of the 411 patients treated by laser for villous adenoma of the rectum, 107 had a pretherapeutic EUS (Bruel & Kjaer rigid probe, Olympus echoendoscopes). Follow-up was always superior to 12 months. 93 were staged T1N0, while 2 were T2N0 and 12 were not staged (poor cleansing, artifacts). The present series deals with the 93 T1N0 patients.*Results:* In these 93 patients, initial biopsies showed carcinoma in 13, severe dysplasia in 21, and moderate dysplasia in 59. During follow-up (mean 49.2 months), 5 patients (5.4%) presented cancer evolution. 1 patient with cancer persistance, was operated on, 4 months after the start of treatment. The tumor was pT2N0 (slight invasion of the muscularis propria). The patient was well 4 yrs later. 3 patients developed cancer during treatment at 4, 12, and 24 months respectively. One was cured by laser (more than 2 yrs follow-up thereafter), 2 were operated on and were both pT1N0. The last patient with cancer initially was considered as cured, but extraparietal recurrence (node?) occurred more than 4 yrs after the diagnosis and the patient finally died from metastasis. Noteworthy, of the 13 patients with carcinoma at initial biopsies, 11 were cured by laser, while one was operated on after 4 months for persistant cancer. The last patient had a local recurrence and died from metastasis 57 m after the diagnosis.*Conclusions:* T1N0 staging of villous adenoma at EUS gave a high percentage of cure by laser. Cancer evolution occurred usually at the wall level and was controlled by careful follow-up and surgery. Node recurrence could be discussed in only one patient, the only death from cancer. As recurrence occurred more than 4 yrs after diagnosis, long-term follow-up is necessary to ensure cure and evaluate treatments. "P P 53 1274"P 53 1274**Argon Plasma Coagulation (APC) after Piecemeal Polypectomy for Colorectal Adenomas**

*J. Regula, E. Wronska, M. Polkowski, J. Pachlewski, E. Butruk

Dept of Gastroenterology, Institute of Oncology, Warsaw, PolandThe purpose of this study was to assess prospectively the efficacy and safety of argon plasma coagulation (APC) as a method ensuring total ablation of neoplastic tissue after piecemeal polypectomy of large sessile colorectal adenomas.Of 309 snare polypectomies in 153 patients performed between March 95' and May 96' APC was employed to treat 31 sessile adenomas in 24 patients after piecemeal polypectomy. Patients' median age was 66 years (range 42–83). Adenomas were located in the rectum (21), sigmoid colon (7) or right colon (3). Ten adenomas were 1–1.9 cm, nine were 2–2.9 cm and twelve were 3–5 cm in diameter. The protocol included histopathology, endoscopic ultrasound, abdominal ultrasound, and serum CEA to exclude carcinoma. Median interval between polypectomy and APC was 3 weeks. After polypectomy and before APC biopsies were taken from polypectomy site to check whether the visible mucosal abnormality represents true remnant adenomatous tissue. Follow-up included endoscopies with biopsies from treated area 1, 3, 6, 9 and 12 months after treatment.To achieve complete destruction of adenomas 1–9 APC sessions at 2–7 days intervals were required. Two patients were excluded from efficacy analysis because biopsies taken before APC did not show dysplasia. One patient had an invasive carcinoma diagnosed after APC was started. He was referred for surgery. Remaining 28 adenomas in 21 patients were followed-up for median time of 6 months (range 1–12 months). Only one reccurrence of adenoma was detected 3 months after treatment (3.5% of treated adenomas). Six patients (25%) reported mild and transient side effects following APC: abdominal pain (5 patients), diarrhea (2 patients) and blood in stools (3 patients).Argon plasma coagulation may be used as a safe and effective supplement to polypectomy of sessile colorectal adenomas. Complete destruction of remnant adenomatous tissue may require repeat treatment sessions. Endoscopy, general: Instrumentation, therapyEndoscopy, specific: Colon, rectumOncology, specific: Colon, rectum }" "Argon Plasma Coagulation (APC) after Piecemeal Polypectomy for Colorectal Adenomas"

"P P 53 1275"P 53 1275**Endoscopic Mucosal Resection for Large Flat or Sessile Colorectal Neoplasia**

*C.R. Teixeira, R.J.S. Torresini, N.H.V. Coelho, C. Saul[1], S. Tanaka[2]

[1] Funda\'e7\'e3o Riograndense Universit\'e1ria de Gastroenterologia, Porto Alegre, Brazil

[2] First Dept. Internal Medicine, Hiroshima University School of Medicine, Hiroshima, JapanEndoscopic treatment of colorectal polyps is essential for the secondary prevention of colorectal carcinoma. Large sessile or flat colorectal lesions are technically difficult to be resected by the standard snare polypectomy. We assessed the safety and usefulness of endoscopic mucosal resection (EMR) for large polypoid colorectal lesions.*Methods:* From July 1994 to March 1996 we have performed 11 EMR for flat or sessile colorectal lesions measuring 2 to 4 cm in diameter (mean 2.7 cm). Seven lesions were located in the right colon and 4 at the rectum. Following the injection of saline solution into the submucosa underneath the lesion, the procedure was done in a similar mode to the standard snare polipectomy. Indigo-carmine was sprayed on all lesions to have the margins demarcated.*Results:* Six lesions measuring 2 cm were resected by single EMR, whereas piece-meal resection was applied to 5 lesions greater than 2.5 cm. Histologic examination disclosed 6 adenomas with moderate atypia, 2 with severe atypia and 3 intramucosal carcinoma. Mild bleeding occurred in one case which was controlled endoscopically. Ten lesions showed biopsy proved normal scaring at follow up colonoscopy. At 6 month follow-up one lesion showed recurrence that was endoscopically managed.*Conclusions:* Endoscopic mucosal resection proved effective and safe for the management of large flat or sessile colorectal neoplasia. Close follow-up colonoscopy is mandatory to evaluate healing.

"P P 53 1276"P 53 1276**Results of Endoscopic Removal of Large Sessile Colorectal Villous Tumors (LCVT): Association of Snare Resection and Laser Therapy**

*Ph. Deplaix, C. Barth\'e9l\'e9my, J.C. Audigier

Department of Gastroenterology, Hospital Nord C.H.U. de Saint-Etienne, 42055 Saint-Etienne Cedex 2, France*Purpose:* Endoscopic removal of LCVT is considered as difficult and hazardous. We analyzed, in this retrospective study, the results and the one-year recurrence of 80 endoscopic removals of LCVT, using a combination of snare and laser therapy.*Methods:* The Nd:YAG laser had a maximal power output of 80 Watts. The energy used in each session varied between 700 and 2500 Joules, and was applied with pulses of 1 to 3 seconds. In most cases, it was used after snare resection, during the same session. Patients were treated every 20 days until complete eradication of the tumor.*Results:* The mean age was 72.6 years (range 45–90 years), for the 43 men and 37 women. Only one tumor was resected for each patient. Most of the lesions were located in the rectum (66.2%). All the tumors were villous and sessile. The size was ranged from 20 to 50 mm (mean: 28.5 mm). Complete resection was obtained in 62 cases (77.5%), with a mean of 1.9 sessions. Histologic examination revealed a grade ranged between mild and severe dysplasia. An invasive carcinoma was detected in 3 patients on biopsy specimens.The treatment was well-accepted by all the patients, without major complication. Only 5 patients (6.2%) experienced moderate hemorrhage. No perforation was observed. Six patients were excluded of the study (3 invasive carcinomas and 3 failures of the treatment).Follow-up evaluation over 1 year was possible in 66 out of the 74 remaining patients (89.2%). Seven patients (11.3%) had a local recurrence. All of them revealed lower size and dysplasia, compared to the original lesion.*Conclusion:* The combination of snare resection and laser Nd:YAG for the treatment of LCVT presents a sure efficacy with a little or none risk. It seems also well-tolerated by the patients. So this method, subject to strict endoscopic survey, could be now considered before surgery for the treatment of benign LCVT. "P P 53 1277"P 53 1277**Endoscopic Stent Implantation for Palliation of Obstructing Rectal Cancer**

*M. H\'fcnerbein, M. Dohmoto, P.M. Schlag

Virchow Hospital, Robert-R\'f6ssle Hospital and Tumor Institute, Humboldt University Berlin, Germany*Purpose:* The rationale of palliative endoscopic treatment is to avoid a colostomy in patients with advanced disease and limited life expectancy. This study was conducted to evaluate the role of endoscopic stent implantation for palliation of obstructing rectal cancer.*Methods:* Overall 11 patients with non-resectable or metastatic rectal cancer were treated by stent insertion after laser recanalization or dilation. Two types of stents self expanding mesh stents (n = 6) and endocoil stents (n = 5) were used to maintain luminal patency.*Results:* Endoscopic stent implantation was successfully performed in all 11 patients. Long term luminal patency and satisfactory bowel function was achieved in 10 of 11 patients. After a median follow up of 4 months 7 of the patients have died and 4 are still alive without evidence of recurrent obstruction. Dislocation of the endoprosthesis occurred in 1 patient. There was no evidence of treatment failure in 5 patients who received endocoil stents. None of the patients experienced serious complications related to the endoscopic procedure.*Conclusion:* Endoscopic stent implantation seems to be a safe and efficient palliative approach to selected patients with obstructing rectal cancer. Currently self expanding coil stents are superior to other devices because of lower risk of dislocation and tumor ingrowth. "P P 53 1278"P 53 1278**Clinicopathological Study on Endoscopic Mucosal Resection of Superficial Early Colon CancerM. Hayakawa**

Dept. of Gastroenterology, Meitetsu Hospital, Nagoya, JapanOver the last 4 years, total colonoscopy was performed in 4,898 patients and 435 colon cancers were detected. Among them 154 were found to be superficial early cancers. In the study with dissecting microscopy, early cancer showed irregular small-sized pit structure more often and disappearance of the pit structure was considered to be the feature of submucosal invasion.On histological examination, all mucosal cancer lesions were demonstrated to be well-differentiated adenocarcinoma. Interestingly, the bill like irregular glandular structure was found the mucosal cancer lesions, which correspond to the irregular small-sized pit structure observed in the dissecting microscopy.We studied the expression of p53 protein immunohistochemically in formal in-fixed paraffin-embedded resected specimens of 20 adenomas, 10 mucosal cancers and 10 submucosal cancers with a monoclonal antibody specific for the p53 protein. P53 protein expression localized in the nuclei was found in 16% of adenomas, 66% of mucosal cancers and 97% of submucosal cancers.When analyzed by plotting p53-positive point on the mucosal structure in the dissecting microscopy, p53 protein expression corresponded with the irregular small-sized pit structure and histologically proven bill like irregular glandular structure.The bill like irregular glandular structure can be regarded to be a characteristic feature of the superficial colon cancer.

"P P 54 1290"P 54 1290**Colonoscopic Follow-Up after Surgery for Colorectal CarcinomaR. Silva,**

*H. Lombaviana, A. Correia, L. Dias, R. Lombaviana

Department of Gastroenterology, Oncology Portuguese Institute, Oporto, Portugal*Objective:* To determine postoperative endoluminal recurrence and metachronous carcinoma incidence and assess the role of colonoscopy in the follow-up of colorectal carcinoma.*Patients and Methods:* 317 patients (161 men and 156 women) submitted to a total of 779 post-surgical colonoscopies in our department during a period of 21 years (1975–95) were retrospectively studied. Mean age at surgery was 61 years. During a 5 years clinical follow-up, from the 317 patients, 114 were examined once, 85 twice, 58 three times and 60 had four or more colonoscopies.*Results:* Neoplastic lesions were found in 121 patients (38%). We observed 20 cases of anastomotic recurrence in 19 patients (6%) 15 – 8 months after surgery for rectal (13), sigmoid (6) and transverse (1) carcinoma. One synchronous carcinoma not detected pre-operatively was diagnosed in a patient. Eight patients (3%) developed a total of 9 metachrounous carcinoma 95 – 63 months after the index tumour. Half of the patients with recurrence or metachronous carcinoma were asymptomatic and no increase of CEA had been detected. Seven of the 9 metachrounous carcinoma were stage I or II (TNM). Those who developed metachrounous carcinoma were in, average, 8 years younger. Adenomas with high grade dysplasia were detected in 13 patients (4%).*Conclusions:* Colonoscopic follow-up after resection for colorectal carcinoma gave a high yield of asymptomatic and initial stage neoplastic lesions and may be particularly useful in younger patients who have a higher risk of developing metachrounous carcinoma. "P P 55 1305"P 55 1305**A Prospective Study of the Prognostic Value of Type IV Collagenase Activity in Colorectal Cancer Tissue**

*S. Ambiru, M. Miyazaki, H. Ito, K. Nakagawa, H. Shimizu, M. Ohtsuka, K. Sasada, M. Shiobara, Y. Shimizu, N. Nakajima

First Department of Surgery, Chiba University School of Medicine, Chiba, JapanThe barrier for an invading epithelial tumor is the basement membrane, consisting of laminin and type IV collagen. The type IV collagenase (IV ase), which is a specific enzyme capable of degrading type IV collagen, has been demonstrated to play an important role in penetration through the basement membrane in the process of tumor invasion and metastasis. The purpose of this prospective study was to evaluate the prognostic value of the IV ase activity in colorectal cancer tissue in 31 colorectal cancer patients on disease-free and overall survival. The clinicopathologic factors studied for prognostic value were age, tumor location, tumor differentiation, preoperative serum levels of carcinoembryonic antigen, Dukes' stage, and IV ase activity in colorectal cancer tissue. Tissue IV ase activity was measured using purified radiolabeled [^{3}H] human type IV collagen. IV ase activities in colorectal cancer tissue were significantly higher in the group of patients with recurrences than in the group without recurrences (P = 0.019). Patients with high IV ase activity in colorectal cancer tissue had a significantly shorter disease-free survival (P = 0.0016) and overall survival (P = 0.022) time than those with low IV ase activity. Univariate and multivariate analyses showed that significant prognostic factors for disease-free survival were Dukes' stage (P = 0.029, P = 0.046, respectively) and IV ase activity status (P = 0.0016, P = 0.0026, respectively). With respect to overall survival, only IV ase activity status provided significant predictive value in multivariate analysis (P = 0.041). This prospective study suggests that IV ase activity could be a valuable prognostic indicator in colorectal cancer patients.

"P P 58 1403"P 58 1403**Digital Image Processing Does Not Identifies Intestinal Metaplasia in Gastric Mucosa**

*L. Sosa Valencia, B. Beker, M. Guelrud

G.I. Unit, Hospital General del Oeste, Los Magallanes, Caracas, VenezuelaEndoscopic images offer an additional domain (color) for tissue characterization. Because intestinal metaplasia (IM) is associated with gastric cancer, noninvasive markers of chronic atrophic gastritis have been sugested. IM is defined histologically but has some difficult endoscopic identification features that has led the examiner to used methilene blue staining in other to obtain guided biopsies. *Aim of the study:* we sought to determine if digital image analysis of endoscopic images allowed accurate identification of gastric (antral) IM. *Patients (pts) and methods:* Digital red, green, and blue signals were obtained directly from the processor of an electronic endoscope (Olympus, video gastroscope EVIS 100) using a 24 bit color frame grabber (Raster Ops Corporation, USA) and stored. Images were obtained from areas of gastric antral pre piloric mucosa with and without IM confirmed by histological samples taken at the same time and from the same area where the images were taken. The areas of interest were marked on the digital images by one of us (MG or BB) and analized separetly by a doctor with computer skills (LS) who was unaware of the endoscopic appearance of the gastritis or the significance of the marked areas. Color analysis was performed using a color analysis program (Adobe Photoshop). This program measures intensity of red, green, and blue on a gray scale basis from 0–256. Thirty nine volunteer patients with gastritis were evaluated according to the Sydney modified 1991 classification, 9 patients had IM and 30 patients had gastritis without IM. One measurement was taken from the area of abnormal tissue. Results are mean – standard deviation and differences were determined non parametrically (Wilcoxon test). *Results:* Age ranged from 28–72 years. In patients with IM, color values were red = 207 – 30, green = 119 – 21, blue = 93 – 17 and gray = 142 – 22. In patients without IM, color values were red = 205 +{ -} 29, green = 118 – 18, blue = 91 – 15 and gray = 141 – 20. There was no identifiable difference between antral gastritis images with or without IM ($p > 0.05$). *Conclusions.* Image processing can not identify intestinal metaplasia in abnormal gastric mucosa. Color information does not provides information for diagnosis of gastric IM. Color reproductivity of endoscopic images should be reached before further evaluation.Key words: intestinal metaplasia, digital images, color Oesophageal gastric duodenal disorders: GD disorders, acid peptic }" "Digital Image Processing Does Not Identifies Intestinal Metaplasia in Gastric Mucosa"

"P P 59 1409"P 59 1409**Massive Arterial Bleeding of the Gastroduodenum and Two-Stage Sclerotherapy-Our Experience**

*V. Vasilevski, M. Krstevski, R. Coleski, P. Mishevska, J. Mishevski, D. Trajanovski, V. Calovska

Clinic of Gastroenterology, Medical Faculty-Skopje, Republic of MacedoniaIn this paper our results of the two-stage sclerotherapy in the treatment of the massive arterial bleeding are presented.In 543 patients, urgently performed endoscopy revealed massive arterial bleeding from the gastroduodenum, but in 32 (5.9%) the source of bleeding was not detectable because of the large quantity of blood in the stomach. Out of 511 detected bleeding lesions, 447 (87.5%) were gastroduodenal ulcers, 31 (6.0%) were Dieulafoye lesions and 33 (6.5%) Mallory-Weiss lesions. According to the classification of Forrest, 327 (64%) were Ia, 184 (36%) Forrest II. Mean age of the patients was 56.5 years. Two-stage sclerotherapy with Adrenaline and 1% Polydocanol was performed in all cases.Initial hemostasis was achieved in 472 (92.3%) of the patients, and of the remaining 39 (7.7%), in 11 hemostasis was achieved with medical therapy, while 28 are urgently operated, of whom 8 (28.5%) died because of postoperative complications or cardiac failure. During the same hospitalization re-bleeding appeared in 26 (5.5%) of primarily effectively sclerotherapy treated patients, so definitive healing was achieved in 446 (94.5%) of the patients treated with sclerotherapy.Out of the 26 rebled patients, 6 died because of hemorrhagic shock, and in five patients hemostasis was achieved with medical therapy. The remaining 15 patients had to be urgently operated, with positive outcome in nine patients. The mortality rate was 60% (surgical complications or cardiopulmonary failure). The rebled patients had lethality of 46%.Direct complications of the sclerotherapy occurred in two patients (duodenal wall necrosis), both in the rebleeding group, with a fatal outcome after the operation.The obtained results showed that in the hands of the experienced endoscopist sclerotherapy is safe and powerful method to control bleeding, and our results are in accordance with those reported in the literature. "P P 59 1413"P 59 1413**Fibrin Sealing — New Method and Concept for Treatment of the Bleeding Peptic UlcerOlaf Friedrichs**

Duisburg Institute of Endoscopy Duisburg, GermanyThe technique of fibrin gluing is a standard haemostatic procedure which uses a two-component adhesive consisting of fibrinogen and thrombin, which when mixed in the tissue, form a fibrin clot via the third phase of the blood coagulation cascade, thereby inducing the mechanisms of wound repair. In a new endoscopic procedure, the components are simultaneously injected into the tissue beneath the bleeding lesion close to the vessel. There they form a mechanically resilient and stable fibrin clot which is firmly anchored into the tissue. This ""bioidentical"" type of procedure can be safely repeated, in contrast to all other thermal and injection methods, thus allowing multiple injections to achieve increased stability and better control. Supported by a scheme of close follow-up endoscopies permitting any number of subsequent therapeutic and prophylactic injections to be given for persistent bleeding stigmata, the new treatment method proves to be not only suitable for initial haemostasis and preventing rebleeding, but — for the first time — enables the limited time interval after initial haemostasis to be used for genuine prophylactic therapy, called ""early elective endoscopic therapy"". We perform the first reendoscopy after 3 to 6 hours after initial haemostasis. Outstanding results can be achieved using this concept.We report about a series of 375 patients cared for as outpatients or day patients, at least (30 patients) with a definite reduction of hospital stay. Thus a clear clinical advantage for the patient could be achieved, in addition with a cost-to-benefit advantage. Using this technique, individual prediction of the outcome seems to be possible. Our results are favourable as compared with a recently published multicentre trial. At the present time this mild form of tissue-compatible therapy offers the only genuine prophylactic therapy. Endoscopy, general: Instrumentation, therapyEndoscopy, general: GI bleedingEndoscopy, specific: Stomach, duodenum }" "Fibrin Sealing / New Method and Concept for Treatment of the Bleeding Peptic Ulcer"

"P P 59 1415"P 59 1415**Six Month Audit of a Management Protocol for Upper GI Haemorrhage**

*S.M. Everett, D.M. Chalmers, A.T.R. Axon

Centre for Digestive Diseases, The General Infirmary, Leeds, UK*Purpose:* In April 1995, a protocol for the management of upper GI haemorrhage was introduced at Leeds General Infirmary. All patients are categorised according to risk status, into shocked (pulse > 100 bpm or systolic bp < 100 mmHg), high risk (age > 60, Hb < 10 g/dl or coexistent cardiovascular disease), or low risk (all others). Depending on risk status, patients are admitted to either a surgical, specialised GI, or general medical ward, with early endoscopy and intensive monitoring, More conservative management is used in low risk cases. This audit was undertaken to monitor the success of the protocol.*Methods:* Details of all upper GI bleeds (including those occurring in in-patients) for the 6 months between April and September 1995 were collected prospectively from casualty records, endoscopy records and discharge diagnostic coding. Notes were reviewed retrospectively, and a standardised proforma completed.*Results:* 89.5% of all case records requested were reviewed. From these there were 256 cases of upper GI haemorrhage. Mean age was 59.0 years, with 19.5% of cases over 80 years. Endoscopy was performed in 81.6% of cases, 85.2% of which was within 24 hours of the bleed. Total rebleed rate was 5.9%, operative rate was 2.4%, and mortality rate was 10.5% (3.4% for new patients; 40.0% for existing inpatients). Results according to risk are tabulated below: Number (%) Rebleed rate (%) Operative rate (%) Mortality rate (%)Low risk 31.2 0 0 0High risk 45.8 6.1 0 13.8Shocked 22.9 13.8 8.9 15.5*Conclusions:* Favourable results in the management of upper GI haemorrhage can be achieved by intensifying management according to risk status, without the use of a specialised bleeding unit. Patients with low risk status can safely be managed in a more conservative fashion. "P P 59 1420"P 59 1420**Endoscopic Hemostasis for GI Bleeding**

*K. Handa, H. Takahashi, K. Kirihara, R. Fujita

Department of Gastroenterology, Fujigaoka Hospital, Showa University Yokohama, JapanThe significance of emergency endoscopy and subsequent endoscopic hemostatic procedures at the onset of upper gastrointestinal hemorrhage is virtually established.The homostatic effects of hemoclipping, the pure ethanol local injection method and the heater probe method on hemorrhagic gastric and duodenal ulcers associated with exposed blood vessels, were compared. The locations of the exposed blood vessels, as well as characteristics and severity of the hemorrhage were discussed. The hemoclipping method was used in 125 patients, the pure ethanol local injection in 52 patients, and the heater probe method in 63 patients.The hemoclipping and pure ethanol local injection method were effective in all the patients with exposed blood vessels around the margin of the ulcers. The efficacy rate was 95%, 100% and 100%, respectively, when exposed blood vessels at the base of the ulcer. The efficacy rate was 96%, 93% and 92% for the three hemostatic methods, respectively, when oozing hemorrhagic lesions was present. The three methods had an efficacy rate in spurting hemorrhagic lesions was 92%, 83% and 88% for the three methods, respectively. The hemoclipping and pure ethanol local injection were effective in 100% of slight and moderate hemorrhagic cases, while the heater probe method was effective in only 95% of moderate cases. The efficacy rate was 85%, 85% and 83% respectively, for severe cases. Overall, the efficacy rate was 88% for the hemoclipping method, 85% for the pure ethanol local injection and 83% for the heater probe method, and there was no significant difference between the three methods with regard of the overall efficacy rate. Rebleeding occurred in 23 of 240 cases of gastric ulcers (9.6%). The presence of exposed blood vessels at the base of the ulcer, spurting and oozing bleeding and severe hemorrhage were thought to be the most important risk factor for rebleeding. "P P 59 1421"P 59 1421**Endoscopic Therapy for Bleeding Vascular Lesions of the Stomach and Duodenum**

*K. Kirihara, H. Takahashi, K. Handa, R. Fujita

Department of Gastroenterology, Fujigaoka Hospital, Showa University Yokohama, Japan*Objective of the study:* To assess the effectiveness of endoscopic therapy in the management of bleeding vascular lesions of the stomach and duodenum.*Material and methods:* Our study consists of 39 patients, diagnosed as having gastric or duodenal bleeding from Dieulafoy ulcer (DU) (28 cases) or angiodysplasia (11 cases), treated at Fujigaoka Hosp. from May 1985 to December 1995. The patients were treated with either heater probe unit (HPU), ethanol injection (EI) or hemoclip, alone or in a combination of these methods if hemostasis was not achieved after using only one methods. Therapy was considered successful when hemostasis was maintained 48 hours after completion of the procedure.*Results:* In the case of Dieulafoy ulcer, hemoclip was used in 21 patients, EI in 1, HPU in 4, hemoclip plus EI in 1, and EI plus HPU in 1. Among those with angiodysplasia, hemoclip was used in 8 patients, HPU in 2 and hemoclip plus HPU in 1. Success was achieved in 38 patients (97%), and only one (3%), bleeding from DU, underwent surgery due to persistent bleeding.*Discussion:* DU and angiodysplasia are infrequent lesions in the stomach and duodenum, but they can cause severe bleeding which is difficult to manage medically, and many of these patients must finally be operated on. The effectiveness of endoscopic therapy, especially that of hemoclip, has not been fully established, but our results indicate that hemostasis can be achieved in most cases.*Conclusion:* We believe that therapeutic endoscopic methods (especially hemoclip) are highly effective in the management of bleeding from DU and angiodysplasia. Endoscopy, general: GI bleedingEndoscopy, specific: Stomach, duodenum }" "Endoscopic Therapy for Bleeding Vascular Lesions of the Stomach and Duodenum"

"P P 59 1422"P 59 1422**Elastic Band Ligation for Gastric AngiodysplasiasV. Delis, V. Balatsos, V. Vamvakousis, A. Germenopoulos, N. Skandalis**

Gastroenterology Department, District General Hospital of Athens G. “Gennimatas”. Athens, GreeceElastic band ligation (E.B.L.) has become the treatment of choice for bleeding esophageal varices and is an alternative treatment for other U.G.I. lesions. Our experience concerning the treatment of gastric angiodysplasias with band ligation, is reported in this study.Nine patients, 5 men and 4 women, age 58–82 years, with a history of single or recurrent U.G.I. bleeding and gastric angiodysplasia being the only U.G.I. endocopic finding, were included in the study. Four patients had single and five multiple (2–7) lesions, diameter up to 15 mm, located in the gastric antrum and/or body.In two patients a multiple shot band ligator (Speed-band, Microvasive) was used and in seven a single shot band ligator (Bard). Endoscopy was repeated in two, four and fifteen days. All patients were given omeprazole 20 mg b.d. for two weeks.All the elastic bands were properly positioned and dropped after 2–4 days. All the remained ulcers were healed in two weeks. There was not any complication and in a mean follow up of 6 months no patients experienced any recurrent bleeding.It is concluded then elastic band ligation is a simple, effective and safe treatment of symptomatic gastric angiodysplasias, sized less than 15 mm and should be considered as an alternative treatment for these lesions. Endoscopy, specific: Stomach, duodenumClinical practice: Management strategy }" "Elastic Band Ligation for Gastric Angiodysplasias"

"P P 59 1424"P 59 1424**NSAIDS Lesions and Non-Variceal Bleeding from Stomach and Duodenum: Endoscopic Findings in 1997 Patients Upper GI Bleeding**

*N. Popovic, M. Bulajic, M. Glisic, P. Popovic, T. Milosavljevic, M. Ugljesic, R. Krstic, D. Popovic, P. Dugalic, D. Tomic, S. \'d0uranovic, K. Todorovic, O. Matejic

Clinic for Gastroenterology and Hepatology, Clinical Center, Belgrade, YugoslaviaFrom Jan. 94 to Dec. 95, we analyzed 1997 patients (pts) – 1195 males (m) and 802 females (f) with upper GI bleeding. We studied the features and frequency of the mucosal changes in the pts with gastric and duodenal bleeding, divided into 2 groups: group I, with a history of NSAIDs intake, and group II, without contact with NSAIDs. All the pts underwent urgent endoscopy within 1–6 h. Pts with gastrectomy, liver cirrhosis, renal failure, gastric cancer or hematological diseases were excluded from the study. Group I presented, besides gastric and duodenal ulcers, multiple erosions of various forms, serpiginous and ulcer-like. EIH (epineph. + polydocanol, or 98% aethanol) was carried out in 239 pts (11.96%) suffering active bleeding from gastric ulcer and duodenal ulcer, of which 129 (12.42%) belonged to group I, and 110 (11.47%) belonged to group II. Group I (pts with Group II (pts with bleeding from melena/hematem., NSAIDs gastroduodenum, without 24–72 h. prior to bleeding) NSAIDs)Age 57.5 (17–91) 55.9 (20–89) Male Female Total Male Female TotalGastric ulcer 101 73 174 (16.76%) 98 60 158 (16.47%)Pyloric ulcer 42 23 65 (6.25%) 17 9 26 (2.71%)Duoden. ulcer 268 108 375 (36.13%) 270 138 408 (42.55%)Erosive gastritis 122 118 240 (23.12%) 94 89 183 (19.08%)Erosive duodenit. 93 90 183 (17.63%) 90 94 184 (19.18%)Total 626 412 1038 569 390 959*Conclusion:* Regarding the results of this study 51.97% pts had NSAIDs intake 1–3 days prior to bleeding. In group I (with NSAIDs) there was a higher incidence of pyloric ulcer, gastric erosions of various forms were frequent in males and in females, and there was a high percentage of actively bleeding ulcers requiring endoscopic treatment. In group II (without NSAIDs) duodenal ulcer and erosive duodenitis were more frequent, while gastric ulcer was equivalently frequent in both groups. Oesophageal gastric duodenal disorders: GD disorders, acid pepticEndoscopy, general: GI bleedingEndoscopy, specific: Stomach, duodenum }" "NSAIDS Lesions and Non-Variceal Bleeding from Stomach and Duodenum: Endoscopic Findings in 1997 Patients Upper GI Bleeding"

"P P 59 1425"P 59 1425**Ambulant Endoscopic Managment of Forrest Ia or Ib Bleeding Duodenal Ulcers in Young Compliant Patients is Cost Effective and Safe**

*P. Janetschek[1], U. B\'f6ckmann[1], B. Kaduk[2]

[1] Tagesklinik M\'fcnchen-Nord, Bereich Gastroenterologie, Frauenlobstr., M\'fcnchen, Germany

[2] Tagesklinik M\'fcnchen, Institut f\'fcr Pathologie, Frauenlobstr., M\'fcnchen, Germany*Purpose:* Managment of upper gastrointestinal bleeding is generally performed in-patient. Thus costs are high, unemployment is long. Therefore we checked safety, efficacy and cost effectiveness of ambulant endoscopic hemostasis and ambulant managment of upper gastrointestinal bleeding.*Methods:* To avoid a hospitalisation and to reduce the overall costs for the managment of upper gastrointestinal bleeding, we performed ambulant endoscopic hemostasis in 12 young healthy compliant patients with a partner at home with Forrest Ia or Ib bleeding duodenal ulcers.In order to lower the frequency of re-bleeding we used a combination of two different hemostatic therapy strategies (application of fibrin tissue seleant and/or hemostase clipping of vessel and/or injection therapy with 1:10.000 epinephrine in water). The efficacy of hemostasis was controlled endoscopically all 12 hours for two days. For another two days controls were done daily; at this period patients were allowed to work again.*Results:* After ambulant endoscopy managment of Forrest Ia or Ib duodenal ulcer bleeding under strict control neither re-bleeding has occurred, nor other complications related to the use of the medication have developed.*Conclusion:* We conclude that ambulant managment of acute upper gastrointestinal bleeding in compliant young patients under strict control and by use of adapted hemostatic therapy strategy is cost effective, safe and prevents long unemployment. Endoscopy, general: GI bleeding }" "Ambulant Endoscopic Managment of Forrest Ia or Ib Bleeding Duodenal Ulcers in Young Compliant Patients is Cost Effective and Safe"

"P P 59 1426"P 59 1426**The Effect of Endoscopic Injection Therapy on the Clinical Outcome of Patients with Peptic Ulcer Bleeding. An Analysis of 1935 CasesK. Thomopoulos,**

*V. Nikolopoulou, K. Mimidis, V. Margaritis, E. Katsakoulis, C. Vagianos

Department of Internal Medicine, Division of Gastroenterology and Department of Surgery, University Hospital, Patras, GreeceAcute bleeding is a life threatening complication of peptic ulcer disease. In recent years endoscopic hemostasis is used as the treatment of choise for these patients. In this study we have examined the effect of endoscopic injection therapy in the clinical outcome of patients with benign peptic ulcer bleeding.*Patients-Methods:* In this study 1203 patients admitted with peptic ulcer bleeding over a 5-year period before endoscopic therapy and 732 patients admitted with peptic ulcer bleeding after introduction of endoscopic therapy in our department were assessed. Endoscopic treatment was performed in all patients with active bleeding or non bleeding visible vessel (NBVV) during emergency endoscopy with injection of adrenaline 1:10,000 in 0.9% saline (A/S).*Results:* The introduction of injection therapy was associated with a reduction in transfussion needs, hospitalisation days, surgical interventions (from 15.7% to 9.4%) and mortality (from 4.5% to 2.2%) ($p < 0.05$). Emergency surgical hemostasis and mortality were reduced in patients with active bleeding or NBVV while in the other patients remained unchanged. Patients with gastric ulcer had a more pronounced reduction concerning emergency surgical hemostasis (from 23.2% to 9%) and mortality (from 8.1% to 2.8%) ($p < 0.05$) than patients with duodenal ulcer. There were no deaths or procedure-related complications.*Conclusion:* These results suggest that endoscopic injection therapy with A/S is a simple, low cost and safe method which improves the clinical outcome and reduces mortality in patients with peptic ulcer bleeding. Endoscopy, general: GI bleeding }" "The Effect of Endoscopic Injection Therapy on the Clinical Outcome of Patients with Peptic Ulcer Bleeding. An Analysis of 1935 Cases"

"P P 59 1427"P 59 1427**Endoscopic Injection Hemostasis in the Treatment of Bleeding Upper GI Ulcers****E. Zdanytė, N.E. Samalavicius, G. Radžiu¯nas, A. Buineviciu¯tė, J. Stanaitis**

""Red Cross"" Hospital of Vilnius University, Vilnius, LithuaniaThe purpose of our study was to evaluate the efficacy of endoscopic injection hemostasis (EIH) in the treatment of bleeding upper GI ulcers.Retrospective analysis of 50 patients who underwent EIH because of bleeding upper GI ulcer during 2 years period from January 1994 to December 1995 was performed. There were 35 males and 15 females, with a mean age of 55.82 years. Data collected included known risk factors, endoscopic findings and management, details of surgery, diagnosis, complications, and mortality. There were 40 (80%) peptic ulcers, 9 (18%) stress-induced and 1 (2%) drug-induced ulcer. The bleeding site was duodenal ulcer in 19 (38%), gastric ulcer in 30 (60%), esophageal ulcer in 1 (2%) cases. Bleeding lesions were graded according to the Forrest classification: arterial bleeding FIa – 4 (8%), oozing FIIb – 25 (50%), clot lying on ulcer base, nonbleeding visible vessel (NBVV) FII – 21 (42%). Techniques included: epinephrine injections around the lesion (0.5–1 mL per injection, up to 20 mL, 1:10,000, N = 15), ethanol injections around NBVV (0.3–0.5 mL per injection, up to 2.5 mL, 80\'b0, N = 15) and combination of them (N = 20).Hemostasis was achieved in all cases. The rebleeding rate 8% (4 cases). No major complication was observed. 9 (18%) patients underwent emergency surgery. There were 7 (14%) deaths exclusively because of severe comorbidity.*Conclusion:* epinephrine and/or ethanol injection is an effective, simple, and economical method of endoscopic hemostasis for bleeding upper GI ulcers. Endoscopy, general: GI bleedingEndoscopy, general: Instrumentation, therapyEndoscopy, specific: Stomach, duodenum }" "Endoscopic Injection Hemostasis in the Treatment of Bleeding Upper GI Ulcers"

"P P 59 1428"P 59 1428**Occult Recurrent Bleeding from Peptic Gastro-Duodenal Ulcers: The Importance of Active Dynamic Endoscopy (ADE)**

*E.D. Fedorov, V.I. Sidorenko, T.M. Suchinina

Department of Abdominal Surgery, Gastroenterology & Digestive Endoscopy; Russia State Medical University, Moscow, RussiaThe purpose of the study: is to reveal the role of AD (""second-look"") endoscopy in making out early diagnosis and the prevention of rebleeding from peptic gastro-duodenal ulcers. Patients (pts.) (n = 40; m-33, f-7; mean age 45.6 + 3.4 yrs.; range 18–60 yrs.) with bleeding peptic ulcers (BPU) (gastric-12, duodenal-28) (Forrest 1a-8; Forrest 2a & 2b – 32) and high rebleeding risk, — according to clinical, endoscopical criteria and the results of computer-aided prediction — were included in a prospective controlled trial. They were randomized in 2 treatment groups: MH. Monopolar hydroelectro-coagulation (n = 20); AE. Absolute ethanol + 25% ethanol-novocain solution (n = 20). Both groups were clinically and endoscopically comparable and treated with anti-secretory drugs in high dose. Initial hemostasis was successful in both groups. ADE was carried out daily till the change of high prognostic index of rebleeding risk. In case of emergence of ""new"" vessels in the ulcer crater we performed additional hemostatic manipulations. Rebleeding occurred from 16 hours to 4 days in 10 (25%) pts.: MH-6 (30%) pts.; AE-4 (20%) pts. It did not show any clinical signs of bleeding (occult rebleeding) and was diagnosed only during ADE in 7 out of 10 pts. Nine pts. underwent emergency surgery, according to tactical approaches of our clinic and the conditions of randomized trial. In one case the bleeding was arrested endoscopically. No significant complications and mortality were reported. The analysis of the rebleeding causes revealed the statistically proved appropriateness between the expansion of an ulcer defect, the emergence of new vessels in the ulcer flour and following rebleeding. Thus the ADE is an important method of timely diagnostics of occult rebleeding and prophylactics of massive recurrent hemorrhage. For high risk patients who are thought unable to survive laparotomy, endoscopic treatment, including ADE is a preferable way to make out an early diagnosis and to attain definitive control of rebleeding. Oesophageal gastric duodenal disorders: GD disorders, acid pepticEndoscopy, general: GI bleedingEndoscopy, specific: Stomach, duodenum }" "Occult Recurrent Bleeding from Peptic Gastro-Duodenal Ulcers: The Importance of Active Dynamic Endoscopy (ADE)"

"P P 59 1429"P 59 1429**Endoscopic Hemostasis for GI Bleeding**

*K. Handa, H. Takahashi, K. Kirihara, R. Fujita

Department of Gastroenterology, Fujigaoka Hospital, Showa University Yokohama, JapanThe significance of emergency endoscopy and subsequent endoscopic hemostatic procedures at the onset of upper gastrointestinal hemorrhage is virtually established.The homostatic effects of hemoclipping, the pure ethanol local injection method and the heater probe method on hemorrhagic gastric and duodenal ulcers associated with exposed blood vessels, were compared. The locations of the exposed blood vessels, as well as characteristics and severity of the hemorrhage were discussed. The hemoclipping method was used in 125 patients, the pure ethanol local injection in 52 patients, and the heater probe method in 63 patients.The hemoclipping and pure ethanol local injection method were effective in all the patients with exposed blood vessels around the margin of the ulcers. The efficacy rate was 95%, 100% and 100%, respectively, when exposed blood vessels at the base of the ulcer. The efficacy rate was 96%, 93% and 92% for the three hemostatic methods, respectively, when oozing hemorrhagic lesions was present. The three methods had an efficacy rate in spurting hemorrhagic lesions was 92%, 83% and 88% for the three methods, respectively. The hemoclipping and pure ethanol local injection were effective in 100% of slight and moderate hemorrhagic cases, while the heater probe method was effective in only 95% of moderate cases. The efficacy rate was 85%, 85% and 83% respectively, for severe cases. Overall, the efficacy rate was 88% for the hemoclipping method, 85% for the pure ethanol local injection and 83% for the heater probe method, and there was no significant difference between the three methods with regard of the overall efficacy rate. Rebleeding occurred in 23 of 240 cases of gastric ulcers (9.6%). The presence of exposed blood vessels at the base of the ulcer, spurting and oozing bleeding and severe hemorrhage were thought to be the most important risk factor for rebleeding. }" "Endoscopic Hemostasis for GI Bleeding"

"P P 59 1431"P 59 1431**Endoscopic Band Ligation for Hemostasis of Non-Variceal Upper Gastrointestinal Bleeding**

*S. Matsui, R. Inoue, K. Takahei, K. Araragi, N. Hirota, M. Sakamoto, M. Kinoshita, N. Aoki

Second Department of Internal Medicine, Kinki University School of Medicine, Osakasayama, Osaka, JapanEndoscopic band ligation (EBL) originally developed by Stiegmann has recently been performed in Japan as an effective treatment of bleeding esophageal varices.*Purpose:* This study was performed to evaluate the hemostasis effect of EBL in non-variceal upper gastrointestinal bleeding.*Patients:* Ten patients (5 males, 5 females) aged from 21 to 66 years were studied between September 1994 and April 1996. Underlying diseases consisted of 4 Dieulafoy's ulcers (Diu), 4 Mallory-Weiss syndromes (MWS), 1 gastric ulcer (GU) and 1 gastric angiodysplasia (GA). All patients showed active bleeding such as spurting and oozing on emergency endoscopy.*Methods:* At emergency endoscopy routinely employing the over tube for the EBL treatment, we determined the location of bleeding and applied there an O-ring of the EBL device for hemostasis.*Results:* Permanent hemostasis was obtained in 4/4 (100%) for MWS, 1/1 (100%) for GU, 1/1 (100%) for GA and 3/4 (75%) for Diu. Rebleeding occurred in one case of Diu. There was no other complication including perforation, fever and epigastric pain.*Conclusion:* EBL is effective and safe as a procedure for hemostasis in patients with Diu, MWS and other diseases which show no or only mild fibrosis. Endoscopy, general: GI bleedingEndoscopy, specific: Stomach, duodenum }" "Endoscopic Band Ligation for Hemostasis of Non-Variceal Upper Gastrointestinal Bleeding"

"P P 61 1489"P 61 1489**Ultrasonographic (US) Assessment of Coeliac Disease (CD) in Children: Comparison with Antiendomysium Antibodies (EMA)**

*D. Micetic-Turk, S. Umek-Bradac, M. Gorenjak

Depts of Pediatrics, Radiology and Biochemistry, Teaching Hospital Maribor, SloveniaMany attempts have been made to find precise screening tests for CD in order to reduce the need for biopsy or to achieve better selection criteria before intestinal biopsy. To facilitate the decision, we decided to evaluate the usefulness of screening for EMA in the diagnosis of CD in children in comparison with the US changes related to CD.*Patients:* we studied 35 children (1–15 years) with untreated CD (N = 15), treated CD (N = 10) and controls (N = 10) undergoing small bowel biopsy in diagnostic procedure.*Methods:* US of the small bowel was done using a 4 or 7 MHz transducer of an ATL HDI 3000 computed sonography device, before biopsy. The thickness of the intestinal wall and the motility of the bowel were carefully recorded. Simultaneously, all children had serum routinely sampled for IgA EMA.*Results:* All controls had a histologically normal small mucosa and the US showed a small bowel thickness of 1 mm with normal movements in 9 children and unspecific US changes in 1 child. In 1 control case EMA was weak positive, in others negative. In 15 children with untreated CD, severe enteropathy and strongly positive EMA was found in 10 cases, in 5 children moderate enteropathy and positive EMA was established. Severe US changes were found in all children (thickness of intestinal wall > 1.6 mm, hyperperistalsis and abundant fluid in bowel). Mild enteropathy was found in 10 children with treated CD (1–3 months gluten free diet). In 2 children EMA was positive and in 8, weak positive. Unspecific US changes were found in 6 children. The estimated sensitivity of the EMA tests is 100% and its estimated specificity is 90%. The estimated sensitivity for US changes is 84% and its specificity 90%. In conclusion, our results indicate that US can offer further information on small-bowel structure, which serves as additional data for the indication of small bovel biopsy. This study confirm stronger association between EMA and CD than between US and CD. Intestinal disorders, absorption: Gluten enteropathyImmunology and microbiology: GI infection, childrenRadiology and ultrasound: Diagnosis }" "Ultrasonographic (US) Assessment of Coeliac Disease (CD) in Children: Comparison with Antiendomysium Antibodies (EMA)"

"P P 64 1531"P 64 1531**Endoscopic Ultrasound (EUS) Can Effectively Diagnose and Predict Resectability of Pancreatic Cancers**

*B. Hoffman, L. Aabakken, D. Cole, L. Baron, D. Daniel, R. Hawes, P. Baron

Departments of Surgery, Radiology, Biometry, and Medicine, Medical University of South Carolina, Charleston, SC*Purpose:* Patients suspected of having cancer of the pancreas frequently undergo extensive testing to confirm malignancy and determine tumor resectability. Radial and linear array EUS systems can be used to identify pancreatic masses and guide fine needle aspiration (FNA) biopsy respectively. The purpose of this study was to determine the ability of EUS to diagnose cancer and judge resectability.*Methods:* Between 5/91–11/95, 54 patients were preoperatively evaluated by contrast-enhanced CT and radial array EUS prior to surgical exploration for potentially resectable cancers of the pancreas and periampullary region. From 6/94–11/95, masses in this region were also biopsied with a 23 gauge needle using the linear array EUS system with color Doppler to identify vascular structures.*Results:* There were 51 adenocarcinomas (42 pancreas, 6 ampulla, 3 distal bile duct) and 3 islet cell tumors. A mass was identified by CT in 36 (67%) cases and by EUS in 50 (93%) cases. In 18 patients, CT failed to visualize masses seen with EUS ($p < 0.001$ by Sign Test). The 4 EUS negative results were during the first 2 years of study. EUS-guided biopsy confirmed cancer in 22 of 23 patients where it was attempted: 19 pancreatic adenocarcinoma (14 head, 3 body, 2 tail), and 3 pancreatic islet cell tumors (2 head, 1 tail). EUS was further analyzed for effectiveness at predicting resectability: EUS stage Total ResectedT1 (localized) 18 12 (67%)T2 (outside pancreas) 14 12 (86%)T3 (invading large vessel) 18 3 (17%)[1,2]1Both ""resected"" T3 tumors were removed by distal pancreatectomy; [2]$p < 0.001$ for T1 and T2 vs T3 by Fisher's Exact Test*Conclusion:* EUS is superior to CT for localizing pancreatic tumors and can direct the FNA of these lesions. Most patients in which EUS identifies vascular invasion (T3) have unresectable cancers, and may therefore be able to avoid the morbidity and expense of numerous preoperative radiologic and endoscopic tests. Echoendosonography: EchoendoscopyOncology, specific: Pancreas }"

"P P 65 1538"P 65 1538**Value of Endoscopy and Computed Tomography in the Diagnosis of HIV-Associated Colonic Diseases**

*A. Adler, F. Knollmann, W. Veltzke, R. Felix, K.E. Hampel, R.E. Hintze

Depts. of Gastroenterology, Central Interdisciplinary Endoscopy and Radiology, Virchow-Klinikum, Humboldt-University of Berlin, Germany*Introduction:* Patients with clinical manifest AIDS often show infections and AIDS-associated diseases of the gastrointestinal tract with watery to bloody diarrhoea. Aim of this study is the definition of the value of colonoscopy and computed tomography (CT) in those diseases. *Methods and patients:* From 7/91 to 10/95 122 colonoscopies in 71 patients with suspicion of a HIV-associated colonic disease were performed. In 46 patients an abdominal CT in a maximum time interval of 6 months to the endoscopy was made. Only these patients were compared in our study (thereof 42 male, all homosexual, 4 female, 3x drug abuse, 1x partner contact, mean age: 31.5 years (min 26–max 62)). All had a value of less than 200 CD4-cells/\'b5l. *Results:* Despite of 3 patients with a colonoscopy without pathological findings, the other 43 patients (100%) showed the following alterations: 36x inflammatory (83.7%) and 7x neoplastic (16.3%); 12x with ubiquitous (27.9%) and 31x with segmental or focal (72.1%) localisation. 18x histologically a HIV-associated unspecific colitis was found (41.9%), 10x a CMV-colitis (23.3%), 5x a Kaposi-sarcoma (11.6%), 4x an MAI-infection (9.3%), 2x a non-Hodgkin-lymphoma (4.7%), 1x Mycobacterium africanum (2.3%), 1x Cryptosporidium (2.3%), 1x Microsporidium with a HIV-coeliac-like enteropathy (2.3%), 1x enterotoxic E. coli (2.3%). The HIV associated unspecific colitis often showed histologically cytomegal-transformed cells but no CMV-typical cytopathologic effects in immunohistology resp. PCR-analysis. In the comparative CT in 33 patients (71.7%) thick intestinal walls, pathologic mesenteric lymph nodes, striated signs of the pericolic fat, target lesions and/or ascites could be found. *Conclusions:* Endoscopy is for HIV-associated colonic mucosal alterations the probative method. A normal CT-finding implicates not a normal endoscopic finding. Kaposi's sarcoma and rectal findings can hardly be demonstrated with CT. In contrary in CT often endoscopically not identified small intestinal alterations are found as well as prognostic relevant pathologic entities as intraabdominal lymphoma, ascites or liver tumors. "P P 65 1539"P 65 1539**Colonoscopic Findings in Patients with AIDS and Diarrhea**

*M. Averbach, R. Cutait, P. Correa, J.L. Borges

Hospital S\'edrio Liban\'eas, S\'e3o Paulo, BrazilDiarrhea is a frequent symptom, affecting around 60% of patients with AIDS during the course of their illness.The recognition of the cause of this symptom is very important to permit the establishment of an specific treatment.This study was done to determine the most frequent causes of diarrhea in AIDS patients, verifying the colonoscopic manifestations of each condition.From November 1993 to March 1995, 86 patients with AIDS and diarrhea, for a minimun period of three weeks, were studied prospectively. According to the CDC classification, the majority (82.8%) of the patients were C2 and C3, showing an advanced disease. The patients were submitted to: stools exams, parasitologic culture and *Cryptosporidium sp.* and *Isospora sp.* surveillance and colonoscopy with biopsies.CMV colitis was the most frequent infection observed in 27.9% of the patients, followed by *Cryptosporidium sp.* diagnosed in 17.4%.The statistic analisis of these data showed the relation between the endoscopic findings and the pathogens identified. The predominant findings in patients with CMV colitis were ulcers (83.3%) mainly in the ascending colon ceacum.In the patients in whom *Cryptosporidim sp.* was the unic pathogen found the most frequent endoscopic alteration was colitis without ulcer.Colonoscopy with biopsies had an specific result in more than half of the patients identifying at least one pathogen. In 18.6% two or more pathogens were found. Therefore, colonoscopy with biopsies is an important tool to find the cause of diarrhea in AIDS patients. Endoscopy, specific: Colon, rectumImmunology and microbiology: GI infections in adults }" "Colonoscopic Findings in Patients with AIDS and Diarrhea"

OT84 1588**Are Pediatric Endoscopes Adapted to Perform Transnasal Oesogastroduodenoscopy in Adults?**

*T. Ponchon, J. Dumortier, B. Moulinier, P. Paliard, F. Zarka, R. Lambert

Department of Digestive Diseases, Hospital E. Herriot, Lyon, FranceRecent literature suggests an improved tolerance to gastroscopy without sedation, when thin endoscopes are introduced by the transnasal route. We conducted a study to determine whether commercially available thin endoscopes adapted to pediatric indications are adapted to perform oesogastro-duodenoscopy in adults.*Method:* transnasal endoscopy was performed in 227 adult patients (115 female, 112 male) referred in the unit for upper digestive endoscopy. The nasal cavities were anesthetized with 4% lidoca\'efne (plus naphazoline for vasoconstriction) on cotton pledgets. The thin endoscope was introduced if possible blindly, or if not, under visual control. Two models were used: – a fiberscope (OLYMPUS N 30, length 925 mm, outer diameter 5 mm) in 77 patients – a videoscope (OLYMPUS N 200, length 950 mm outer diameter 6 mm) in 150 patients. Efficacy in routine endoscopy was assessed on the following 4 criteria: successful passage in the nasal cavities, ability to reach the 2nd part of the duodenum, quality of vision, interpretation of biopsies with small forceps.*Results: Nasal passage:* The thin endoscope was introduced transnasally in 195 patients (86%). The 5 mm fiberscope (success: 90%) was easier to introduce than the 6 mm videoscope (success 82%). Transnasal introduction of the endoscope failed in 32 patients for the following reasons: – difficulty to advance in the nasal cavities in 17 – nasal pain in 6 – epistaxis in 5 – refusal in 4 patients. *Progression:* the endoscope was advanced to the second portion of the duodenum in 197 patients (87%); the respective rates with the fiberscope and the videoscope were 79% and 91%. *Vision:* its quality was judged good in 215 patients and poor in 12, because of lavage or aspiration. This is explained by the absence of a specific air-water channel on both endoscopes. *Pathology:* the interpretation of the biopsies was satisfactory in all cases. Finally, by taking into account the combined effect of all 4 parameters, the use of pediatric endoscopes was determined satisfactory in 161 patients (71%); the respective rates with the fiberscope and the videoscope being 67% and 72%.*Conclusion:* Pediatric endoscopes are adapted to perform transnasal oesophago-gastro-duodenoscopy in around 70% of cases. Technical improvements of the material (length, outer diameter, air-water channel) are required for routine use. Endoscopy, specific: OesophagusEndoscopy, specific: Stomach, duodenum }"

OT84 1589**Usefulness of a New Auto-Fluorescence Endoscopic Imaging System for the Diagnosis of Gastric Neoplasm**

*H. Watanabe, T. Ogihara, A. Namihisa, Y. Imai, T. Murai, T. Terai, R. Iwazaki, R. Ohkura, H. Miwa, N. Sato

Dept. of Gastroenterology, Juntendo Univ., Sch. of Med., Tokyo, JapanGastrointestinal neoplastic tissue has been reported to show intrinsic auto-fluorescence which is different from the auto-fluorescence of normal tissue when excited by blue or violet light. For the imaging of the regions of dysplasia and carcinomas in gastrointestinal tract, auto-fluorescence endoscopic imaging system (LIFE-GI system; Xillix technology Corp., Canada and Olympus optical Co., Japan) was newly developed using mercury light for excitation. We investigated the usefulness of LIFE-GI system for the detection of gastric neoplasm. We also evaluated the possibility of the detection by applying LIFE-GI system to the small remnant of gastric neoplasm after endoscopic treatment of gastric cancer and adenoma. *Methods:* Auto-fluorescence was observed by LIFE-GI system in 36 patients with or without gastric cancer and the findings were compared with the findings obtained by conventional endoscopy. Moreover, we studied the small remnant of gastric neoplasm in followed-up patients after endoscopic treatment of gastric lesion. Biopsy specimens from abnormal region detected by conventional endoscopy or LIFE-GI system were examined histologically. *Results:* 1) Twenty-six lesions, including all 20 carcinomas, showed abnormal fluorescence images by LIFE-GI system; 6 lesions were benign tissues by histological examination. 2) Remaining of tumor after endoscopic treatment was suspected in 7 lesions by LIFE-GI system; 3 lesions were proven histologically as dysplasia or adenocarcinoma, other 4 lesions were regenerative or erosive change histologically. *Conclusion:* We applied the newly developed autofluorescence endoscopic imaging system (LIFE-GI) for gastric neoplastic lesions. LIFE-GI system made it possible to detect the gastric cancer or dysplasia as well as conventional endoscopy. Small neoplastic lesions such as the remnant after endoscopic resection, which were difficult to be diagnosed by conventional endoscopy, could be detected by the LIFE-GI system. This suggests that the LIFE-GI system may be useful in the detection of small malignant lesions.

OT84 1590**Hepatitis C Virus RNA on Digestive EndoscopesD. Smith[1], J.M. Raymond[1], P. Trimoulet[2], V. De Ledinghen[1], H. Fleury[2], M. Amouretti[1], P. Couzigou[1]**

[1] CHU du Haut L\'e9veque, Bordeaux, France

[2] University de Bordeaux II, FranceIn 20 to 40% of cases, routes of contamination by hepatitis C virus (HCV) remain unknown, and digestive endoscopy has been suspected to be one of them. The aim of this study was to detect HCV viral nucleic acid on endoscopes and biopsy-forceps used in patients with known chronic HCV infection.*Methods:* First, to assess the method of sampling, a biopsy-forceps was artificially immersed in an HCV-positive serum sample and this serum was aspirated into the suction-biopsy channel of a gastrointestinal endoscope. Then, an oesogastroscopy with biopsy was performed in patients with known chronic HCV infection (RIBA 2+) and ASAT > 2N. All patients had a positive HCV viraemia on the day of the endoscopic procedure. Samples were obtained after pushing 10 ml of sterile water through the suction-biopsy channel and after immersion of the biopsy-forceps in 2 ml of sterile water. This sampling technique was used three times: immediately after endoscopic procedure (t0), after washing with detergent (t1) and after an immersion for 20 minutes in 2% glutaraldehyde solution (t2). Samples were stored immediately at { -}20\'b0C. A polymerase chain reaction (PCR) was subsequently used to detect HCV RNA presence.*Results:* The suction-biopsy channel and the biopsy-forceps of the control endoscope were positive at t0 and negative at t1 and t2. Serial samples were tested for HCVRNA by PCR in 18 cases at t0, 1 out of 18 patients had detectable genomic HCVRNA on biopsy-forceps at t0, no suction-biopsy channel was positive at t0. To date samples at t1 and t2 were only tested for 7 patients, they were all negative, either the suction-biopsy channel, either the biopsy-forceps.*Conclusion:* This study emphasizes the difficulty in finding HCV RNA in such samples. It confirms the theoretical possibility of HCV patient-to-patient transmission by endoscopic procedures. OT84 1591**A New Expandable UV-Cured Plastic Endoprosthesis for the Management of Malignant Esophageal Strictures**

*J. Haringsma, J. Ferwerda, W. Dekker, H.L.F. Brom

Depts. of Medicine & Surgery, Kennemer Gasthuis, Haarlem, The NetherlandsExpandable stents have provided a major advance in the palliative treatment of dysphagia caused by malignant strictures of the esophagus. Current metal expanding endoprosthesis often require balloon dilatation in assistance to stent placement. After deployment these stents can not be removed, while misplacement and migration occur in up to 20%.In an attempt to produce a more satisfactory modality for palliative stricture and fistula relief, we developed a teflon esophageal endoprosthesis that is inserted over a bow-tie shaped dilatation balloon. Stricture dilatation is combined with stent placement. After correct positioning and deployment, the stent is cured by polymerization with UV light. Potentially, the stent can be disintegrated and removed with a special rescue-catheter. Our initial experience is reported.*Results* Four patients, aged 49–81 years (67 yr), had esophageal carcinoma causing grade 2–4 dysphagia (2.6). Stricture length averaged 5.0 cm. A tubular stent with an internal shaft diameter of 15.5 mm and a 26 mm funnel at both ends was inserted over a guidewire without prior dilatation. Stent placement was successful in all patients and no procedural complications occurred. All patients responded clinically with significant improvement in dysphagia. Complications included pain of limited duration in one, tumor overgrowth in two patients. One early death occurred, unrelated to the procedure. With one patient still in follow-up, average stent survival exceeds 88 days.*Conclusions* This newly developed UV-cured esophageal endoprosthesis is effective in relieving dysphagia in patients with malignant esophageal stenosis. It is safe, easily implanted and has potential advantages over covered metal expanding prosthesis. However, further evaluation is required. Endoscopy, specific: OesophagusEndoscopy, general: Instrumentation, therapyOncology, specific: Oesophagus }" "A New Expandable UV-Cured Plastic Endoprosthesis for the Management of Malignant Esophageal Strictures"

OP1 0001 **Early Administration of Natural Somatostatin (S) Increases the Efficacy of Sclerotherapy (ES) in {\ul A}cute {\ul B}leeding {\ul O}esophageal {\ul V}ariceal {\ul E}pisodes: The European ABOVE Study**

*A. Avgerinos, F. Nevens, S. Raptis, J. Fevery, ABOVE Study Group, M. Adler, A. Armonis, D.J. Bac, N. Bourgeois, B. Burtin, T. Darcis, J. Decruyenaere, M. Deman, A. Elewaut, M. Hautekeete, D. Katsaros, L. Lepoutre, S. Manolakopoulos, O. Natens, G. Poulianos, H. Reynaert, Ch. Tzathas, H.R. Van Buuren, P. Van der Spek, A. Zacharopoulos

Athens, Greece

Aalst, Brussels, Gent, Jette, Leuven, Belgium

Rotterdam, The Netherlands

UCB Pharma, BelgiumThe additional efficacy of S to emergency ES in cirrhotics with an acute upper gastrointestinal bleeding episode was assessed. Immediately after admission, 205 subjects were randomly assigned to receive continuous iv infusion of S (6 mg/24 hr for 120 hr), or placebo (Pl) in a double blind way. Additionally, iv boluses S (250 \'b5g) or Pl were injected: a) after start of infusion, b) before endoscopy and c) if active bleeding occurred. ES was performed between 1 to 8 h after initiation of treatment. The study drug was continued in 151 pts (74%) in which oesophageal varices were the origin of bleeding (S = 75, Pl = 76). Overall failure during the 5 day study period was defined as: death or clinical signs of rebleeding or the requirement of an excess of blood products or rescue therapy. Both groups S/Pl were comparable with regards to age (mean – sd = 59.5 yrs – 12.1/58.8 yrs – 3.9), gender (M: 52/52, F: 23/24), Child's-class (A = 10/11; B = 38/39; C = 26/25) and alcoholic origin (40/46). Overall failure was observed in 32 subjects (S) and 51 (Pl) with p = 0.003. During the infusion 2 patients (2.7%) died in S and 7 (9.2%) in Pl (p = 0.17); units of blood products transfused: 2.6 – 0.35 (S) vs 3.6 – 0.35 (Pl) (i.t.t., p = 0.05). In conclusion the results of this study suggest that the early administration of natural S increases the efficacy of ES in the control of acute bleeding from oesophageal varices in cirrhotics. Liver and bile ducts, 1: Cirrhosis: portal hypertensionEndoscopy, general: GI bleedingEndoscopy, specific: Oesophagus }" "Early Administration of Natural Somatostatin (S) Increases the Efficacy of Sclerotherapy (ES) in Acute Bleeding Oesophageal Variceal Episodes: The European ABOVE Study"

OP1 0003 **The Actin Bundling Protein Fascin, Is Upregulated by Transforming Growth Factor-{ a}**

*A.U. Jawhari[1], P.D. McCrea[3], M.J.G. Farthing[1], M. Pignatelli[2]

[1] Digestive Diseases Research Centre, St. Bartholomew's and the Royal London School of Medicine and Dentistry, London, UK

[2] Department of Histopathology, Hammersmith Hospital, London, UK

[3] Department of Biochemistry and Molecular Biology, Anderson Cancer Centre, Houston TXFascin is a highly conserved, ubiquitously expressed actin-bundling protein, involved in the assembly and reorganisation of actin bundles and networks necessary for locomotion, maintenance of cell polarity, and attachment to intercellular contacts and the substratum. A recent report has suggested interaction of fascin with the cadherin-catenin complex at adherens junctions.*Aims:* 1. To examine the expression of fascin in gastric and colonic carcinoma cell lines and its response to stimulation of the epidermal growth factor receptor (EGFR) by TGF-{ a}. 2. To examine the interaction of fascin with the E-cadherin-catenin complex in these cell lines.*Methods:* Fascin expression was examined in gastric (MKN45 & HSC39) and colonic cell lines (HT29, HCT116, & LS174T) by immunocytochemistry and Western blotting. Intensity of expression was assessed on days 1–4 following seeding and in response to stimulation of the EGFR by TGF-{ a} (10 ng/ml for 24 hrs). Immunoprecipitation of fascin-associated proteins followed by Western blotting was performed.*Results:* Fascin co-localised with E-cadherin at the cell membrane. A 55 kDa band consistent with fascin was demonstrated in all cell lines. Band intensity was inversely proportional to monolayer confluence. Stimulation by TGF-{ a} was associated with increased fascin expression in MKN45 & HT29. Immunoprecipitation experiments confirmed fascin interaction with E-cadherin, { b} and { g}-catenin.*Summary and conclusions:* TGF-{ a} stimulation is associated with upregulation of fascin expression. The interactions between the cadherin-catenin complex, fascin and the EGFR may play a role in modulating cell-cell adhesion and cytoskeletal interaction during cell migration in epithelial repair, and invasion by neoplastic cells. OP1 0004 **Preoperative Radiotherapy in Rectal Carcinoma: Influence of the Interval between Radiotherapy and Surgery: A Multicenter Randomised Trial from LyonY. Fran\'e7ois**

Department of Surgery, Centre Hospitalier Lyon Sud, Pierre-B\'e9nite, FrancePreoperative radiotherapy has been shown to decrease local recurrence after surgery in rectal carcinoma. However the best moment for surgery after completion of radiotherapy is not known. Therefore the aim of this prospective multicenter randomised trial was to determine the influence of the interval between radiotherapy and surgery on sphincter conservation, complications of surgery and local recurrences.*Methods:* Operable patients with rectal carcinoma reachable at digital examination, staged T2–T3, Nx, MO were included. Preoperative radiotherapy delivered 39 Gy in 13 fractions within 17 days. Randomisation was performed before radiotherapy in 2 arms: in the ""short"" arm, patients were operated on within 2 weeks after completion of radiotherapy, while in the ""long"" arm, surgery was performed 6 to 8 weeks after radiotherapy.*Results:* 210 patients were randomised between 1992 and 1995. 177 patients had for the moment completed a 6 month follow-up, 90 in the short arm, 87 in the long arm. There were 113 male and 64 female, mean age 63 yrs (range 35–82). There was no statistical difference between the 2 groups for sex, age, and the mean distance between the lower part of the tumor and the anal verge as determined by rigid endoscopy and endosonography (respectively 5.8 cm and 6.1 cm). 21 patients (12%) could not have curative resection (liver, peritoneum metastasis, parietal invasion). Sphincter preservation was possible in 68% (61/90), short arm and 76% (66/87) (long arm ($p = 0.25$). After radiotherapy, decrease in tumoral size (> 50%) measured by digital examination was observed more in the long arm, 69% vs 55% ($p < 0.05$). Operative specimen showed no or only a few tumoral cells in 11/86 vs 25/83 ($p = 0.008$). Median operative stay, peroperative mortality, anastomotic complications and reinterventions were similar in the 2 groups. With a median follow-up of 20 months, actuarial survival was at 1, 2 and 3 yrs, 89, 83, 78% in the short arm, 91, 77 and 64% in the long arm (NS). Local recurrence was observed in 6 patients in the short arm and 5 in the long arm. All these patients had sphincter saving surgery.*Conclusion:* In this large series of rectal carcinoma with preoperative radiotherapy, sphincter conservation was possible in 72% of patients. Patients of the long arm has a more important tumor regression than in the short arm. However there was not statistical difference in the pourcentage of sphincter saving intervention or operative complications. A longer follow-up will confirm the lack of difference in survival and local recurrence. OP1 0005 **Effects of Smoking on the Clinical Course of Crohn's DiseaseR. Sostegni,**

*G. Rocca, A. Musso, M. Astegiano, S. Greco, M.T. Fiorentini[1], M. Rizzetto, A. Pera[1]

Dipartimento di Gastroenterologia, Ospedale Molinette, Torino, Italia

[1] Divisione di Gastroenterologia, Ospedale Mauriziano, Torino, Italia*Purpose* A previous study by our group showed no relationship among 1) years of smoking 2) the cumulative estimate of the total amount of cigarette smoked and the long term medical and surgical course of the disease. This suggested that the effect of smoking is not long-lasting. In order to test the hypothesis of a short-term effect of smoking during long-term follow up a phone interview based on a standardized questionnaire about smoking habits was performed.*Patients and Methods* Of 203 patients (127 M, 76 F) with a follow-up of more than 10 years duration, 73 (36%) stopped smoking after the diagnosis of CD and were excluded from the study. The median follow-up period for the remaining 130 patients is 16 years (10–33). At the time of diagnosis the disease involved: ileum 60 (46%), ileum-colon 29 (22%) and colon 41 (32%). The effect of daily cigarette smoking irrespective of life time exposure was evaluated by dividing patients in 64 smokers (49%) and 66 non-smokers (51%).*Results* The comparison of non-smokers versus smokers shows: mean age 49 and 46 ($P = 0.17$), mean age at diagnosis 33 and 29 ($P = 0.13$), months between first symptom of CD and diagnosis 38 and 22 ($P = 0.09$), pain at diagnosis 45 and 55% ($P = 0.09$), weight loss at diagnosis 39 and 61% ($P = 0.04$), mean number of hospital admission 2.9 and 3.6 ($P = 0.06$), steroid months 18 and 26 ($P = 0.08$), azathioprine months 7 and 18 ($P = 0.12$). Disease localization, number of major surgical operations, indications for surgery, number of postoperative recurrences, and mortality are not statistically associated with smoking. There is no difference in the timing of the first, second, third and further operations estimated by life table analysis.*Discussion* This study confirm the absence of both long-standing and cumulative effects of smoking on Crohn's disease. Our data suggest that smoking could have a short-term effect on some symptoms, signs and disease severity as indicated by the statistical association or consistent trend with age at diagnosis, latency between symptoms and diagnosis, hospital admission and therapeutic needs as suggested recently by Cosnes et al. Intestinal disorders: IBD, etiology and genetics }" "Effects of Smoking on the Clinical Course of Crohn's Disease"

OP1 0006 **Hepatitis G Virus Infection in Patients with Hepatocellular Carcinoma**

*F. Pfeffel, Ch. M\'fcller, M. Peck-Radosavljevic, Ch. Oesterreicher, D. Petermann, J. Pidlich

Univ. Klinik f. Innere Medizin IV, Klin. Abtl. Gastroenterologie und Hepatologie, University of Vienna, Austria*Purpose of the study:* Hepatitis G virus (HGV) is a RNA virus and has been implicated as a causative agent in acute and chronic hepatitis. We investigated the prevalence of HGV in patients with hepatocellular carcinoma (HCC).*Methods:* Serum of 76 patients (53 m, 23 f, 61 – 11 yrs) with HCC was studied for the presence of HGV-RNA by reverse-transcription polymerase-chain reaction (RT-PCR).*Results:* 15 (20%) of 76 patients with HCC were infected with HGV. In 6 patients (8%) HGV was the only hepatotropic virus found. In 9 patients (12%) coinfection of HGV with other hepatitis viruses was present. 4 patients (26%) were HBsAg+, 5 others (33%) were HCV-RNA+; in none of our patients triple infection of HBV, HCV and HGV was found. Of 67 patients with HCC 30 patients (39%) had no evidence of infection with hepatotropic viruses, 46 patients (61%) had markers virus infection: of those 12 patients (27%) were HBV infected, 26 patients (59%) were positive for HCV-RNA, and 6 patients (14%) were HGV-RNA+. In 61 control patients with chronic hepatitis B (without HCC) 10 patients (16%) were HGV-RNA+, whereas 4 of 12 HBsAg+ patients with HCC (30%) were infected with HGV. 16 of 68 patients (21%) with chronic hepatitis C (without HCC) and 5 of 26 of HCV-RNA+ patients with HCC (20%) were positive for HGV. The prevalence of HGV in patients with HCC (20%) was significantly higher than that found in healthy controls (3%; p = 0.003).*Conclusion:* The prevalence of HGV is significantly increased in patients with HCC as compared to the healthy population. HGV could be a risk factor for HCC. Liver and bile ducts, 1: Hepatitis viral, diagnosisOncology, specific: Liver, biliary }" "Hepatitis G Virus Infection in Patients with Hepatocellular Carcinoma"

[3] Liver and Surgery Units, Cochin Hospital, Paris, France

[4] Liver and Surgery Units, Jean Verdier Hospital, Paris, France

[5] Liver and Surgery Units, Antoine Beclére Hospital, Paris, FrancePrognosis of patients with LC often depends on development of extrahepatic metastasis, particularly after liver transplantation. We have developed a sensitive test, specifically detecting the spontaneous circulation of circulating tumorous cells (CTC) and spreading of liver cells due to chimioembolisation (CE) and alcoholisation (A). *Methods:* Alphafetoprotein (AFP) mRNAs detection in peripheral blood cells by RT-PCR. Test of sensitivity by spiking HepG2 cells (derived from human LC) in blood of healthy volunteers. 76 patients with LC (group A: 39 treated by surgical resection; group B: 37 not treated surgically, including 12 patients tested before, 1 hour after and 24 hours after CE or A), 100 controls (group C: 10 patients with benign liver tumors or liver metastasis from intestinal cancers; group D: 53 patients with chronic hepatitis and/or cirrhosis without HCC, group E: 37 blood donors). *Results:* Sensitivity: one HepG2 cell detected when mixed with 10^7 leukocytes. Controls (group C, D and E): all negative. Group A: 13/39 positive. Group B: 13/37 positive. Patients with metastasis: 4/5 positive. Patients tested before and after CE or A: 6/12 positive after therapy, including 2 positive after CE and 4 after A. Three patients became positive 1 hour and negative 24 hours after therapy. Three other patients became positive 24 hours after therapy. *Conclusions:* 1) We have developed a highly specific and sensitive technique to detect CTC in patients with LC. 2) 30% of patients with LC have detectable CTC 3) Locoregional therapy (CE and A) may spread hepatic cells including tumorous cells in the peripheral blood.

OP2 0009 **Pivotal Role of Granulocytes in Immunoregulation in Inflammatory Bowel Disease?S. Nikolaus, J. Hampe, J. Bauditz, M. Ortner, E. Reichelt, H. Lochs, U. Schindler[1], S. Schreiber**

IVth. Medical Department, Charit\'e9, Berlin, Germany

[1] Tularik, San Francisco, USA*Background:* Pro-inflammatory cytokines (IL-1{ b}, TNF-{ a}, IL-8, IL-1ra) are increased in intestinal inflammation in IBD. Monocytes as well as epithelial cells have been discussed as a source. However, predominant cells in inflammatory infiltrates are granulocytes (PMN). The *Aim:* of this study was to evaluate the capacity of PMN to secrete pro-inflammatory cytokines as well as the regulatory capacities of IL-4 and IL-10 in PMN. *Methods:* PMN from 35 patients with ulcerative colitis (UC), 28 patients with Crohn's disease (CD) and 25 normal volunteer controls (NC) were obtained from peripheral blood by dextran sedimentation and density centrifugation. Release of pro-inflammatory cytokines (ELISA) into culture supernatants as well as mRNA (semiquantitative RT-PCR) were assessed. *Results:* Only low levels of pro-inflammatory cytokines were secreted spontaneously. After stimulation with LPS, PMN from patients with active UC or CD secreted significantly more IL-1{ b}, TNF-{ a} and IL-1ra than NC (Figure). Pro-inflammatory cytokine secretion was related to disease activity. IL-4 as well as IL-10 down-regulated pro-inflammatory cytokine secretion as well as mRNA levels in a dose dependent manner without differences between IBD and NC PMN. Elements of IL-4 receptor signal transduction (STAT-6) were induced by stimulation of PMN with IL-4. *Conclusions:* PMN could be an important contributor to enhanced concentrations of pro-inflammatory cytokines in intestinal mucosa or feces of IBD patients. PMN appear to be fully capable to partake in mucosal immunoregulation by anti-inflammatory cytokines. Elements of IL-4 signal transduction (STAT-6) are fully conserved in PMN. Future therapeutic developments need to consider PMN as potent pro-inflammatory cells capable of partaking in mucosal immunoregulation.

OP2 0011 **Self-Reported Ulcer Incidence and Changes in Levels of Serum IgG Antibodies to *H. Pylori;* A Prospective Cohort Study Comprising 2,404 Unselected Danes**

*S.J. Rosenstock, L.P. Andersen, O. Bonnevie, T. J\'f8rgensen

Dept. of Surgery K, Bispebjerg Hospital, the Copenhagen Hospital Corporation, the Glostrup Population Studies, University of Copenhagen, 2400 NV Denmark*Aim:* To examine the relationship between changes in levels of IgG antibodies to *H. pylori* and the incidence of self-reported peptic ulcers (PUD) in an 11-year period. *Methods:* A random sample of 3,589 Danes aged 30–60 years entered a population-based prospective cohort study in 1983. After 11 years, 2,656 participants attended a follow-up examination. Blood samples were drawn at both attendances (n = 2,404). IgG antibodies against *H. pylori* were measured with an in-house ELISA assay. Antibody levels were categorized as sero-negative, border-line, or sero-positive. People who sero-converted in IgG antibodies to *H. pylori* were regarded as having acquired *H. pylori* infection within the study period. Participants with no history of peptic ulcer disease at study entry reported if they had had an ulcer diagnosed at follow-up. Information on life-style practices, socio-economic factors, and medical history was obtained from a questionnaire. *Results:* Cumulated 11-year incidence of PUD was 28.3 [21.7–34.9] per 1,000 persons at risk. Ulcers were more often reported in those who were seropositive at both attendances (OR 2.18 [1.13–4.21]), in people with an increase in IgG antibodies from border-line to seropositive levels (OR 4.89 [1.13–4.31]), in heavy tobacco smokers (OR 6.24 [2.45–15.91]), and in people categorized as psychical vulnerable at study entry (OR 2.86 [1.45–5.56]). Age, sex, family history of PUD, sero-conversion in IgG antibodies, and alcohol consumption did not act as risk factors to PUD in this study. *Conclusions:* Long-term *H. pylori* infection, tobacco smoking, and psychic vulnerability are independent risk factors to PUD. An increase in IgG antibody levels may be useful as a marker for ulcer formation. Recent infection with *H. pylori* (< 11 yrs.) may not be a risk factor to PUD. Oesophageal gastric duodenal disorders: Helicobacter PyloriOesophageal gastric duodenal disorders: GD disorders, acid pepticClinical practice: Epidemiology (non cancer) }" "Self-Reported Ulcer Incidence and Changes in Levels of Serum IgG Antibodies to H. OP2 0012 **Diagnosis of Pancreatic Cancer with FDG-PET: Comparison with CT, US and Endoscopic UST. Inokuma, T. Okamoto, T. Ogami, T. Uchida[1],**

*S. Katsushima[2], T. Higashi, T. Torizuka, T. Honda, N. Tamaki, J. Konishi[3]

[1] Department of Medicine, Takamatsu Red-Cross Hospital, Kagawa, Japan

[2] Department of Medicine, Osaka Teishin Hospital, Osaka, Japan

[3] Department of Radiology and Nuclear Medicine, Kyoto University Faculty of Medicine, Kyoto, Japan*Purpose:* Clinical value of PET for identification of pancreatic cancer was prospectively evaluated in comparison with CT, US and endoscopic US (EUS).*Methods:* 74 preoperative patients with suspected pancreatic neoplasm underwent PET, CT and US. EUS was performed in 66 patients. Images were independently interpreted and compared with the histopathologic findings or with clinical follow-up findings for over six months. PET was performed one hour after intravenous injection of 185 MBq of F-18 fluorodeoxyglucose (FDG) under fasting state. Focal FDG uptake in the pancreatic region was considered as sign of malignancy, and was evaluated quantitatively with standardized uptake values (SUVs).*Results:* In 54 (96%) of 56 patients, foci of pancreatic carcinomas (10–100 mm in diameter) were identified as an increase in FDG uptake, whereas CT, US, and EUS depicted the foci in 51, 51, and 46 cases, respectively. In 12 (86%) of 14 with chronic pancreatitis, no increased FDG uptake was observed. Specificities of the other modalities were lower. False-positive findings were obtained in two of chronic pancreatitis and in two of vascular-rich benign neoplasms. In the semiquantitative analysis, SUVs accurately differentiated malignant (4.16 – 2.16) from benign (2.05 – 0.93) tumors ($p < 0.01$), and SUV cut-off values of 2.20 best separated the two groups.*Conclusion:* FDG-PET, which provides biochemical information, is accurate in identifying pancreatic cancer, and has significantly higher sensitivity and specificity than CT and US. PET CT US EUSSensitivity 54/56 (96%) 51/56 (91%) 51/56 (91%) 46/48 (96%)Specificity 14/18 (78%) 10/18 (56%) 9/18 (50%) 12/18 (67%)Accuracy 68/74 (92%) 60/74 (81%) 61/74 (82%) 58/66 (88%) Oncology, specific: PancreasRadiology and ultrasound: Diagnosis }"

"P P 1 0013"P 1 0013 **Human Papillomavirus (HPV) Infection and p53 Overexpression as Prognostic Factors in Patients with Esophageal Squamous Cell Carcinoma.M. Iwasa, S. Ogoshi, A. Takahashi, H. Ono, Y. Ohmori, Y. Iwasa, A. Yamamoto**

Department of Surgery II, Kochi Medical School, Okoh, Nankoku, Kochi 783, JapanInfection with high-risk human papillomavirus (HPV) has been detected in high percentages of patients with several types of cancer such as in the uterine cervix, anus, skin and esophagus. On the other hand, p53 protein mutation and overexpression in the multistep process of esophageal carcinogenesis is still under debate. The present study was undertaken in order to investigate the possible involvement of HPV in the esophageal squamous cell carcinoma (ESC) and the relation between p53 overexpression and prognosis of patients in ESC.*Material and Methods.* One hundred twenty three samples, formalin fixed and paraffin embedded, were examined for this study. The detection of HPV was performed with dot blot hybridization (DBH), polymerase chain reaction (PCR) and in situ hybridization (ISH) methods. p53 protein were analyzed immunohistochemically with a monoclonal antibody and the avidin–biotin complex (ABC) procedure. The relationship between HPV infection, p53 overexpression and prognosis of patients with ESC were analyzed by multivariate survival analysis.*Results.* The detection rate of HPV were 21% by DBH and PCR, respectively. In ISH method, HPV types 16, 18 and 33 were detected in 30% (37/123). In addition, 43 of 123 samples (35%), nuclear immunohistochemical reactivity for p53 protein overexpression was detected. The survival rate (Kaplan–Meier methods) in HPV positive group was markedly worse than negative group and in p53 protein overexpression positive group was significantly worse ($p < 0.05$) than negative group.*Conclusion.* These results suggest that the HPV infection and p53 protein overexpression were detected in a high percentage of ESC. The presence of HPV and p53 protein overexpression have strong impact on the prognosis of the patients with ESC. However, additional studies on a large series of patients with ESC will be necessary for verification of these results. "P P 1 0014"P 1 0014 **Esophageal Squamous Cell Papilloma and Human Papillomavirus (HPV) Infection**

*S. Michopoulos, M. Sotiropoulou[1], M. Botos, H. Bouzakis, I. Vougadiotis, E. Papaspyrou[1], V. Pavlou[1], P. Tsibouris, S. Markaki[1], K. Nikolaidis, N. Kralios

Gastroenterology Unit, ""Alexandra"" University Hospital, Athens, Greece

[1] Pathology Unit, ""Alexandra"" University Hospital, Athens, GreeceHuman papillomaviruses (HPV) are involved in the development of cervix, larynx, lung and anus papillomas as well as the progression of the papilloma into cancer. Esophageal squamous cell papilloma (ESCP) is a rare benign condition, considered as precancerous, but its etiology and pathogenesis remain controversial. The prevailing etiological considerations are chronic chemical irritation from gastric juice and HPV infection. In addition HPV and particularly of type 16 or 18, is detected in a percentage of squamous esophageal malignancies. The *aim of our study* was to investigate the possible relationship between HPV and ESCP in an area of low prevalence of squamous esophageal cancer. *Patients and methods:* 14 ESCPs (5–15 mm of diameter) from 12 patients (29–72 years old) were analysed for HPV using in situ hybridization (ISH) from paraffin-embedded tissue (ENZO *PathoGene*'). The HPV types researched according to the DNA probe reagents provided were 6/11, 16/18, 13/33/51. The method was validated as the manufacturer suggests, using 2 control slides inoculated with 6 and 16 HPV types. Gastroesophageal reflux was diagnosed in 5 patients, one patient had gastroduodenal ulcer while the rest of the patients (6) had a fiberoscopy for chronic dyspeptic syndrome. One patient had 2 adjacent but distinct papillomas at mid-esophagus while the other patient had a recurrence at the same place of mid-esophagus, one year after ablation. *Results:* No evidence for HPV DNA was detected in any of the examined specimen. *Conclusions:* 1) We were unable to detect HPV DNA using ISH in all ESCP that we tested 2) Other authors using more sensitive methods, like PCR, rarely report HPV DNA in ESCPs. This supports our findings and suggest that other than HPV infection, pathogenetic mechanisms are more important for ESCP's etiology at least in our area.

"P P 1 0015"P 1 0015 **Clinicopathological Study of Esophageal Squamous Papilloma-Including Immunohistochemical StainingH. Yamagiwa, N. Onishi, T. Onishi, M. Nishii**

Dept. of Pathol., Mie University Hospital and Onishi Hospital, Mie, JapanClinicopathological study for 100 cases of esophageal squamous papilloma were performed. Patients were frequently found in 6th and 7th decades. The majority of patients had no remarkable complaint and complication, and easophageal squamous papillomas were accidentally found at the investigation of gastric disease by X-ray and endoscopy.The white colored elevated lesions located frequently in lower 1/3 (60%) and middle 1/3 (30%) of esophagus showing lobulated or villous appearances. Hemispherical and sessile polypoid lesions (94%) were frequently found compared with the pedunculated ones. Single lesion was found in 90% of the cases, and 83% of the lesions were within 5 mm in diameter. Histologically, squamous epithelial thickening and papillomatous growth without atypia were observed.Although several factors like as regurgitation of gastric juice associated with gastric resection, hiatal herniation, gastric ulcer, etc., and HPV (human papilloma virus) infection have been reported in relation to the histogenesis of esophageal squamous papilloma, genuine mechanism has been unknown.According to the immunohistochemical staining, positive rate was 21.2%, 7.6%, 0%, 15.4%, 23.1%, 0% and 7.6% for PCNA (proliferating cell nuclear antigen), p53, c-erbB-2, EGF, EGFR, K-ras and HPV, respectively. These positive rates were extremely low in comparison to those of esophageal carcinoma. It seemed likely that esophageal squamous papilloma is not precancerous. "P P 1 0016"P 1 0016 **A Retrospective Review of a Consecutive Series of 90 Oesophageal Resections**

*P. Kolh, J.L. Gielen, C. Azzam, P. Honore, M. Legrand, N. Jacquet

Digestive Surgery Service, University of Liege, CHU, Liege, BelgiumTo assess the perioperative mortality and morbidity of oesophageal surgery, we present a retrospective series of 90 patients who underwent oesophageal resection at our institution from 1.1.1989 through 31.12.1995.There were 73 males and 17 females, mean age was 64.2 years (range: 21–78 years). Indications for resection were esophageal cancer in 64 patients, cardial adenocarcinoma in 20, and benign lesions in six. Twenty-five patients received preoperative radiochemotherapy. In 78 patients surgery was performed in a curative intent and was palliative in twelve. There were thirty-seven total esophagectomies, nineteen thoracic esophagectomies, and thirty-four partial oesophagogastrectomies. Digestive continuity was restored with a gastric transplant in 62 patients, a colonic graft in 24, and a jejunal loop in four. Hospital mortality was 10%, and 30-day mortality was 7%. Comparing the periods until 1992 and since 1993, hospital and 30-day mortalities decreased respectively from 18.5% to 3.8%, and from 10.5% to 3.8%. Three patients died from myocardial infarction, four from anastomotic fistula, and three from pulmonary complications. Among the 9 patients who died, five had a total oesophagectomy, and in all but one a gastric transplant was used. Nonfatal postoperative complications occurred in 32 patients (nine in the colonic graft group and 23 in the gastric pull-up group), and consisted in pulmonary problems in 26 patients, cerebrovascular accident in one, renal insufficiency in two, recurrent nerve palsy in four, and anastomotic fistula in six. Twelve patients were reoperated for technical reasons: anastomotic fistula (6), anastomotic stenosis (1), hemorrhage (3), and transplant ischemic injury (2). We observed 14 pulmonary complications in the subgroup of patients who received preoperative radiotherapy.We conclude that: 1) with experience, major oesophageal resection can be performed with low mortality, 2) the use of a colonic graft doesn't increase the incidence of perioperative complications, 3) pulmonary complications are responsible for a significant morbidity after oesophageal surgery, particularly in patients with preoperative radiotherapy. }" "A Retrospective Review of a Consecutive Series of 90 Oesophageal Resections"

"P P 1 0017"P 1 0017 **An Original Evaluation of Gastric and Colonic Transplants after Oesophageal Resection**

*P. Kolh, J. Gielen, C. Azam, P. Honore, M. Legrand, Boverie, N. Jacquet

Digestive Surgery Service, University of Liege, CHU, Liege, BelgiumWe present a clinical and radiological evaluation of gastric and colonic grafts used to restore digestive continuity after oesophageal resections.Out of 90 patients who underwent an oesophageal resection at our institution, from 1.1.1989 through 31.12.1995, we evaluated the alimentary comfort and the quality of life with a standard questionnaire, and performed a dynamic contrast-swallowed radiography (radiocinema) in 35 patients who were alive more than one year after oesophageal resection.There were 23 males and 12 females; mean age was 64 years. In 30 patients esophageal resection was performed for cancer and for benign lesions in five. 28 patients had a gastric pull-up and in 7 patients an isoperistaltic colon segment was used to restore the digestive continuity. Major long-term complaints were sensation of early fullness during eating in 8 patients, nocturnal cough in seven, postprandial sweating in five, dysphagia in four, and diarrhea in three. Most patients considered the side effects of the operation as mild to moderate and mean rating of alimentary comfort was 8.2/10. Twenty-four patients qualified their quality of life as good, eight as satisfactory, and four as poor. Thirty patients led active lives. With radiocinema the following observations were made: colon transplants were essentially non contractile and emptied by gravity; in gastric grafts, the contrast progressed passively in the non-antral portion but isoperistaltic contractions were observed in the antral segment. The best functional results were seen with partial oesophagectomies and gastric transplants: the proximal oesophageal segment triggered the movement with strong contractions, followed by passive progression in the non-antral segment of the gastric pull-up, and subsequently by antral contractions. These radiological observations correlate well with the clinical evaluation.We conclude that in most patients the quality of life and alimentary comfort are good after esophageal resection and gastric or colonic pull-up. Radiocinema shows a better function of the gastric transplant, as compared to the colonic graft, particularly when the proximal portion of the oesophagus triggers the progression.

"P P 1 0018"P 1 0018 **Five-Year Survival Following Resection for Oesophageal Cancer in 733 PatientsJ.M. Catheline, B. Meunier, S. Landen, E. Bardaxoglou, B. Chareton, J.P. Campion,**

*B. Launois

Digestive Surgery and Transplantation Unit, University of Rennes, Pontchaillou Hospital, Rue Henri Le Guilloux, 35033 Rennes Cedex, FranceThe aim of this retrospective study was to determine survival and prognosis factors of a group of 733 patients having undergone surgery for oesophageal cancer between 1981 and 1991. Cancers of the pharyngoesophageal and oesophageal gastric junction were excluded from this study.*Patients and methods:* The group comprised 696 males and 37 females with a mean age of 59 years. 528 resections were performed using various surgical procedures: Sweet (5%), Ivor-Lewis (30%), Akiyama (18%), Thorek (6%), MacKeown (18%), transhiatal oesophagectomy (23%). The tumor was located at the upper, middle and lower third of the oesophagus in 14%, 65%, and 21% of patients respectively. 95% of tumors were squamous cell carcinomas.*Results:* The resectability rate was 72% and 76% of resections were considered as being curative. Thirty-day operative mortality was 9%. Excluding operative mortality, 5-year actuarial survival following curative resections was 25.7% versus 3.4% following palliative resections ($p < 0.0001$). When TNM staging was considered, 5-year actuarial survival was 87% for stage 0 lesions, 51% for stage I lesions, 25% for stage IIA and 13.6% for stage IIB lesions, 6% for stage III lesions and 0% for stage IV lesions ($p < 0.0001$). 5-year survival showed no relationship to patient gender or histology.*Conclusions:* There exists a statistically significant relationship between TNM tumor staging for oesophageal cancer and 5-year survival. "P P 1 0019"P 1 0019 **Results of the Operative Treatment for Esophageal Squamous-Cell Carcinoma**

*M. Fraczek, P.M. Paczkowski, M. Krawczyk, W. Otto, A. Karwowski

Medical Academy of Warsaw, Warsaw, PolandFrom 1988 to 1995 one hundred and fifty eight patients with squamous-cell esophageal carcinoma located in its thoracic part were treated in our Department. According to the preoperative staging (TNM) 84% of patients were classified as stage III/IV.The most common and most important presenting symptom was dysphagia, which occurred in 96% of patients (mean 4.6 months).Patients qualified to the operative resectional procedures included those in good general condition, in whom the weight loss have not exceed 20% of body weight.Resectional operations were carried out in 64 patients (42%). The operation of choice was the resection of thoracic esophagus with tumor as well as the lesser curvature of the stomach. Two-field lymphadenectomy (mediastinal and upper abdominal lymph nodes) was also performed. The continuity of the alimentary tract was achieved by stomach graft placed in the anterior mediastinum, with cervical esophagogastric anastomosis. In only 17% of patients the colon was used for reconstruction.Pulmonary (14 patients – 21.9%) and cardiovascular (6 patients – 9.4%) complications were significant source of morbidity following esophagectomy. Anastomotic leak occurred in 5 patients (7.8%).Early mortality (30-days) was of 19% (12 patients).One-year survival equaled 45% (29 patients). Six patients (9%) survived 3 years and 2 (3%)- 5 years.*Conclusions:*Better results of treatment of esophageal squamous-cell carcinoma depend on early diagnosis and treatment, aggressive surgical procedures and appropriately chosen adjuvant therapy (chemo- and/or radiotherapy). "P P 1 0020"P 1 0020 **Esophageal Functional Evaluation of Laryngectomees Rehabilitated with Esophageal Voice**

*S. La Manna, D. Pellicoro, G. Coppola, V. Pellegrini

III Department General Surgery–Surgery Oncology Institute of Otorhinolaryngical Pathology and Clinic and Phoniatrics, ""Federico II"" University, Naples, Italy*Aim:* laryngectomees who had laryngeal Ca and rehabilitated with esophageal voice were studied to evaluate the incidence of alterations regarding the esophageal motility and the presence of gastroesophageal reflux disease (GERD). We studied 75 patients (males, age range: 44–71 years, mean age 54 ys) with larynx Ca and who were to undergo surgical total laryngectomy and subsequent phoniatric rehabilitation with ""esophageal voice"". GERD symptoms were absent in these patients. All subjects underwent pre and post-operative study protocol (generally after six months) including: anamnesis, video-taped oesophagus-stomach Rx and manometric and 24 hours pHmetric evaluation. No patient showed GERD symptoms or pathologies. The protocol was repeated after the logopedic treatment, generally one year after the surgical intervention. Of the patients investigated: 26 (34.7%) reported GERD symptoms, 12 (16%) dysphagia, 2 (2.6%) presented hiatal, 17 (22.7%) abnormal sliding of abdominal oesophagus, 22 (29.3%) acid pathologic GER at the pHmetry, 37 (49.3%) alterations of esophageal motility. All patients were considered ""good speakers"" referring to the quality of the esophageal voice. The patients were given Omeprazole 20 mg/die and Cisapride 10 mg 4 times a day for an average period of 8 weeks. GERD symptoms were significantly decreased by this therapy in 24 pts. The result of our study showed a certain incidence of GERD and alterations of esophageal motility following the speech therapy and suggested that a therapy of prokinetics can be useful during logopedic treatment in order to avoid esophageal diseases. "P P 1 0021"P 1 0021 **Comparison of Double Neoplasms of Oesophagus and Head and Neck: Metachronous Versus Synchronous**

*J.P. Metges, O. Sparfel, M.A. Giroux, J.P. Malhaire, J.A. J\'e9z\'e9quel, J.P. Labat, H. Gou\'e9rou

F\'e9d\'e9ration de Canc\'e9rologie, Service d'ORL, CHU Morvan, 29609 Brest Cedex, FranceHead and neck neoplasms and oesophageal neoplasms have the same risk factors. They can occur in the same patient. The purpose of this study was to compare our series of metachronous and synchronous neoplasms.*Patients and Methods:* Between 1989 and 1995, 669 oesophageal neoplasms and 569 head (H) and neck (N) cancers have been treated in our institution. Fourty-eight patients had a double localization: 25 were synchronous (group I) and 23 metachronous (group II). We have compared clinical features, TNM classification, strategies of treatment, survey.*Results:* The mean age was not significantly different between the two groups: 60 yrs (group I) and 58.21 yrs (group II). In both groups, patients had alcohol and tobacco abuse. In the group I, the first localization found was oesophagus (n = 19) and H and N (n = 6). In the group II, the first localization was H and N (n = 21), oesophagus (n = 2). The oesophageal localization was principally middle third (n = 14) for the group I and upper third (n = 11) for the group II. The H and N localization was principally oropharyngeal (n = 14) in group I and oropharyngeal or hypopharyngeal (n = 14) in group II. The treatment in the group I was radio-chemotherapy (n = 19) with 14 complete responses. Radiotherapy and surgery (n = 11) for head and neck cancers and radio-chemotherapy (n = 15) for oesophageal neoplasms were the principal strategy of treatment in the group II with only 9 complete responses. The major problem was the field of radiotherapy. The survey was 16.85 months in group I and 18 months after the second neoplasm in the group II.*Conclusion:*Oesophagus is the first site found in case of synchronous neoplasm, and head and neck cancers in case of metachronous neoplasm. Main difficulties were the field of radiotherapy in the group I and few possibility of surgery in the group II. "P P 1 0024"P 1 0024 **Perioperative Immunotherapy with Recombinant Granulocyte-Colony Stimulating Factor (rhG-CSF) in Patients Undergoing Surgery for Esophageal Cancer****H. Sch\'e4fer[1], K. H\'fcbel[2], V. Diehl[2], H. Pichlmaier[1], A. Engert[2]**

[1] Department of Surgery, University of Cologne, Germany

[2] I Department of Internal Medicine, University of Cologne, GermanyNeutrophilic granulocytes play an important role in host defense mechanisms, including those of microbicide, inflammation and wound healing. We investigated the effects of rh-GCSF (Filgrastim) on the function of neutrophiles and the high infection rate in patients undergoing surgery of esophageal cancer. Here we report our results of the first 14 patients. There were 8 males and 6 females. The mean age was 60 years (range 49–75). All patients received 300 \'b5g/d (< 75 kg) or 480 \'b5g/d (> 75 kg) of Filgrastim s.c., starting on day { -}2 before surgery until day 7 after surgery. Application stopped when leucocytes increased above 50 000/\'b5l. The treatment was well tolerated. One patient was found with low grade wound healing disorder; no other complications or infections were observed. To evaluate the effect of G-CSF on neutrophil function, we measured the percent of neutrophiles with phagocytosis and the oxidative burst on day { -}2, 2 and 10. 10 patients undergoing major surgery served as controls. Phagocytosis increased in the study group (day 2: IgG-beads: +30% – 29%, Albumin-beads: +22% – 47%; day 10: IgG-beads: +9% – 47%, Albumin-beads: +28% – 82%) and decreased in the control group (day 2: IgG-beads: { -}1 – 35%, Albumin-beads: { -}1 – 19%; day 10: IgG-beads: { -}1% – 18, Albumin-beads: { -}18% – 27%). The microbicidal activity as measured by the oxidative burst was substantially higher in the G-CSF-treated study group (day 2: +219% – 167%, day 10: { -}37% – 77%) as compared with the control group (day 2: { -}11% – 55, day 10: { -}46% – 46%). In conclusion, perioperative immunotherapy using G-CSF to stimulate neutrophil function in patients with esophageal cancer might be effective to prevent infection after surgery. Enrollement is continuing. Immunology and microbiology: Inflammation }" "Perioperative Immunotherapy with Recombinant Granulocyte-Colony Stimulating Factor (rhG-CSF) in Patients Undergoing Surgery for Esophageal Cancer"

"P P 1 0025"P 1 0025 **Retrospective Analysis of Treatment of 640 Patients with Esophageal Squamous-Cell Cancer**

*V.A. Chernishov, E.I. Sigal

Clinical Cancer Centre, Kazan, RussiaThe aim was to study the immediate results of surgical and combined treatment in esophageal cancer. In 1980–1994 640 patients (523 males and 117 females) aged 46–70 years (1/3 being of 60 years and older) were treated in the centre. Superior esophageal cancer was in 33 patients, midesophageal-in 406, inferior-in 201 patients. There were 6 cases of stage I, 226-of stage IIa, 30-of stage IIb, 164-of stage III, 214-of stage IV. We have performed esophagectomy in 393 cases with 48 cases of palliative character. Resectability was 61.4%. 376 patients underwent only surgical treatment, 264-combined treatment with preoperative radiotherapy. Resectability was 56.9% and 67.8%, respectively. Esophagectomy by Torek (without primary esophagoplasty) was performed in 36 patients, with one-stage esophagoplasty through the laparothoracotomic access along with cervicotomy in 231 patients, with one-stage esophagoplasty through the transchyathalic access in 158 patients. Patients underwent esophagoplasty were 301 (using gastric tube), 63 (using solid stomach), 4 (large intestine) and 2 (small intestine). Transplant was performed postromediastinally, presternally and retrosternally in 198, 167 and 2 cases, respectively. One-stage anastomosis was fulfilled in 257 patients, long-term anastomosis in 110 patients. Esophagectomy operative mortality was 14%. Postoperative morbidity was 43%. Among the postoperative complications: pneumonia and pleuritis (17%), mediastinitis (7%), peritonitis (3%). 78 patients had cervical anastomosis failure with most cases of presternal transplant. No postoperative complication dependance upon preoperative radiotherapy was observed. The main mortality reasons were pneumonia (60%) and mediatinitis (25%) irrespective of the type of treatment. So esophageal cancer resectability increases by 10% in patients with combined treatment with no increase of postoperative complications and mortality. Oncology, general: TherapyOncology, specific: Oesophagus }"

"P P 1 0026"P 1 0026 **Tissue Polypeptide Specific Antigen in Esophageal Cancer**

*R. Pinto, Ferra M. Am\'e9lia, P. Fidalgo, A. Oliveira, Leit\'e3o C. Nobre, Mira F. Costa

Servi\'e7o de Gastrenterologia, Instituto Portugu\'eas de Oncologia Francisco Gentil, Lisbon, PortugalTissue Polypeptide Specific antigen (TPS) is a tumor associated antigen which reflects more accurately cell proliferation than tumor mass. It's clinical use has been studied in several carcinomas, with promising results. *Aim:* This study was undertaken to investigate the importance of TPS in the diagnosis and in the prognosis of the squamous cell carcinoma of the esophagus (SCE).*Methods.* Eighty two patients with SCE were included from 1989 to 1994. Staging was based upon the histopathological analysis of the ressected tumors (when ressection had been possible), thoracic and abdominal CT scan, echoendoscopy and/or bronchoscopy. Blood samples were collected in the time of diagnosis. TPS was determined by an ""in vitro"" monoclonal radioimmunoassay; the value of 70 U/L was considered the upper limit of normal. For statistical analysis of data, ANOVA and the proportional hazards survival model were used.*Results.* Seventy three patients (89.0%) were male; mean age was 61.6 – 10.3 years (40–88). In only 24 patients (29.3%) had it been possible to undertake surgical ressection. Forty four patients (53.7%) were dead, 28 (34.1%) alive and 10 (12.2%) were lost after a median follow-up of 4.5 months (range: 0–41); 22 (26.8%) were stage II, 36 (43.9%) stage III and 24 (29.3%) stage IV. TPS values were above normal in 34 patients (41.5%). TPS correlated positively with stage ($p < 0.001$) and inversely with survival ($p < 0.002$), the hazard ratio for patients with a TPS value above 70 U/L being 2.7 (95% CI: 1.4–5.1). After controlling for surgical ressectability, TPS kept it's independent prognostic significance.*Conclusions.* 1) TPS has little diagnostic accuracy in SCE. 2) TPS values correlated with stage and showed promising prognostic meaning in SCE.This research was funded in part by Beki Diagnostics AB, Bromma, Sweden. "P P 1 0027"P 1 0027 **Multiple Primary Malignancies and Oesophageal Cancer**

*H. Lombaviana, A. Correia, R. Silva, L. Dias, R. Lombaviana

Dept. of Gastroenterology, Oncology Portuguese Institute, Oporto, PortugalThe association between multiple primary malignancies, synchronous (s) or metachronous (m) is an interesting subject in Oncology. With the aim of detecting any association between the oesophageal cancer and other malignancies, the authors made a rectrospective study in 407 patients, in which oesophageal cancer was diagnosed between July 1974 and December 1995.Among these 407 patients, 20 (4.9%) had at least one other cancer associated. Sixteen patients (80%) presented metachronous malignancies and four (20%) synchronous ones. Fourteen patients (70%) were male, with an average age of 66.1 years old, and six (30%) were female with an average age of 69.6 years old. The oesophageal cancer was associated to another malignancy in 18 cases and with two other cancers in 2 cases. The time interval between the diagnostic of the metachronous primary malignancies ranged from 6 months to 27 years, with an average of 5.6 years. The follow up after the diagnostic of the oesophageal cancer ranged from 1 to 84 months, with an average of 15.7 months. The mortality at the end of the first year was 60% (12 patients) and at the end of the third year was 95% (19 patients).*Conclusions:* 1 – the occurrence of multiple primary malignancies in patients with oesophageal cancer was 4.9%; 2 – high incidence in male; 3 – higher incidence of metachronous malignancies than synchronous ones; 4 – more active association between the oesophageal cancer and others of the head and neck (50%); 5 – reduced time of follow up (15.7 months) of the patients with oesophageal cancer; 6 – very high mortality (95%). "P P 1 0032"P 1 0032 **Implantation of Nitinol Self-Expanding Stents for Palliation of Esophageal Malignant Stricture**

*G. Piccinni, A. Lippolis, M. Lospalluti, A. Scardigno, O. Caputi IambrenghiThree years' experience in positioning nitinol self-expanding-stent to restore swallowing and improve the quality of life in patients affected by esophageal malignant strictures is reported.In the period 1993–95 eleven patients were treated: five affected by non-resectable lung cancer, four by esophageal cancer and two for cancer of the cardia. All patients had a 3 or 4 grade dysphagia. We always used ULTRAFLEX stents (MICROVASIVE-Boston Scientific Corp. Watertown MA). In the last two patients we positioned a coated self-expanding stent of the same type. The stents were perorally implanted after mild sedation and under combined endoscopic and fluoroscopic guidance; when necessary previous balloon dilation was performed. To evaluate the success of palliation the Grading system of Dysphagia (DG) and Quality of Life Index (QLI) were used.All endoprostheses expanded at a diameter of 14–20 mm. within 24 hrs. and an immediate improvement of dysphagia was achieved (a DG score reduction was observed). One patient died for cardiorespiratory failure 3 days after stenting. The average follow-up of the surviving ten pts. was 97 days (range 30–360): the QLI varied from 5 to 9 with an improvement of nutritional parameters (Lymphocite count, Albumin, Cholinesterase and Weight). Three pts. presented an episode of stent-obstruction within 3 months; in two cases the obstruction was caused by cancer ingrowth, in the third by food impaction. All were treated endoscopically.The application of Nitinol Self-Expanding Stents, seems to offer safe, fast and effective palliation of malignant dysphagia. "P P 1 0035"P 1 0035 **Argon Plasma Coagulation in Palliative Treatment of Malignant Dysphagia**

*W. Niezychowski, J. Regula, J. Fijuth, K. Przytulski, E. Butruk

Department of Gastroenterology and Department of Brachytherapy, Institute of Oncology, Warsaw, Poland*Aim of study*Argon plasma coagulation is a new method of non-contact destruction of tissues by means of argon gas. Argon applicator can be introduced through the biopsy channel of the standard endoscope. The aim of this study was to evaluate the efficacy and safety of this technique in palliative treatment of malignant dysphagia.*Methods*23 patients (19 M, 4 F, age 45–85) with oesophageal malignancy (13 adenocarcinoma, 10 squamous-cell carcinomas) not suitable for radical treatment were followed prospectively. Five of them presented with dysphagia causing inability to swallow some solids (grade I), six could swallow semisolids (grade II) and eleven swallowed liquids only (grade III). One patient declared aphagia. Argon plasma coagulation was applied in several sessions every 2–3 days. Seven patients had oesophageal dilation with Savary-Gilliard bougies up to 13 mm prior to coagulation.*Results*Complete remission of dysphagia as a result of treatment was achieved in 17 patients. Five other patients had improvement in swallowing (one grade at least). These results were achieved after 1 to 6 sessions of argon plasma coagulation. In one patient treatment had to be terminated because tracheo-oesophageal fistula had occurred. The perforation in the tumour region was observed 7 days after treatment in another patient. No other complications were encountered.*Conclusion*Argon plasma coagulation appeared to be an effective method in palliative treatment of oesophageal malignant stenoses. Although argon beamer causes only 2–3 mm deep tissue damage, the procedure may be complicated by tracheo-oesophageal fistula formation or delayed perforation in the region of the tumour. "P P 1 0036"P 1 0036 **Small Cell Carcinoma of the Oesophagus: a Ten-Year Experience 1986–1996**

*J. Goh, H. Fenlon[1], J.C. O'Keane[2], D. Carney[3], P. MacMathuna

Departments of Gastroenterology

[1] Radiology

[2] Histopathology and

[3] Medical Oncology, Mater Misericordiae Hospital, Dublin, IrelandExtrapulmonary small cell carcinoma is becoming more recognised. Small cell carcinoma of the oesophagus (SCOO) is rare and distinct from the squamous cell or adenocarcinoma variety. No more than 200 cases of SCCO have hitherto been reported.We present data on 6 cases of SCCO accounting for 1.84% (6/326) of all primary oesophageal carcinomas seen during a ten year period (1986–1996). Mean age at presentation was 65.3 years (range 49–76) with an equal sex ratio. All patients presented with dysphagia and weight loss while three described odynophagia. Mean time between onset of symptoms and presentation was 15.2 weeks (range 6–24). Putative risk factors include heavy cigarette smoking in 5/6 and previous radiotherapy in 1 patient. The diagnosis of SCCO was made histologically with a primary pulmonary tumor excluded on the basis of a negative CT thorax. 4/6 tumours were located at the lower third of the oesophagus. The tumours took the form of an ulcerated stricture (n = 4) and sessile polyps (n = 2). All but one patient had metastatic disease at presentation. Five were treated with single (VP16) or combination (VAC) chemotherapy. Two underwent palliative endoprosthesis insertion, one receive adjuvant radiotherapy while another had undergone an oesophagectomy at the referring hospital. Overall survival was 7.27 months (range 10 days to 17 months) with only and patient alive at 6 months without metastatic disease.*Conclusion.* Histology of oesophageal lesions showing small cell carcinoma does not imply pulmonary invasion. SCCO presents late and its natural history and prognosis resemble those of its pulmonary counterpart. Chemotherapy and endoscopic palliation may be beneficial. "P P 1 0037"P 1 0037 **Conservative Treatment of Oesophageal Perforations after Endoscopic Palliation in Advanced Oesophageal Cancer**

*T. Bisgaard, M. W\'f8jdemann, H. Heindorff, L.B. Svendsen

Dept. of Surgical Gastroenterology, Rigshospitalet, Copenhagen, Denmark*Purpose:* The aim of the study was to evaluate the effect of conservative treatment of oesophageal perforations due to endoscopic palliation in patients with unresectable oesophageal or cardiac cancer.*Methods:* From January 1993 to January 1996, 148 consecutive patients with advanced oesophageal or cardiac cancer were subjected to a total of 686 palliation procedures (argon plasma electrocoagulation, Nd:YAG laser photogoagulation, dilatation, intubation and stenting procedures). When palliation-related perforations were diagnosed, patients received conservative treatment: Broad spectrum antibiotics, fasting and nasogastric suction. Pneumothorax or pleural effusions were drained. Stenting or intubation was also regarded as conservative treatment.*Results:* Perforations were seen in 9 patients (6%) corresponding to 1% of palliation procedures. The mean time lap between perforation and treatment was 30 hours (1–56 hours). Conservative treatment succeeded in 6/8 patients (75%) and the perforation-related mortality after conservative treatment was 1/8 (13%). One patient died without further treatment due to age and poor general condition prior to palliation. Two patients did not respond to the conservative treatment (1 patient developed a tracheooesophageal fistula and 1 patient developed pleural empyema, and decortication with drainage was performed).*Conclusions:* Conservative treatment of oesophageal perforations seems sufficient in selected patients with advanced oesophageal or cardiac cancer. Clinical practice: Management strategyOncology, specific: OesophagusEndoscopy, general: Complications }" "Conservative Treatment of Oesophageal Perforations after Endoscopic Palliation in Advanced Oesophageal Cancer"

"P P 1 0042"P 1 0042 **Preoperative Chemotherapy and Concurrent Irradiation for Localized Esophageal Carcinoma: Results of a Phase II Study**

*M. Ychou, P. Senesse, C. Debrigode, P. Rouanet, F. Quenet, S. Salas, B. Saint Aubert, C. Astre, J.B. Dubois

C.R.L.C. Val d'Aurelle- Montpellier- France*Purpose.* A prospective phase II study to determine the outcome of patients (pts) with oesophageal cancer who receive preoperative chemoradiotherapy.*Patients and methods.* Between January 1992 and October 1994, 46 pts, with localized esophageal carcinoma were treated with chemotherapy and concurrent external beam irradiation followed by esophagectomy. Each patient received two courses of chemoradiotherapy on day 1 to 5 and on day 21 to 25. Chemotherapy consisted of leucovorin 200 mg/m^2/d followed by 5 FU 400 mg/m^2/d in one hour infusion and Cisplatinum 70 mg/m^2 on day 2. Irradiation was delivered one hour after 5 FU, at 3 Gy per fraction for a total dose of 30 Gy. Twenty three pts had lesions measuring 5 cm or less, 20 had lesions measuring more than 5 cm and data was unknown in 3 cases. Thirty two pts had squamous cell carcinoma and 14 had adenocarcinoma.*Results.* Forty three pts underwent surgical procedure (2 pts died during chemoradiotherapy and 1 became metastatic), 32 had a complete resection and 18% of these pts had no or minimal residual tumor. Post operative mortality rate was 11.6%. The median survival and the 2 years survival were respectively 21 months and 45% for all pts and 44 months and 66% for resected pts. The disease-free survival for the 32 resected pts was 28 months. In the univariate analysis, 3 factors are statistically correlated with a better survival: weight loss less than 10% ($p = 0.005$), complete tumoral resection ($p < 0.001$) and complete or major pathologic response ($p = 0.001$).*Conclusion.* This multimodality treatment for oesophageal carcinoma seems to be efficient in well selected patients but needs further comparative studies. "P P 1 0043"P 1 0043 **Severe Radiation-Related Pericarditis after Postoperative Concomittant Radio-Chemotherapy for Esophageal Cancer**

*G. Savoye[1], B. Paillot, P. Michel[1], J. Heintz[2], S.H. Seng[2], A.M. Queuniet[2], A. Kunlin[2], J.P. Dauce[2], Ch. Duval[2]

[1] Centre des Tumeurs Digestives, Hospital Ch. Nicolle, 76031, Rouen Cedex, France

[2] Centre H. Becquerel, 76038 Rouen Cedex, FranceLocal failures and metastases are often observed in esophageal cancer and this has induced a great interest for a multimodality approach including radio and chemotherapy. We report a dramatic pericardic complication in order to point out the importance of the dose fractionation and the schedule of the therapeutic sequences.Between March 1983 to December 1993, two phase II studies were performed and forty consecutive patients were included after curative resection. 20 patients (Gr 1) received a split course radiotherapy using a daily dose of 4 Gy on day 1 to day 5 for two cycles. D1 to D1 was 21 days (total dose 40 Gy) and chemotherapy on D1 was cisplatin 100 mg/m2 IV for 6 cycles. D1 to D1 was 21 days and 2 cycles were concomittant to radiation therapy. 20 patients (Gr 2) received a split course radiotherapy using a daily dose of 2 Gy on day 1 to day 12 of two cycles. D1 to D1 was 28 days (total dose 40 Gy) and chemotherapy cisplatin 75 mg/m2 on D1 and 5FU 750 mg/m2 in continuous infusion D1 to D5. Six cycles were performed D1 to D1 = 28 days. The 2 first were concomittant of radiotherapy.Both groups were similar for age, sex distribution, weight loss, serum albumin rate, location of tumor and pathologic findings according to UICC 1987. The median survival was 19 months in group 1 and 18.3 in Gr 2. 6 cases of tamponnade were observed, all in group 1, with a mean time between irradiation and occurrence of ten months (range 6–14). All patients need pericardical evacuated punction in emergency because of hemodynamic failure, and 5 patients underwent a partial pericardectomy. All patients developed pleural effusion. No case of clinical pericarditis was detected in Gr 2 ($p < 0.02$).We conclude that a split course radiation using a daily dose of 4 Gy is not be used after surgery. If combined therapy is performed it could take place either before surgery with this regimen (Gignoux Ann Chir 1987) or in the postoperative period, but at a lower daily dose.

*A. Coutinho, C. Baptista, R. Albuquerque, A. Figueiredo, C. Machado, B. Rodrigues, M. Ramos, A. Mouro, W. Ferreira, M. Quina

S. Medicina III, S. Anat. Patol\'f3gica, H. Pulido Valente Dep. Microbiologia–FCML, Lisboa, Portugal*Purpose:* to study the relation of characteristic histological features of chronic hepatitis C, with HCV genotypes, their eventual correlation with ALT and GGT values, and Knodell Index. *Methods:* the study includes a group of 40 patients (24 M, 16 F; mean age: 44.0 – 15.5 years) with the diagnosis of chronic hepatitis C, confirmed by serological tests (RIBAIII-Chiron), presence of RNA-VHC (PCR-Amplicore) and liver biopsy. Epidemiological inquiry revealed prior history of transfusion (27.5%), IV drug use (30%), and sporadic hepatitis (42.5%). HCV genotype was determined with a line-probe assay (LiPA-Innogenetics), in accordance with Simmonds classification. *Results:* HCV genotype distribution in this patient group was similar to the usually observed in the portuguese population: 1a–22.5%; 1b–45%; 2a–2.5%; 3a–12.5%; mixed infection (all with 1b)–17.5%. Conventional histological diagnosis revealed: Ch. persist. H-15%; Ch. lobular H.-5%; Ch. active H.-57.5%; liver cirrhosis-22.5%. HCV morphological features were observed as follows: lymphoid aggregates (LA)-62.5%; acidophil bodies (AB)-67.5%; perisinusoidal lymphocites (PL)-20%; bile duct lesions (BDL)-55%; steatosis (STE)-45%. Genotype 1b was more prevalent in the presence of LA and PL and also, more often associated with the absence of BDL and STE (SS- Chi-sq). However, the higher proportion of liver cirrhosis in the genotype 1b patients (27.8%), could have biased the latter data, for loss of typical HCV features due to architectural distortion. A significant correlation between ALT and BDL score was found (linear regression: $r = 0.397$; $p = 0.001$); there was no correlation between any of the 5 specific features and Knodell Index and its subscores (inflammation; fibrosis). *Conclusions:* HCV genotype association with the rate of disease progression, suggested by the higher rate of liver cirrhosis in 1 b patients, may be related to different prevalence of specific morphological lesions, namely lymphoid aggregates. Liver and bile ducts, 1: Hepatitis viral, diagnosis }" "Histological Features of Chronic Hepatitis C and HCV Genotype: Correlation with Biochemical Data and Knodell Index"

*P. Peixe[1], M. Parente, J. Vaz Patto, H. Madeira, M. Micaelo, H. Santos, M. Marques Silva, A. Vilar, G. Peixe[1]

Department of Gastrenterology, Instituto Portugu\'eas de Reumatologia, Lisbon, Portugal

[1] Department of Gastrenterology, Hospital Egas Moniz, Lisbon, PortugalHepatitis C infection may induce several immune alterations including rheumatoid factor and type II cryoglobulinemia production. The purpose of our study is to find the prevalence of HCV in a miscellaneous of rheumatic diseases and detect a pattern to suspect the virus presence in this population. *Methods:* We performed a longitudinal study in 279 patients, aged 53.7 – 15.3 years followed at a rheumatology outpatients clinic, regarding ALT, AST, Alkaline Ph, { g}GT, leukocyte count, anti-nuclear antibody (ANA), rheumatoid factor (RF), HCV determination by ELISA (3rd gen.) and RNA by PCR. An hepatic biopsy was performed in patients RNA+. We considered 5 major groups of rheumatic diseases: osteoarthrosis (n = 43), fibromyalgia (n = 30), Rheumatoid arthritis (n = 61), Sj\'f6gren's Syndrome (n = 27), miscellaneous (misc) not belonging to any of the previous groups (n = 118). *Results:* OA (43) Fibrom (30) pSS (27) RA (61) Misc (118) Total (279)HCV (Elisa) 2.3% 3.3% (1) 11.1% (3) 9.8% (6) 16.1% (19) 9.7% (27)RNA (PCR) 2.3% 3.3% 0% 8.2% (5) 8.5% (10) 6.5% (18) RF+ ANA > 1/160RNA+ in ""Misc. Group"" (10/118) 80% (8) 40% (4)*Conclusions:* We found a higher prevalence of HCV in a heterogeneous group of 118 patients (16.1%), associated frequently with immunological alterations: Mixed Cryoglobulinemia (3), Cutaneous vasculitis (3), Weber-Christian Disease (1), Peripheral neuropathy (1), Primary Biliar Cirrhosis with Sj\'f6gren S. (1), Oligoarthritis (2), MCTD (1), SLE (1), Carpal syndrome (1), Poliarthralgias (1), osteoporosis and tendinitis (3). }" "Hepatitis C and Rheumatic Diseases"

"P P 2 0049"P 2 0049 **Prevalence of a Positive Pathergy Test in Patients with Chronic HCV InfectionO. Uzunalimoglu, H. Cetinkaya, H. Bozkaya, C. Yurdaydin, H. Erverdi, A. Gurler, S. Cagsin, S. Karayalcin**

Ankara University, School of Medicine, Division of Gastroenterology, Ankara, Turkey*Background:* Chronic HCV infection has been found to be associated with several extrahepatic diseases including mixed cryoglobulinemia, Sjogren syndrome, and Behcet's disease all of which are characterized by vasculitis. Positive pathergy test, a cutaneous hyperreactivity reaction characterized by vasculitis, is detected in 60–92.5% of patients (pts) with Behcet's disease while only 1% of normal population and 1.5% of disease controls including chronic liver disease have positive reaction in Turkey.*Aim:* To evaluate the prevalence of positive skin pathergy test in pts with chronic HCV infection.*Patients and Methods:* Sixty pts, 32 female, 28 male, mean age 50.5 yr, 48 with chronic hepatitis, 11 with cirrhosis and 3 with chronic hepatitis + cirrhosis were studied. HCV infection was diagnosed by using both anti-HCV (ELISA) and HCV RNA (PCR) determinations. None of the pts had co-existing Behcet's disease. Pathergy test was performed by intradermal injection of 0.1 ml sterile saline in five different locations and a positive result was defined as occurrence of erytema, papule and pustule at the injection site 48–72 hrs after the injection.*Results:* Eleven of 60 pts (18%) had a positive skin pathergy test. This ratio was significantly higher compared to those seen in normal (1%) and disease controls including liver diseases (1.5%) in Turkey. Light microscopy showed a vasculitis in 9 of 11 pts (82%). Cryoglobulinemia was found in only 4 of 60 pts (6.6%) and 1 of 11 pts (9%) with a positive pathergy reaction had cryoglobulinemia.*Conclusion:* A positive pathergy test is more frequently seen in patients with chronic HCV infection compared to normal and disease controls and may represent an extrahepatic phenomenon associated with HCV infection. Further studies are ongoing to determine the immunohistological characteristics of the pathergy reaction in this group of patients. Liver and bile ducts, 1: Hepatitis viral, diagnosis }" "Prevalence of a Positive Pathergy Test in Patients with Chronic HCV Infection"

"P P 2 0050"P 2 0050 **Infants and Neonates Screening for Hepatitis C Virus Infection**

*Abou EL Magd Enas, EL Rashidi Zeinab, Saad Eldin Kouka, Khalifa Ahmed, Nabawy Zekry Abdel Rahman

Faculty of Medicin for Girls, Al-Azhar University, Cairo EgyptThe aim of this study was to screen infants borne to anti-HCV seropositive and seronegative mothers for evidence of HCV markers.Symptoms free 61 mother infants pairs were classified into 4 groups according to infant's age. Blood samples were taken from all mothers and infants. Saliva samples was collected from all infants.Collective and specific (core, NS3, NS4 and NS5) IgG anti HCV antibodies, IgA and IgM anti HCV antibodies by ELISA test, HCV RNA by RT. PCR and HCV antigen in lymphocyte Lysate by Dot ELISA test were done.Eight out of 61 (13.1%) of mothers were seropositive for collective IgG anti HCV antibodies, 5 of them were seropositive for IgG anti-core and NS3, 4 of them were seropositive for IgG anti NS4 and only one was seropositive for IgG anti NS5. 5 mothers were seropositive for IgG anti-core, NS3 and HCV RNA. Only 4 had infants who were seropositive for IgG anti HCV core and NS3 but only 3 were seropositive for IgG anti NS4 and only one was Seropositive for IgG anti HCV (NS5). HCV RNA were detected in 2 out of 4 IgG anti HCV seropositive infants. The same 2 infants were also positive for HCV Ag in Lymphocyte Lysate, but only one was positive for salivary IgA anti-HCV. All seronegative mothers and infants for IgG anti-HCV were also negative for HCV RNA and other markers tested.In conclusion mother to infants transmission of HCV does exist. Clinical practice: Epidemiology (non cancer)Liver and bile ducts, 1: Hepatitis viral, diagnosis }" "Infants and Neonates Screening for Hepatitis C Virus Infection"

"P P 2 0051"P 2 0051 **Hepatitis C Virus Infection among Medical Personnel**

*El Sherif Ahmas, El Sherif Assem, Saad Eldin Kouka, Aal Maged Abdel, El Shinnawy Gamal

Faculty of Medicine, Al Azhar University, Cairo, EgyptThe aim of the present work was to study the prevalence of HCV seromarkers indicative of past or current infection of medical personnel as a high risk group.This study was carried out on 202 volunteer medical and paramedical staff members working in different hospitals and medical institutes. Sera were collected and tested serologically for HCV-antibodies using 3rd generation ELISA Technique and the positive cases were subjected to PCR test, liver function tests, HBsAg and abdominal ultrasonography. Saliva samples were also obtained and examined for anti-HCV.The results revealed that anti-HCV was detected in 13.86% of the medical personnel while only 4.95% of them showed positive PCR reaction indicative of viraemia. A significant increase in the frequency of anti-HCV was noticed with increasing age and duration of employment. A positive correlation was also found between the serum level of anti-HCV (optical Density Level) and the presence of anti-HCV antibodies in saliva.From this study, it is obvious that frequent contact with blood, blood products and body secretions during health care practice carries a definite risk of HCV transmission as high frequency of HCV seropositivity was found among laboratory personnel. Clinical practice: Epidemiology (non cancer)Liver and bile ducts, 1: Hepatitis viral, diagnosis }" "Hepatitis C Virus Infection among Medical Personnel"

"P P 2 0052"P 2 0052 **HCV Genotypes in French Haemophiliacs: Kinetic and Reappraisal of Mixed Infections**

*R. Tuveri, C. Rothschild[2], S. Pol[3], T. PersicoC. Gazengel[2], C. Br\'e9chot, V. Thiers[1]

[1] INSERM 370 Necker and CBMS, Pasteur Institute, Paris France

[2] Hemophilic Center F. Josso Paris France

[3] Hepatology Unit Necker Hospital Paris France

[4] Dept. of Public Health U of Cagliari Italy

[5] Dept. Obstetric and Gynecology U of Milan Italy*Aims:* The aims of this study were to investigate the distribution and kinetic HCV genotypes and prevalence and molecular bases of mixed infections, among haemophiliacs repeatedly exposed to non-virus inactivated clotting factor. *Patients and methods:* We analysed 45 patients with A or B haemophilia or Von Willebrand's disease (37, 7, 1 respectively). All were anti-HCV positive, 21/45 also anti HIV1 positive. For evaluation of HCV genotype dynamics, serum samples from 36 haemophiliacs were genotyped two times with a mean of 98.3 months follow up (min = 56–max = 171). We analysed the HCV genotype in the core and 5{\'a2} untranslated regions by means of modified core method and InnoLiPA assays, respectively. Serotyping assay based on the detection of type specific NS4 antibodies was performed for 43 patients. *Results 1) HCV genotype prevalence:* We revealed genotypes 1 (n = 23: *51%,* 1a n = 10: *22%,* 1b n = 13: *28%*); 2 (n = 10: *22%,* 2a n = 3, 2b n = 4 2NC n = 3), and 3a (n = 10: *22%*). *2) ""Mixed infections"":* Genotyping in 5{\'a2}UTR revealed 2/8 mixed infections (1a + 1b and 2nc + 3a). Our core modified method showed 8/45 mixed infections: 6/8 1a + 1b and 2/8 3 + 2. By designing new primers more specific to HCV types 1a and 1b we could confirm such 1a + 1b mixed infection in only 1/6 cases. This result was also confirmed by direct sequencing. *3) Evolution upon time:* Only 5/33 haemophiliacs showed a change of genotype during follow-up: 2 from 1a to 1b, 1 from 1b to 1a, 1 from 1a to 2a and 1 from 1b to 3a. *4) Serotyping:* Seventeen of 21 anti HIV-patients showed concordance with 5{\'a2}UTR genotype; only 6/19 anti HIV+ patients showed detectable serological reactivity. 3 serum samples showed reactivity toward 2 HCV types, whereas genotyping assays only revealed 1 type in these three cases. *Conclusions:* We have 1) observed a similar HCV genotypes distribution between French haemophiliacs and non-haemophilic HCV+ patients; 2) demonstrated the difficulties to assess with the available genotyping and serotyping assays the real prevalence of mixed infections in polytransfused subjects. "P P 2 0053"P 2 0053 **Analysis of the Core Region of HCV Genome Isolated from Patients with Chronic Hepatitis C during Intervals of Normal ALT Concentration**

*K. Arataki, T. Nakanishi, T. Ohbatake, J. Matsuo, T. Moriya, G. Kajiyama

First Department of Internal Medicine, Hiroshima University School of Medicine, Hiroshima, JapanThere are several reports on hepatitis C virus-specific cytotoxic T lymphocytes (CTLs) recognizing an epitope in the core region. In this study, we determined core region nucleotide sequences of specimens from patients with chronic hepatitis C during intervals of normal ALT concentration without treatment.*Materials and Methods:* Six patients analyzed in this study had chronic hepatitis C and their ALT concentrations had remained normal for more than one year without treatment. In one patient, we were able to compare the amino acid sequence during normal ALT concentration with that during elevated ALT. The core region of the HCV genome was amplified by the PCR. PCR products were then cloned. At least 5 independent clones were sequenced.*Results:* In 2 of the 6 patients, some clones that could be sequenced showed deletions. In 3 of the 6 patients, most of the isolated clones that could be sequenced had mutations at specific amino acids. When the ALT concentration was normal, we could sequence 10 independent clones. However, when the ALT concentration in the same patient was elevated, six of ten clones that could be sequenced were equivalent to one clone that was obtained during normal ALT concentration.*Conclusion:* These results suggest that expression of the wild-type HCV core region genome as well as diversity of the HCV core region genome was associated with liver cell damage. Immunology and microbiology: Host defense mechanismsImmunology and microbiology: Inflammation }" "Analysis of the Core Region of HCV Genome Isolated from Patients with Chronic Hepatitis C during Intervals of Normal ALT Concentration"

"P P 2 0054"P 2 0054 **Relationship between Hepatitis C Virus (HCV) Genotypes and Sources of Infection in a Sample of Patients from Northern PortugalT. Vasques[1],**

*J.A. Sarmento[2], F. Carneiro[1], G. Macedo[2], A.M. Vale[2], J.I. Riezu[3], T. Ribeiro[2], J. Prieto[3]

[1] Institute of Molecular Pathology and Immunology of University of Porto (IPATIMUP), Medical Faculty, Porto, Portugal

[2] Gastroenterology Unit of H. S. J., Porto, Portugal

[3] Internal Medicine, University of Navarra, Pamplona, Spain*Aims:* To study the relationship between HCV genotypes and gender, age, and putative source of HCV infection, in a sample of patients from northern Portugal.*Patients and methods:* The present study included 143 patients anti-HCV-positive (ELISA) (94 men, mean age 43 – 15 years) referred to H.S.J. between 1989/95. Patients were divided according to age ({\'a3} 40 years and > 40 years) and source of infection (past history of blood transfusions (BT), intravenous drug users (IVDU) and unknown cause of infection (UCI)). HCV-RNA was detected in serum by nested PCR with primers directed to the 5{\'a2}-UTR. Genotyping was performed by means of a hybridization procedure using specific probes for HCV genotypes 1a, 1b, 2, 2a, 2b, 3a and 4, according to Simmonds *et al.* and the amplified nested PCR product of the HCV Core region. The Qui-square method was used to statistical analysis.*Results:* HCV-RNA was detected in 119/143 patients (83.2%) and genotyping was done in 107 patients from the latter group: 1a (17.8%); 1b (53.3%); 2 (2.8%); 3a (19.6%); 4 (2.8%), 1b + 2b (1.9%); unclassifiable (1.9%). The statistical analysis was performed after excluding double infections and unclassifiable genotypes: Genotypes (%) n 1a 1b 2 3a 4 p valueAge {\'a3} 40* 41 36.6 19.5 0.0 39.0 4.9Age > 40 62 6.5 79.0 4.8 8.1 1.6 < 0.0001Male 71 18.3 50.7 2.8 25.4 2.8Female 32 18.8 65.6 3.1 9.4 3.1 n.s.BT 16 18.8 50.0 0.0 31.3 0.0IVDU 22 36.4 4.5 0.0 50.0 9.1UCI 65 12.3 73.8 4.6 7.7 1.5 < 0.0001*IVDU in this group (51.2%) was higher (p = 0.0001) than in > 40 years (1.6%).*Conclusions:* I. Genotype 1b was the most prevalent in this sample; 2. Genotype distribution by source of infection showed predominance of genotype 3a in IVDU group, in contrast with the predominance of genotype 1b in the other two groups (BT and UCI); 3. Differences in genotyping distribution by age probably reflect the predominance of IVDU in the group of patients younger than 40 years. Clinical practice: Epidemiology (non cancer)Liver and bile ducts, 1: Hepatitis viral, diagnosis }" "Relationship between Hepatitis C Virus (HCV) Genotypes and Sources of Infection in a Sample of Patients from Northern Portugal"

"P P 2 0055"P 2 0055 **Glucose Tolerance, and Insulin and C-Peptide Response to Glucose Load in Chronic HCV Infection**

*F. G\'fcnsar, U.S. Akarca, G. Ers\'f6z, O¨ Topalak, Y. Batur, M. T\'fcz\'fcn, U. Ege

Medical School, Dept of Gastroenterology, Izmir, T\'fcrkiyeDiabetes mellitus (DM) has been found often in patients (pts) with chronic HCV infection (HCVi). Although it has not been investigated in detail, it is suggested that this association is a manifestation of autoimmune extrahepatic disorders of HCVi. To clarify the glucose metabolism in HCVi, in this continuing study we studied 39 patients with biopsy proven HCVi (23 noncirrhotics, 16 with compensated cirrhosis), 10 controls, 17 patients with chronic HBV infection with/without (7/10) cirrhosis. OGTT with serum insulin and C-peptide determination with related parameters were studied and compared between the groups. Anti-insulin (AIA) and anti-insulin receptor (AIRA) antibodies were also determined along with the other autoantibodies. The other parameters which can effect the glucose metabolism were also accounted for in the statistical evaluation.*Results:* 1) Of 23 HCVi pts without cirrhosis, 2 were diabetics (9%) and 2 (9%) had glucose intolerance (the rates were not different from in pts with noncirrhotic B hepatitis and controls). Five (31%) cirrhotic pts diabetics and 3 (19%) had glucose intolerance. 2) Glucose values during the OGTT were not different between the groups. 3) Basal insulin and C-peptide levels were found to be higher in noncirrhotic (0.370 – 0.122 nmol/l and 0.867 – 0.103 nmol/l) and cirrhotic patients (0.275 – 0.037 nmol/l and 1.338 – 0.177 nmol/l) with HCVi than in controls (0.144 – 0.069 nmol/l and 0.216 – 0.204 nmol/l) (basal C-peptide values was also higher in cirrhotics ($p < 0.05$)). 4) C-peptide increment during OGTT was blunted in pts with HCVi either cirrhotics or noncirrhotics while the insulin values were higher in these patients than in controls. 5) Peak insulin response in pts wig HCVi was more strong comparing with the pts with chronic B infection. 6) Of 15 chronic HCV infection pts studied 5 had anti-insulin antibodies (33%); none of the pts in controls and with HBV infection had AIA. AIRA was found to be negative in each pts. The parameters studied were not different between the pts who were AIA positive and negative. *Conclusions:* 1) The prevalence of diabetes mellitus was not higher in pts with chronic HCV infection if they have no cirrhosis. 2) The glucose metabolism in the pts with HCVi is similar with that observed in cirrhosis in general (increased basal insulin and C-peptide values, increased insulin but blunted C-peptide response following glucose challenge and insulin resistance). 2) Although AIA may be positive in some patients, DM if occurrs in chronic HCV infection seems to be due to the liver damage, at least partly. Liver and bile ducts, 1: Hepatitis viral, diagnosis }" "Glucose Tolerance, and Insulin and C-Peptide Response to Glucose Load in Chronic HCV Infection"

"P P 2 0056"P 2 0056 **HCV Genotypes in Relation to Age, Sex and Period of InfectionS. Lobello, D. Infantolino[1], R. Biasin[1], U. Lorenzoni, A. Floreani, A. Vian, R. Naccarato, M. Chiaramonte**

Dept. of Gastroenterology, Padua University, Italy

[1] Dept. of Patology, General Hospital Castelfranco V., ItalySo far, HCV genotypes had been variably correlated to the severity of liver disease, to the prognosis, to the route of infection, to the patient age and the geographical origin. Few studies, however, correlated genotypes to epidemiological clusters or to secular trends of infection.To verify the possible epidemiological clusters and/or secular changes in the genotype spread we studied 120 HCV-RNA positive patients, all caucasians, living in North-East Italy and we correlated HCV genotypes to age, gender, place of birth and area of residence, route of infection and attributable infection period. Epidemiological data were collected before HCV genotype test. HCV-RNA was determined by RT-PCR and genotype was named in accordance with Simmonds' classification.*Results:* Genotype 1b was the most frequent (56%) followed by the 2c (20%), 3a (11%), 1a (8%), 2a (2.5%), 4 (2.5%). 1b 2c 3a 1a 2a 4N 67 24 13 10 3 3M/F 1.0 2.4 3.3 4.0 0.3 2.0Year of birthbefore 1945 69% 50% 8% – 67% -after 1945 31% 50% 92% 100% 33% 100%Infection periodbefore 1970 63% 75% – – 100% -1970–1980 27% 13% 31% 50% – -after 1980 10% 12% 69% 50% – 100%*Conclusions:* Genotype 1b was more frequent in more aged patients with suggestions of old infection by parenteral inapparent routes. Genotype 2c was distributed in the old ages and was related mostly to iatrogenic factors. Genotypes 3a and 1a were more frequent in young males and related to drug addiction. These data are consistent with the hypothesis of secular changes in HCV genotype spread. Liver and bile ducts, 1: Hepatitis viral, diagnosis }"

"P P 2 0057"P 2 0057 **Soluble IL2 Receptor Levels in Peripheral Blood of Patients with Chronic Hepatitis and Asymptomatic Hepatitis Virus Carriers —in Special Comparison with B type and C Type—Hiroaki Ishimaru**

!st Dept of Intern Med, St. Marianna Univ School of Med, Kwasaki, JapanIt is known that soluble IL2R (sIL2R) levels in peripheral blood can be used as index of activated T cells. In present study, IL2R levels were measured in peripheral blood of patients with chronic hepatitis positive for HBV or HCV and asymptomatic carriers, using EIA kits for sIL2R measurement.*(Subjects and Methods)* Cases with chronic hepatitis (CH) and asymptomatic carriers (ASCs) were positive for HBV or HCV. Classification (CIH, CAH IIa, CAH IIb) of CH was done due to basis on histological findings, and ASC was diagnosed due to normal level of serum transaminase for two years, non-increased level of { g}-globulin and normal finding of liver and spleen by abdominal US. In methods, sIL2R in peripheral blood was measured, using cell-free IL2R measurement kit of EIA (T cell diagnostics company).*(Results)* In HBV carriers, serum sIL2R revealed normal to high levels in order of ASC, CIH and CAH. In HCV carriers, sIL2R revealed the increased levels in each group., which were higher in later in order of ASC, CIH and CAH. The level of sIL2R was higher in C-ASC rather than in B-ASC. In fatty liver with increased level of serum transaminase, it was within normal range. Furthermore there was the significantly positive relationship between the levels of serum sIL2R and transaminase. There was not the significant change of serum transaminase levels at an interval of several months. sIL2R showed the significant high level one week after start of IFN-{ a} therapy, compared with one before it. The change was similar to one of ratios of T cell subsets positive for IL2R on the membrane. The levels of sIL2R and transaminase were lower two months after start of SNMC (glycirrhycin) – intravenous injection, compared with ones before it. Next capacity of IL2 production in peripheral blood mononuclear cells (PBMN) increased in B-CH and B-ASC and in C-CAH IIb. Capacity of IL2R response in PBMN was not significantly different between each group.*(Conclusion)* Circulating sIL2R levels either in HBV or HCV carrier were higher in CH than in ASC, and increased in progression of CH. In comparison with HBV and HCV carriers, it was suggested that the activation of T cells might be accerelated in HCV carrier rather than in HBV carrier. }" "Soluble IL2 Receptor Levels in Peripheral Blood of Patients with Chronic Hepatitis and Asymptomatic Hepatitis Virus Carriers /in Special Comparison with B type and C Type/"

"P P 2 0058"P 2 0058 **Cirrhosis, HCV Infection and Diabetes MellitusG. Macedo, A. Correia, N. Fernandes, H. Queiroz, J. Pires, T. Pinto, J.A. Sarmento, A.M. Vale, T. Ribeiro**

Gastro Unit and Faculty of Medicine, Porto, Portugal*Introduction and aim:* It is known for long the association between cirrhosis, glucose intolerance and Diabetes Mellitus (DM), and several contributive factors have been proposed: hyperinsulinemia, insuline resistence, reduced glucose uptake by cirrhotic livers. In cases with pancreatic disease associated (hemochromatosis, alcoholism) or with underlying autoimmune disorders, DM is a common observation. As HCV infection is associated with autoimmune phenomena, and being clinically observated a high prevalence of DM in those patients, we compared the prevalence of DM in cirrhotics from different etiologies.*Material and methods:* In a retrospective study of 95 cirrhotic patients, several parameters were registered: age, sex, etiology, HCV, DM, steroids use, B blockers use. DM diagnosis was based upon the need for oral hypoglicemic ajunt or insuline, or glucose > 12 mmol/l.*Results:* The distribution of etiology and DM prevalence was: Diagnosis Nr. of cirrhotics Nr. of DM patientsAlcohol 38 4 (11%)HCV 28 15 (54%)HBV 13 1 (7%)PBC 5 0 (0)Hemoc. 5 4 80%Crypto. 4 0 (0)PSC 2 0 (0)No patient had been on B blockers before DM diagnosis, and one had been treated with steroids for uveitis.*Conclusion:* DM prevalence is significantly higher in HCV cirrhotic patients than in other common etiologies (HBV, alcohol).This retrospective study supports a genuine link between HCV cirrhosis and DM. "P P 2 0059"P 2 0059 **Only Some Autoimmunity Markers Are Associated with Hepatitis C Virus**

*J. Graus, R. B\'e1rcena, V. Ure\'f1a, A. Moreno

Hospital Ram\'f3n y Cajal de Madrid, Spain*Purpose:* To investigate if the Hepatitis C Virus (HCV) induce autoantibody production in Chronic Hepatitis C patients.*Methods:* We analyzed antinuclear (ANA), antimitochondrial (AMA), antismooth (SMA) and antiliver and kidney micrososms antibodies (LKM) in 153 patients HCV+ (91 males); antimicrosome (AM) and antithyroglobulin antibodies (AT) in 162 patients (92 males), and thyroid stimulating antibody (TSAb), islet cell antibodies (ICA), antipituitary (Ap), antiinsuline (Ai) and antiadrenal antibodies (Ad) in 125 patients (74 males). We determinated rheumatoid factor (RF) in 143 patients, 59 of them with liver biopsy. The same antibodies were investigated in 88 people (16 males) not infected by HCV.*Results:* Mean RF in HCV+ patients was 92.8.L141. Mean RF in controls was 21.6 – 0.31, the difference being statistically significant in a Student t test ($p < 0.001$). There was no relation between RF and ALT values. However, RF values correlated with portal necrosis grade ($r = 0.28$).Healthy controls and HCV+ patients showed no significant differences in ANA, AMA, AM, AT, Ad, ICA, Ap, Ai and TSAb titles. HCV+ males showed a significantly higher SMA prevalence if compared to controls ($p < 0.05$). HCV+ females also showed higher LKM prevalence compared to controls ($p < 0.1$).*Conclusions:* 1.- RF titles are higher in CHC patients than in controls, their values being directly related to portal necrosis.2.- SMA male prevalence and LKM females prevalence are significantly higher in HCV+ patients than in controls.3.- Other antibodies's prevalence was not significantly higher in HCV+ patients compared to controls. "P P 2 0060"P 2 0060 **Thyroid Dysfunction in Chronic Active Hepatitis (C)**

*H. Rizk[1], N.A. Gharib[2]

[1] Department of Internal and Tropical Medicine, Mansoura University, Egypt

[2] Department of Clinical Pathology, Mansoura University, EgyptThyroid disorders are now considered as an extrahepatic manifestation of chronic hepatitis C. The aim of this work is to study the changes in thyroid function tests and thyroid autoantibodies in chronic active hepatitis C and also to find if there are correlations between the degree of hepatic damage and these changes. In this study, 20 patients with chronic active hepatitis C (12 males & 8 females) age ranging from 28 to 60 years were included. Statistically significant reduction in Free T_3 level in both compensated and decompensated chronic active hepatitis C groups and in the level of TBG level in decompensated HCV Versus control group (P {\'a3} 0.001) and significant reduction in Free T_4 in decompensated HCV Versus control group (P {\'a3} 0.01). Also statistical difference was observed between chronic hepatitis C patients and control group concerning the antithyroperoxidase titre (51.971 – 64.501 Versus 7.414 – 5.371: P {\'a3} 0.05). And no significant difference was observed concerning the antithyroglobulin titre (55.849 – 26.711 Versus 41.689 – 17.913; P > 0.05). 6 patients revealed border line elevation in anti TPO (30%) and only one female patient showed significantly high anti TPO level > 125 I\'b5/ml (5%). On the other hand only one female (5%) revealed border line increase in anti TG levels. Also, there were statistically significant positive correlation between (the level of albumin and Free T_4, Free T_3, and TBG levels), (ALT level and TBG level), and (prothrombin activity and Free T_4, and Free T_3 levels), and there were statistically significant negative correlation between (Total bilirubin and Free T_4, and Free T_3 levels) and (Alkaline phosphatase and Free T_3 levels). From this study it can be concluded that, in addition to the characteristic low T_3 syndrome and low T_3–T_4 syndrome which can occur with any non thyroidal illness. Chronic HCV infection is commonly associated with presence of thyroid autoantibodies indicating that immunologic stimulation and direct effect of HCV on the thyroid gland may play a role in thyroid disturbance in chronically infected HCV patients. Liver and bile ducts, 1: Hepatitis viral, diagnosis }"

"P P 2 0061"P 2 0061 **Lack of Autoimmune Disease in Irish Hepatitis C PatientsS. Sachithanandan, J.F. Fielding**

Depts. of Gastroenterology & Hepatology, Beaumont Hospital, Dublin 9, Ireland*Purpose:* To determine the prevalence of autoimmune disease and/or autoantibody positivity in Irish Hepatitis C patients. *Methods:* 90 Irish Hepatitis C patients (55 Anti-D recipients, 25 Intra-Venous Drug Abusers and 10 Transfusion recipients) were surveyed clinically and by autoimmune serology to anti-nuclear (ANA), anti-smooth muscle (SMA), anti-mitochondrial (AMA), liver-kidney microsome (LKM-1), thyroid microsomal, thyroid globulin, gastric parietal antibodies and rheumatoid factor.*Results: Anti- D group* (all female); 2 of the Anti-D group and 1 of the transfusion group complained of generalised musculoskeletal symptoms but without clinical signs. In 6/55 (10.9%) thyroid microsomal antibodies were detected (2/6, thyroid globulin antibodies also positive). In 5/55 (9.1%), ANA titres were weakly positive and in 5/55 (9.1%), gastric parietal antibodies were positive. 47/55 were genotype 1 and 8/55 were genotype 3. *IVDA group* (8 females, 17 males); No autoantibodies were detected. Of 7/25 genotypes tested, 3 were genotype 3 and 4 were genotype 1. *Transfusion group* (5 females, 5 males); No autoantibodies were detected. 5 were of genotype 3 and the other 5 were of genotype 1. *Conclusions:* These findings suggest that in Irish Hepatitis C patients, neither genotype nor source (and dose) of innoculum contributes to the development of autoimmune disease. The question of if and how HCV is associated with autoimmune disease remains unknown. If the association exists, it may at least in part be genetic, and HLA typing may provide an answer. Larger numbers are also required before genotypic influence can be excluded. Liver and bile ducts, 1: Chronic non viral hepatitis }" "Lack of Autoimmune Disease in Irish Hepatitis C Patients"

"P P 2 0062"P 2 0062 **Jaundice at Onset Signifies a Good Prognosis in Anti-D Associated HCV InfectionS. Sachithanandan, J.F. Fielding**

Dept. of Gastroenterology & Hepatology, Beaumont Hospital, Dublin 9, Ireland*Introduction:* Acute hepatitis presenting with jaundice occurs in less than a quarter of patients infected with the hepatitis C virus. These patients may be associated with a more benign clinical course than those who are asymptomatic. *Purpose:* To compare and contrast the PCR and RIBA status, serum ALT levels and histological scores in age, disease duration and viral load matched HCV anti-D recipients with and without a history of jaundice. *Methods:* HCV status was confirmed by detecting HCV-RNA by PCR and antibodies to HCV using ELISA and RIBA-3. Serum ALT levels were measured in all patients and a liver biopsy was performed in 26/34 patients. All patients were genotyped. *Results:* 14/17 jaundiced patients were PCR negative and only 4/17 had RIBA scores greater than nine whereas all non jaundiced patients were PCR positive and all seventeen had RIBA scores > 9. 13/17 jaundiced had normal ALT values; 3/17, mildly elevated (41–100) and 1/17 > 100. 6/17 non-jaundiced had normal ALT levels, 9/17 (41–100) and 2/17 (> 100). 7/9 jaundiced had mild histological scores, 0/9 moderate and 2/9 severe. 5/17 non jaundiced had mild, 9/17 moderate and 3/17 severe. All 34 patients were of genotype 1b. *Conclusions:* Patients with jaundice were associated with lower antibody scores, increased PCR negativity, normal serum ALT levels and low/normal histological scores. Jaundice at onset was an indicator of good prognosis. Liver and bile ducts, 1: Chronic non viral hepatitis }" "Jaundice at Onset Signifies a Good Prognosis in Anti-D Associated HCV Infection"

"P P 2 0063"P 2 0063 **Chronic Cryptogenic Hepatopathy: A Still Puzzling Entity in 1995V. Bourgeois, M.-O. Peny, O. Le Moine, N. Bourgeois, C. Deprez, S. Sa\'efkali, L. Debaisieux,**

*M. Adler

Medico-surgical Department of Gastroenterology, Hospital Erasme-ULB, Brussels, BelgiumEven now, chronic elevation of transaminases without evidence of viral, toxic, alcoholic, genetic, autoimmune or vascular liver disease (defined as chronic cryptogenic hepatopathy: CCH) is still a clinically puzzling entity. The charts of 257 immunocompetent patients submitted between 01/93 and 10/95 to liver biopsy (percutaneous: 138, laparoscopic: 2, transvenous: 117) because of chronic elevation of transaminases were reviewed retrospectively. Thirty patients (12%) satisfied the criterion of CCH. Blood HCVRNA measured in 25 of them was always negative. These 30 patients with CCH (group I) were matched according to their sex and age to 30 HCV + VC patients (group II) and clinical, biochemical and histological features were compared between the two groups using univariate analysis (Chi-square or Fisher exact-test).Patients from group I had mean values of 46 y.o. for age, 93 IU ($N < 35$) for aminotransferases, 25.6 for body mass index ($N < 25$) and consumed 45 g alcohol per week ($N < 140$ g for women and < 210 g for men). None of these parameters differed in the two groups even so for blood glucose, ferritin, transferring saturation index and sex. Cholesterol and triglyceride levels were significantly elevated ($p < 0.02$) in group I. Histological analysis revealed greater inflammatory activity (using Metavir classification), higher number of lymphoid aggregates, greater portal inflammation and greater sinusoidal activation in group II. Final histological diagnosis in group I patients was steatosis/fibrosis in 18, chronic hepatits in 5, normal liver in 4 and cirrhosis in 1.CCH represents thus 13% of chronic parenchymal liver disease and is characterized by abnormal lipid profile and histologically by steatosis/fibrosis in most cases with minor inflammatory activity.This entity could represent a new metabolic dysregulation or a new non A non B non C viral hepatitis. Liver and bile ducts, 1: Chronic non viral hepatitis }" "Chronic Cryptogenic Hepatopathy: A Still Puzzling Entity in 1995"

"P P 2 0064"P 2 0064 **Prevalence of Anti-HCV Antibodies in Healthy Individuals, Alcoholics and Immigrant Population from Albania in North Western GreeceG.N. Dalekos[1], E. Zervou[2], D. Christodoulou[1], E.V. Tsianos[1]**

[1] Division of Inrernal Medicine, School of Medicine, University of Ioannina, Greece

[2] Blood Bank at the University Hospital of Ioannina, Greece*Purpose:* The aim of the present study was an attempt to the better approach of the real prevalence of anti-HCV antibodies in Epirus region, (north western Greece) where epidemiologic studies can be done with good accuracy. Comparison between the prevalence in Epirus with that of some special groups of individuals belonging to the high risk groups for infectious diseases such as refugees from Albania and alcoholics with or without liver disease (LD), was also done. *Methods:* We investigated 6.742 healthy (5.285 male and 1.457 female, mean age: 38.5 years, range: 0–60 years), 684 refugees from Albania (473 male and 211 female, mean age: 39.2 years, range: 0–70 years) and 151 alcoholics (145 male and 6 female, mean 56.5 years, range: 30–80 years). This latter group consisted from 83 alcoholics with LD and 68 without LD. 5835 subjects from healthy were blood donors who were accounted for only once during the study while more than 50% of them were first time donors. Third generation enzyme immunoassays and immunoblot assays were used (EIA 3.0 and RIBA-III). *Results:* We found that: (a) 0.83% of healthy (56/6742) were reactive with EIA 3.0 but 21.4% (12/56) of them were positive by RIBA-III, (b) 1.75% (12/684) of refugees were positive both with EIA 3.0 and RIBA-III and (c) 1.32% (2/151) of alcoholics (1/83 with LD and 1/68 without LD) were also positive both with EIA 3.0 and RIBA-III. The seropositivity for anti-HCV antibodies was significantly more frequent among refugees than healthy ($p < 0.05$) but not between alcoholics and the other two groups (comparison between male only). In addition, the presence of anti-HCV antibodies in healthy controls was significantly ($p < 0.01$) more frequent in older ages (more than 30 years). The latter finding, however, was not confirmed for the refugees. *Conclusions:* (1) The prevalence of anti-HCV antibodies in our region is approximately similar with that reported in most European countries. (2) The refugees from Albania had significantly higher prevalence of these antibodies than healthy controls. (3) By contrast, the present study did not confirm the presence of high prevalence of anti-HCV antibodies among alcoholics which has been reported by others. Clinical practice: Epidemiology (non cancer) }" "Prevalence of Anti-HCV Antibodies in Healthy Individuals, Alcoholics and Immigrant Population from Albania in North Western Greece"

*A. El-Zayadi[1], Osaima Selim[2], H. Dabbous[1], Sawsan S. Hafez[2], M.K. Shaker[1], H. Hamdy[1], A. Ahdy[3], Sanaa M. Kamal[1]

[1] Department of Tropical Medicine, Faculty of Medicine, Ain Shams University, Cairo, Egypt

[2] Department of Clinical Pathology, Faculty of Medicine, Ain Shams University, Cairo, Egypt

[3] Cairo Liver Center, Cairo, Egypt*Purpose:* It is well known that both HCV and HBV share several routes of transmission. It is our aim to assess the prevalence and clinical significance of hepatitis B markers in chronic hepatitis C patients.*Methods:* A total of 372 chronic hepatitis C (CHC) patients with elevated ALT were studied; 306 males and 66 females with a mean age of 42 years. All cases were ELISA-2, repeatedly positive, HCV-RNA-PCR was performed as a pre-requisite before antiviral therapy. They were tested for hepatitis B markers (HBsAg, HbeAg/Ab HBcAb IgG, whereas cases positive for HBsAg were screened for HBV-DNA-PCR). Liver biopsy was performed in 242 patients.*Results:* HBV seromolecular data are demonstrated in the following table: No. % anti- HCV-RNA HBsAg { -}HBeAg/ anti-HBc HBV-DNA of pts HCV+ve PCR Ab IgGG1: HCV + HBV 19 5 + + + +/{ -} + +dual infectionG2: HCV + HBsAg 44 12 + +/{ -} + { -}/{ -} +ve { -}carrierG3: HCV + HBV 207 56 + +/{ -} { -} { -}/+ + { -}past infectionG4: Isolated HCV 102 27 + + { -} { -}/{ -} { -} { -}infectionHistological diagnosis in dual infection versus (vs) isolated HCV infection revealed CPH in 16% vs 19.6%, CAH in 21% vs 58.8%, cirrhosis in 63% vs. 21.5% respectively.*Conclusion: The results show a* {\ul h}igh prevalence of markers of past HBV infection among HCV viremic patients. Results also might suggest suppression of HBV replication by coexisting HCV infection. We also concluded that dual HBV & HCV infection hasten the progress & severity of liver disease. "P P 2 0066"P 2 0066 **Lack of Evidence of IgA Deficiency in Hepatitis C Virus Infection**

*M.A. Heneghan, L. Geoghegan, J. McWeeney, T.A. O'Gorman, C.F. McCarthy

Department of Medicine, Clinical Science Institute, University College Hospital, Galway, IrelandA previous study (Ilan et al. Arch. Int. Med. 1993; 3: 1588–1592) has suggested that IgA deficiency predisposes towards chronic Hepatitis C Virus (HCV) infection in some patients. It has also been suggested that IgA deficiency may occur as a secondary event as a result of the viral infection.*Aims:* To determine the prevalence of both selective IgA deficiency (IgA < 0.05 g/L), and partial deficiency of IgA (IgA < 0.82 g/L) in a group of patients with chronic HCV infection attending our clinics.*Methods:* Immunoglobulin levels including IgG, IgA and IgM were determined in 67 HCV infected patients using a nephelometric technique. These patients had been infected with HCV contaminated blood, or anti-D immunoglobulin between 1977 and 1990. Mean immunoglobulin concentration (g/L) was compared with 100 controls without HCV infection.*Results:* 59 women and 8 men were examined with HCV infection, mean age 45.3 years (range 27–72 years). No patient was found to be either selectively or partially deficient in IgA. Mean IgA 2.59 g/L versus 2.81 g/L in the control group (2 tailed p = 0.980). Furthermore, no deficiency of serum IgG or IgM was found in either patients or controls.*Conclusion:* No evidence of IgA, or other immunoglobulin deficiency states exist among this group of patients with chronic HCV infection. While it is possible that IgA levels may decrease transiently following infection, no evidence exists that this phenomenon persists in the long term (mean duration of infection = 15.01 years). Differences between this study population and the previous report may relate to ethnic factors alone. Liver and bile ducts, 1: Hepatitis viral, diagnosis }"

"P P 2 0067"P 2 0067 **Quality of Life of Italian Patients with Chronic Hepatitis C**

*F. Arpinelli, G. Visona', G. De Carli, U. di Luzio Paparatti, N. Caporaso[1], A. Craxi'[2], A. Bellobuono[3], E. Roda[4], G. Recchia

Glaxo Wellcome S.p.A. Research and Development, Verona, Italy

[1] Gastrointestinal Dept. of Naples, Italy

[2] Gastrointestinal Dept. of Palermo, Italy

[3] Gastrointestinal Dept. of Milan, Italy

[4] Gastrointestinal Dept. of Bologna, ItalyAfter the diagnosis, patients (pts) suffering from chronic hepatitis C undergo to several changes of their life style, because of treatments, fear to infect wife/husband, progress of the disease etc. Measurement of health related quality of life (QoL) is an important index to evaluate outcomes induced by therapies and the use of QoL questionnaires is the most suitable way to collect these informations.A multicentre survey to measure the QoL of Italian CHC pts started during the spring of 1996As in Italy no specific questionnaire for CHC pts is available, the protocol provided for the use of Italian version of the general questionnaire SF36. It was administered to anti-HCV positive males and females with compensated CHC and serum ALT values at least 1.5 times the upper limit of normal, who never underwent a hepatic biopsy, were not previously treated with interferon and/or antiviral drugs and/or corticosteroids, who were free from relevant psychiatric or neurological diseases and were HIV-1 negative. SF36 was administerd to over 500 patients by 50 Investigators throughout Italy.Analysis of the first 62 pts (mean age 46 y, 65% males) showed that scores in some domains of SF36 were lower than the norm: role physical { -}2.0%, general health { -}7.0%, social functioning { -}4.4%, role emotional { -}6.4%, mental health { -}3.1%. Other domains scored greater than the norm: physical functioning +3.6%, bodily pain +11.1%, vitality +1.1%.These data suggest that CHC pts perceive their disease as a serious risk for their health, with limitations of social functions in spite of having a good enough physical functioning and lack of symptoms. It is notable that psychological aspects of pts are lower than normal however pts were not treated with any drugs and this does not support hypotheses on psychotropic effects of specific drug for CHC. }" "Quality of Life of Italian Patients with Chronic Hepatitis C"

"P P 2 0068"P 2 0068 **Hepatic Glutathione Deficiency in Chronic Hepatitis C: Quantitative Evaluation and Correlations with Plasmatic and Lymphocytic Concentrations in HIV-Positive and HIV-Negative Patients**

*G. Barbaro, G. Di Lorenzo, M. Soldini, G. Bellomo[1], G. Belloni[2], B. Grisorio[3], G. Barbarini[2]

[1] Departments of Emergency Medicine, Medical Sciences and Infectious Diseases, University ""La Sapienza"", Rome, Italy

Departments of Emergency Medicine, Medical Sciences and Infectious Diseases, University of Torino, Italy

[2] Departments of Emergency Medicine, Medical Sciences and Infectious Diseases, University of Pavia, Italy

[3] Division of Infectious Diseases, General Hospital, Foggia, Italy*Introduction.* Reduced glutathione (GSH) is decreased in plasma and in peripheral blood mononuclear cells (PBMC) of subjects affected by chronic hepatitis C (CHC) as well as in plasma, lung epithelial-lining fluid and T lymphocytes of Human Immunodeficiency Virus (HIV)- positive subjects. Since the liver is the most important source of plasmatic GSH, we measured the concentrations of GSH in the liver (H-GSH) of HIV-positive and HIV-negative patients with CHC, correlating it with the concentrations of GSH in plasma (P-GSH) and in PBMC (L-GSH), with the replication activity of HCV in PBMC, with the activity of the liver disease and with the state of immunodeficiency in HIV-positive patients.*Methods.* The study has considered 125 patients with serologically and histologically demonstrated CHC (65 HIV-positive and 60 HIV-negative); 61 healthy individuals served as a control group for P-GSH and L-GSH concentrations. H-GSH concentration was determined by High Performance Liquid Chromatography on liver specimens obtained by ultrasound-guided biopsies according to the method described by Reed et al.. The concentrations of P-GSH and L-GSH were determined according to the method described by Suarez et al. The detection of HCV-RNA strands in PBMC was performed according to the method described by Qian et al.*Results.* H-GSH, P-GSH and L-GSH were significantly reduced in patients affected by CHC compared with healthy controls ($p < 0.001$); H-GSH was significantly correlated to both P-GSH ($r = 0.91$; $p < 0.001$) and L-GSH ($r = 0.65$; $p < 0.001$). The reduction of H-GSH, P-GSH and L-GSH were significantly correlated to the replication activity of HCV in PBMC [$r = 0.97$ vs H-GSH ($p < 0.001$); $r = 0.92$ vs P-GSH ($p < 0.001$); $r = 0.97$ vs L-GSH ($p < 0.001$)] and to the grade of activity of the liver disease assessed by the values of ALT [$r = 0.74$ vs H-GSH ($p < 0.001$); $r = 0.83$ vs P-GSH ($p < 0.001$); $r = 0.64$ vs L-GSH ($p < 0.001$)] and by the histological score of CHC ($r = 0.75$ vs H-GSH; $p < 0.001$). H-GSH and, particularly, L-GSH were more significantly reduced in HIV-positive patients compared with HIV-negative ones ($p < 0.001$), without significant correlation with the values of T cells subset CD4+ ($r = 0.065$; $p = 0.507$ vs H-GSH and $r = 0.0933$ vs L-GSH; $p = 0.343$). In both groups of CHC patients L-GSH was more significantly reduced in drug addicts compared with non drug addicts patients ($p < 0.001$).*Conclusions.* In patients with CHC and, particularly, in HIV-positive patients, a systemic depletion of GSH is present. This depletion may be a factor underlying the resistance to interferon therapy and, in HIV-positive patients, to antiretroviral drugs, fostering HCV and/or HIV replication. This may represent the biological basis for GSH replacement therapy with

GSH-prodrugs. "P P 2 0069"P 2 0069 **HCV Heterogeneity and Response to Alpha IFN Therapy in French Patients with Chronic Hepatitis CB. Le Guen[1], Gio. Squadrito, S. Pol[2], B. Nalpas[2], P. Berthelot[2], C. Brechot**

[1] Inserm U370, CHU Necker, Paris, France

[2] Liver Unit, CHU Necker, Paris, France

[3] Dep. Internal Medicine, Univ. of Messina, Italy*Objectives:* It has been suggested that Hepatitis C virus (HCV) genome heterogeneity might be a predictive virologic parameter for responsiveness to IFN treatment. We have investigated this issue in a serie of French patients treated by IFN for HCV related chronic active hepatitis. *Methods:* Ninety-five patients (19/95 cirrhosis) before IFN treatment were classified into three groups: long term responders (LTR) (n = 20), relapsers (n = 31) and non-responders (n = 44). The HCV genotype was determined by restriction fragment lenght polymorphism analysis (RFLP), 1b (n = 45), 1a (n = 11), 2 (n = 8), 4/5 (n = 2) and 3a (n = 29) and HCV RNA quantitation was analyzed by the Branched DNA assay (Quantiplex' 2.0). The quasispecies complexity of HCV HVR 1 was analyzed by PCR-mediated single-strand conformation polymorphism (SSCP) and classified as low (SSCP band {\'a3} 3) or high complexity patterns (SSCP band > 3). Univariate and multivariate analyses were performed (BMDP Statistical Software Inc., Los Angeles, CA, USA). *Results:* In univariate analysis high complexity pattern showed the highest correlation to IFN efficacy followed by age, HCV genotypes and viral load (p < 0.0001). A low complexity pattern was associated with long term response for genotype 3a (10/14). Multivariate analysis showed that the high complexity pattern was the most informative predictive factor of non response or relapse with odds ratio of 19, compared to 11.6 for HCV viremia and 7.48 for HCV genotype. *Conclusions:* The high degree of HCV genome heterogeneity is a negative independent predictive factor of response to IFN in patients infected by HCV types associated to both low (1b) or high (3a) response rates. It should be important to prospectively include the analysis of HCV heterogeneity in the design of therapeutic strategies for HCV infection. [4] Institut Pasteur, Paris, France

[5] Functional Organization of the Nucleus, CNRS UPR9044, Villejuif, France

[6] INSERM U321, Paris, FranceThere are evidences for a role of HCV core in both encapsidation and modulation of gene expression. Its subcellular localization is however controversial. We have analyzed these points by two approaches:1) *Immunofluorescence and confocal microscopy* were performed in CHO and HepG2 cells stable expressing HCV core. The protein showed a cytoplasmic distribution with a perinuclear (CHO) or peripheric (HepG2) pattern localized in globular structures unrelated to the position of the cell in cell cycle. A nuclear localization was excluded by confocal analysis and by double labelling with a nuclear membrane marker. *Electron microscopy* analysis showed presence of lipidic droplets absent in control cells. Immunostaining with an anti-core antibody revealed a concentration of the signal on the surface of the droplets both in CHO and HepG2 cells. Detailed analysis of the lipidic composition of the droplets showed a prevalent presence of triglycerides and confirm the association to the HCV core.2) The association of the core to cellular protein was studied by employing *the yeast two hybrid system.* We obtained from a human liver cDNA library 3 independent clones coding for the apolipoprotein AII for 65 currently analysed. Confocal analysis of double immunofluorescence for Apolipoprotein AII and core protein in HepG2 cells showed colocalization of the two proteins. Further studies are in progress in order to confirm the biochemical interaction ""in vivo"".*Conclusions:* Our results show: 1) Accumulation of lipidic storage vesicules upon HCV core expression. 2) Association of cytoplasmic HCV core to these Triglycerides rich vesicules and colocalisation with AII. These observations stress the potential importance of these interactions in HCV infection pathobiology. "P P 2 0071"P 2 0071 **Nosocomial Transmission of HCV****P. Angelis[1], M. Papadaki[2], P. Garzonis[1], K. Liosis[1], Ch. Papamichail[1],**

*A. Simos[1]

[1] Medical Unit of “Sotiria” General Hospital of Chest Diseases of Athens-Greece

[2] Blood Transfusion Centre of “Sotiria” General Hospital of Chest Diseases of Athens-Greece*Purpose:* The study's purpose is the determination of HCV dispersion in patients with chronic disease and the investigation of the possible significance of hospitalization as a risk factor for HCV infection.*Patients and Methods:* 657 patients with chronic disease, who were hospitalized in our hospital between Sept. 91 and Dec. 94, were studied. They were classified in two groups. Group A included 248 transfused patients, 157 males and 91 females, with a mean age 65.2 years, a mean number of hospitalizations 15.8, a mean duation of hospitalization 8.8 months and a mean number of transfusions 5.5 units. Group B consisted of 409 non transfused patients, 262 males and 147 females, with a mean age 67.3 years, a mean number of hospitalizations 15.9 and a mean duration of hospitalization 9.2 months. Patients with other risk factors for hepatitis C were excluded from the study. As a control group were used 480 individuals with a history free of chronic disease, hospitalizations or transfusions and with comparable features concerning age and sex. Individuals who were at high risk for hepatitis C were excluded from the control group as well. The determination of anti-HCV was performed by ELISA-2 ABBOTT and furtherly confirmed by RIBA-2 ORTHO. The statistical analysis was made on PC (D Base IV, SPSS).*Results:* Antibodies against HCV, confirmed by RIBA-2, were found in 11.3% in group A, in 9% in group B and in 1.4% in the control group. The statistical analysis showed important difference regarding the presence of anti-HCV between groups A, B and the control group. A positive correlation between serum positivity and number of transfusions in group A and number and duration of hospitalizations in group B was confirmed.*Conclusion:* Our results demonstrate a high dispersion of HCV in patients with chronic disease and multiple hospitalizations, independently of transfusions and indicate that the factor “exposure to hospitalization” represents a significant risk factor for HCV infection. "P P 2 0072"P 2 0072 **The Genotype 1b Replicates More Actively and It Is More Resistant to the IFN in the Patients with Chronic Hepatitis C**

*A. Castro, M. Hermida, S. L\'f3pez Calvo, P. Vega, R. Torr\'f3n, J. Bali\'f1as, J.D. Pedreira

Internal Medicine Service, Hospital Juan Canalejo, La Coru\'f1a, Spain*Objective:* To study the influence of viral genotype and viremia on the response to IFN alpha treatment in chronic hepatitis C patients.*Patients and Methods:* 50 hepatitis C patients, diagnosed by liver biopsy and the presence of anti-HCV in serum (ELISA and RIBA-II), were treated with IFN alpha (Welferon, Wellcome) for one year: 3 MU daily for 10 weeks followed by 3 MU thrice to week. Viremia was determined immediately before and after treatment by quantitative PCR (Monitor, Roche). HCV genotype was determined before treatment by INNO-LiPA (Boheringer Ingelheim). To normalize ALT level following treatment was considered as response to IFN.*Results:* Of the 50 patients treated, 34 (68%) showed no response and 16 (32%) responded, 8 of whom (16%) maintained the response after one year of follow-up. HCV RNA level was 100 000 eq/ml for the responders and 600 000 eq/ml for non responders ($P < 0.0032$). All but one of those who didn't respond were RNA HCV positive at the end of treatment but to much reduced level: 150 000 eq/ml ($P < 0.0058$). They were accomplished genotipifications with the basal serum of 37 (74%) of 50 patient. 15 of 16 responders were genotyped (94%) and 22 of 34 non responders (64%). The most frequent genotype was 1b (26/37) (70%). 19 of 22 non responders genotyped were 1b (86.3%), while only 7 of 15 (46.6%) responders genotyped were 1b ($p = 0.0130$). It has been studied the patients that were presenting the genotype 1b as compared to those which were presenting other genotypes in relation to the viremia. The viremia mean of the patients with genotype 1b was 5.7 times; 10^5 (standard desviation: 9.7 times; 10^5) and that of the others genotypes (non-1b) was 9.8 {\'b4} 10^4 (standard desviation: 1.37 times; 10^5) ($p < 0.0019$).*Conclusion:* The replication of HCV is greater in the patients infected with the type 1b and the response to IFN treatment in these patients is lower. Furthermore the genotype 1b is the most frequent in the population. Liver and bile ducts, 1: Hepatitis, viral, treatment }" "The Genotype 1b Replicates More Actively and It Is More Resistant to the IFN in the Patients with Chronic Hepatitis C"

"P P 2 0073"P 2 0073 **Chronic Hepatitis C and Severe Autoimmune DiseasesL. Pascalis,**

*G. Pia, G. Aresu

University Cagliari Italy*Objectives* – To test the effectiveness and tolerance to { b} Interferon combined with low-doses of CsA and steroids for the treatment of patients with chronic hepatitis C virus (HCV) and exacerbation of severe autoimmune diseases.*Methods* – 20 Patients (12 females and 8 males) ages ranging from 25 to 42 years were included in the study. Each patient were affected with chronic hepatitis with actively replicating HCV and/or Rheumatoid Arthritis (new ARA classification criteria) 10 patients, and/or L.E.S. (new ARA classification criteria) 6 patients, vasculitis (histological or arteriographic evidence) 4 patients. Inclusion criteria for patients: a therapy refractory condition after an at least 3-weeks treatment with prednisone at a dose of 1 mg/Kg body weight, which usually corresponded to 40–70 mg. { b} Inteferon (Frone–Serono) was administered at a dose of 5 million U./week on 5 days for 6 months. Cyclosporyn A (CsA) was administered initial daily dose of 5 mg per Kg body weight (ideal weight in the case of overweight subjects). Blood levels of the drug were between 100 and 200 mcg/l by the third day of treatment. All the patients also received Fluocortolone at a dose to control disease activity, that is, 80–70 mg/week on 5 days depending on the case, and then tapered in relation to the course down to a maintenance dose of 15–20 mg/week administered on 3 days.*Results* – All Patients presented a significant improvement of the clinical picture. 2 months after onset of treatment the AST had normalized and there was a statistically significant decrease in clinical outcome variables (morning stiffness; Pain, 100 mm VAS; Lee functional index) and biological parameters (C reactive protein, ESR, { a}$_1$-glicoprotein acid). The disease activity indexes remained normal for the rest of the follow period (24.12 – 2.33 months, range 21–27).All side effects were mild. No renal toxicity was observed in any patients. "P P 2 0074"P 2 0074 **Rheumatic Manifestations of HCV InfectionR.J. Farrell, D. McGonagle, R. Pilkington, E.B. Casey, D. Kelleher**

Departments of Hepatology and Rheumatology, St James's Hospital, Dublin 8, Ireland*Introduction:* Hepatitis C Virus (HCV) infection is associated with several connective tissue diseases. The most well recognized is Cyroglobulinemia, a Sjogren's like syndrome, an asymmetrical inflammatory arthropathy and non-specific arthritis. In 1977–78 Anti-D Immunoglobulin batches infected with HCV were inadvertantly administered as prophylaxis against Rhesus blood group incompatibility. Virtually all patients exposed to HCV whether symptomatic or not have been evaluated thus allowing accurate determination of the true prevalence of rheumatic conditions at a mean time of 18 years since exposure. *Methods:* HCV was diagnosed using RIBA testing and confirmed with PCR. Groups where HCV was acquired by other means (IVDU, blood transfusion, sexually, bone marrow transplant and sporadic) were included for comparison. Patients with suggestive symptoms were carefully re-evaluated with full auto-antibody screen, cryoglobulins and Schirmer test. *Results:* 136 patients who acquired HCV through Anti-D were evaluated. Mean age: 42.5 (range 33–60) yrs. 83 were PCR+ve; 71 type 1b, 2 type 2b, 10 type 3. At mean follow-up of 18 years there was no clinical evidence of cryoglobulinemia. However 1PCR+ve case with small joint arthralgia had a cryocrit of 2%. There was 1 case of mild seropositive RA and 1 of palindromic RA. 4 had small hand joint arthralgia while 1 PCR+ve case had Sjogren's syndrome with xerostomia and xeropthmalia, positive ANA, Ro and La antibodies and a positive Shirmer test. Six cases had frozen shoulders, 3 of which were PCR+ve. 90 patients who acquired HCV through means other than Anti-D (All HBV and HIV negative) were evaluated. Mean age: 27.1 (range 17–72) yrs. 64 were PCR+ve; 29 type 1b, 2 type 2, 32 type 3. There was no case of cryoglobulinemia. One PCR+ve lady had long standing RA and thyroiditis and 3 cases of peripheral symmetrical arthralgia. There was no confirmed case of Sjogren's Syndrome, however 2 cases had xerostomia and xeropthalmia but were Ro and La antibody negative. Two cases had frozen shoulders one of which was PCR+ve. *Conclusions:* Despite the well reported association between HCV infection and cryoglobulinemia the prevalence with chronic HCV infection appears to be low. Sjogren's Syndrome does not appear to be more prevalent than in the general population. 5% of the anti-D group had persistent small joint arthralgia with 2 documented RA cases while 4.5% had frozen shoulders. Liver and bile ducts, 1: Hepatitis viral, diagnosis }" "Rheumatic Manifestations of HCV Infection"

"P P 2 0075"P 2 0075 **Abdominal Lymphadenopathy and Histological Pictures in Chronic Hepatitis C****M. Soresi, G. Bonfissuto, A. Carroccio, V. Agate[1], C. Magliarisi, F. Bascone, A. Cartabellota, F. Aragona[1], G. Montalto**

[1] Cattedra di Medicina Interna, Universit\'e0 di Palermo, Italy

Istituto di Anatomia Patologica, Universit\'e0 di Palermo, Italy*Aim:* To evaluate the relationship between ultrasonography (US) findings of upper abdominal lymphadenopathy and histological activity index (HAI) and serum liver function tests (LFTs) in subjects with chronic hepatitis C.*Methods:* 58 subjects (41 M, 17 F) (mean age 46.4 – 12.4 years), with chronic hepatitis C were studied. None were HBsAg +ve, alcoholics or had other known causes of liver disease or neoplasia. US scans was performed using a real time equipment (Toshiba SSA 240 A) with a 3.5-Mhz convex transducer. Liver biopsies were performed with needles 16 G (Surecut, Hospital Service, Rome). HAI was evaluated with Knodell's score (K), which expresses necrosis-inflammation and fibrosis, and Desmet's score which separately determines grading (G) necrosis-inflammation and staging (S) expressing fibrosis. The common LFTs (AST, ALT, ALP, GGT, total bilirubin, prothrombin activity, serum albumin, { g}-globulin) were assayed. Statistical analysis was performed using Student's test, Pearson's and Spearman's coefficient correlation r.*Results:* 36 subjects did not present lymph nodes (LN) on US (LN{ -}), while 22 did (LN+). Mean values of the K and G scores were significantly higher in the LN+ than the LN{ -} subjects: K GLN+ (n = 22) 10.0 – 3.0* 8.4 – 2.47** LN{ -} (n = 36) 7.9 – 3.6* 6.5 – 2.9** *p < 0.03; **p < 0.02There was no difference for the serum LFTs. There was a significant correlation between number of LN and K and G scores (p < 0.05 and p < 0.01 respectively) and with serum { g}-globulin (p < 0.04) but not with S or the remaining serum LFTs.*Conclusion:* The presence of LN on US is a parameter of greater inflammation and severe necrosis which can be confirmed histologically; LN are thus indicative of a more severe evolution of liver disease, even in absence of LFTs alterations. "P P 2 0076"P 2 0076 **Hepatitis C Infection in Non-Hodgkin Lymphoma**

*H. Senturk, M. Akdogan, A. Mert, A. Sonsuz, S. Ozdemir, P. Akin

Department of Internal Medicine, Cerrahpasa Medical Faculty of Istanbul University, Istanbul, TurkeyChronic hepatitis C viurs (HCV) infection was proposed as a predisposing factor in the development of non-hodgkin lymphoma. Despite its oncogenic mechanism is far from clear, HCV is known to infect both B and T lymphocytes and its long-term presence in immune system may promote the infiltration of bone marrow with expanded clones of Ig-secreting lymphocytes. We examined the serum samples from 30 patients (17 male, 13 female, median age 52, range 16–84 ys) with non-hodgkin lymphoma (NHL) and 18 patients (10 male, 8 female, median age 26, range 17–61 ys) with hodgkin lymphoma (HL) for anti-HCV antibodies by ELISA II (Abott, HCV EIA.) Anti-HCV positive sera was tested for HCV-RNA by nested-PCR as well. The serologic results from sera of 9488 healthy blood donors (age range 18–65 ys) were used as controls. 4/30 (13%) of patients with NHL, and 74/9488 (0.8%) of blood donors were anti-HCV positive ($p < 0.001$.) None of the 18 patients with HL was +ve for anti-HCV. There was no correlation between the transfusion history and anti-HCV positivity (2/4 of anti-HCV +ves vs. 13/26 of anti HCV -ves in NHL and 5/18 in HL.) Serum ALT levels of 2/4 of anti-HCV positives were elevated. Liver biopsy showed chronic hepatitis in these patients. Biopsy was not performed for the other two with normal serum ALT. HCV-RNA was present in the sera of all but one of the anti-HCV +ve patients.It was concluded that chronic HCV infection is more common in the patients with NHL in comparison to general population. There is no correlation between the history of transfusion and anti-HCV positivity in lymphoma. Liver and bile ducts, 1: Hepatitis viral, diagnosisOncology, specific: Lymphoma }" "Hepatitis C Infection in Non-Hodgkin Lymphoma"

"P P 2 0077"P 2 0077 **Intra-Hepatic and Peripheral Blood Lymphocytes (IHL, PBL) in Patients with Chronic Hepatitis C (CHC)****Albert Tran[1], Guang Yang[1], Michel Ticchioni[2], Alain Bernard[2], Patrick Rampal[1], Sylvia Benzaken[2]**

[1] Liver Unit, Archet Hospital, Nice, France

[2] Department of Immunology, Archet hospital, Nice, FranceThe host immune response have been suggested to play a role in liver injury occurring in patients with chronic hepatitis C. In order to explore the relationship between the relative proportions of intrahepatic and peripheral blood lymphocytes (ILL, PBL), the levels of viremia, and the histological hepatitis activity score, three-colour fluorescence-activated cytometric analysis was performed for 36 patients with chronic hepatitis C before interferon therapy and 6 control subjects without chronic hepatitis.Each liver specimen was divided into two parts: one for histological examination and one for immunological analysis. Tri-color CD45 was used to improve ""lymphogating"". Fluorescein isothiocyanate- or phycoerythrin-conjugated monoclonal antibodies with specificity for CD3, CD4, CD8, and CD20 (lymphocyte subpopulations), for CD69 (activated lymphocytes), and for CD16/56 (natural killer cells) were used. Levels of viremia were determined by quantitative PCR (Monitor, Roche Diagnostic Systems).The proportion of IHL CD4+ was significantly increased in patients with chronic hepatitis C, resulting in an IHL CD4+/CD8+ ratio significantly higher than in control subjects (0.55 – 0.21 vs 0.23 – 0.12, p = 0.046). The livers of patients with chronic hepatitis C contained a higher percentage of CD8+ T lymphocytes (40.7 – 13.9% vs 26.0 – 6.6%, p = 0.0001) and a smaller percentage of CD4+ T lymphocytes (20.7 – 7.3% vs 48.3 – 6.8%, p = 0.0001) which exhibited marked expression of CD69, compared to peripheral blood. No statistical correlation was found between the intrahepatic CD4+/CD8+ ratio and the level of viremia, Knodell's score, or transaminase activities.Our findings indicate that a cellular immune response does take place in HCV-infected livers, and could contribute to the pathogenesis of HCV-induced liver damage. Liver and bile ducts, 1: Hepatitis viral, diagnosis }" "Intra-Hepatic and Peripheral Blood Lymphocytes (IHL, PBL) in Patients with Chronic Hepatitis C (CHC)"

"P P 3 0078"P 3 0078 **High Prevalence of Antibodies to Hepatitis A Virus (HAV) Infection in Healthcare Workers****E. Rajan, S. Ai'Bloushi, M.G. Courtney, B. O'Farrell[1], A.G. Shattock[1], J.F. Fielding**

Department of Medicine, Beaumont Hospital, Ireland

[1] Virus Reference Laboratory Dublin, Ireland*Objective:* To determine the occupational risk of contracting HAV infection among healthcare workers in a large general adult hospital which should represent the relative risk among healthcare workers in other general hospitals.*Methods:* 625 healthcare workers were recruited of which 264 were student nurses, 98 medical students, 87 staff nurses, 65 administrative staff, 50 physicians, 31 laboratory staff and 30 physiotherapists. Each participant completed a questionnaire by interview and 10 mi of venous blood was withdrawn which was tested for total anti HAV immunoglobulin (primarily IgG) using an ELISA competitive assay.*Results:* 17% of student nurses were HAV antibody positive, 18% of medical students, 48% of staff nurses, 41.5% of administrative staff, 40% of physicians, 41% of laboratory staff and 23% of physiotherapists were also HAV antibody positive. Staff nurses, physicians, laboratory technicians and administrative staff are at significant risk of HAV infection whereas physiotherapists, medical students and student nurses were not.*Conclusion:* These findings suggest that patient exposure does not alone account for the increased susceptibility. This suggests that healthcare workers may be at increased risk of HAV infection and would benefit from a HAV vaccination programme. Clinical practice: Epidemiology (non cancer) }" "High Prevalence of Antibodies to Hepatitis A Virus (HAV) Infection in Healthcare Workers"

"P P 3 0079"P 3 0079 **Origin and Course of a Local Epidemic of Hepatitis-A in Germany**

*R. Eissele, U. Kajdan, C. Fischer, R. Arnold

Dept. of Gastroenterology, Philipps University, Marburg, GermanyGermany has a low rate of endemic hepatitis-A infection. Therefore, natural immunity is reduced, which predisposes to local epidemics. We report about the origin and the course of a local epidemic with hepatitis-A and discuss possible implications on active vaccination. *Patients:* In 42 patients (19 female and 23 male) with icteric hepatitis-A infection a common origin could be found. The diagnosis of hepatitis-A infection was confirmed by serology. The mean age of patients was 32 (2–62) years. Twenty-six patients were treated in the hospital with a mean duration of 10 (2–42) days, and 16 were out-patients. *Focus of infection:* Primary infection occurred in 3 members of a family running a small restaurant and in one guest. All of them had been infected by contaminated sea-food. After 2–6 weeks another 29 patients suffered on acute hepatitis-A. All of them had eaten in the restaurant during the incubation period of the index family. A few weeks later 9 family members of these patients were diseased on hepatitis-A. *Clinical course:* The mean incubation period was 25 (16–37) days. The most common symptoms were: dark urine (69%), nausea (60%), lack of apeptite and weight loss (54%), and vomiting (54%). The maximal increase of ALT was below 2000 U/l in 2/3 of patients and above 2000 U/l in 1/3 of patients. Serum bilirubin increased in 13 patients by more than 10 (up to 46) mg %. In 16 patients a transient decrease of the prothrombin-time was measured. In 40 patients no complications were observed, whereas 2 patients had a severe recurrent clinical course. *Conclusions:* In countries with a low rate of endemic hepatitis-A infections limited epidemics can be induced by ""food workers"". These infections could be prevented by active vaccination of persons working in the food-industry. Liver and bile ducts, 1: Hepatitis viral, diagnosisLiver and bile ducts, 1: Hepatitis, viral, treatment }" "Origin and Course of a Local Epidemic of Hepatitis-A in Germany"

"P P 3 0080"P 3 0080 **Incidence of HBV Positivity and Behaviour of HBsAg Carrier State in Cancer Patients, during Chemotherapy (CT)C.G. Alexopoulos[1],**

*M. Vaslamatzis[1], G. Hatzidimitriou[2]

[1] Dpt Med. Oncology, Evangelismos Hospital Athens, Greece

[2] Tranfusion Unit, Evangelismos Hospital Athens, Greece*Aim:* We prospectively studied: 1) The incidence of HBV markers positivity in cancer pts & 2) the changes in HBV profile of HBsAg carriers during CT.*Patients-Methods:* Serum HBsAg, HBeAg, HBsAb, HBcAb & HBeAb were determined using specific third generation ELISA (Abbott) in 1008 of 1402 (72%) cancer pts admitted in our Dpt between 1986–95 & in all 920 who received CT. Liver biochemistry was also performed.*Results* 1) 443 of 1008 pts (44%) had at least one HBV marker positive: 54 pts (5.3%) were HBsAg carriers while none was HBeAg+ve, 405 (91%) were HBcAb+ve, 321 (72%) were HBsAb+ve & 212 (48%) were HBeAb+ve positive: 50 pts (5.4%) were HBsAg carriers, 374 (41%) were HBcAb+ve, 280 (30%) were HBsAb+ve & 178 (19%) were HBeAb+ve. 2) In the 50 HbsAg carriers, serial HBV profile before, in the middle, after CT & in follow up & liver biochemistry before each CT course, demonstrated: in 43 pts (86%) stable HBs antigenaemia without clinical or biochemical signs of hepatitis. Seven of 50 pts (14%) developed hepatitis with significant increase of hepatocellullar enzymes. Hepatitis was very severe in 3 pts (6%) with a bilirubin of 17 mg% & transaminases above 1500 units. In all 7, anti-HBs antibiodies appeared in the serum with associated decrease of HBsAg titers. Serum HBsAbs appeared temporarily in 3 & permanently in 4 of 7 pts.*Conclusions:* a. The incidence of HBsAg carrier state in cancer pts is not different than in the general Greek population (5%) b. Reactivation of HBV infection with sometimes severe hepatitis during cancer CT, is not a rare phenomenon (14% in our series) c. Disappearance of HBs antigenaemia as a result of cancer CT is mostly a temporary phenomenon. "P P 3 0081"P 3 0081 **Nosocomial Transmission of HBVP. Angelis, M. Kymissis, P. Garzonis, N. Sofoulis, N. Koumentakis,**

*A. Simos

Medical Unit of “Sotiria” General Hospital of Chest Diseases of Athens-Greece*Purpose:* The study's purpose is the determination of the dispersion of HBV in chronic patients and the investigation of the possible significance of hospitalization as a risk factor for HBV infection.*Patients and methods:* 657 chronic patients, who were hospitalized in our hospital between Sept. 91 and Dec. 94, were classified in two groups. Group A consisted of 248 transfused patients, 157 (63.3%) males and 91 (36.7%) females, with a mean age 65.2 years (23–92), a mean number of hospitalizations 15.8 (2–60), a mean duration of hospitalization 8.8 months (3–30) and a mean number of transfusions 5.5 units (1–25). Group B consisted of 409 non transfused patients, 262 (64%) males and 147 (36%) females, with a mean age 67.3 years (22–92), a mean number of hospitalizations 15.9 (5–70) and a mean duration of hospitalization 9.2 months (3–50). Patients with other risk factors for hepatitis B were excluded from the study. As a control group, fully comparable for age and sex, we used 480 healthy controls without a history of chronic disease, hospitalizations or transfusions. High risk individuals for hepatitis B were excluded from the control group as well. The determination of the dispersion of HBV was made through the search of anti-HBcAg and HBsAg using the ELISA method. The statistical analysis was made on PC (D Base IV, SPSS).*Results:* In group A the prevalence of anti-HBcAg was 60.3% and of HBsAg 8.9%, in group B 54.6% and 7.85%, whereas in the control group 34.5 and 4.5% respectively. The statistical analysis showed important difference regarding the presence of HbsAg and anti-HBcAg between groups A, B and the control group. A positive correlation between serum positivity and number of transfusions in group A and number and duration of hospitalizations in group B was confirmed.*Conclusions:* The results show a high dispersion of HBV in chronic patients and demonstrate that besides transfusion hospitalization consists a significant risk factor for HBV infection as well. Liver and bile ducts, 1: Hepatitis viral, diagnosis }" "Nosocomial Transmission of HBV"

"P P 3 0082"P 3 0082 **Prediction of Severity in Chronic Active Hepatitis B (CAHB) by PCR-RFLP Method**

*H. Ueda, H. Tanaka, M. Miyano, M. Kinoshita, K. Mimura, S. Yukawa

3rd Dept. Internal Medicine, Wakayama Medical College, JapanWe have reported that amino acid substitutions ILe (I) to Leu (L) at codon 87 and Ser to Gly (G)/Asn (N) at codon 97 due to DNA mutation in core region were noted in patients with CAHB, whose serum GPT (sGPT) were below 100 IU/*l* (published in 4th UEGW). However, it is time consuming to detect mutations by DNA sequencing. We studied whether these mutations could be detected or not by Restriction Fragment Length Polymorphism (RFLP) method.Twenty-six patients with CAHB were studied. CAHB were characterized of two groups according to sGPT value. In group 1 (10 patients) and group 2 (16 patients), sGPT were over 100 IU/*l* and below 100 IU/*l,* respectively. HBV DNA were extracted from patient's sera and amplified by PCR with core region specific primer. Digestion study at codon 87 and 97 for PCR products was performed with Alu1 and Dde1, respectively. To prevent incomplete digestion. PCR products were incubated with restriction enzyme at 37\'b0C over night and analysed for agarose gel-electrophoresis.In group 1, DNA fragments ladder was the same pattern as wild type adr. The other hand, different ladder pattern (mutant type) were found in group 2. In digestion with Alu1, DNA fragment of 88 bp was detected in group 1, but not in group 2. And also, in digestion with Dde1, DNA fragment of 410 bp was detected in group 1, but not in group 2. Further, ladder pattern that mixed both wild and mutant type, mixed type, was frequently found in group 2. Therefore, in group 2, mutant or mixed type were detected by RFLP.In this study, amino acid substitutions ILe to Leu at codon 87 and Ser to Gly/Asn at codon 97 due to DNA mutation in core region were associated with severity in CAHB. And these mutations were simply detected by RFLP. These results showed that PCR-RFLP at codon 87 and 97 is available for prediction of severity in chronic active hepatitis B without DNA sequencing. Liver and bile ducts, 1: Hepatitis viral, diagnosisLiver and bile ducts, 1: Hepatitis, viral, treatment }" "Prediction of Severity in Chronic Active Hepatitis B (CAHB) by PCR-RFLP Method"

"P P 3 0083"P 3 0083 **Is There a Real Nuclear Localization of HBV Core Protein? A Detailed Subcellular Localization Study**

*H. Sirma, O. Rosmorduc, D. Kremsdorf, C. Bréchot

INSERM U370, Paris, FranceThe subcellular distribution of HBV capsid protein (C) and its implications for the viral life cycle is still a matter of debate. In the present study we examined the localization of C in different cell lines as well as in the livers of humans and replicative transgenic mice (TG) in dependance from cell cycle and viral replication status. *Methods:* I*n vitro:* Huh7, COS and NIH 3T3 cells were stably and/or transiently transfected with constructs containing HBV, dHBV (generated from singly spliced 2.2 kb HBV RNA) or C-ORF alone. Huh7 cells were synchronized using TGF{ b}, double thymidine block and nocodazol (N). The intracellular distribution of C was studied by confocal microscopy (CM) and biochemical fractionation of synchronized cells. *In vivo:* Localization of C in the livers of highly replicating HBV TG (kindly provided by F. Chisari) and humans from both high and low HBV replicators was studied by Immunocytochemistry (IC) and CM permitting 3D reconstructions (3D). *Results:* I*n vitro:* There was no evidence for a cell cycle related nuclear translocation of C, contrasting with recently reported data. C was in fact exclusively cytoplasmic characterized by diffuse to granular staining with perinuclear attentuation. Transfection of COS cells stably expressing large T-Antigen (LTA) revealed C is not a nucleoprotein like LTA. Double labelling with antibodies against nuclear pore complex (NPC) and lamin showed further an association of C with nuclear membrane (NM). Biochemical fractionation of synchronized cells confirmed further the in situ localization data. In addition, N -arreting cells in mitosis- led to a dimunition of C as revealed by immunoblotting. *In vivo:* TG showed cytoplasmic C staining in centrilobular hepatocytes whereas nuclear C was panlobular revealed by IC as recently reported (Guidotti et al.). The human livers from high replicators showed in virtually all hepatocytes cytoplasmic C in addition to the nuclear staining. In low replicators C was restricted only to the nuclei. A detailed CM analysis of nuclear C distribution in TG and human hepatocytes with a 3D provided evidence for a localization of C only at the NM. *Conclusions:* Our results show 1) that C is restricted exclusively to the cytoplasm. However, we provide evidence for an association of C with the NM and mitotic disassembly of NM destabilize C. 2) In vivo, cytosolic C is an indicator of high viral replication. Altogether our data are consistent with the following scenario: low viral replication is accompanied by low C expression. The reported nuclear localization signal of C leads to its binding to the NM but is not sufficient for a translocation through the NPC. The accumulation and stabilization of C at the NM is disturbed with each mitotic NM disassembly.

"P P 3 0084"P 3 0084 **Randomised Controlled Trial of Interferon { a}2B in Prolonged Hepatitis B***

*K.T. Shenov, K.B. Leena

Dept. of Gastroenterology, Medical College, Trivandrum, India*Objective:* With the hypothesis that interferon is effective and well tolerated in prolonged hepatitis B (> 10 weeks), we designed this randomised controlled trial.*Setting:* Tertiary referral centre.*Participants:* Patients with virus B hepatitis of > 10 weeks and positive of anti HBclgM, HBeAg with elevated alanine aminotransferase (1.5 {\'b4} N) were recruited.*Intervention:* { a}-interferon (INTRON A) 3 MU thrice weekly (group A) for sixteen weeks or conventional treatment (group B) was given.*Study variables:* Clinical status (weekly), biochemical and haematological parameters (monthly) and HBV markers at 4, 8 and 16 weeks of therapy. Subjects were followed up for 6 months after the trial. Compliance to therapy and side effects were monitored.*Outcome variable:* Clinical improvement, clearance of HBsAg and HBeAg.*Results:* Of 20 patients enroled, 9 received interferon and 11 conventional treatment. Age ranged from 18 to 42 years and baseline characteristics were similar in both groups. Compliance therapy was 100% and side effects such as malaise and arthralgia were noted two patients. HBsAg became negative in two patients each in group A & B. HBeAg was negative in 3/9 (group A) and 2/11 (group B). One patient in group B progressed to subacute hepatic failure and expired.*Conclusion:* Interferon treatment is beneficial in prolonged B hepatitis and is a promising modality of treatment. Further long term trials are needed in larger samples.* Study funded by Fulford India Limited (Schering Plough, USA). Liver and bile ducts, 1: Hepatitis, viral, treatment }" "Randomised Controlled Trial of Interferon alpha2B in Prolonged Hepatitis B*"

"P P 3 0085"P 3 0085 **Pre-Core Stop Codon Mutations among Patients with Chronic HBV Infection in TurkeyA.M. Bozdayi, O. Uzunalimoglu, H. Bozkaya, H. Cetinkaya, H. Aydogan, M. Arslan, H. Ozsan, C. Yurdaydin, S. Karayalcin**

Department of Gastroenterology, Ankara University, School of Medicine, Ankara, Turkey*Background:* Pre-core stop codon mutation, G to A substitution at nucleotide 1896 that preclude the production of HBeAg develops around the time of HBe seroconversion. Pre-core stop codon mutation (A1896) is not found in patients (pts) infected with HBV genotypes that have a C at nucleotide 1858 due to base-pairing in the stem-loop structure of the pregenome encapsidation signal. Thus the prevalence of the pre-core stop codon mutant (A1896) among HBeAg{ -}ve pts varies in different geographical areas depending on the predominant HBV genotype.*Aim:* To determine the prevalence of pre-core stop codon mutation (A1896) in Turkish pts with HBeAg+ve and HBeAg{ -}ve chronic hepatitis B.*Patients and Methods:* Sera from 14 HBeAg+ve and 18 HBeAg{ -}ve pts were analyzed by direct sequencing of the pre-core region of PCR amplified DNA.*Results:* All the patients studied had T at nucleotide 1858. Three of 14 HBeAg+ve pts had mixture of wild type and stop codon mutant A1896, the other 11 had wild type sequence only. Fifteen of 18 (83%) HBeAg{ -}ve pts had the stop codon mutation (A1896). Three pts had another commonly described mutation involving the G to A change at nucleotide 1899. Mutations involving the initiation codon was not observed in any pts studied.*Conclusion:* Most HBeAg{ -}ve Turkish pts with chronic hepatitis B have the pre-core stop codon mutation (A1896). The high prevalence of A1896 is related to the fact that the predominant HBV genotype in Turkey has a T at nucleotide 1858 which permits G to A mutation at nucleotide 1896. "P P 3 0086"P 3 0086 **Hepatitis B X-Protein is Exclusively Located in the Cytoplasm and Colocalizes with Proteasomes**

*H. Sirma, O. Rosmorduc, D. Kremsdorf, C. Bréchot

INSERM U370, Paris, FranceIn view of the potential implication of HBV X-Protein (X) in hepatocarcinogenesis we have studied its subcellular distribution during the cell cycle for the following reasons: *I.* The subcellular localization of X is still a matter of debate *II.* X may exert, depending on its sublocalization, different effects and interact with proteins which are temporary expressed and compartmentalized in function of the cell cycle. *Methods:* \'b4*1* 1) Huh7 cells were stably transfected with HBV and dHBV (generated from singly spliced 2.2 RNA) containg constructs. 2) Expression of X was studied by immunoblotting. 3) Cell synchronization was achieved by TGF{ b} (G1), double Thymidine block [dT] (S) and Nocodazol [N] (M). S-Phase was additionally labelled by BrdU pulse. Cellular localization of X was studied by immunofluoresence (IF). \'b4*2* To analyse the behaviour of X in living cells we have used the green fluorescent protein (GFP). GFP was used as a C-terminal tag to create X-GFP chimera and was expressed in cells by transient transfection. Subsequently, the distribution of GFP and X-GFP was analysed in living cells by fluorescence microscopy. Using fixed cells, we have further performed double-labelling using 7-Actinomycin D and antibodies against Lamin and Proteasomes. The biological activity of the chimer protein was tested using the stimulation of NF-kB dependent transcription by X. *Results:* \'b4*1* The cells could be synchronized to high degree (> 80%). X was distributed irregularly as granules embedded in diffuse cytoplasmic staining with perinuclear dominated corona. \'b4*2* GFP alone was diffusely located both in the nucleus and the cytoplasm. In contrast, X-GFP was located only in the cytoplasm as granulo-globular structures and juxtanuclear caps. Using double labelling in fixed cells, CA confirmed the exclusively cytoplasmic location of X as already seen in living cells. IF and CA studies further demonstrated a colocalization of the cytoplasmic proteasomes at sites of X. X-GFP chimer activate NF-kB dependent transactivation consistent with recently reported data. Thus, addition of GFP to X does not alter one of its well characterized biological activity. *Conclusions:* 1) X is located exclusively in the cytoplasm. There is no cell cyle dependent translocation into the nucleus. These data support a model of X acting indirectly on transcriptional process. 2) The colocalization of X with proteasomes suggest that X may interefere with cellular protein degradation leading to modulation of the half-life and activity of transcriptional and other regulatory factors; this would provide an unifying explanation for the markedly pleiotropic effects of X. "P P 3 0087"P 3 0087 **Hepatitis B: Flare of Hepatitis during Alpha Interferon Therapy**

*J. Areias, I. Pedroto, T. Freitas, A.M. Saraiva

Dept. Gastroenterology, Hospital Geral de Santo Ant\'f3nio and Instituto de Ci\'eancias Biom\'e9dicas Abel Salazar, University of Oporto, Oporto, PortugalCurrent treatment of HBV-related hepatitis includes alpha interferon (IFN).*Aim* – To assess the incidence and severity of the HBV flare with IFN-{ a}.*Patients and Methods* – We have studied 36 patients with chronic hepatitis B histologically proven, that were enrolled in two randomized controlled trials of IFN-{ a}. Eighteen patients were initially treated with 5 MU of IFN-{ a}. Clinical data were analyzed on 13 (36%) responders (loss of HBe Ag and HBV DNA by dot blot) and 23 (64%) non responders. Flare was defined as an elevation of ALT greater than 3 times of the median pre-treatment value and > 200 U/L during the 24 weeks of therapy.*Results* – Sixteen of 36 (44%) treated patients had a flare during IFN { a} therapy. None of 23 untreated control subjects had a flare during a period of observation of 6 months. ALT levels during the flares ranged from 226 to 894 U/L. No patient had decompensated liver disease. Patients with and without a flare were similar concerning age, sex, initial mean ALT level, HBV DNA and liver histology. Patients who had a flare were more likely to loss HBe Ag and HBV DNA (30.5% vs 8.7%). Among the 13 responders, 7 (61.5%) experienced a flare with IFN{ a}, and all had cleared viremia. Flares in responders had higher ALT levels (538 vs 226 U/L, $p < 0.05$) than in non responders.*Conclusions* – During IFN-{ a} therapy for chronic hepatitis B: 1) flares of hepatitis occurred in 44% of patients; 2) there was an association with a higher rate of HBe Ag and HBV DNA loss; 3) Early HBV flare with significant enzyme elevation results in sustained viral clearance. Liver and bile ducts, 1: Hepatitis viral, diagnosis }" "Hepatitis B: Flare of Hepatitis during Alpha Interferon Therapy"

"P P 3 0088"P 3 0088 **Prevalence of Hepatitis E Virus Antibodies in Tunisia**

*M.F. Khediri, M.R. Bouali, M. Ben Moussa, H. Ben Abdallah, J. Hamida, A. Amor

Department of Gastroenterology and Department of Microbiology, Military Hospital, Tunis, TunisiaHepatitis E virus (HEV) infection is common in Asia and Africa, but its prevalence is unknown in our country. Furthermore, although HEV represents the main etiological agent of enterically transmitted non-A, non-B (NANB) hepatitis, the risk factors associated with anti-HEV positivity are not well known yet.*Aim:* This study investigates the prevalence of HEV antibodies in different populations and compares it to hepatitis A and C antibodies prevalence.*Method:* We studied the prevalence of anti HEV IgG in 205 asymptomatic male volunteer blood donors (AVBD), 87 health related staff (HRS), 49 hemodialysis patients and 21 cirrhotic patients. All samples were tested with HEV EIA (Abbott Laboratories). ELISA technique was used to detect anti-HAV IgG and anti-HCV antibodies.*Result:* (see table). n age (years) anti HEV anti HAV anti HCVAVBD 205 24 4.9% 100% 0.49%HRS 87 32 8%* 98% 1.7%*Hemodialysed 49 47 14%* 98% 41%*Cirrhotic patients 21 60 19%* 100% 86%**p < 0.05 referring to AVBD*Conclusions:* The prevalence of HEV antibodies varies from 4.9% (AVBD) to 8% (HRS) in healthy people. It is lower than rates incountered in India and other parts of Africa, and higher than European rates. This prevalence is about 14% and 19% respectively in hemodialysis and cirrhotic patients, suggesting that these two conditions may represent risk factors for HEV infections (but this may also be related to the more advanced age in these two groups). Clinical practice: Epidemiology (non cancer)Liver and bile ducts, 1: Hepatitis viral, diagnosis }" "Prevalence of Hepatitis E Virus Antibodies in Tunisia"

"P P 3 0089"P 3 0089 **Detection of Hepatitis G/GB-C Viral RNA but not HCV RNA in the Different Semen Fractions of Infected Patients**

*T. Persico, V. Thiers[1], R. Tuveri[1], M. Di Fine[3], A.E. Semprini[2], C. Brechot[1]

[1] INSERM-U370 Necker and CBMS Pasteur Institut Paris, France

[2] Dept. Obstetrics and Gynecology, ISBM San Paolo, Univ. of Milan, Italy

[3] C. M. S. Patrignano, Rimini, ItalyThe issue of sexual transmission of HCV is still debated. A new RNA virus, HGV/GB-C, related to HCV, has been recently identified. There is no information on the risk of its sexual transmission. *Objective:* Investigate the presence of HCV and HGV RNA in the different fractions of semen: seminal plasma (SP), spermatozoa (Spz.), round cells (RC, leukocytes and spermatogenesys cells), swim-up (SU) by PCR. *Methods:* 90 anti-HCV (+) Italian previously drug addicted males, were included (27 HIV+). The different fractions of the semen samples were obtained after discontinous Percoll gradient. HCV RNA was tested in sera and different semen fractions by PCR (5{\'a2} NCR). HGV RNA was tested in sera and in some selected semen samples by PCR (NS_3/NS_5). Negative results were only interpreted in semen fractions in the absence of PCR inhibition (previously reported in such samples). *Results: Serum:* HCV RNA was detected in 55/90. 26/90 samples were positive for HGV/GB-C including 15 HCV RNA (+) and 11 HCV RNA ({ -}). *Semen fractions:* HCV RNA was detected in none of the 22 SP, 50 RC, 50 Spz and 50 SU tested. HGV/GB-C RNA was detected in the seminal plasma of 6/24 (25%) tested, serum HGV RNA (+) individuals. *Conclusions:* Our results: 1) demonstrate that even in HCV-viremic subjects each semen fraction (SP, RC, Spz) results uninfected from HCV, confirming that sexual transmission of HCV is rare; 2) confirm the high prevalence of HCV/HGV coinfections in IVDU. 3) show, that HGV/GB-C genome can be detected in sperm raising the possibility of distinct modes of transmission from HCV. Liver and bile ducts, 1: Hepatitis viral, diagnosisClinical practice: Epidemiology (non cancer) }"

"P P 3 0091"P 3 0091 **Infections from Viral Hepatitides and HTLV-I/II after Open-Heart Surgery in North Western Greece. A Preliminary Study****G.N. Dalekos[1], G.K. Liapi[2], E. Zervou[3], J. Goudevenos[2], E.V. Tsianos[1], D. Sideris[2]**

[1] Department of Internal Medicine (Division of Internal Medicine), School of Medicine, University of Ioannina, Greece

[2] Department of Internal Medicine (Division of Cardiology), School of Medicine, University of Ioannina, Greece

[3] Blood Bank at the University Hospital of Ioannina, Greece*Purpose:* The aim of the present preliminary study was an attempt to determine the prevalence of several markers of viral hepatitides (B-E) and HTLV-I/II infections in patients (pts) from northwestern Greece who underwent an open-heart surgery. *Methods:* We investigated 104 pts (90 having coronary artery bypass grafting and 14 having replacement of mitral or aortic valve) and 113 healthy controls matched for age and sex. Forty six pts had been operated on before 1991, among them 83 pts had the open-heart surgery done in Greece and the remaining 21 pts abroad. The pts had at least a 6 month period from the time of the operation to the entrance the study. The serological determinations of the various viral markers were done using commercially available enzyme immunoassays as well as confirmatory immunoblot assays (for HCV and HEV). *Results:* We found that none of the pts was positive for the HBsAg or the anti-HTLV-I/II antibodies. By contrast, the markers of a previous infection by HBV were found more frequent in pts (HBcAb: 46.1%, HBsAb: 37.3%, HBeAb: 37.3%) than in healthy controls (30.9%, 24.8% and 7.95% respectively). These differences were statistically significant ($p < 0.05$, $p < 0.10$ and $p < 0.0001$ respectively). The presence of the markers of previous HBV infection among pts was not associated with age, sex, place of the operation or the number of transfusions, but with a longer duration from the day of the open-heart surgery (HBcAb: 70.7 – 65.2 in positive vs 49.6 – 38.4 in negative ($p < 0.05$), HBsAb: 75.3 – 68.7 in positive vs 49.9 – 39.1 in negative ($p < 0.10$) and HBeAb: 70.9 – 70.3 in positive vs 52.5 – 38.8 in negative ($p < 0.0001$)). Anti-HCV and anti-HEV antibodies were detected in 1.92% and 3.94% of pts respectively but this frequency was not statistically significant when compared to healthy controls (0% for both antibodies). *Conclusions:* We conclude that: (1) this group of pts does not appear to be a high risk group for HTLV-I/II infection as we have already reported it for other groups; (2) although none of the pts was positive for HBsAg, the presence of significantly increased incidence of markers of previous HBV infection compared to healthy could suggest this group as a high risk one for HBV infection and a intensive vaccination schedule against HBV before the operation seems rationale; (3) the presence of anti-HEV antibodies among the pts needs further evaluation, since, the oral fecal route of transmission of HEV may be not the only one. Clinical practice: Epidemiology (non cancer) }" "Infections from Viral Hepatitides and HTLV-I/II after Open-Heart Surgery in North Western Greece. A Preliminary Study"

[3] Department of Radiology, Ospedale Civile, Modena, Italy

[3] Department of Chair of Medical Statistics, University, Modena, Italy*Background & Aim* Ultrasound (US) finding of a \lquotebright\rquote liver (BL) is accurately predictive of fatty liver allowing non-invasive surveys of this common condition. Our purpose was to ascertain factors independently associated with a BL US finding in our series. The hypothesis was that a cluster of features characterize the so-called *\lquoteBright Liver Syndrome\rquote* (Lonardo A, Endoscopy 1995; 27 A61. Lonardo A, Am J Gastroenterol 1995; 90: 2072–2074). *Series & Method* 97 subjects underwent liver US scanning, anthropometric and laboratory evaluation. Criteria for exclusion were: pregnancy, thyroid disease, exposure to hepatotoxic drugs or chemicals, familial heterozygous hypobetalipoproteinemia (Lonardo A, Gastroenterology 1996; In Press). The following data were registered: age (ys); alcohol consumption (g/day); body mass index (BMI, in Kg/m^2); serum levels of GOT and GPT (mu/ml), albumin (g/dl), total cholesterol (ch), HDL-ch, triglycerides (tg), apoB, fasting glucose (all in mg/dl). Based on the liver-kidney contrast (Yajima Y. Tohoku J Exp Med 1983; 139; 43–50) cases were classified as controls (n = 50; 40 males) or BLs (n = 47; 35 males). Data were analyzed through SPSS package. *Results* Mean values were as follows (control vs. BL): age 65.6 vs. 56.4; BMI 25.8 vs. 29.2; alcohol 26.1 vs. 35.8; glucose 91.6 vs. 96.8; ch 195 vs. 225; ch-HDL 38.3 vs 43.2; apoB 1.23 vs. 1.44; tg 134.6 vs. 178.1; albumin 3.5 vs. 3.9. Univariate F-ratio analysis selected BMI (0.0001), serum albumin (0.0004), age (0.0005), ch (0.0009), tg (0.005), apoB (0.005) and ch-HDL (0.02) as significantly different in cases with BL vs. controls. Using BL as a dependent variable, logistic regression analysis (LRA) carried out through backward stepwise approach disclosed BMI (0.0072), age (0.0080), apo B (0.0359) and tg (0.0822) to be independent predictors of BL. However, when forward stepwise approach was adopted, BMI (0.0072) ch (0.0143) and age (0.0185) turned out to be significant. LRA allowed correct classification of cases with 74.22% accuracy. *Conclusions* Obesity, younger age, hypercholesterolemia, hypertriglyceridemia and elevated serum apo B levels are independent predictors of BL in our series. These findings support the existence of the *""Bright Liver Syndrome""* and highlight its metabolic significance. "P P 4 0093"P 4 0093 **Ultrasonographic Score (USS) of Chronic Hepatitis**

*G. Palasciano, V.O. Palmieri, F. Ungaro, A. Velardi, P. Portincasa

Chair of Semeiotica Medica, Department of Internal and Occupational Medicine, University of Bari Medical School, Bari, ItalyAn ultrasonographic score (USS) has been prospectively correlated to the histological activity index (HAI) in 20 patients with chronic hepatitis (10 HCV, 6 HBV, 1 HBV and HCV, 2 alcohol-correlated). USS was determined within 24^ from liver biopsy by 3 independent operators without knowledge of the biopsy results, clinical data and previous US. The parameters of USS were classified as hepatic, extrahepatic and vascular: hepatic echogenicity, distal attenuation, liver edge, periportal fibrosis, portal hypertension, echogenecity of hepatic veins wall with doppler waveform, porta hepatis lymphnode, Morrison space thickness and Harbin index (caudate lobe transverse diameter/right lobe transverse diameter). Each parameter was scored as 1, 2 or 3. A recently proposed score (Williams et al., J Hepatol 1995; 22: 513–21) involving 3 parameters (hepatic echogenicity, liver edge and periportal fibrosis) was simultaneously evaluated in each patient. Comparisons were made between the USS and the results of histological examinations using the Spearman Rank correlation coefficient.USS was highly and positively correlated with HAI (n = 20; r = +0.73; p < 0.001) and the results were better than applying the score proposed by Williams (n = 20; r = +0.55; p < 0.05).The accuracy of the USS in the diagnosis of cirrhosis was also evaluated: Cut-off value Sensitivity SpecificityWilliams score {\'b3} 6 66.7% 99.8%USS {\'b3} 18 83.4% 100%The USS proved to correlate with the histological activity of hepatic disease and allowed the identification of patients with cirrhotic chronic liver disease. The utility of the USS for grading and staging of diffuse hepatic diseases is under evaluation. "P P 4 0094"P 4 0094 **Nitrous Oxide Analgesia for Intercostal Liver Biopsies: Results of a Prospective Randomized Trial**

*L. Castera[1], I. Négre[2], N. Gueroult[1], K. Samii[2], C. Buffet[1]

Service des Maladies du Foie et de l'Appareil Digestif C.H.U. de Bic\'eatre, 94275 Kremlin-Bic\'eatre, France

D\'e9partement d'Anesth\'e9sie R\'e9animation C.H.U. de Bic\'eatre, 94275 Kremlin-Bic\'eatre, FrancePre-mixed 50% nitrous oxide and oxygen mixture (Entonox') analgesia has previously been shown to be effective in pediatrics for painful acts. It is widely used during labour, is safe and can easily be administered by the patient. Liver biopsy is essential for the diagnostic and severity assessment of most chronic liver diseases, however it may be painful to the patient. Sedation is not routinely given before biopsy because no protocole has proven to be effective so far.*Aims:* to study prospectively the effects of Entonox' on pain relief and comfort in comparison with a placebo in patients undergoing intercostal liver biopsy using a randomized study design.*Methods:* 48 consecutive patients admitted since march 1996 to our unit for intercostal liver biopsy (chronic hepatitis C: 26, alcoholic liver disease: 12, others: 10) were enrolled after local ethical comittee approval and written informed consent. They were randomized to receive during biopsy either (i) a breathing mixture of even parts of oxygen and nitrous oxide (Entonox') from a face mask with a demand valve (group E, n = 23), or (ii) a breathing oxygen placebo from the same valve setup (group P, n = 25). Liver biopsy was performed by 2 senior operators according to the Menghini technique after adequate local anesthesia with Xyloca\'efne 1%. Pain after biopsy was assessed at the end of procedure (D0) and the next morning (D1) using visual analogue scales (VAS) scoring from 0 to 100. The following data were also assessed: comfort scored from 0 to 100 (VAS); anxiety scored from 0 to 100 (VAS); amount of antalgic drugs (paracetamol mg) required within the 12 hours following biopsy; acceptance of a new biopsy; incidents and side effects observed.*Results:* Pain scores at D0 were 10.95 – 2.66 and 29.72 – 4.7 for groups E and P respectively ($p < 0.002$). Pain scores at D1 were 15.7 – 4.6 and 35 – 5.4 for groups E and P respectively ($p < 0.01$). Comfort scores were 84.4 – 3.35 and 68.44 – 5.28 for groups E and P respectively ($p < 0.02$). Anxiety scores were 31.3 – 4.85 and 34.08 – 6.27 for groups E and P respectively ($p = 0.7$). All patients agreed for new biopsy with the same conditions. No serious adverse effect was observed. Amount of antalgic drugs required was not statistically different between the 2 groups. The average cost of Entonox' use was 4$ per biopsy.*Conclusions:* Administration of Entonox' during intercostal liver biopsies resulted in a significant decrease in pain at D0 and D1 and in discomfort of patients without influence on anxiety. If such results are confirmed on a larger group of patients, Entonox' could increase the acceptability of liver biopsy in the follow up of patients with chronic liver diseases. "P P 4 0095"P 4 0095 **Serum Erythropoietin Level in Cases of Normocytic Normochromic Anaemia in Hepatic Fascioliasis**

*M.N. El-Khashab, A.M. Mahmoud, M.Z. Nasar, I.M. Hegazi, E.G. El-Badrawy

From Tropical Med. and Clinical Pathology Departments, Faculty of Medicine, Zagazig University, EgyptIn Egypt, human fascioliasis is an increasing health problem especialy in the Nile Delta. This study was conducted on 35 anaemic* patients with fascioliasis, 20 anaemic* patients with schistosomiasis (parasitic control group) and 10 persons (healthy control group).Serum erythropoietin ""EPO"" and ferritin were measured using a sandwich ELISA technique, aslo other ferrokinetic parameters were done.In patients with fasciolisis, EPO level (19.05 – 13.3 mU/ml) was significantly higher than those of healthy control (7.23 – 1.6 mU/ml) and of schistosomisis (12.3 – 2.85 mU/ml) groups ($P < 0.001$).Serum ferritin was significantly higher in fascioliasis group (384.8 – 51.1 ng/ml) than in schistosomisis (174.7 – 83.4 ng/ml) and in healthy control (117.5 – 29.5 ng/ml) groups. ($P < 0.001$).Other ferrokinetic studies showed low serum iron, subnormal trasferrin saturation, low total iron binding capacity, inspite of adequate iron stores shown by high serum ferritin, these findings together with normal reticulocytic count were similar to those found in the anaemia of chronic disorders.The presence of anaemia inspite of high EPO level and adequate body iron stores may be explained by unresponsiveness of bone marrow to high EPO level which may be due to blocking the action of EOP by some cytokines as interleukin -1, tumour necrosis factor, and gamma interferon which were proved to be abundant in hepatic fascioliasis, or it may be due to an inhibition of bone marrow by large amount of proline which is usually present in hepatic fascioliasis.After treatment, cases of hepatic fascioliasis showed a good improvement of all parameters which were more or less comparable to those of healthy control.* Normcytic Normchromic anaemia. Liver and bile ducts, 1: Liver diseases, childrenLiver and bile ducts, 1: Chronic non viral hepatitis }" "Serum Erythropoietin Level in Cases of Normocytic Normochromic Anaemia in Hepatic Fascioliasis"

"P P 4 0096"P 4 0096 **Cirrhosis and Cryoglobulinemia: Relation with Severity and Evolutivity of Liver Disease**

*I. Allemand, M. Perr\'e9ard, P. Pagliero, P. Bellon, D. Monges, M.A. Chrestian, A. G\'e9rolami

Service d'H\'e9pato-Gastroent\'e9rologie, CHU Timone, 13005 Marseille, FranceRecent studies have reported a relationship between presence of mixed cryoglobulinemia (CG) and cirrhosis in patients with alcoholic or viral liver disease. The aim of this study was to assess the prevalence and the prognostic significance of CG.*Patients and methods.* 77 cirrhotic patients (53 men, 24 women) were enroled in this study. All the patients were tested for anti-HCV antibodies by a third generation ELISA test, for HCV-RNA by PCR, and for HBS Antigen. Cryoglobulinemias were characterized by immunoblotting. The causes of cirrhosis were alcohol (31 patients), HCV (30 patients) and miscellaneous (16). In addition, 101 patients with chronic hepatitis caused by HCV but without cirrhosis, were included.*Results.* CG was found in 66% of our patients with cirrhosis (58% in alcoholic cirrhosis, 74% in HCV-cirrhosis: NS), however, the CG level was higher in HCV patients. There was no significant difference in age between patients with CG and without CG (56 – 9 y. vs. 61 – 9 y. in alcoholics, 59 – 12 y. vs. 53 – 14 y. in HCV infected patients). There was no difference in prevalence of CG according to CHILD' score. Among the patients without cirrhosis, CG was found in 54,4%. There was no difference in age between patients with and without CG (42 – 14 y. vs. 41 – 15 y.).*Conclusion.* These results confirm the high prevalence of CG in liver disease, and the role of HCV infection. The fact that CG is unrelated with the CHILD's score nor with and early occurrence of cirrhosis suggests that it is an epiphenomenon without consequence on the evolution of the liver disease. Liver and bile ducts, 1: Hepatitis viral, diagnosis }" "Cirrhosis and Cryoglobulinemia: Relation with Severity and Evolutivity of Liver Disease"

"P P 4 0097"P 4 0097 **Child-Pugh-MEGX Score in Assessment of Prognosis in Cirrhotic Patients**

*R. Testa, S. Caglieris, E. Giannini, L. Arzani, S. Alvarez, G.L. Guido, A. Remagnino, G. Celle, D. Risso[1], P.B. Lantieri[1], R. Pellicci[2], L. Mondello[2], G. Dardano[2], U. Valente[2]

Gastroenterology Unit, DIMI, Italy

[1] Institute of Medical Statistics, Italy

[2] Transplant Center, University of Genoa, ItalyPrognostic evaluation of cirrhotic patients is a basic step for liver transplantation. The Child-Pugh's score is the usual tool and monoethylglycine xylidide (MEGX, lidocaine metabolite) formation was proposed as an additional test. Aim of this study was to verify the prognostic usefulness of the combined score Child-Pugh-MEGX in cirrhotic patients. One hundred forty-three patients (104 males, 39 females, mean age 49 – 9), consecutively admitted to our Units for functional hepatic evaluation, were studied. According to Child-Pugh's score 32 patients were class A, 79 class B and 32 class C. Serum MEGX (ng/ml) at 30 min after i.v. lidocaine (1 mg/Kg) was measured by TDX fluorescent polarization immunoassay. MEGX 30 min were scored as follows: score 1 to > 30 ng/ml; 2 to 30 \'f7 10 and 3 to < 10. The modified Child-Pugh-MEGX score was calculated by adding MEGX-score to Child-Pugh original score. In the follow-up period, ranging from 6 to 60 months, twenty patients died and thirty were transplanted. Kaplan-Meier survival curves were calculated for patients: 1) with Child-Pugh scores {\'a3} 9 and for those with scores > 9 (whole survival was 93% versus 63%, Cox's test p < 0.00001); 2) with MEGX levels {\'b3} 10 ng/ml and for those with levels < 10 (94% versus 70% survivors, p = 0.001), and 3) for patients with Child-Pugh-MEGX scores {\'a3} 12 and for those with scores > 12 (92% versus 58% survivors, p < 0.00001). These whole survivals reflect those at 12 months. Excluding Child-Pugh's class A patients, Cox's test significativity was p = 0.00008 for Child-Pugh score, p = 0.00049 for MEGX level and p = 0.00001 for Child-Pugh-MEGX score. These results suggest that MEGX test can improve prognostic evaluation only in Child-Pugh's class B and C patients. Liver and bile ducts, 1: Liver transplantation }" "Child-Pugh-MEGX Score in Assessment of Prognosis in Cirrhotic Patients"

"P P 4 0098"P 4 0098 **The Changes of the Lipid Profile in Hepatitis PatientsY. Baykal, M.R. Mas,**

*S. Nalbant, H. \'d6zotuk, C. G\'f6nl\'fcsen, F. Kocabalkan

GATA Int. Med. Dept. Ankara/TurkeyThe liver has an important role in the metabolism of cholesterol, cholesterol esters, phospholipid and trigliserid. The transportation of cholesterol, trigliserid and phospholipid are carried by apolipoproteins. The lipid profile changes in acute and chronic liver disease. Activity of the plasma lesitin cholesterol acil transferase (LCAT) which is produced by the liver and esterifies the plasma cholesterol, decreases. So HDL and VLDL decrease; LDL and trigliserid increase. Some reports declared that annexin-V and apoprotein-H facilitate the bounding of protein-S of HBsAg to hepatosit. We studied lipid fractions in hepatit-C, chronic active hepatitis (CAH), chronic persistent hepatit (CPH). Cont (n. 34) HBV (n. 30) HCV (n. 14) CPH (n. 13) CAH (n. 44)Cholest. 208.11 – 31 190.16 – 54 203 – 53.7 192.8 – 39 181.8 – 33.6Trigliserid 190.02 – 84 155.83 – 83 163.46 – 83.6 126.1 – 50.4 102.55 – 41.1HDL 37.55 – 6.4 40.66 – 11.1 49.4 – 5.2 38.6 – 4.9 45.17 – 10.1LDL 138.52 – 27.4 119.33 – 58.6 122.6 – 54.6 133.5 – 39.3 115.42 – 34.4VLDL 38.4 – 17.4 31.08 – 16 32.6 – 17 25.2 – 15.3 20.4 – 8.1We found low cholesterol values in subjects, specially in CAH patients. It was nearly the same for trigliserid. HDL-cholesterol was the highest in active HCV infectious patients. LDL-cholesterol was lowest in CAH group. When we compared the CAH with CPH cholesterol, it was obtained that trigliserid and cholesterol values were lower at CAH but it was not statistically significant $(p > 0.01)$. HDL was higher and LDL was lower at CAH group. $(p < 0.05)$. Cholesterol and trigliserid were lower HBV infection group $(p > 0.05)$. HDL was higher at HCV group and LDL was lower at HBV group $(p > 0.05)$. As a conclusion, We obtained high lipid levels at all of the subjects according to control group. But you can not explain these changes only with some metabolic changes at the level of hepatosit (disorders of the Lechitin metabolism, decreasing LCAT enzyme activity) and disorders at the level of membrane receptors and changes of the metabolism of the hepatic synthesis. So we need more studies for explaining that pathophysiologic event. Liver and bile ducts, 1: Chronic non viral hepatitisLiver and bile ducts, 1: Hepatitis viral, diagnosisClinical practice: Management strategy }" "The Changes of the Lipid Profile in Hepatitis Patients"

"P P 4 0099"P 4 0099 **Increase of Urinary Neopterin Levels in Chronic Liver Disease**

*H. Simsek, A. Kadayifci, Z.Z. Altindag, G. Sahin, M.A. Ozturk, Y. Akcan

Hacettepe University, Ankara, TurkeyNeopterin is a pteridine which is produced under the control of interferon-gamma by human mononuclear phagocytes. Although, physiological role of neopterin is not yet clear, it is generally accepted as one of the indices of cell-mediated immune activation. Increased serum and urinary neopterin levels have been found in conditions causing activity of cellular immunity, including various malignancies, autoimmune disease, certain viral infections and transplant rejection. Therefore, it is a useful tool in the diagnosis and monitoring the therapy of these conditions. This preliminary study was carried out to evaluate the urinary neopterin levels in chronic liver disease (CLD). Fifteen patients with liver cirrhosis, 13 patients with chronic active hepatitis C (CAH-C), and 16 healthy subjects were enrolled to the study. The diagnose was based on clinical findings and liver biopsy in all patients. Early morning urine samples were obtained from all of the subjects and urinary neopterin was measured by high pressure liquid chromatography. The mean levels of urinary neopterin (ng/ml) between three groups were compared by Student's t test (Table 1)Table 1. Neopterin levels in patients and controls. Groups n M/F median age Neopterin (mean – SEM)1. Cirrhosis 15 11/4 49 399 – 972. CAH-C 13 6/7 47 182 – 623. Control 16 9/7 44 123 – 16An overall increase of neopterin levels in CLD were observed. This increase was most prominent in liver cirrhosis and statistically significant compared to controls (p = 0.007). Therefore, neopterin levels in CAH-C patients did not show marked elevation as found in cirrhosis. Neopterin levels in cirrhotic patients did not affected by etiology of disease, its clinical severity and are not correlated with serum alanine aminotransferase and aspartat aminotransferase levels. *Conclusion:* This study suggest that urinary neopterin value was elevated in CLD, especially in cirrhosis. Cell-mediated immune activation may be responsible for increase in urinary neopterin level in these patients. Immunology and microbiology: Host defense mechanismsLiver and bile ducts, 1: Cirrhosis: portal hypertensionLiver and bile ducts, 1: Hepatitis viral, diagnosis }" "Increase of Urinary Neopterin Levels in Chronic Liver Disease"

"P P 4 0100"P 4 0100 **Increments in Plasma Prothrombin Fragment 1.2 Concentrations in Chronic Liver Disease**

*H. Simsek, A. Kadayifci, I. Haznedaroglu, S. Kirazli

Hacettepe University Medical School, Ankara, TurkeyProthrombin fragment 1.2 (PF 1.2) is a peptide fragment that is generated during the conversion of prothrombin into thrombin which is a main key event within the coagulation cascade. As a good molecular marker of thrombin formation, quantitative PF 1.2 determination may be used to assess the hypercoagulable/prethrombotic states. Abnormal hemostasis is a common complication of liver diseases, and its underlying pathogenesis is still an enigma. In this study, we have measured the plasma levels of PF 1.2 in patients with chronic liver diseases (CLD) in order to assess in vivo coagulation in these patients. Twenty-six patients with liver cirrhosis, and 14 patients with chronic active viral hepatitis were included. Age and sex matched 15 healthy subjects were also studied as controls. Venous blood samples, which were obtained without venous stasis, were collected in standard citrated tubes and centrifuged. Supernatant plasma was stored at { -}30\'b0C until assayed up to 3 months. Plasma PF 1.2 level in all samples was detected by EIA (Enzygnost F1 + 2 micro kit). The reference range and measuring range of kit was 0.44–1.1 nmol/L and 0.04–10 nmol/L, receptively. Data was expressed as mean – SEM and significance of differences between groups was tested by one way analyze of variance and by unpaired student's t test. The mean plasma level of PF 1.2 in patients with liver cirrhosis (4.2 – 0.5) significantly elevated when compared to that of both patients with CAH (2.6 – 10.3) and that of healthy subjects (1.7 – 0.05) (p = 0.03 and p = 0.0001, respectively). The difference between CAH and controls was also statistically important (p = 0.01).*Conclusion:* These results suggest that patients with CLD, especially cirrhosis is often associated with a derangement in hemostatic process. Elevated concentrations of PF 1.2 in these patients might be accepted as a clue of thrombotic risk such as portal and other venous thrombosis. Therefore, long term follow up of CLD patients with elevated plasma PF 1.2 levels is required to assess its clinical importance.

"P P 4 0101"P 4 0101 **The Assessment of Arrhythmogenic Side-Effect of Interferon-{ a} 2A by Heart Rate Variability Tests in Chronic Active Hepatitis**

*A. Kadayifci, K. Aytemir, M. Arslan, S. Aksoyek, M.C. Savas, B. Sivri, B. Kayhan

Hecettepe University Medical School, Ankara, TurkeyCardiac arrhytmia and sudden death have been reported recently in various clinical trials of interferon. In this study, the cardiac arrhythmogenic side-effects of recombinant interferon-{ a} 2A (rINF-{ a} 2A) were investigated prospectively with heart rate variability (HRV) tests, in a group of patients with chronic active viral hepatitis (CAH). Sixteen patients with CAH type B, 14 patients with CAH type C and one patients with CAH type D were included in the study and 4.5 MIU, 3 MIU and 9 MIU of rINF-{ a}2A was administrated thrice weekly to these patients, respectively. The HRV analysis of all patients were made with a standard record of 7 minutes at the beginning of the study and at the first and sixth month of interferon therapy and also 6 months later ceasing the therapy. Two-time domain variables were calculated as being the mean RR intervals (MRR) and the mean of squared differences between successive intervals (MSD). In addition, power of the low frequency peak (P1) and power of the high frequency peak (P2) are calculated for spectral analysis as the determinants of frequency-domain analyses. The mean values of data obtained from all patients are shown in Table 1.Table 1. The mean values of data obtained from HRV analysis. Parameters MRR (msn) MSD (msn) P1 (ms^2/Hz) P2 (ms^2/Hz)Before therapy 71.25 – 55.3 31.8 – 3.7 962 – 460 201 – 180First month 72.4 – 48.9 30.2 – 4.2 969 – 515 196 – 167End of therapy 70.7 – 52.4 31.2 – 2.7 966 – 380 198 – 281After 6 month 70.1 – 47.8 32.3 – 3.9 921 – 338 187 – 1156No significant difference was observed in all parameters of HRV analysis before, during and after the rINF-{ a}2A therapy.*Conclusion:* These results indicate that rINF-{ a}2A alone does not produce an arrhythmogenic potential. Atrial and ventricular arrhythmia and cardiac sudden death attributed to interferon in previous reports are questionable in CAH patients. "P P 4 0102"P 4 0102 **Nocturnal Protein Turnover and Liver Glycogen Stores in Patients with Cirrhosis**

*A.A. Tanis, J.W. Vandenberg, T. Rietveld, J.L.D. Wattimena, G.R. Swart

University Hospital Rotterdam-Dijkzigt, Rotterdam, The NetherlandsIn patients with cirrhosis of the liver nocturnal administration of glucose has a sparing effect on the nocturnal protein breakdown. Suggesting an early onset of the use of protein for gluco-neogenesis because of glycogen depletion.To further study this phenomenon the nocturnal protein turnover using 15N-glycine as a label was studied simultaneously with measurement of the depletion of liver glycogen. For the latter we used a new developed technique of labelling the liver glycogen pool with naturally 13C-enriched dietary carbohydrate. Oxidation of the labelled glycogen was measured indirectly by 13CO2-enrichment in breath. Concurrently insulin, glucagon and the glucose response to glucagon i.v. were studied in 12 cirrhotics (P) and 12 healthy volunteers (V).Though bodyweight did not differ, the body cell mass (BCM) was 25.4 kg (SD4.9) in P versus (vs) 33.0 kg (SD7.0) in V, $p < 0.01$. The nocturnal protein break-down was 0.78 gr N/kg BCM/9 hr (SD0.28) in P vs 0.46 gr N/kg BCM/9 hr, (SD0.06) in V, $p = 0.002$. The protein balance did not differ between P and V. After 14 hours fasting the contribution of liver glycogen to 13CO2 production was 44% of initial value in P vs 73% in V, $p < 0.005$. The molar insulin-glucagon ratio was 4.48 (SD2.28) in P vs 32.21 (SD22.84) in V, $p < 0.005$. The blood glucose rose 0.74 mmol/l (SD.38) in P vs 2.11 in V, $p = 0.0001$ in response to 1 mg glucagon i.v. after 15 hours of fasting.In patients with cirrhosis the liver glycogen pool is smaller and depleted earlier. The degree of depletion correlates with the molar insulin-glucagon ratio, while in cirrhosis this ratio is significantly lower compared with healthy volunteers. The nocturnal protein breakdown is increased. No correlation between the two phenomena could be demonstrated. "P P 4 0103"P 4 0103 **Randomized Trial Comparing Intravenous Ceftriaxone with Oral Cefixime for Treatment of Spontaneous Bacterial Peritonitis (SBP) in Cirrhotic Patients: Pilot Study**

*F.A.F. Figueiredo, H.S.M. Coelho, R.G. Alvariz, F.D. Silva, F. Godinho, E. Salgueiro

UFRJ and UERJ, Rio de Janeiro, Brasil*Background/Aims:* SBP is a common and potentially fatal complication of cirrhosis. The use of antibiotics oral will contribute greatly to advance in the treatment of SBP. The aim of this study was to assess the efficacy of cephalosporin orally (cefixime) versus cephalosporin intravenous (ceftriaxone) for the treatment of non-severe SBP in patients with cirrhosis and ascites.*Methods:* We enrolled 37 patients in a prospective randomized trial: 18 in the oral group and 19 in the intravenous group. SBP was defined by an ascitic fluid polymorphonuclear count exceeding 250 cells/mm^3 without evidence of surgically treatable intra-abdominal source of infection. Patients with advanced encephalopathy and arterial hypotension were excluded. The infection was treated with 1 g ceftriaxone every 12 hours or 400 mg cefixime once a day until two days after the ascitic neutrophils count decrease below 250 cells/mm^3.*Results:* There was no difference between the two groups for age (p = 0.55), underlying liver disease (p = 0.39), recent gastrointestinal bleed (p = 0.58), degree of ascites (p = 0.83), Child-Pugh score (p = 0.33), serum albumin (p = 0.48), prothrombin time (p = 0.19), ascitic fluid total protein (p = 0.53) and ascitic fluid polymorphonuclear count (p = 0.44). The organisms most frequently isolated were gram-negative bacteria. The mean time of treatment was 7.2 – 2.5 days for the intravenous group and 8.3 – 2.5 for the oral group (p = 0.15). The mortality was similar between the two groups (p = 0.59). A total of 89% patients treated with cefixime and 94% of patients treated with ceftriaxone were cured of their infections (p = 0.52). Side-effects could not be attributed to the drugs.*Conclusions:* Our results suggest that cefixime is an efficacious, safe and cost-effective measure to treat non-severe SBP in cirrhosis. "P P 4 0104"P 4 0104 **Type of Estrogen Receptors (ERs) Determines Response to Antiestrogen Therapy**

*E. Villa, A. Dugani, L. Camellini, E. Fantoni, P. Buttafoco, A. Grottola, I. Ferretti, F. Manenti

Gastroenterology, University of Modena, ItalyTamoxifen (TAM) for inoperable HCC has given contradictory results, possibly explained by the presence in many HCCs of variant ERs (*v*ER) modified in the hormone binding domain [1]. These cases might respond to megestrol (MEG), which blocks estrogen action at post-receptor level. We therefore planned a pilot study in which TAM or MEG were used depending on ER transcript type.*Methods:* RNA, extracted from liver tumor of 7 pts with unresectable, multifocal HCC, was reverse transcribed and amplified by RT/PCR with primers localized in exons 4 and 6. Tumor growth was evaluated by magnetic resonance (MR) at baseline and after 3 months without therapy. Pts with *wt*ER were then started on TAM 80 mg/day while pts with *v*ER were assigned to MEG 160 mg/day. MR was repeated after 9 months of therapy. Success was defined as a growth during treatment not exceeding that in the 3 months without therapy.*Results:* Spontaneous tumor growth was higher in *v*ER tumors. After 1 year, 4/4 TAM-treated and 2/3 MEG-treated pts showed inhibition of growth. Incremental volume fraction by MR in the 2 periods of observation is indicated in the table: V_{T3}/V_{T0} (no therapy) V_{T12}/V_{T3} (on therapy)*wt*ER (TAM) 1.6 – 0.4 0.8 – 0.2*v*ER (MEG) 3.0 – 0.8 2.1 – 0.9*Conclusions:* 1. growth of tumors characterized by *v*ERs is extremely aggressive; 2. the choice of antiestrogen in relation with type of ERs determined an overall high response rate, significantly improving the known response rate to tamoxifen.

"P P 4 0105"P 4 0105 **Impaired Hepatocellular Integrity in Pre-Eclampsia as Assessed by Measurement of Plasma Glutathione S-Transferase Alpha1-1**

*T. Mulder[1], M. Knapen[2], R. Penders[2], E. Steegers[2], W. Peters[1]

[1] Department of Gastroenterology, University Hospital Nijmegen, The Netherlands

[2] Departments of Obstetrics and Gynaecology, University Hospital Nijmegen, The NetherlandsPre-eclampsia is a complication of pregnancy characterized by elevated blood pressure and proteinuria. The term HELLP syndrome describes a group of pre-eclamptic women with Haemolysis, Elevated Liver enzymes, and Low Platelets. Deterioration of hepatic function is a crucial determinant as whether to terminate pregnancy. Glutathione S-transferase Alpha1-1 (GSTA1-1) constitutes as much as 1% of the cytosolic protein in the liver, has a uniform hepatic distribution, and a plasma half-life of less than 2 hours.Seventy-five women during uncomplicated pregnancy, 26 women with pregnancy induced hypertension, 40 women with pre-eclampsia and 20 women with the HELLP syndrome were included in the study. Plasma GSTA1-1 levels were measured by ELISA.Of the women with non-complicated pregnancy five subjects (7%) had elevated GSTA1-1 levels and two (3%) had elevated alanine aminotransferase (ALAT) levels. Both ALAT and GSTA1-1 were elevated in four (15%) patients with pregnancy induced hypertension. Fifteen patients with pre-eclampsia (75%) had elevated GSTA1-1 levels whereas 10 (50%) had elevated ALAT activities. In the eight patients where both parameters were elevated, the median rise in plasma GSTA1-1 was more pronounced (5.7 times upper normal reference limit; UNRL) than the median rise in ALAT (2.7 times UNRL). All patients with the HELLP syndrome had elevated ALAT and GSTA1-1 levels. However, the median rise in plasma GSTA1-1 (34.4 times UNRL) was significantly ($P < 0.01$) higher than the median rise in ALAT (8.3 times UNRL).*Conclusion:* Plasma GSTA1-1 levels may provide an early and sensitive indicator of hepatocellular damage during pre-eclampsia and the HELLP syndrome.

"P P 4 0106"P 4 0106 **Is Carbohydrate-Deficient Transferrin (CDT) a Valid Marker for Harmful Alcohol Intake among Surgical Patients?**

*H. T\'f8nnesen, M. Carstensen, P. Maina

Department of Surgery, Copenhagen County Hospital in Herlev, University of Copenhagen, DK-2730, DenmarkAlcohol abusers are at special risk at surgery. Daily consumption of at least 60 g (35 beverages/week) is related to 3–4 fold increased development of complication after colorectal resection. (Lancet 1992; 340: 334–337)*Purpose:* Examination of the validity of CDT as a marker of harmful alcohol intake in surgical patients previous to operations.*Methods:* Consecutive adult patients admitted to the department of surgery were included after informed consent. Until the deadline for abstracts June 1, 1996 213 patients (108 women, 105 men) have been included. Nobody denied to enter the study. Eleven patients were not included due to immediate admission to ICU (4), deafness (1) and by mistake (6).Alcohol interviews were performed and blood samples were obtained. Se-CDT were analysed by a modyfied radioimmunoassay. Positive CDT was defined as values above 20 U/l for men and above 26 U/l for women.*Results:* The median alcohol intake was 5 beverages per week. (range 0–350). The correlation between alcohol intake and CDT was 0.65, p {\'a3} 0.001.The sensitivity and specificity of CDT were high (100% and 95%). The positive predictive value was 62% and the negative predictive value was 100%.*Conclusion:* CDT is a useful marker of harmful alcohol intake among surgical patients. }" "Is Carbohydrate-Deficient Transferrin (CDT) a Valid Marker for Harmful Alcohol Intake among Surgical Patients?"

"P P 4 0107"P 4 0107 **Tissue Inhibitor of Metalloproteinases-1 in Liver in Patients with Chronic Liver Disease**

*Yoshikazu Murawaki[1], Yujiro Ikuta[1], Youko Idobe[1], Yukisato Kitamura[2], Hironaka Kawasaki[1]

[1] Second Department of Internal Medicine, Tottori University School of Medicine, Yonago, 683, Japan

[2] Second Department of Pathology, Tottori University School of Medicine, Yonago, 683, JapanTissue inhibitor of metalloproteinases (TIMP)-1 is an important regulator of matrix metalloproteinase activity. To clarify its changes in diseased liver, we measured TIMP-1 concentrations in liver tissue samples from patients with chronic liver disease using an enzyme immunoassay after the extraction with 2 M guanidine.The subjects were 68 patients, who were classified by the histological findings as 10 almost normal liver/fatty liver, 18 chronic persistent hepatitis (CPH), 24 chronic active hepatitis (CAH) 2A, 10 CAH2B, and 6 liver cirrhosis (LC).As compared with the controls, the liver TIMP-1 level increased 2.2-fold in CAH 2A, 2.9-fold in CAH 2B and 4.1-fold in LC, but not in CPH. Liver TIMP-1 levels were closely correlated with the histological degree of periportal necrosis, of portal inflammation and of liver fibrosis.When the localization of TIMP-1 was examined immunohistochemically, TIMP-1 was stained mainly in hepatocytes, and the intensity was stronger in CAH and LC than in CPH.Gel filtration of the liver extract from a cirrhotic liver showed that the major peak of TIMP-1 was eluted at around 40 kDa, although the TIMP-1 antigenicity was heterogenous.When the relationship between serum and liver levels of TIMP-1 was examined, both levels were closely correlated, indicating that serum TIMP-1 could reflect the change of liver TIMP-1 in patients with chronic liver disease.In conclusion, the liver TIMP-1 concentration increased with the progress of liver disease, where the degradation of extracellular matrix proteins would be decreased, resulting in the development of liver fibrosis. "P P 4 0108"P 4 0108 **Expression of a Non-MDR2-Coded Phosphatidylcholine Membrane Transport Protein from Rat, Mouse and Human Liver in Xenopus Laevis OocytesL. Cornacchia, A. L\'f6chel, J. M\'f6ssner,**

*F. Berr

Dept. of Medicine II, University of Leipzig, GermanyPhosphatidylcholines (PC) are secreted into the bile via hepatocyte canalicular membrane transport protein(s). Evidence for ATP-dependent mdr2-encoded PC transport as well as carrier-mediated PC transport had been demonstrated by expression of specific liver mRNA species/fractions. *Aim:* To test in Xenopus laevis oocytes, whether the functional expression of MDR2 is involved in the PC transport induced by functional expression of liver mRNA. Transport was assayed using a water-soluble, radiolabeled PC homolog, ^{14}C-dibutyroyl-PC (diC_4PC). *Results:* Functional expression of rat or mouse mdr2 cRNA in Xenopus laevis oocytes did not result in detectable uptake of diC_4PC in presence or absence of ATP. By contrast, expression of rat, mouse and human liver total mRNA resulted in saturable, carrier-mediated and ATP-independent uptake of diC_4PC with an apparent Km of 9.6 mM, 7.7 mM and 11.6 mM, respectively. Antisense inhibition of MDR2 expression increased diC_4PC uptake encoded by total liver mRNA from mouse and rat by 40%–50%. In addition, a clear difference in mRNA size was shown between MDR2 and the diC_4PC carrier, after size fractionation of rat liver mRNA. *Conclusion:* The data prove the existence of a specific mRNA for a non-MDR2-coded cell membrane PC carrier in mouse, rat and human liver which exhibits similar transport affinity for diC_4PC as the PC carrier previously characterized (J Biol Chem 268: 3976; 1993) in rat liver canalicular membranes. "P P 4 0109"P 4 0109 **Cyclosporine and Hypercholesterolemia. Cyclosporine Down-Regulates Low Density Lipoprotein Receptors in Cultured Liver Cells**

*C.-H. Flor\'e9n, O. Al Rayyes, A. Wallmark

Department of Internal Medicine and the Wallenberg Laboratory, Malm\'f6 University Hospital, Malm\'f6, Sweden*Purpose:* Cyclosporine is today one of the most widely used immunosuppressive drugs and it is used in most transplantation centres to prevent organ rejection. Patients, who are transplanted, and use this drug are, however, prone to be afflicted by cardiovascular disease, due to the development of atherosclerosis as a result of Cyclosporine-caused elevation of blood low density lipoprotein (LDL) cholesterol levels. The mechanism whereby Cyclosporine causes high LDL cholesterol levels to occur, has not yet been clarified.*Methods:* As the main part of LDL is catabolized in the liver, by its hepatocytes, an in vitro system using cultured hepatocytes was used. HepG2 cells, a hepatoma cell line, which is highly differentiated and with functional LDL receptors, was studied.*Summary:* The results showed that Cyclosporine reduced cellular LDL uptake and degradation by mainly inhibiting the LDL receptor mediated pathway. HMG-CoA reductase inhibitors, which upregulate LDL receptor activity, reversed the Cyclosporine caused downregulation of LDL receptor activity.*Conclusion:* Cyclosporine causes hypercholesterolemia in transplanted patients by inhibiting LDL receptor activity. This effect can be reversed by HMG-CoA reductase inhibitors. This argues for treating patients with Cyclosporine caused hypercholesterolemia with HMG-CoA reductase inhibitors. Liver and bile ducts, 1: Liver transplantationLiver and bile ducts, 1: Cell biology, collagen, fibrosis }" "Cyclosporine and Hypercholesterolemia. "P P 4 0110"P 4 0110 **Effects of Oltipraz, { a}-Tocopherol, { b}-Carotene and Phenethylisothiocyanate on Glutathione S-Transferases of the Rat Digestive Tract**

*E.M.M. Van Lieshout, W.H.M. Peters, J.B.M.J. Jansen

Dept. of Gastroenterology, St. Radboud University Hospital, Nijmegen, the NetherlandsMany studies have linked consumption of naturally occurring anticarcinogens, present in vegetables and fruits, to the prevention of gastrointestinal tumours. The mechanism is unclear, but induction of glutathione S-transferases (GSTs) seems crucial. GSTs are a family of isozymes, divided into classes Alpha, Mu, Pi and Theta, which serve a major role in the detoxification of many substances, including carcinogens. In order to understand better their anticarcinogenic potential, four anticarcinogens (oltipraz, { a}-tocopherol, { b}-carotene and phenethylisothiocyanate [PEITC], incorporated in the diet at 0.03, 0.02, 0.02, and 0.045% w/w, respectively) were studied with respect to their effects on oesophageal, gastric, colonic, and hepatic GST activity and GST isoenzyme levels. Male Wistar rats were fed normal or supplemented lab chow for two weeks. Organs were removed and cytosolic fractions were prepared. Herein, GST activity towards 1-chloro-2, 4-dinitrobenzene was measured and GST isozymes were quantified after immunodetection of Western blots. Wilcoxon rank sum test was used to assess statistical significance of differences. GST activity was significantly increased in oesophagus and colon by PEITC and in liver by oltipraz. Oltipraz, { a}-tocopherol, and PEITC induced hepatic GST Alpha. GST Mu was increased by { b}-carotene and PEITC in stomach and liver, by oltipraz in liver and by { a}-tocopherol in stomach. PEITC induced colonic GST Pi. In conclusion, oltipraz, PEITC, and to a lesser extent { a}-tocopherol and { b}-carotene, may exert their chemoprotective effects in liver, colon and oesophagus by enhancing GSTs, resulting in a more efficient detoxification of carcinogens. Oncology, general: Screening, preventionNutrition: Metabolism }" "Effects of Oltipraz, alpha-Tocopherol, ß-Carotene and Phenethylisothiocyanate on Glutathione S-Transferases of the Rat Digestive Tract"

"P P 4 0111"P 4 0111 **Prospective Evaluation of Circulating Hepatocytes by Alpha-Fetoprotein mRNA in Humans during Liver Surgery****A. Lemoine[1], D. Azoulay[2], T. Le Bricon[1], M. Salvucci[1], P. Pham[1], H. Bismuth[2], B. Debuire[1]**

[1] Biochemistry, Paul Brousse Hospital, Villejuif, France

[2] Hepato-Biliary and Liver Transplantation Center, Paul Brousse Hospital, Villejuif, France\lquoteTissue-specific\rquote mRNAs have been used for the detection of circulating micrometastatic tumor foci of hepatocellular carcinoma (HCC). However, the interpretations of the results have been equivocal. The specificity of these tests remains to be clearly established for clinical use, especially to decide chemotherapy. To establish the specificity of detecting liver tumor cells dissemination by alpha-fetoprotein (AFP) mRNA, a prospective study was performed in a random group of 64 consecutive patients (pts) undergoing hepatic resection for various tumors (HCC: n = 20, secondary metastatic liver: n = 27 and non tumoral etiologies: n = 17). AFP mRNA was evaluated in peripheral blood by reverse transcription-polymerase chain reaction (RT-PCR) before surgery and at 2 intraoperative time intervals during surgery. Prior to hepatectomy, AFP mRNA was detected in the blood of 17% of pts which included 5 out of the 20 pts with HCC. Intraoperatively, 53% of the pts (8/20 operated for HCC, 17/27 for secondary metastases and 9/17 for non tumoral etiologies) were found to be AFP mRNA positive, regardless of the disease, the type of surgery or clinical parameters surrounding their disease. Thirty two pts (50% of which were positive intraoperatively) were examined 6 months after surgery and all but one were negative for AFP mRNA. None of the pts treated for HCC in this series had recurrence 6 months after surgery (2 died of liver failure). Although liver surgery seems associated with a transient release of AFP mRNA positive cells in the circulation, this gene transcript is not a specific marker of circulating micrometastases from HCC. It would be imprudent to attempt clinical application of this marker until a more accurate test is devised which can link specific gene markers to circulating tumor foci. }" "Prospective Evaluation of Circulating Hepatocytes by Alpha-Fetoprotein mRNA in Humans during Liver Surgery"

"P P 4 0112"P 4 0112 **Cholestatic Liver Injury Induces a Rapid Increase in Proliferation and Expression of { b} PDGF Receptor in Hepatic Stellate Cells**

*O. Goria, M. Maratrat[1], C. Rey, F. Ballet, R. Poupon, C. Housset

Unit\'e9 d'H\'e9patologie et INSERM U 402, Hospital Saint-Antoine, Paris

[1] Rh\'f4ne-Poulenc Rorer, AlfortvilleThe molecular mechanisms of hepatic stellate cells (HSC) activation have been well described *in vitro* but have not been fully elucidated *in vivo,* particularly in cholestatic liver injury. Increased proliferation is one of the major aspects of HSC activation. PDGF has been identified as the most potent mitogen for HSC *in vitro.* However, the mitogenic effect of PDGF *in vitro,* requires up-regulation of { b} PDGF receptor in these cells. The aim of our study was to determine the kinetics of HSC proliferation and that of { b} PDGF receptor expression in HSC, following cholestatic liver injury.*Materials and methods:* Cholestatic liver injury was induced in male Sprague-Dawley rats by double ligation with sectioning of the common bile duct (BDL). Sham-operated rats served as controls. Liver injury induced by biliary obstruction was assessed by liver tissue histology and by the measurement of serum bile acids (Enzabile') and of bilirubinemia. HSC proliferation was assessed by *in vivo* incorporation of bromodeoxyuridine (BrdU), which was administered intraperitoneally (50 mg/kg) one hour before cell isolation. HSC were isolated by *in situ* liver enzymatic dissociation and cell separation on density gradient, 1, 2, 3 and 7 days after bile duct ligation, respectively. Freshly isolated cells were subsequently analyzed by flow cytometry, in order to quantify incorporated BRDU. In separate experiments, HSC plasma membrane expression of PDGF receptors was also analyzed by flow cytometry using an anti-PDGF (R) { b} polyclonal antibody.*Results:* Cell purity, as determined by fluorescence of retinoid-containing vacuoles under UV excitation, was > 95%. Biochemical determinations, semi-quantitative analysis of ductular reaction, and incorporation of BRDU in HSC are shown in the following table (M – SEM, n = 3). D1 D2 D3 D7 BDL SHAM BDL SHAM BDL SHAM BDL SHAMBilirubin (\'b5mol/l) 94 – 21 1 – 0 144 – 31 1 – 0 163 – 25 1 – 0 170 – 15 1 – 0Bile acids (\'b5mol/l) 563 – 63 12 – 2 565 – 19 18 – 3 674 – 139 16 – 3 398 – 22 18 – 9Ductular reaction + { -} ++ { -} +++ { -} ++++ { -}anti-BrdU + cells (%) 5 – 0 4 – 1 19 – 8 4 – 1 19 – 1 5 – 1 25 – 6 10 – 1In addition, HSC proliferation was associated with a more than ten-fold increase in { b} PDGF receptor density on the plasma membrane.In conclusion, complete bile duct obstruction induces ductular reaction and HSC proliferation within 24 h and 48 h following bile duct ligation, respectively. HSC proliferation is associated with an increased expression of { b} PDGF receptors. These results suggest that cholestatic liver injury induces a rapid increase in HSC proliferation, which could result at least partly from the up-regulation of { b} PDGF receptors. "P P 4 0113"P 4 0113 **Expression of Gap Junction Protein Connexin 32 in Experimental Rat Liver Cirrhosis**

*I. Takashimizu[1], T. Ohkusa[1], K. Fujiki[1], A. Araki[1], K. Ariake[1], K. Shimoi[1], K. Honda[1], Y. Enomoto[1], T. Sakurazawa[1], T. Horiuchi[1], S. Suzuki[1], K. Ishii[1], S. Endo[1], H. Hosoi[1], S. Tokoi[1], N. Sazaki[1], C. Sato[2]

[1] First Department of Internal Medicine, Tokyo Medical and Dental University School of Medicine, Tokyo, Japan

[2] Division of Health Science, Tokyo Medical and Dental University School of Medicine, Tokyo, JapanGap-junction-protein levels of connexin 32 (Cx 32) were reported to be decreased in neoplastic foci induced by hepatochemicals in rat livers. However, there were no reports whether the expression of Cx 32 was decreased in experimental liver cirrhosis. We examined immunohistochemically the expression of Cx 32 in cirrhotic rat livers induced by diethylnitrosamine (DEN).*Methods:* Male Wistar rats were treated with DEN for 6 weeks. After sacrifice, the livers were resected, and immediately frozen by liquid nitrogen for immunohistochemistry and H&E stain. The immunohistochemical detection of Cx 32 was performed using an avidin-biotin complex peroxidase technique with a mouse monoclonal anti-Cx 32 antibody. The number of Cx 32 positive spots/100 \'b5m^2 was counted at random in 15 photographic fields (magnification {\'b4}1000).*Results:* Macular Cx 32 spots were observed at intercellular borders of hepatocytes. The number of plaques in control and cirrhotic livers was 133 – 30.7 spots and 79.4 – 25.8 spots/100 \'b5m^2, respectively. The number of spots in the cirrhotic livers was significantly decreased compared with that in the control livers ($p < 0.05$).*Conclusion:* The expression of connexin 32 is decreased in cirrhotic rat livers treated with DEN when compared with that in normal livers. [1] NMR Unit, Hammersmith Hospital, Department of Medicine, Royal Infirmary of Edinburgh

[2] ICH, London, Department of Medicine, Royal Infirmary of Edinburgh*Background:* About 20–30% patients become encephalopathic following TIPSS. TMAO is nitrogenous, diet related, produced by gut flora, crosses the blood brain barrier, is present in the portal circulation, is metabolised by the liver and inhibits Ca^{2+} ATPase. This study was designed to test the hypothesis whether TMAO or other biogenic amines may contribute to the development of encephalopathy.*Methods:* Plasma was collected prior to TIPSS and at 3 months when the patients attended for routine portography and stored at { -}70\'b0C. Two patients were clinically encephalopathic prior to TIPSS. *In vitro* ^{1}H magnetic resonance spectroscopy was performed on the plasma using a spin echo sequence on an 11.7 Tesla magnet (JEOL). Spectra were analysed on a Sun-Sparc computer'. Amino acids were measured in the plasma using HPLC.*Results:* The severity of encephalopathy worsened in the 2 patients who were encephalopathic before TIPSS and 2 others became encephalopathic. The changes in TMAO correlated significantly with the changes in the portal pressure gradient ($r = 0.58$, $p < 0.02$). TMAO levels in controls and, patients before and after TIPSS is illustrated in Fig 1. No significant change was noted in capillary ammonia or amino acids.

Conclusions: TMAO may be important in the development of encephalopathy and deserves further investigation. Liver and bile ducts, 1: Cirrhosis: portal hypertensionLiver and bile ducts, 1: Cirrhosis: ascites, encephalopathy }" "Trimethylamine-N-Oxide (TMAO) / Important in the Pathogenesis of Hepatic Encephalopathy after TIPSS?"

"P P 4 0115"P 4 0115 **Collagen Type IV and Laminin in Alcoholic and Nonalcoholic Liver Diseases. Relationship with Portal Hypertension**

*Z. Krastev, L. Mateva, A. Alexiev, B. Alexiev, R. Ivanova

Clinic of Gastroenterology, University Hospital ""St. Ivan Rilsky"" Sofia, BulgariaCollagen type IV and laminin are markers of basement membrane formation and sinusoid cappilarization. In this study we investigated the localization and expression of collagen type IV and laminin in alcoholic and nonalcoholic liver diseases. The expression of collagen type IV and laminin was studied by immunocytochemistry on liver biopsy specimens from 30 patients with different stade of alcoholic liver disease (15-fatty liver, 5-alcoholic hepatitis, 10-incipient liver cirrhosis), 20 nonalcoholic liver disease (5-viral chronic active hepatitis, 5-viral liver cirrhosis, 12-PBC) and 3 controls. All patients were clinically follow-up for a period over 3 years about severity of liver damage and appearance of portal hypertension. The expression of collagen type IV and laminin was various intensity around blood vessels and bile ducts in the portal tracts, sinusoidal walls, areas with cell infiltration and liver cell necrosis, fibrotic septa and perisinusoidal spaces in all patients. The expression of collagen type IV and laminin in perisinusoidal areas in alcoholic cases was more intensive than other cases. In alcoholic patients there was also relationship between the intensity of staining reactions in perisinusoidal spaces and appearance of portal hypertension ($r = 0.890$, $p < 0.001$) for the follow-up period and the verity of liver damage ($x = 46.14$, $p < 0.001$) for conclusion liver fibrosis and cappilarization play a central role in liver function impairment and portal hypertension in chronic liver diseases, especially in alcoholics.

"P P 4 0116"P 4 0116 **Longterm Outcome and Predictive Factors of Efficiency, Encephalopathy (EH) and Obstructions after TIPS Placement for Refractory Ascites (RA)****C. Renou, F. Castex, Pascal L. Canva-Delcambre[1], G. Sergent[2], C. L'Hermine[2], R. Sambuc[1], J.C. Paris**

[2] Service d'Hepatogastroent\'e9rologie et de Radiologie CHRU Lille, 59037 Lille, France

[1] Departement d'Informatique m\'e9dicale 13000 MarseilleThe aim of this study was to assess the TIPS efficiency and to evaluate prognostic factors for EH, obstruction, efficiency and mortality after TIPS for RA. *Methods:* Between 04/92 and 11/95, 33 patients with RA followed 18 mo (2 d–38 mo) underwent TIPS placement. A favorable response to TIPS was defined as an improvement of RA, with or without diuretics or occasionally paracentesis (< 1 by 3 mo). 28 parameters of the pre-TIPS screening were examined as potential prognostic factors. *Results:* 12 mo after TIPS placement, RA was resolved or improved in 75% patients. Cumulative rates of obstruction were respectively 19, 50, 66 and 66% at 1, 12, 24 and 30 mo. After reinterventions TIPS free of obstruction were respectively 70, 80, 66 and 80%. 6 parameters were predictive of EH: pre-TIPS EH history (p = 0.05), hypoalbuminemia (p = 0.04), hemoglobinemia (p = 0.0003), Child score (p = 0.03), Prothrombine Time (p = 0.002) and proaccelerin (p = 0.003). 3 were predictive for thrombosis: recent operators experience (p = 0.02), hypoalbuminemia (p = 0.01), lack of anticoagulant therapy (p = 0.02). For TIPS free of obstruction, only 2 parameters were predictive of efficiency: anticoagulant therapy (p = 0.04) and Child score (p = 0.005). None parameters was predictive for stenosis. 5 were predictive of mortality before 15 mo: Child score (p = 0.0004), hemoglobinemia (p = 0.015), Prothrombine Time (p = 0.004), proaccelerin (p = 0.01) and blood alcalin phosphatases (p = 0.02). One-year survival was 70%. After TIPS Child score improved 7.85 – 1.73 vs 9.27 – 0.88 before TIPS (p = 0.0001). *Conclusion:* During long term follow-up, TIPS might be a treatment of RA and complications might decrease under the following conditions: 1) only Child B must be treated, 2) early reintervention in case of obstruction, 3) lactulose and antibiotics treatments should be prescribed before TIPS and anticoagulant therapy after. Liver and bile ducts, 1: Cirrhosis: ascites, encephalopathy }"

"P P 4 0117"P 4 0117 **Utility of Thoracentesis in Cirrhotic Patients**

*X. Xiol, M. Delgado, R. Cort\'e9s, J. Guardiola, E. Ses\'e9, M. Da Costa, L. Guerrero, J. Castellote

Gastroenterology Service, Hospital de Bellvitge L'Hospitalet, Barcelona, SpainAbout 10% of cirrhotic patients with ascites have an associated pleural effusion, but the utility and safety of thoracentesis is not well established. *Aim:* To prospectively study complications of thoracentesis in cirrhotic patients with pleural effusion. *Material and methods:* From October 1994 to December 1995 a diagnostic thoracentesis (DT) was performed on all cirrhotic patients with pleural effusion at admission or when a spontaneous bacterial empyema was suspected. A therapeutic thoracentesis (TT) was performed in patients with dyspnea secondary to the effusion. To detect complications, a chest radiograph and exhaustive follow up were done after the procedure. *Results:* 106 thoracentesis have been performed in 33 cirrhotic patients, 77 DT and 29 TT. Of the 77 DT, no pleural fluid was obtained in 4 (5.2%), pleural fluid analysis was compatible with hydrothorax in 57 (74%) and pleural fluid analysis provided a definitive diagnosis in 16 (20.8%): tuberculosis in 2 cases, malignancy in 2 and spontaneous bacterial empyema in 12. In 23 (79.3%) of the 29 TT pleural fluid could be evacuated (mean volume 1990 – 685 ml). Major complications were pneumothorax in 6 (5.66%), 4 of them required chest tube insertion, and uncomplicated wall haematoma in 4. Pneumothorax appeared in 2 (2.6%) of the 77 DT and in 4 (13.8%) of the 29 TT ($p < 0.05$, Fisher exact test).*Conclusions:* 1. – In 20% of the thoracentesis performed in cirrhotic patients, pleural fluid analysis provides a definitive diagnosis other than hepatic hydrothorax. 2. – Diagnostic thoracentesis in cirrhotic patients is a useful and safe procedure. 3. – Therapeutic thoracentesis is an effective procedure having greater morbidity than diagnostic one. "P P 4 0118"P 4 0118 ***Helicobacter Pylori*** **Infection and the Risk of Peptic Ulcer among Cirrhotic Patients**

*C.H. Wang, L.R. Mo, R.C. Lin, J.Y. Kuo, K.K. Chang

Department of Internal Medicine Tainan Municipal Hospital, Tainan, Taiwan, R.O.C.*Helicobacter pylori* and peptic ulcer are known to be associated and there is a high prevalence of peptic ulcer in cirrhotic patients. However, whether *H. pylori* is a risk factor for peptic ulcer in cirrhosis remain controversial. The aim of the present study was to determine whether there is a significant correlation between *Helicobacter pylori* infection and peptic ulcer in liver cirrhosis. In a prospective study, 49 cirrhotic patients were endoscoped regardless of symptoms. Another group of 75 controls without liver disease were also examined routinely. Both groups of patients were subdivided into ulcer and non-ulcer patients. The presence of *H. pylori* was assessed by culture, histologic findings, and rapid urease test of antral biopsy specimens. The prevalence of *H. pylori* in cirrhosis was significantly lower than in control group (49% vs. 68%, $p < 0.05$). The presence of *H. pylori* was more frequent in ulcer than non-ulcer patients in controls (91.3% vs. 57.6%, $p < 0.005$), whereas this difference was not significant in cirrhosis (56.7% vs. 36.8%, $p > 0.05$). As for peptic ulcer between two groups, *H. pylori* was identified in 56.7% of cirrhotic patients compared with 91.3% of controls ($p < 0.01$). The positive rate of *H. pylori* in cirrhosis group is directly related to the presence of serum hepatitis B surface antigen. There is no strong evidence to substantiate an etiologic role of *H. pylori* in the development of peptic ulcer among cirrhotic patients. *H. pylori* may frequently infect hepatitis B virus-related cirrhotics. "P P 4 0119"P 4 0119 **The Effect of Ceftazidime on the Prevention of Peritonitis after Recurrent Ascites Paracentesis****C. Petrogiannopoulos, A. Zacharof, A. Tzoumani, J. Panagopoulos, N. Papageorgiou, J. Poulikakos**

2nd Department of Medicine, Hellenic Red Cross Hospital, Athens, GreeceA common complication of recurrent paracentesis of ascites in cirrhotics is the appearance of bacterial peritonitis.*Aim of the study:* was to evaluate the efficacy of Ceftazidime (Solvetan) on prevention of bacterial peritonitis due to recurrent ascites paracentesis in cirrhotic patients with tense ascites.*Material and methods:* This study included 26 patients with non compensated cirrhosis and tense ascites. During their hospitalization (1–2 months) all the patients got recurrent paracentesis every once or twice weekly. After each procedure 15/26 patients (Group A) were received Ceftazidime (Solvetan) 1 gr IV while the rest of them (Group B) received nothing. Clinical and laboratory investigation was done every day.*Results:* Only one patient (6%) from group A appeared clinical symptoms of bacterial peritonitis (fever, local pain and increased blood and ascitic fluid white cells), while in group B 4/11 (36.6%) patients got typical clinical picture of bacterial peritonitis with positive ascitic fluid cultures in 2 of them.*Conclusions:* Ceftazidime (Solvetan), a third generation cephalosporin, is quite effective on the prevention of bacterial peritonitis due to reccurent evacuant paracentesis in cirrhotics with tense ascites. "P P 4 0120"P 4 0120 **Pattern of Dapsone Induced Liver Injury and OutcomeJoeffe[1],**

*K.T. Shenoy

[1] Dept. of Dermatology, Medical College, Trivandrum, India

Dept. of Gastroenterology, Medical College, Trivandrum, India*Objective:* Paucibacillary Hansen's disease (PHD) is emerging as a major public health problem in developing countries. We studied the pattern of liver injury and their outcome in paucibacillary Hansen's disease administered Dapsone.*Setting:* Tertiary referral centre.*Participants:* 362 cases of PHD administered Dapsone (100 mg), Clofazimine (50 mg) daily and Rifampicin (600 mg) monthly.*Study variables:* Onset of jaundice, its temporal relationship with drug therapy, alcoholism, biochemical parameters (S. bilirubin, transaminases, alkaline phosphatase and S. albumin), tests for haemolysis, HBsAg and haematology.*Results:* Of 362 subjects (190 males and 172 females), 15 developed jaundice (M:F = 2:1). Jaundice occurred 3 to 6 weeks after drug therapy; fever and erythematous rash with exfoliation 100%; body pain and malaise 50%; altered behaviour 20%; congestion of eyes 20%. Clinical signs were tender liver (100%), asterixis (14%), leg edema (14%) and lymphadenopathy (20%). Five males were alcoholics. Serum bilirubin and transaminases were elevated in all those with jaundice and HBsAg was negative. One patient progressed to hepatocellular failure and expired. None had evidence of haemolysis.*Conclusion:* Multidrug therapy for PHD resulted in hepatocellular injury in 4.1% and has significant morbidity and mortality. Liver and bile ducts, 1: Hepatotoxicity, ethanol }"

"P P 4 0121"P 4 0121 **Helicobacter Pylori: Is It a Risk Factor for Hepatic Encephalopathy in Cirrhotic Patients?**

*Enas A.R. Al-Kareemy, Madeha M. Zakhary[1]

Department of Internal Medicine (Gastroenterology & Hepatology Unit), Faculty of Medicine, Assiut University, Assiut, Egypt

[1] Department of Biochemistry, Faculty of Medicine, Assiut University, Assiut, Egypt*Objective:* To determine whether Helicobacter pylori (Hp) infection is a risk factor for hepatic encephalopathy in patients (pts) with liver cirrhosis. *Methods:* 108 cirrhotic pts undergoing upper GI endoscopy for detection of oesophageal varices were included in this study: 34 pts Child-Pugh grade A, 60 pts grade B and 14 pts grade C. The aetiology of liver cirrhosis was either posthepatitic or mixed; Bilharzial fibrosis and posthepatitic cirrhosis. Diagnosis of Hp infection was done by histopathology using antral and fundal biopsies, hp fast test and serologically by estimating Hp IgG antibody titers by ELISA (more than 20 u/ml). Estimation of serum NH_3 using an enzymatic assay for all pts was done and the results were compared with that of 24 normal subjects as a control group.*Results:* Serum NH_3 is significantly higher in cirrhotics than in normal controls ($P < 0.001$) 86 cirrhotic pts with Hp +ve were similar 22 Hp. { -}ve with regard to age, sex, aetiology of cirrhosis and Child score. Hp. +ve had significantly high NH_3 in comparison with Hp{ -}ve pts ($P < 0.01$). Also significant high NH_3 in pts grade C compared with grade A ($P < 0.01$) and grade B ($P < 0.01$). Detection of Hp IgG antibodies by ELISA is a sensitive test as it was positive (more > 20 u/ml) in all pts with positive hp fast test and positive histopathology for Hp. There was a significant positive correlation between serum NH_3 levels and Hp IgG antibody titers in cirrhotic pts ($r = 0.9$, $P < 0.001$).*Conclusion:* Hp infection as ammonia producer can be considered as a risk factor for hepatic encephalopathy in cirrhotic patients and may warrants eradication. "P P 4 0122"P 4 0122 **The Reduction of Celebral Blood Flow in Cirrhotic Patients Precedes the Appearance of Overt Encephalopathy****M.R. Biagini, B. Mallardi, A. Galli, E. Surrenti, O. Morelli, M.T. Passaleva, M. Romano, S. Faenzi, C. Surrenti**

Gastroenterology Unit, Department of Clinical Physiopathology, University of Florence, ItalySeveral studies have shown cerebral morphologic abnormalities by CT and MNR and reduction of cerebral blood flow by single photon emission tomography (SPECT) in cirrhotic patients. However, it is unknown if these abnormalities precede or accompany the appearance of overt encephalopathy. *Aim of the study:* to analyze whether alterations in cerebral blood flow evaluated by SPECT in cirrhotic patients is associated with or precedes the onset of hepatic encephalopathy. *Patients and Methods:* SPECT was performed in 20 cirrhotic male patients (50–70 years), without history of alcoholic abuse, diabetes, cardiovascular and neuropsichiatric diseases. The presence of encephalopathy was assessed by clinical examination, EEG, ammonia blood levels, event related potentials (ERPs) and psychological tests. Latent encephalopathy was defined as absence of clinical signs, in the presence of normal EEG, normal blood ammonia levels, abnormal ERPs and psychological tests. *Results:* 6\20 patients showed clinically assessed encephalopathy and reduction of talamic blood flow by SPECT; 14\20 showed neither signs nor simpthoms of encephalopathy but 7\14 showed ERPs, psychological tests and SPECT abnormalities. Two of these seven patients showed a specific SPECT alterations while five showed the same alterations of overt encephalopathy patients. *Conclusions:* Our data suggest that SPECT might be useful to detect subclinical encephalopathy in cirrhotic patients. }" "The Reduction of Celebral Blood Flow in Cirrhotic Patients Precedes the Appearance of Overt Encephalopathy"

*Y. Uzun, A. D\'f6kmeci, H. \'d6zkan, H. Bozkaya, \'d6. Uzunalimoglu

Department of Gastroenterology, Ankara university, School of Medicine, Ankara, Turkey*Purpose:* Somatostatin therapy is known to be effective ini cesseating of bleeding oesophageal varices. Effects of somatostatin in renal functions in patients (pts) with cirrhosis is controversial. Purpose of the study is to evaluate the effect of somatostatin on renal functions in cirrhotic pts with ascites.*Patients and methods:* Twenty cirrhotic pts with ascites were studied. None of the pts had bleeding oesophageal varices and received no diuretic therapy at least 1 week before the study, During the control period Dextrose 5% solution (2 ml/min) for 2 hr was infused. 24 hr after control period somatostatin infusion (250 \'b5l/hr in Dextrose 5%) was given for 2 hr. Urine was collected during the infusion and 2 hr postinfusion period in both control and somatostatin experiment. Basal and postinfusion blood samples were collected and mean arterial blood pressure (MABP) was monitorized.*Results:* There was no change in MABP. Changes in urine volume (V), urine osmolarity (U_{osm}), creatitine clearence (C_{cr}), free water clearence (C_{H20}, urinary Na (U_{Na}), fractional Na excretion (FE_{Na}) under somatostatin infusion were given below table. V U_{osm} C_{cr} C_{H20} U_{Na} FE_{Na} (ml/min) (mOsm/kg) (ml/min) (ml/min) (\'b5m/min) (X10)Control P. 0.7 – 08 406 – 27 92 – 14 100 – 18 12 – 3 0.7 – 0.6Test P. 1.2 – 0.1 318 – 29 153 – 18 126 – 18 21 – 6 0.06 – 0.03p value < 0.05 < 0.05 < 0.0001 NS NS NSNS: non-significant*Conclusion:* Somatostatin therapy has no deteriorating effect on renal functions in cirrhotic patients with ascites. "P P 4 0124"P 4 0124 **Relationship Between KLA Genotype and Phenotypic Expression in Irish Families with Genetic Haemochromatosis**

*E. Ryan, M. Kelly, S. Pathmakanthan, P. MacMathuna, J.C. O'Keane[1], K. Ennis, J. Crowe

Mater Misericordiae Hospital

[1] Liver Unit and Dept. of Pathology, Dublin, Ireland*Introduction.* The association between genetic Haemochromatosis (GH) and HLA locus has allowed early identification of affected siblings. The proportion of subjects vulnerable to iron overload that are homozygous (HH) or heterozygous (Hn) is unclear. Studies correlating clinical features with HLA type in families from Ireland — a putative source of this Celtic trait have not been described.*Methods.* This study correlated clinical, biochemical and pathologic features of GH with HLA typing (lymphocytotoxicity assay) in 67 first degree relatives of 12 probands.*Results.* Initial analyses identified 12 HH, 40 Hn and 15 nn (normal) individuals. Eleven of 40 individuals initially thought to be Hn had stainable iron on liver biopsy confirming GH and therefore HH status. Further HLA analysis revealed 7 homozygous x heterozygous matings and identification of all disease haplotypes within each pedigree allowed final classification of 30 HH, 25 Hn and 12 nn individuals.*Conclusions.* (1) Initial HLA haplotyping misclassified 18 GH homozygotes mainly due to unsuspected homozygous x heterozygous matings (7 in 12 families). (2) Correlation of HLA haplotype with iron saturation and biopsy findings identifies homozygotes and HH x Hn matings. (3) High frequency of HH x Hn matings in this Irish population supports a Celtic origin of the GH gene. "P P 4 0125"P 4 0125 **Activation of Human Neutrophil Phospholipase D (PLD) is Impaired in Alcoholic Liver Diseases (ALD)**

*L. Lora, S. Pigozzo, A. D'Odorico, D. Martines, R. Naccarato

Department of Gastroenterology, University of Padua, PaduaIt is well known that alcoholics have higher morbidity and mortality in bacterial infections. Defect in the superoxide anion production of polymorphonuclear granulocytes (PMN) has been suggested as pathogenic mechanism. PLD contributes to the production of phosphatidic acid (PA) that plays a second messenger role in the activation of NADPH-oxidase (responsible for the respiratoy burst) in human PMN. One widely used method for the detection of PLD is based on the formation of phosphatidylethanol (PEth), an uncommon phospholipid that is generated selectively through PLD by transphosphatidylation when ethanol is present. To evaluate whether PLD activity is altered in patients with ALD, we compared Peth syntesis in response to chemotactic peptide (fMLP) or PKC stimulator (PMA) by PMN from patients with alcoholic steatosis (AS, n = 8), alcoholic cirrhosis (AC, n = 18), acute alcoholic hepatitis (AAH, n = 6) and from control subjects (n = 17). *Methods:* peripheral blood PMN isolated by dextran sedimentation and Ficoll-Hipaque separation were labeled with ^{3}H-lysophosphatidylcholine (10 \'b5Ci), stimulated with fMLP or PMA in the presence of ethanol (0.5%) and cytochalasin B (10 \'b5mol/l). PEth was separated by TLC using chloroform:methanol:acetic acid (65:17:2 v/v) as solvent system. Plates were scraped and the radioactivity incorporated in the various phospholipids was analyzed through liquid scintillation counting. The amount of radioactively labeled PEth was expressed as percent of phospholipid labeling. Results (mean – ES):Stimulus Controls AS AC AAHfMLP* 1.81 – 0.27 1.21 – 0.13 1.29 – 0.11 1.01 – 0.22PMA 1.09 – 0.16 0.96 – 0.17 0.96 – 0.13 1.28 – 0.22*ALD vs Controls p < 0.03 Kruskal-Wallis analisis of variance*Conclusions:* fMLP-induced activation of PLD is impaired in ALD whereas PLD activity in response to PMA is normal. This defect may be of significance for the enhanced susceptibility to infectious agents in ALD. "P P 4 0127"P 4 0127 **Interest of a Higher Dose of Interferon Alpha in Non Responder Patients with Chronic Hepatitis C: A Prospective Randomized Study**

*A. Rolachon, G. K\'e9zachian, X. Causse, M. Baud, J. Fournet, J.P. Zarski

Services d'H\'e9patologie de Grenoble et d'Orl\'e9ans, et Laboratoire de Virologie M\'e9dicale Mol\'e9culaire, C.H.U. de Grenoble, BP 217, 38043 Grenoble Cedex 9The aim of our study was to evaluate the interest of a higher dose of interferon (IFN) in non-responder patients to a first treatment by IFN 3 MIU TIW 6 months.Open prospective randomized and bicentric study concerned 23 patients (17 males, 6 females) with histologically proved chronic hepatitis C. Mean age was 38.7 – 9.1 years. Non-response was defined by ALT {\'b3} 2 ULN during first treatment duration. Patients were randomized in simple blind in 2 groups: group 1 (n = 14): IFN { a}2b 10 MIU TIW 2 months then 6 MIU TIW 4 months; group 2 (n = 9): IFN { a}2b 6 MIU TIW 6 months. The 2 groups were similar for age, sex, mode of contamination, duration of disease, genotype, quantitative viremia (MONITOR'), Knodell score and Metavir index. ALT activity (ULN) and viremia (AMPLICOR', MONITOR') were evaluated for each patients at M3 D1, M7 D1, M13 D1, and Knodell score and Metavir index at M13 D1.No difference was observed between the two groups at M3 D1, M7 D1, M13 D1 concerning ALT normalisation [respectively 29%, 30% and 0% in group 1 and 33%, 37% and 25% in group 2 (NS)], and HCV RNA negativation [respectively 69%, 50% and 10% in group 1 and 75%, 56% and 14% in group 2 (NS)]. A significant decrease of Knodell score (9.2 – 2.5 vs 5.4 – 3) ($p < 0.05$) and Metavir index was observed in group 2, particularly for activity index (1.8 – 0.7 vs 0.9 – 0.7) ($p < 0.05$). On the other hand, HCV RNA negativation was statistically more frequent at M7 D1 in non 1b (82%) than in 1b genotype patients (14%) ($p < 0.01$). The Knodell score (8.7 – 6.4 vs 6.4 – 3.5) and the Metavir index was significantly decreased (1.7 – 1.8 vs 1.1 – 0.8) in non 1b genotype patients.In conclusion, our results suggest that it is possible to obtain an immediate biochemical and virological response in non-responder patients to first treatment by using higher dose of IFN, particularly in non 1 b genotype patients. Indeed, a significant histological improvement is observed in non 1b genotype patients. Further studies should compare this schedule with a longer duration to IFN-Ribavirine association in this group of patients. Liver and bile ducts, 1: Hepatitis, viral, treatment }" "Interest of a Higher Dose of Interferon Alpha in Non Responder Patients with Chronic Hepatitis C: A Prospective Randomized Study"

"P P 4 0128"P 4 0128 **Influence of Flumazenil on Hepatic Coma: Clinical and Neurophysiological Study**

*G. Golubovic, L. Burg, A. Vlahovic, N. Djukic

Clinical-Hospital Center Zemun, Belgrade, Yugoslavia*Purpose.* It has been shown that flumazenil, a benzodiazepine receptor antagonist, has beneficial effect on cerebral function in patients with hepatic coma caused by liver cirrhosis. The aim of this study was to examine the influence of flumazenil on clinical and neurophysiological changes in 10 patients with hepatic coma as a consequence of underlying alcoholic liver cirrhosis.*Methods.* Clinical and neurophysiological (electroencephalogram-EEG, and visual evoked responses by ""flash"" stimulation) parameters were analyzed after administration of flumazenil.*Results.* The initial dose of flumazenil was 0.2 mg, while the full dose varied from 0.8–6.0 mg. Positive effect of flumazenil was expressed by patients' awakening and manifested in the first 6 hours by motoric excitability, aggressiveness and mental confusion, followed by drowsiness, but without pyramid deficit. After flumazenil administration, acceleration of average electrical activity from 2.9–4.6 cycles per second was noted on EEG, and shortening of latency period (P-100) on visual evoked responses from 69 to 61 msec (average values). In summary, flumazenil administration showed positive effect on awakening, EEG and visual evoked responses in 8/10 patients (80%). Survival rate was 60% (6/10 patients) at 6 months and 40% (4/10 patients) at one year.*Conclusion.* Our results suggested that endogenous bezodiazepines have significant role in pathogenesis of hepatic coma. The administration of flumazenil should be recommended in patients with hepatic coma. Liver and bile ducts, 1: Cirrhosis: ascites, encephalopathy }" "Influence of Flumazenil on Hepatic Coma: Clinical and Neurophysiological Study".

"P P 5 0129"P 5 0129 **Epidemiology of Hepatocellular Carcinoma in the Department of Calvados (France). Risk Factors and Prognostic Factors in a Non-Selected Population**

*C. Even, G. Launoy[1], M.A. Piquet, O. Duval, T. Collet, M. Gignoux[1], J.C. Verwaerde, T. Dao

[1] Departments of Hepato-gastro-enterology, Registry of digestive tumours of Calvados, C.H.U., CAEN, FranceThe aim of this study was to determine the epidemiological characteristics of hepatocellular carcinoma (HCC), and to study risk factors and prognostic factors in a non-selected population.*Methods:* Between 1984 and 1990, every case of HCC was registered by the registry of digestive tumors of Calvados. Standardized incidence rates were calculated for male and female. Prognostic factors were determined with the Cox's multivariate method.*Results:* 213 HCC have been registered. Diagnosis of HCC was based on: histology (50p.100), imaging + AFP {\'b3} 250 ng/ml (34p.100), imaging alone (16p.100). Standardized incidence rates were 7.5/100.000 in men and 0.4/100.00 in women. Sex-ratio was 17.1. Mean age was 66.4 – 1.2 years. HCC was uncommon before age of 50 (3p.100). HBsAg was present in 10/119 cases (8p.100), anti-HCV antibodies (EIA 1) were present in 6/22 cases (27p.100). Presence or absence of an underlying liver disease was established in 191 cases: normal liver (histologically proven) in 10p.100, cirrhosis in 86p.100, non cirrhotic liver disease (histologically proven) in 4p.100. The cause of cirrhosis was known in 150 cases: alcoholic 73p.100, cryptogenetic 9p.100, viral 7p.100, alcoholic + viral 5p.100, hemochromatosis 5p.100. The global survival (n = 203) at 1 year, 3 years and 5 years was respectively 21p.100, 8p.100 and 3p.100. The multivariate study pointed out 4 prognostic factors: number of tumors {\'a3} 2, lack of ascitis, AFP {\'a3} 10 ng/ml, HCC revealing a liver disease well-compensated until diagnosis time.*Conclusion:* In a french non-selected population, at least 10p.100 of HCC occurs on normal liver. Occurence of HCC seems to be linked to cirrhosis, male sex and age > 50, which could constitute main selection criterias for HCC screening. Unknown cirrhosis is associated with a better prognostic, suggesting the interest of early cirrhosis diagnosis. "P P 5 0130"P 5 0130 **HB X RNA and Antigen Detection and Sequence Analysis of the X Gene in the Tumorous and Non Tumorous Tissue of HBsAG Negative Patients with HCCK. Poussin[1], H. Dienes[2], M. Minami[1], C. Br\'e9chot,**

*P. Paterlini[1]

[1] INSERM U-370, CHU Necker, Paris, France

[2] Department of Pathology, Mainz, Germany

[3] Liver Unit, Hospital Necker, Paris, FranceDeleted HBV genomes persist in hepatocellular carcinomas (HCC) developed in HBsAg negative patients and the X region is often selectively transcribed [1]. In order to understand the role of HBV in these tumors we have: 1) looked for the X protein in the tumorous (T) and non tumorous tissues (NT) and 2) analysed by sequencing the X and the preC/C regions in HBsAg negative patients with HCC.*Methods:* HBV-DNA PCR with 8 sets of primers covering the HBV genome; HBV-RNA analysis with primers on the S, X and C gene; X antigen detection by immunohistochemistry; sequence analysis of the X and, as a ""control"", preC/C region by a combination of direct and after cloning sequencing. *Results:* The structure and RNA expression of the HBV genome were analysed in the T and NT of 9 HBsAg negative patients. HBV-DNA PCR revealed frequent genomic deletions. S and C RNAs were never expressed in the T and NT: conversely, X specific transcripts were found in the T and NT tissues of 7/9 patients. Seven patients were tested for the HBxAg in the T and NT: 5 scored positive and 2 negative, the results being in agreement with RNA results. In 2 of these patients the sequence analysis of the X region showed a high T/NT aminoacid divergence rate (23.3% and 11.6%): mutations were found in cell protein binding and transactivating domains and in the common AA with kunitz domain of serine protease inhibitors, suggesting a modification of the X function. By contrast, a very low rate of T/NT nucleotide divergence was found in PreC/C sequences (0.28% and 0.34%).*Conclusions:* Our study demonstrates the expression of both the X RNA and protein in the T and NT liver tissues of HBsAg negative patients and identifies mutations which might modify the X function. These results are consistent with a role for the X protein in the HBV related liver oncogenesis in HBsAg negative patients.

"P P 5 0131"P 5 0131 **Mass Screening for Detecting Hepatocellular Carcinoma**

*Y. Yoda, A. Kashiwagi, T. Kanai, I. Takayama, F. Kitahara, K. Kobayashi[1], Y. Akahane, M.A. Fujino[2]

[1] Health Care Center, Yamanashi Preferctural Welfare Federation of Agricultural Co-operatives

[2] First Department of Medicine, Yamanashi Medical University, Yamanash, JapanA total of 278,448 inhabitants of Yamanashi prefecture, Japan, were screened for hepatocellular carcinoma (HCC) by using ultrasonography (US) from April 1986 through March 1994. Among 80 HCC patients detected by US, 25 patients were screened annually (group A), the other 55 patients were found at the first screening or at screening after two or more years interval (group B).The detection rate of HCC was calculated as 28.7 per 100,000. The male/female ratio was 5.7 : 1. All patients were asymptomatic at the time of detection. In respects to most important risk factors for HCC, 12 patients were positive for HBsAg from 79 examined, and 40 patients were positive for anti-HCV from 53 examined.Five patients were negative for both HBsAg and anti-HCV, but they showed the same abnormalities in liver function tests.As compared with group B, group A had a tendency to detect in more smaller size and at more earlier stage. Small HCC ({\'a3} 2 cm) in group A and B were 9 patients (36%), 15 patients (33%) each. Solitary HCC in group A and B were 19 patients (76%), 32 patients (58%) each. For the survival rate of HCC, group A (1/3/5 year : 92/74/31 %) was significantly higher than group B (73/35/0 %).In conclusion, repeated mass survey by US within one year interval was effective for detecting the HCC at early stage and for expecting good prognosis. "P P 5 0132"P 5 0132 **Albumin mRNA in Peripheral Blood a Poor Prognostic Marker for Recurrence of Hepatocellular Carcinoma after Orthotopic Liver Transplantation**

*M. Peck-Radosavljevic, M. Bergmann, P. Ferenci, M. Riegler-Keil, C. Seelos, E. Lipinski, F. L\'e4ngle, R. Steininger, A. Gangl, F. M\'fchlbacher, J. Pidlich

Dept. of Gastroenterology, Dept. of Transplant Surgery, University of Vienna, A-1090 Vienna, AustriaSurvival after orthotopic liver transplantation for hepatocellular carcinoma is limited by a high rate of tumor recurrence. A PCR-assay based on the detection of albumin mRNA expression in peripheral blood for detection of hematogenous micrometastasis of hepatocellular carcinoma has been described, which may help to select candidates for orthotopic liver transplantation.The prognostic value of a highly sensitive nested RT-PCR assay was evaluated in comparison to the TNM-classification of the UICC in a population of liver transplant candidates.80 patients with liver disease and 42 control patients were evaluated. Six of 21 patients with hepatocellular carcinoma and 11 of 59 patients with diseases of the liver were positive on albumin RT-PCR, making this assay a good indicator of ongoing liver damage without absolute specificity for hepatocellular carcinoma. Twelve patients with hepatoma were followed after liver transplantation and 7 of those patients had a tumor recurrence within 12 months. Six of these patients with recurrence had UICC stage IV A tumors preoperatively, while only one of them were positive on albumin RT-PCR before transplantation. Only one patient with a stage I to III tumor had a recurrence within 12 months.Albumin mRNA RT-PCR seems to be an unreliable marker for assessing hematogenous spread of hepatocellular carcinoma before orthotopic liver transplantation. UICC stage IV A was a much better predictor of tumor recurrence compared to albumin mRNA RT-PCR. The practical value of albumin mRNA RT-PCR for patients undergoing liver transplantation seems to be very limited. Oncology, specific: Liver, biliaryLiver and bile ducts, 1: Liver transplantation }" "Albumin mRNA in Peripheral Blood a Poor Prognostic Marker for Recurrence of Hepatocellular Carcinoma after Orthotopic Liver Transplantation"

"P P 5 0133"P 5 0133 **Diagnostic Value of Color Doppler Ultrasonography in Hepatocellular Carcinoma**

*Vedat G\'f6ral, Levent Mumbu\'e7, Arslan Bilici, Aydin Kemaneci

Dicle University School of Medicine, Division of Gastroenterology, Diyarbakir, TurkeyHepatocellular carcinoma accounts for 80 to 90 percent of liver carcinomas. There is a wide variation in the incidence of hepatocellular carcinoma in different parts of the world, and a numbers of etiologic factors may be important.*Aim:* A differential diagnosis of liver tumors was attempted on the basis of the pattern of blood within and around tumors on color Doppler flow images.*Methods:* The study comprised 47 patients with liver mass lesions: 22 patients had hepatocellular carcinoma, 15 had hemangiomas, 4 had metastastic liver cancer, 3 had liver abscess, 3 had liver cyts. Color Doppler flow imaging and Doppler flow velocity were established and compared according to the Tanaka classification.*Results:* Color Doppler flow imaging was observed in masses of all of 22 patients with hepatocellular carcinoma, of 3 patients with liver metastasis, of 3 patients with hemangiomas. Doppler signals were not observed in 1 patient with liver metastasis, in 3 patients with liver abscess, in 3 patients with liver cyts. The mean of maximum blood flow velocity was 80.7 cm/sn in hepatocellular carcinoma, 49.3 cm/sn in metastatic liver cancers, 10.3 cm/sn in hemangiomas. A basket pattern (a fine blood-flow network surrounding the tumor nodule) was observed in 17 (77%) of the 22 hepatocellular carcinomas. An image of vessels within the tumor (blood flow that runs into and branches within the tumor) was observed in 5 (23%) of the 22 hepatocellular carcinomas. These two findings were observed only in hepatocellular carcinomas. In three of 15 hemangiomas, a spot pattern (color-stained dots or patches in the central region of the tumor) was seen.*Conclusion:* According to the this results, hepatocellular carcinomas have some characteristic appearances on Doppler flow images. Therefore, color Doppler ultrasonography can aid in the diagnosis of liver mass lesions. Radiology and ultrasound: DiagnosisOncology, specific: Liver, biliaryOncology, general: Screening, prevention }" "Diagnostic Value of Color Doppler Ultrasonography in Hepatocellular Carcinoma"

"P P 5 0134"P 5 0134 **Cholangiocellular Carcinoma: Pathological, Ultrasonographic and Angioechographic Correlation**

*R. Popova-Jovanovska, A. Saito[1], K. Takasaki[1], M. Yamamoto[1], N. Hayashi[1]

Clinic of Gastroenterology, Medical Faculty, Skopje, Macedonia

[1] Institute of Gastroenterology, Tokyo Women's Medical College, Tokyo, JapanCorrelation were sought among histopathologic, ultrasonographic (US) and angioechographic findings in 27 resected cholangiocellular carcinoma (CCC) cases. According to macroscopic appearance CCC was classified into three types: nodular, peruductal and intraductal. This classification was accepted because clinico-pathological features, as well as prognosis, differed among tumor types. A tumor mass was clearly visible in nodular type tumors. 17 were large tumors and 3 were small less than 3 sm. The large tumor were ill-defined (70%), showed hypoechoic rim (65%), had an echo pattern which tended to be more echogenic and were associated with bile duct dilatation (59%). Vascular structures within the tumor were of importance as US characteristics of CCC: Portal tract passing through the tumor (23%), disappearing portal tract (29%) and the ""vessel like structures"" sign (53%). Tumor mass could not be identified or was poorly visualised in periductal and intraductal type CCC. A disappearing portal tract sign was noted in four while bile duct dilatation was seen in all five periductal type cases. The two cases had intraductal type CCC. Tumor mass filling the bile duct was seen in one case.In addition angiechography was performed in 9 of these CCC cases. After CO_2 gas injection three angioechographic patterns were discernible, peripheral enhancement in three cases, whole tumor enhancement in four cases and partial tumor enhancement in two cases. There was a tendency for the angioechographic pattern to change from whole to peripheral enhancement as the tumor increased in size. The comparisons contribute to understand the significance of the different US and angioechographic appearances of CCC. Oncology, specific: Liver, biliaryRadiology and ultrasound: Diagnosis }"

"P P 5 0135"P 5 0135 **Cytology Study of Localisation of Hepatitis B Surface Antigen in Hepatocellular Carcinoma Using Orcein Staining**

*K.T. Shenoy, J.V. Panicker Jalesh, Joy Augustine

Department of Gastroenterology and Pathology, Medical College, Trivandrum, India*Objective:* To test the hypothesis that orcein staining of cytological specimen from hepatocellular carcinoma (HCC) can detect hepatitis B surface antigen (HBsAg) and to determine the observer variability and agreement.*Methods:* 20 cases of suspected HCC were evaluated clinically and cytological examination of fine needle aspiration cytology material for malignancy by papanicolaou and orcein staining for HBsAg was carried. Modification of orcein staining was done to suit cytology. Using cytomorphological features, HCC was diagnosed. HBsAg was detected in serum using ELISA. Observer variability and agreement were assessed on orcein positivity by two independent cytopathologists. Data were analysed using Kappa statistics for observer agreement.*Results:* Of 20 suspected HCC, 13 had definite HCC. 8 HCC had HBsAg positivity and 8 had orcein positivity as judged by observer 2 and 7 by observer 1. A Kappa value of 0.837 was statistically significant.*Conclusion:* A high degree of observer agreement between cytopathologists in the interpretation of orcein positivity was noted and there was excellent correlation with HBsAg status. This technique is cheap, safe and quick and need further evaluation as a test for laboratory diagnosis of HBV related HCC. Oncology, specific: Liver, biliary }" "Cytology Study of Localisation of Hepatitis B Surface Antigen in Hepatocellular Carcinoma Using Orcein Staining"

"P P 5 0136"P 5 0136 **HCC Prevalence in Liver Cirrhosis: A Prospective Study on 121 CasesS. Pistoso, G.P. Aimo, W. Piubello**

Med. Dept. Salo' General Hospital, Salo' ItalyPrevalence of Hepatocellular carcinoma (HCC) in patients suffering from cirrhosis is high and its prognosis generally poor. The early detection of HCC could improve treatment chances and survival. We monitored 121 consecutive patients (73 men, 48 females ages, average age 58, ranging from 28–73) with semiannual controls of alfafetoprotein and ultrasonography. Cirrhosis was viral in 48 patients, ethanol related in 63 and due to other causes in 10. At the moment of enrollment 64 of the patients were classified in class A of Child, 39 in B and 18 in C. The average length of our observation was 48 months (range 11–102). There were 20 HCC diagnosed, 15 of them male. In relation to aetiology, 12 HCC developed in patients with viral cirrhosis (25%) and 8 in alcoholic disease (12.6%). In 11 HCC underlying cirrhosis was classified in Child grade A, in 8 B, and in one case C. In 10 cases tumor size was smaller then 5 cm in diameter. The levels of Alfafetoprotein were high in 12 patients with HCC (60%) and in 7 (8%) with chirrosis. Cumulative incidence of HCC became greater with the length of follow up: 2.5% at the first year, 22.4 at the sixth, with annual incidence of about 4%.In conclusion our results suggest that the semiannual screening of cirrhotic patients permits the diagnosis of HCC in its early stages in 50% of the cases. Alfafetoprotein measurement alone is an unsatisfactory index of HCC development for its low sensibility. In patients with Child grade C cirrhosis background liver disease itself determine the prognosis, so that screening for HCC development seems to be unnecessary. Oncology, specific: Liver, biliaryOncology, general: Screening, prevention }" "HCC Prevalence in Liver Cirrhosis: A Prospective Study on 121 Cases"

"P P 5 0137"P 5 0137 **Serum Carbohydrate-Deficient Transferrin in Patients with Nonalcoholic Liver Disease and with Hepatocellular Carcinoma**

*Yoshikazu Murawaki[1], Masahiko Koda[1], Isao Yuasa[2], Hironaka Kawasaki[1]

[1] Second Department of Internal Medicine, Tottori University School of Medicine, Yonago, 683, Japan

[2] Department of Legal Medicine, Tottori University School of Medicine, Yonago, 683, JapanSerum carbohydrate-deficient transferrin (CDT) test is a reliable and specific marker for detecting alcohol consumption. However, recent studies have shown false-positive of CDT test results in nonalcoholic liver disease. We examined the clinical significance of serum CDT in nonalcoholic liver disease and especially in hepatocellular carcinoma (HCC), using alcoholic liver disease as a positive control.The subjects included 23 teetotalers, 56 patients with alcoholic liver disease (39 liver fibrosis and 17 LC), 84 patients with chronic viral liver disease (24 CPH, 33 CAH, 27 LC) and 67 patients with HCC. Serum CDT was measured with an Axis % CDT RIA kit (Axis Biochemicals AS, Oslo, Norway) and expressed as percentages of the total transferrin (% CDT).The serum % CDT was 1.2 – 0.8% in the teetotalers. The mean serum % CDT value was increased 1.8-fold in alcoholic liver fibrosis and 3.8-fold in alcoholic LC compared with the teetotalers. The serum % CDT values in viral chronic hepatitis were similar to those in teetotalers, and were increased 2.0-fold in nonalcoholic LC. False-positive results were found in 10 (37%) of the 27 patients with nonalcoholic LC, but not in viral chronic hepatitis. The mean serum % CDT value was increased 2.5-fold in HCC, and false-positive results were found in 31 (46%) of the 67 patients. CDT was also recognized by isoelectric focusing followed by immunofixation in the false-positive serum from patients with HCC. The serum % CDT value in HCC was related to the size of tumor and the grade of histological differentiation.These results suggest that the ability of serum CDT measurement to detect chronic alcoholism may be reduced in patients with nonalcoholic liver cirrhosis and with hepatocellular carcinoma. Liver and bile ducts, 1: Hepatotoxicity, ethanol }" "Serum Carbohydrate-Deficient Transferrin in Patients with Nonalcoholic Liver Disease and with Hepatocellular Carcinoma"

"P P 5 0138"P 5 0138 **Precancerous Potentiality of Macroregenerative Nodules in Liver Cirrhosis**

*M. Bonelli, S. Signorelli, B. Paris, F. Negrini, E. Marzo, M. Girola

Third Department of Medicine, Ospedali Riuniti di Bergamo, 24128 Bergamo, Italy*Background/Aims.* A close follow-up with ultrasonographic (US) examination and alpha-fetoprotein (AFP) measurement is the current policy for early diagnosis of hepatocellular carcinoma (HCC) in patients with cirrhosis. Large hepatocellular nodules, histologically defined as benign macroregenerative nodules (MRNs), are sometimes picked-up by ultrasound. The significance of these lesions, which have a differing sonographic texture, is still debated. In the present study the pre-malignant potential of these nodules is evaluated, by following them up with regularly scheduled US examinations and US-guided fine needle biopsy (FNB).*Methods.* 14 focal lesions (with an average size of 24 mm in diameter) in 11 cirrhotic patients (10 males and 2 females, age 52–75 years), with histological diagnosis of MRNs, made by US-guided fine needle biopsy, were followed from 1989 to 1996. Mean follow-up was 41 months (range 12 to 77). During the observation period a regular US and clinical evaluation at an interval of 4 months was carried out. When some changes occurred in nodules size, US pattern or AFP levels, a rebiopsy was performed. US and clinical features, including Child's classification, alcohol intake, AFP and HBV/HCV positivity were investigated (chi-square test was used for statistical analysis of data).*Results.* 12 out of 14 nodules (78.5%) increased in size during the follow-up period, and became histologically malignant (HCC) after 28.7 + 10 months (mean + SD). There was no statistical correlation between neoplastic transformation and US pattern or clinical data at the time of entry into the study.*Conclusions.* The pre-malignant nature of MRNs in cirrhotic liver is very likely and the treatment of these lesions should be encouraged. "P P 5 0139"P 5 0139 **Retroviral Thymidine Kinase Gene Transfer and Ganciclovir Therapy (GCV) Generate Anti-Tumoral Immunity and Bystander Effect Against Non Transduced Liver Tumors Cells in Rat**

*Rad A.R. Kianmanesh, Y. Panis, M. Fabre, D. Houssin, D. Klatzmann

Surgical Research Lab. (Hospital Cochin), Pathology (Hospital Kremlin-Bic\'eatre) and CNRS (Hospital de la Piti\'e9-Salp\'eatriére), Paris, FranceSignificant regression of liver metastases in rats was observed after in situ retroviral transfer of thymidine kinase gene from Herpes Simplex Type 1 (HSV1-TK), followed by GCV. However, few tumor cells were effectively transduced. This could be explained by bystander effect (intercellular crossing of toxic form of GCV) and/or anti-tumoral immunity. The aim of this work was to study these two mechanisms in rat liver metastases and hepatoma.*Material and Methods:* (a) *bystander effect* was studied in 16 rats after intrahepatic injection of colon cancer cells mixture with variable rates of transduced TK+ (0, 25%, 50% and 100% TK+) and TK{ -} cells. After 5 days, rats were treated with GCV for 5 days. Rats were sacrificed at Day 12; (b) *anti-tumoral immunity* was studied in 12 rats after intrahepatic injection in 2 different locations of hepatomas cells: in each rat, left lobe received TK{ -} cells and right lobe TK+ cells. At Day 14, 6 rats were treated with GCV for 5 days. The 6 others rats received no treatment. Two weeks later, all the rats were sacrificed.*Results:* (a) significant tumor regression was obtained from tumors with 25% TK+ cells: mean tumor volumes were: 30 – 16 mm^3 (0% TK+) vs 10 – 5 (25% TK+; $p < 0.04$) vs 4 – 4 (50% TK+) vs 0.2 – 0.2 (100% TK+); (b) in control rats with double liver tumors, mean tumor volume for TK+ was 4895 – 4360 and TK{ -} 6494 – 7329 mm^3 (N.S.). After GCV, mean tumor volume for TK+ was 11 – 13 ($p < 0.006$ vs control TK+) and TK{ -} 30 – 41 mm^3 ($p < 0.004$ vs control TK{ -}).*Conclusions:* (a) bystander effect was responsible of a significant anti-tumoral effect even if only 25% of tumor cells were effectively transduced; (b) the unexpected significant regression of TK{ -} liver tumors suggested a possible role of host immunity.This study demonstrated that 2 different mechanisms could amplify the therapeutic effect observed after HSV1-TK retroviral gene transfer and GCV: the bystander effect and the generation of anti-tumoral immunity against TK{ -} cells after destruction of TK+ cells. Oncology, specific: Liver, biliaryOncology, general: Molecular biology, genetics }" "Retroviral Thymidine Kinase Gene Transfer and Ganciclovir Therapy (GCV) Generate Anti-Tumoral Immunity and Bystander Effect Against Non Transduced Liver Tumors Cells in Rat"

[1] Catholic University, Istituto Superiore di Sanit\'e0, Rome, ItalyOxygen radicals play an important role in multistep carcinogenesis and antioxidant substances can inhibit the carcinogenesis. Hepatocellular carcinoma (HCC) is a neoplasm mostly arising on cirrhotic liver. The aim of our study was to evaluate on liver specimens obtained by echo-guide percutaneous biopsy from patients with neoplastic and/or chronic liver diseases: A) the activity of the two types of antioxidant enzyme Superoxide Dismutase (Mn-SOD and CuZn-SOD); B) the level of some elements (Mn, Cu, Zn, Fe) involved in free radicals metabolism.We evaluated: the SOD activity on specimens from 8 normal livers, 17 chronic hepatitis (CH), 11 cirrhosis, 4 dysplastic nodules (DN) and 11 HCC; the element levels on specimens from 4 normal livers, 14 CH, 16 cirrhosis, 1 DN and 4 HCC. Total-SOD \'b5g/mg prot Mn-SOD \'b5g/mg prot CuZn-SOD \'b5g/mg protNormal liver 12.4 – 1.0 6.4 – 0.8 6.0 – 0.4CH 7.9 – 0.6\bullet 4.5 – 0.5∅ 3.4 – 0.4\bulletCirrhosis 7.0 – 0.8\bullet 3.6 – 0.4∅ 3.4 – 0.5\bulletDN 5.2 – 0.8\bullet 3.1 – 0.6∅ 2.1 – 0.2\bulletHCC 4.9 – 0.9\bullet 3.6 – 0.6∅ 1.3 – 0.5\bullet\bulletp < 0.001 vs. normal liver, ∅p < 0.05 vs. normal liver Mn \'b5g/g dw Cu \'b5g/g dw Zn \'b5g/g dw Fe \'b5g/g dwNormal liver 4.08 – 0.08 3.90 – 1.04 65.2 – 10.2 156 – 85CH 5.43 – 0.52 6.30 – 1.12 165.7 – 59.3 388 – 65Cirrhosis 6.89 – 1.56 9.96 – 1.14 222.3 – 60.4 715 – 202DN 5.28 15 68.2 200HCC 4.62 – 0.91 3.17 – 1.83 81.8 – 28.6 1024 – 246In present study a reduction of SOD activity has been found progressing from chronic liver diseases to HCC; this reduction could to be involved in the pathogenetic mechanism underlying the natural history of HCC. In our study the level of Mn, Cu and Zn (cofactors of the two types of SOD) aren't lower in liver diseases, thus they aren't involved in down regulation of SOD. On the contrary, the iron, element involved in free radicals production, is higher in all liver diseases. "P P 5 0141"P 5 0141 **Hepatocellular Carcinoma (HCC) in HCV-Related Cirrhosis Treated and Not Treated with Interferon**

*A. Vian, U. Lorenzoni, S. Lobello, A.R. Floreani, F. Farinati, R. Naccarato, M. Chiaramonte

Dpt of Gastroenterology, University of PadovaHepatocellular carcinoma (HCC) is a complication of long-standing cirrhosis, especially with viral aetiology. In an Italian population the HCC incidence/100 pts/year in Child A HCV-related cirrhosis is 3.62 (Ital J Gastroenterol, 1994: 26; 164) Recent reports suggested that IFN treatment can reduce the risk of HCC development in HCV related cirrhosis (Lancet, 1995: 346; 1051, J Hepatol, 1996: 24; 141).With the Aim to verify whether in our population IFN treatment can reduce the incidence of HCC in Child A cirrhotic patients, we studied two group of patients, prospectively followed up, and treated or not with IFN.*Methods:* IFN treated group: 44 patients (26 M, 12 F; mean age 56 Range 28–64) enrolled in Alpha-IFN trials between 1991–1994 and followed-up for at least 12 months (mean 37.6 Range 12–56) after the end of full treatment. Control group: 157 non treated patients (81 M, 76 F; mean age 54.2 Range 30–72) enrolled in a prospective follow-up study between 1981–1994. All patients had well compensated cirrhosis (Child A), biopsy proven at the enrolment, and no statistically significant differences in demography were detectable. In the treated group 8 pts (18.2%) were responders, 27 (61.3%) non-responders and 9 (20.5%) responders with relapse.The results were statistically analysed by the Mantel Haesnzel life table analysis.*Results:* 5 (11.4%) patients in the treated group developed HCC. The respective incidences in responders, non responders and relapsers were 2/5 (female), 3/5 (all males) and 0/5. In non treated patients 32/157 (20%) developed HCC. After adjustment for the follow-up period, the Mantel Haesnzel life table analysis showed that the probability of remaining HCC free was not statistically different between the two groups (p = 0.30)In *Conclusion* our results, based on a prospective follow-up study of cirrhotics, treated or not with IFN, failed to confirm the above early evidence that IFN treatment reduce the HCC incidence in well compensated cirrhosis. "P P 5 0142"P 5 0142 **Trial of a New Therapy Combining DDS with Hyperthermia for Liver Cancer**

*M. Imamura, T. Seki, K. Kunieda, T. Tamai, T. Nakagawa, A. Nishimura, K. Inoue, Y. Obiya[1], K. Harada[1]

The 3rd Dept. of Int. Medicine, Kansai Medical University, Moriguchi, Osaka 570, Japan

[1] PL Botanical Inst., PL Gakuen Women's Jr. College, Tondabayashi, Osaka 584, JapanWe have been developing a new form of therapy to achieve more effective local control of liver cancer.First, we designed a new anticancer drug delivery system (DDS) targeting liver cancer. Then, we developed a drug complex bound to hydroxyapatite (HAP) including doxorubicin hydrochloride (DOX) and buthionine sulfoximine (BSO). This drug complex was named the HAP system. DOX is an anthracycline anticancer drug, and BSO is a selective inhibitor of GSH (intracellular glutathione; { g}-glutamyl-cysteinyl-glycine) biosynthesis. GSH is a scavenger of free radicals in tumor cells. We found in an *in vitro* experiment that DOX and BSO were eluted from the HAP system over the first 3 hrs of incubation, and that from 4 hrs onwards the remaining DOX was released continuously, showing a slow-release property. This property is likely to be favorable because it allows continuous attack on tumor cell DNA after the initial depletion of GSH by BSO.Also, we performed an *in vivo* experiment using sarcoma 180 tumors transplanted into the thigh of the right hind leg of mice. After measuring the tumor volume every day we evaluated the inhibitory effect of the HAP system on tumor growth. The inhibitory effect of the system was remarkable, the tumor volume ratio (DOX-HAP complex-treated group/DOX & BSO-HAP complex-treated group) on the 31st day being 1.93.We then examined experimentally the inhibitory effect on tumor growth of the HAP system + hyperthermia (42\'b0C for 40 min) on the 7th day after HAP system transplantation. On the 28th day after transplantation of this system, the tumor volume in the DOX & BSO-HAP group was 6.36 {\'b4} 10^4 mm^3 whereas that of the DOX & BSO-HAP + hyperthermia group was 2.29 {\'b4} 10^4 mm^3. The latter group showed significant suppression of tumor volume to 64%, as compared with the former group (t-test, $t < 0.05$). Therefore, it was assumed that the HAP system + hyperthermia treatment was more effective for cancer therapy than the other treatments.We have also been studying the inhibitory effect on tumor growth of the HAP system + hyperthermia using VX_2-transformed livers (hepatic tumor) in Japanese white rabbits, and obtained results similar to those for sarcoma 180. [3] Chiba Kaihin Municipal Hospital, Chiba, JapanWe studied the clinical usefulness of hepatic arterial infusion chemotherapy based on an chemosensitivity test.Seventy eight patients with unresectable HCCs were treated by hepatic arterial chemoinfusion using a percutaneously implanted reservoir. Before chemoinfusion, we selected an anticancer drug by in vitro chemosensitivity test using a biopsy specimen, in which karyologic changes of cancer cells were observed microscopically as an indicator of drug sensitivity.Forty four patients were treated by chemosensitivity-positive drugs (group A). The remaining 34 patients (group B), failing to have chemosensitivity-positive drugs, were treated by randomly selected 1 of 4 drugs (pirarubicin, epirubicin, carboplatin, mitoxantrone). The overall response rate by WHO criteria was 46% in group A and 12% in group B. The 1-year and 2-year survival rates of group A were 69% and 42%, while, those of group B were 58% and 0%, respectively.The arterial infusion chemotherapy based on the chemosensitivity test improved therapeutic results in the patients with unresectable HCCs. "P P 5 0144"P 5 0144 **High Preoperative Serum Alanine Transaminase Level Increases the Risk of Liver Resection for Hepatocellular Carcinoma (HCC) in Childs' Grade A Cirrhotic Patients**

*O. Farges, P. Jagot, R. Noun, J. Belghiti

Department of Digestive Surgery, Hospital Beaujon, University Paris VII, Clichy, FranceLiver resection in patients with liver cirrhosis (even in the absence of overt liver insufficiency) is associated with a greater risk than in patients without underlying liver disease. Because the incidence of HCV-cirrhosis related HCC is anticipated to increase rapidly in the near future we have assessed, by multivariate analysis, parameters associated with in-hospital mortality and morbidity in a consecutive series (1984–1994) of 108 Childs' grade A cirrhotic patients undergoing liver resection of an HCC (1 or less liver segment, 2 segments or 3 or more segments in 42, 23 and 43 patients respectively). Parameters entered for analysis included age, aetiology of cirrhosis, preoperative serum bilirubin, AST, ALT, GGT, albumin, creatinine levels as well as prothrombin time, presence or absence of pathological features of superimposed active hepatitis, extent of resection, type and duration of vascular clamping and amount of intraoperative blood loss. Overall incidence of in-hospital death and major postoperative complications were 8.3% and 48.1% respectively. By univariate analysis, preoperative serum ALT levels (p = 0.001) and intraoperative transfusions (p = 0.01) were the only parameters significantly associated with in-hospital death. However, only serum ALT concentrations was an independent risk factor. In-hospital mortality in patients whose preoperative serum ALT was below 2 N (n = 77), comprised between 2 and 4 N (n = 23) and greater than 4 N (n = 8) was 3.9%, 13.0% and 37.5% respectively. Increased ALT levels (> 2 N) was also associated with an increased incidence of postoperative ascites (58 vs. 32%, p = 0.01), kidney failure (16 vs. 0%, p = 0.0003) and UGI bleeding (6.4 vs 0%, p = 0.02).*Conclusion:* Preoperative serum ALT level is an independant and reliable predictor of in-hospital mortality and morbidity following liver resection in Child A cirrhotic patients. Our results suggest that cirrhotic patients with ALT > 2 N should undergo only a limited resection. If a larger resection is necessary other therapeutic option should be considered. Oncology, specific: Liver, biliary }" "High Preoperative Serum Alanine Transaminase Level Increases the Risk of Liver Resection for Hepatocellular Carcinoma (HCC) in Childs' Grade A Cirrhotic Patients"

"P P 5 0145"P 5 0145 **Low Morbidity after Liver Resection with Ultrasonic Dissector in Cirrhotic and Non-Cirrhotic Patients**

*R. Dionigi, L. Dominioni, A. Benevento, A. Ferrari

Department of Surgery, University of Pavia in Varese, Varese, ItalyAim of this study is to evaluate the postoperative (30 days) morbidity and mortality in a consecutive series of 144 liver resections carried out with the ultrasonic dissector (CUSA).From 1987 to 1996 144 patients (M/F: 90/54, mean age 64 years) underwent liver resection for hepatocarcinoma (n = 51), liver metastases (n = 62), bile ducts carcinoma (n = 5), hemangioma (n = 11), and other benign tumors (n = 15). Fortysix patients were cirrhotic and 98 patients had a normal residual liver. Hepatic resections included: 43 major resections (left, right or extended right hepatectomy), 21 segmentectomies and 80 atypical or subsegmental resections. Surgical technique included the use of CUSA, which allowed the meticulous identification and ligation of major as well as minor hepatic vessels and ducts crossing the resection plane, thus preventing local surgical complications.The morbidity and mortality observed are detailed in the table: Complications All patients Cirrhotic Non cirrhotic (n = 144) (n = 46) (n = 98)Liver failure 6 (2*) 2 (1*) 4 (1*)Liver bleeding 1 1 –Gastrointestinal bleeding 2 (1*) – 2 (1*)Biliary leakage 2 – 2Septic shock 2 (1*) 1 (1*) 1Hearth, lung, renal failure; MOF 11 (3*) 5 (1*) 6 (2*)Total complications 24 8 15Total pts with complications 16 (11%) 7 (15%) 9 (9%)Mortality 7 (5%) 3 (7%) 4 (4%)*fatal outcomeIn conclusion, our results indicate that liver resection can be done in cirrhotic and non-cirrhotic patients with low morbidity (11%) and low mortality (5%), by using the ultrasonic dissector, which allows a better hemostasis and control of biliary leakage of the liver transection surface, as compared to the finger dissection technique. Oncology, specific: Liver, biliaryOncology, general: TherapyClinical practice: Management strategy }" "Low Morbidity after Liver Resection with Ultrasonic Dissector in Cirrhotic and Non-Cirrhotic Patients"

"P P 6 0146"P 6 0146 **Quantification of Intra-Hepatic HCV-RNA According to Histology and to Genotypes after Liver TransplantationV. Di Martino, C. F\'e9ray, F. Saurini, D. Samuel, M. Gigou, M. Reynés[1], H. Bismuth**

[1] Hepato-Biliary Surgery and Liver Transplant Unit, Pathology, CHU Kremlin-Bic\'eatre, France

Paul Brousse Hospital, Villejuif, CHU Kremlin-Bic\'eatre, FranceA relation between genotypes 1b and severity of recurrent liver disease due to HCV has been described after liver transplantation. However, the mechanism of such severity remains unknown.*The aim* of this study was to analyse in liver transplanted patients remaining serum HCV RNA positive, the relations between the level of intrahepatic replication of HCV, the severity of liver disease and the genotypes.*Samples and methods:* 98 post-transplant biopsies from 33 liver transplanted patients (21 were genotype 1b) were available. Intrahepatic HCV RNA was quantitated by competitive PCR on serial dilutions of HCV cDNA. For all biopsies, a similar competitive method was used for the quantification of 28S ribosomal RNA permitting to normalize the quantitation of HCV between the biopsies.*Results:* Levels of intra-hepatic replication was higher in case of lobular hepatitis than in case of chronic active hepatitis, rejection, cholestasis and subnormal histology (10 competitor Unit (CU) vs 2; 1; 1.8 and 2.2 p < O.01). Level of replication decreased with time after LT and was not related to genotype 1b.*Conclusions:* Our results show that intra-hepatic replication of HCV 1) exist in liver graft with normal histology; 2) was only increased in case of acute lobular hepatitis; 3) decreased with time after transplant. 4) was not related to genotype 1b. These findings suggest a direct cytopathic effect of HCV at the time of acute hepatitis and that pathogenicity of HCV type 1b is an intrinsec property not related to an increased level of replication. }" "Quantification of Intra-Hepatic HCV-RNA According to Histology and to Genotypes after Liver Transplantation"

"P P 6 0147"P 6 0147 **Value of Transjugular Intrahepatic Portosystemic Shunt in Cirrhotic Patients Awaiting Liver TransplantationD. Azoulay, J. Raccuia, D. Castaing, H. Bismuth**

Hepato-Biliary Surgery and Liver Transplant Center, Paul Brousse Hospital, Villejuif, FranceFrom November 1991 to January 1995, 34 transjugular intrahepatic portosystemic shunt (TIPS) were attempted in 34 cirrhotic patients (mean 46.4 – 2.4; 22–66) candidates for liver transplantation (LT).Patients were classified Child class A in 5 cases, B in 11 cases, C in 18 cases. Indication for TIPS was sclerotherapy failure in 23 cases and intractable ascites in 11 cases. Two patients were excluded because of technical failures which were treated by OLT in one case and open calibrated porta-caval shunt in one case. The follow-up with LT as end point was 1 to 34 months (7.6 – 1.6 M).*Results:* Early thrombosis (< 3 months) occurred in 8 cases: 6 were desobstructed via the internal jugular vein and 2 were desobstructed surgically together with calibrated porta-caval shunt. Late thrombosis occurred in 1 case with portal vein thrombosis and was treated by mesenterico-caval shunt followed by LT 6 months later.Recurrence of hemorrhage occurred in 2/22 patients who underwent TIPS for sclerotherapy failure (one rupture of varices, one duodenal ulcus). Ascites disappeared in 7/10 patients who underwent TIPS for intractable ascites and was controlled together with diuretics in 2 patients. Ascites remained unchanged in 1 patient.21 patients were transplanted following TIPS with a mean delay 6.4 – 1.6 (range: 1– 26) months. During the same period, 7 patients with cirrhosis and surgical open porta-caval shunt were transplanted. Comparison of patients with TIPS to patients with surgical open shunt showed a shorter duration of operation for patients with TIPS (332 – 351 vs 467 – 480 min, P > 0.05), less blood transfusion (3.5 – 2.1 vs 7.3 – 2.6 L, P < 0.05). Graft and patient survival at 3 months were comparable.We conclude that TIPS controles the complications of portal hypertension in patients awaiting transplantation. TIPS diminishes blood requirement during liver transplantation procedure. }" "Value of Transjugular Intrahepatic Portosystemic Shunt in Cirrhotic Patients Awaiting Liver Transplantation"

"P P 6 0148"P 6 0148 **Prospective Evaluation of Serum GST{ a} in Liver Transplantation**

*D. Azoulay[1], A. Lemoine[2], M. Salvucci[2], R. Adam[1], H. Bismuth[1], B. Debuire[2]

[2] Biochemistry Dept, Paul Brousse Hospital, Villejuif, France

[1] Hepato-Biliary Center, Paul Brousse Hospital, Villejuif, FranceThe cytosolic enzyme, Glutathion S transferase { a} (GST) has been proposed as a marker of acute graft rejection following liver transplantation (LT). GST may offer significant clinical advantages over conventional liver function tests (LFT; wide hepatic distribution and shorter in vivo plasma half life). The value of this test over LFT remained to be assessed and was the impetus for the present study. A prospective daily evaluation of plasmatic GST using a new enzyme immunometric assay (Hepkit, Biotrin, Ireland) was performed in 45 recipients (men: 46%, 46 – 13 y), in the first 20 days following LT. The results were compared to conventional LFT and significant clinical events. Twenty patients experienced biopsy proven acute graft rejection episodes (only 15 were treated); 15/20 had an increased GST *vs* 11/20 for transaminases. The sensitivity of GST assay for the occurrence of treated acute graft rejection was 100% and the specificity 73% *vs* 73% and 88% for ALT, respectively). The positive predictive value was 75% and the negative one was 100%. GST increased earlier than the conventional LFT before acute graft rejection and decreased also more rapidly when treatment was efficient. GST remained elevated in case of steroid-resistant graft rejection. In the first 3 days of the post operative period, GST was significantly correlated with the prothrombin time at D3 and D5 ($p < 0.007$) and with the occurrence of acute graft rejection. The slower was the decrease, the higher was the occurrence of acute graft rejection. According to the early increase before acute graft rejection and the rapid decrease following efficient treatment of graft rejection, GST assay seems to be a useful marker of acute graft rejection to use in combination with conventional LFT. Moreover the initial GST release following LT was correlated with early graft function. }" "Prospective Evaluation of Serum GSTalpha in Liver Transplantation"

"P P 6 0149"P 6 0149 **Liver Transplantation for Hepatocellular Carcinoma on Cirrhosis: Prognostic Impact of an Adapted Patient SelectionH. Bismuth, R. Adam**

Hepato-Biliary Surgery and Liver Transplant Research Center, Paul Brousse Hospital, Villejuif, FranceHepatocellular carcinoma (HCC) is an established but still debated indication of liver transplantation (LT). The high risk of recurrence and five year- survival rates significantly lower (0–50% in different series) than those of benign diseases have questionned the place of LT for HCC in the current period of organ shortage. We report in this study the consequences of a new selection of patients adapted from prognostic indicators established in the first phase of a same series. From November 1985 to March 1994, 109 patients with cirrhosis were transplanted for HCC. Of these 109 patients, only 95 patients with HCC diagnosed before LT were included in the study. The presence of extrahepatic deposits on pretransplant staging or pre-roperative exploration was considered as a contraindication to LT. In the first period of our experience (November 85–December 91), the selection criteria only included the absence of any extrahepatic tumour (60 patients). After assessment of prognostic factors in this first period (mainly tumor size > 30 mm, number of nodules > 3 and presence of a portal thrombosis), we proceeded to a more restrictive selection of those patients at very high risk of recurrence. Results in terms of patient selection and 3 year-survival were as follows: 1st period (85–91) 2nd period (92–94) p n = 60 n = 35No nodules > 3 24 (40%) 6 (17%) 0.03Size > 30 mm 29 (48%) 12 (34%) 0.01Portal thrombosis 6 (10%) 1 (3%) NSNo and Size < 30 mm < 3 nod 21 (35%) 22 (63%) 0.04> 30 mm > 3 nod. 14 (23%) 5 (14%)Recurrence 20 (33%) 4 (11%) 0.013 yr-Surv. (Overall – Disease free) 55% – 49% 76.5% – 70% NS – 0.07*Conclusion:* An adapted selection of patients with HCC for LT allows a significant decrease of the recurrence rate and a trend to improved survival. This warrants the indication of LT for HCC even in the current period of organ shortage. }" "Liver Transplantation for Hepatocellular Carcinoma on Cirrhosis: Prognostic Impact of an Adapted Patient Selection"

"P P 6 0150"P 6 0150 **Impact of Cytomegalovirus (CMV) on Morbidity and Mortality after Liver Transplantation (LT)F. Saliba, O. Farges, D. Samuel, P. Ichai, M.F. David, D. Mathieu, E. Dussaix, H. Bismuth**

Hepato-Biliary and Liver Transplantation Center, Paul Brousse Hospital, Villejuif, FranceCMV is the predominant cause of viral infection after LT. The aim of this study was to analyse the impact of the CMV on the results of LT. From January 1987 to December 1992, 789 LT were performed in 688 patients. 76 CMV seronegative recipients (R{ -}) received livers from CMV seronegative donors with CMV free blood transfusions (D{ -}) (group I: 34 M, 42 F; mean age 44.3 – 16 years) and the 612 other patients were either seropositif (R+) or acquired the virus from the graft or from transfusions (D+) (group II: 365 M, 247 F; mean age 46.3 – 13 years). LT was performed in emergency for fulminant liver failure in 18.4% of the R{ -}D{ -} group and in 19.2% of the other group. ABO incompatible graft were used in 5.2% and 4.6% of group I and group II patients respectively. Among group II patients, 37.5% developed a CMV infection, 21% a CMV disease and two died of CMV disease. None of the R{ -}D{ -} patients developed a CMV infection. There was no statistical difference in the cumulative actuarial incidence of acute rejection between group I (36%) and group II (35%). The cumulative actuarial incidence of chronic rejection was comparable in the two groups (7%). There was a statistical difference in actuarial patient survival rate (group I: 81% vs group II: 70% at five years, $p < 0.01$). No statistical difference was seen in actuarial graft survival rate (group I: 70% vs group II: 64%).*In conclusion:* Despite improvements in early diagnosis, prevention and treatment of CMV disease, morbidity is lower and survival better in R{ -}D{ -} patients than in R+ or R{ -}D+ patients. Despite scarcity of organ donors, it is of the utmost importance to match CMV seronegative recipients with CMV seronegative donors. }" "Impact of Cytomegalovirus (CMV) on Morbidity and Mortality after Liver Transplantation (LT)"

"P P 6 0151"P 6 0151 **RNA-HCV Higher Levels in Orthotopic Liver Transplantation Treated with Steroid because of Acute Rejection**

*R. B\'e1rcena, S. Campo, M. Garc\'eda, E. Vicente, A. Candela, A. Moreno

Ram\'f3n y Cajal Hospital, Alcala de Henares University Madrid, Spain*Aim:* To study the influence of steroid treatment on hepatitis C virus (HCV) RNA titres in orthotopic liver transplantation patients (OLT) because HCV chronic hepatitis.*Materials and Methods:* 26 OLT patients with HCV infection were studied. All of them comprise: a) HCV-RNA positive by PCR before OLT and in the 5-day determination after OLT; b) At least 3 months post-OLT survival; c) no receiving antiviric or autoimmune treatment after OLT.All of them were treated with immunosupresive therapy (cyclosporin, steroids, azathioprine). Rejection episodes were treated with 3 metilprednisolone pulses (1 gr/d). OKT_3 was used in those who no response was observed. In the 6–7 months follow-up steroid doses were tappered. At 12th month all patients received 8–4 mg/d of steroid treatment and at 15th month has been suppressed in all patients. Acute rejection episode was observed in 14 patients. OKT_3 was administrated to one patient. In 16 patients serum samples had been stored on 5th day post-OLT, 9 of them before the acute rejection episode. Another serum sample of these patients were stored between 15–30 days post-OLT. In all patients serum samples were stored 2 months after-OLT, in 23 at 6 months after-OLT, and in 8 patients after steroid therapy suppression. RNA-HCV titre was assessed by amplification. Mean age: 51 – 10 yrs (16 males). Follow-up: 456 – 235 d. (r: 95–924)*Results:* No differences were observed in relation to age, sex, mean ciclosporin levels, time of azathioprine treatment and infections in patients who developed or not an acute rejection episode. RNA-HCV levels at 5 days post-OLT were 912 – 1220 {\'b4} 10^3 Eq/ml. Patients treated with 3 pulses of steroids had higher titres of RNA-HCV at second samples (15–30 d) (4153 – 7692 {\'b4} 10^3 Eq/ml) than at 5 day (657 – 393 {\'b4} 10^3) ($p > 0.05$). Titres at 2 months (9435 – 10868 {\'b4} $10^{3\ Eq/ml}$) and 6 month (8348 – 8217 {\'b4} 10^3) were higher than titres at 5 day post-OLT ($p < 0.05$) and higher than RNA-HCV levels in patients without acute rejection episodes. After steroid withdrawal RNA-HCV titre fallen to 1298 – 1029 {\'b4} 10^3; no statistically difference was observed.*Conclusions:* OLT-HCV positive patients treated with steroid pulses present higher levels of HCV viremia at 2 and 6 months after-OLT than immediately post-OLT levels and than patients no treated with steroid pulses. Steroid suppression was followed by a decrease HCV viremia, although no difference was observed with 6 months values. Liver and bile ducts, 1: Hepatitis, viral, treatmentLiver and bile ducts, 1: Liver transplantation }" "RNA-HCV Higher Levels in Orthotopic Liver Transplantation Treated with Steroid because of Acute Rejection"

"P P 6 0152"P 6 0152 **Transjugular Intrahepatic Portosystemic Shunt (Tips) is of Benefit to Orthotopic Liver Transplantation (OLT)****H. Sunyach[1], J.-M. Perarnau[1], S. Bramli[1], J.-J. Raabe[1], P. Wolf[2], K. Boudjema[2]**

[1] Service de M\'e9decine B CHR 57038 Metz, France

[2] Fondation Transplantation C.H.U. 67000 Strasbourg, FranceAlthough patients waiting for a liver transplantation are considered as the better indication for TIPS, interest of this procedure has not been clearly demonstrated and results show some discrepancies.*Aim:* To determine the benefit of TIPS in OLT, we have compared in a retrospective case-control study, patients who, during the same period, underwent OLT after TIPS (T+) and control OLT patients without TIPS (T{ -}).*Method:* 15 Patients and 15 controls were matched for age (\'b1 5 yrs), gender, Child-Pugh stage and cirrhosis etiology.*Results:* No difference between the two groups was observed in Apache Scores, previous ascites, previous encephalopathy episodes and previous abdominal surgery:; delay between registration on the waiting list and OLT was identical in the 2 groups. Differences were significant concerning the presence of peritoneal adherences (0 (T+)/5 (T{ -}); p < 0.02) and portal thrombosis (0 (T+)/5 (T{ -}); p < 0.02). A trend toward a decrease in procedural time (5.6 h. – 1.2 (T+)/7.2 h. – 3.3 (T{ -}); ns) and a decrease of amounts of transfusion (5.3 blood unit – 3.5 (T+)/9 – 10 (T{ -}); ns) was noticed. There was a significant decrease in the intensive care unit stay: (3.9 d. – 1.2 (T+)/6.5 d. – 4.5 (T{ -}); p < 0.05).*Conclusion:* Because of the reduction of portal hypertension, TIPS allowed to simplify the OLT procedure and to reduce the length of post OLT intensive care unit stay. A prospective randomized study is necessary to confirm these data for patients waiting for OLT with and even without complications. Liver and bile ducts, 1: Liver transplantationLiver and bile ducts, 1: Cirrhosis: portal hypertension }" "Transjugular Intrahepatic Portosystemic Shunt (Tips) is of Benefit to Orthotopic Liver Transplantation (OLT)"

"P P 6 0153"P 6 0153 **Bile Duct Reconstruction affects the Results of Orthotopic Liver Transplantation**

*R. Diller[1], K. Schleimer[1], I. Kranz[2], H.U. Spiegel[1]

[1] Department of Surgery, Westf. Wilhelms University, M\'fcnster, Germany

[2] Department of Pathology, Humboldt University, Charite, Berlin, GermanyAim of the study was to assess the effect of bile duct reconstruction (splint technique according to *Zimmermann*) on the postoperative course, the liver function parameters and on the histomorphological changes in the liverparenchima after orthotopic liver transplantation (ORLT).Three groups, each consisting of 10 syngenic rats, were compared: I. sham operation, II. bile duct reconstruction, III. ORLT. After the operation the clinical course and the serological parameters were monitored. 4 weeks postoperatively the histomorphological changes according to a semiquantitative score (scale: 0–103 points) and the proliferation rate (using the proliferation marker BrdU) were evaluated.Survival rate was 100% in I and II, 90% in III; early postoperative elevation of transaminases was normalized after 4 weeks in all groups. Morphological changes as bile duct alterations, Kupffer cell proliferation, increase in fibrous tissue and hepatocellular necrosis and regeneration were minimal in I (2.5 points), accentuated in II (36.5 points) and prominent in III (45 points). Hepatocellular proliferation was low after sham operation, significantly increased after bile duct reconstruction, and again doubled after ORLT.The lasting effect of bile duct reconstruction on the morphological results necessitates the inclusion of a mere bile duct reconstruction as a control group in ORLT-experiments. "P P 6 0154"P 6 0154 **HCV Recurrence after Liver Transplantation**

*S. Targhetta[1], S. Fagiuoli[1], P. Burra[1], G. Zanus[2], P. Boccagni[2], G. Bombi[3], F. Farinati[1], R. Naccarato[1]

[1] Divisione di Gastroenterologia, Universit\'e0 di Padova

[2] Clinica Chirurgica I, Universit\'e0 di Padova

[3] Servizio di Microbiologia, Universit\'e0 di PadovaRecurrence of HCV infection is extremely frequent after liver transplantation (OLT) for HCV-induced cirrhosis. The incidence and severity of graft disease occurring after HCV infection recurrence is still controversial. Aim of our study was to evaluate the features of HCV recurrence after OLT. From November 1990 until November 1995, 41 patients (33%) were transplanted for HCV-related cirrhosis out of a total of 123 patients transplanted at our institution. Patients who died in the perioperative period were excluded from analysis. A total of 35 patients were included in the study: 28 males and 7 females, with a mean age of 49 years (range 25–61 yrs); 17 pts (49%) had HCV alone, 7 (20%) concomitant alcohol abuse, 5 (14%) HCC, 4 (11%) coexistent HBV infection, 1 Wilson's disease and 1 PSC. Mean age at OLT for patients with HCV alone was 52.5 – 6.9 years, compared with 42.6 – 12.6 years in patients with multiple etiology ($p < 0.02$). All patients were anti HCV(+)ve prior to OLT, whether 29 (83%) were HCV-RNA by PCR(+). A total of 28 recipients (96%) remained HCV-RNA by PCR positive during the post-transplant follow-up. None of the 6 antiHCV(+)/HCV-RNA({ -}) recipients became HCV-RNA(+) after OLT. Post-OLT liver histology 6 months 12 months 24 months N m M C N m M C N m M C{\'ab}AST/ALT 7 1 – 4 1 – 4 – 1{\'ad}AST/ALT 6 3 – 2 6 1 2 2 1Total 13 13 4 – 5 6 7 1 1 6 2 2 $p < 0.01$N = normal, m = mild, M = moderate, C = cirrhosisTwo patients died as a result of HCV recurrence: 1 died of sub-acute HCV recurrence and the other with cirrhosis respectively at 4 and 27 months after OLT. *Conclusion:* 1) HCV-RNA positivity prior to OLTx is the best predictor of HCV recurrence; 2) Recurrent histologic HCV disease is very common after OLT, and as a result end-stage liver disease can occur even within 2 years from OLT; 3) Serum transaminases are not a reliable follow-up marker of recurrent disease. "P P 6 0155"P 6 0155 **Predictors of Survival in Acute Hepatic FailureM.K. Mohana Das,**

*K.T. Shenoy

Dept of Gastroenterology, Medical College, Trivandrum, India*Objective:* To determine the prognostic factors and survival in hyperacute, acute and subacute liver failure.*Setting:* Tertiary referral centre.*Study Design:* Prospective prognostication and survival.*Participants:* 60 subjects with hepatic failure (8 hyperacute, 29 acute & 23 subacute) selected as per Roger Williams criteria, 1993.*Study Variables:* 32 clinical and laboratory variables which included liver span, h/o seizures, asterixis, biochemical and haematological parameters.*Outcome variables:* Prognostic factors and survival or death in the hepatic failure subgroups.*Data Analysis:* Descriptive, independent \lquotet\rquote test, proportions by chi square, survival rate by Kaplan Meier (KM) product limite method and univariate & multivariate analysis using Cox Proportional Hazard Model.*Results:* 17 subjects expired (hyperacute 2, acute 6, subacute 9). Age, onset of encephalopathy, liver span, blood glucose, transaminases and platelet count did not differ between survivors and non-survivors. Serum bilirubin (mg/dl) was 20.96 – 7.43 among survivors & 24.95 – 5.76 in non survivors (P = 0.048). KM survival probability for hyperacute, acute and subacute were 0.75 (95% CI 0.31–0.93), 0.79 (95% CI 0.59–0.90) and 0.61 (95% CI 0.38–0.77). Hazard ratio was 3.77 for those with encephalopathy gr 3 & 4 and prothrombin time > 25 sec (P = 0.001).*Conclusion:* Acute and subacute hepatic failure have poor prognosis and grade of encephalopathy with abnormal prothrombin time and low platelet count are poor prognostic factors. Liver and bile ducts, 1: Hepatitis viral, diagnosisLiver and bile ducts, 1: Hepatitis, viral, treatment }" "Predictors of Survival in Acute Hepatic Failure"

"P P 6 0156"P 6 0156 **Cholestatic Liver Disease in Protoporphyria: Treatment with Cholic Acids and Liver Transplantation**

*M.O. Doss, M. Frank

Div. of Clinical Biochemistry and Dept. of Internal Medicine, Philipp University Hospital, D-35033 Marburg, GermanyIn erythropoietic protoporphyria with ferrochelatase deficiency an unpredictable hepatobiliary course of the metabolic disease develops in a quarter of patients: erythrohepatic protoporphyria. The effect of ursodeoxycholic acid (UDCA) was studied in 7 patients (age 33–71 years; 2 females, 5 males) with protoporphyrin (PP)-induced liver cirrhosis and cholestasis. PP accumulating in liver tissue is hepatotoxic in high concentrations. Five patients underwent liver transplantation.*Patients and methods.* The patients with protoporphyria-associated liver disease exhibited an excessive PPemia (> 30 \'b5mol/l, normal < 1), elevation of fecal PP and a pathologic coproporphyrinuria up to 700 nmol/24 h (normal < 120) with dominance of isomer I. They were treated with UDCA (10 mg/kg) for 1–19 months. Porphyrins were analyzed by HPTLC and HPLC.*Results.* A decrease was observed concerning 1. hyperbilirubinemia (200–400 \'b5mol/l) of 65% up to normal levels, 2. PPemia of 40–70%, and 3. coproporphyrinuria of 70% ($p < 0.001$). In spite of improved biliary PP elimination a clinical remission occurred only in one case; 5 patients were liver-transplanted after UDCA therapy; the other died of liver failure. All patients were treated with UDCA after liver transplantation. In two patients UDCA treatment was continued up to 5 years. Porphyrin parameters remain moderately elevated. The clinical status improved in 4 patients.*Conclusion.* The dissociation observed between metabolic and clinical course results from irreversible liver disease caused by PP accumulation in liver cells. A long-lasting remission of hepatobiliary involvement by UDCA therapy can be achieved only in the early phase of complicated protoporphyria. A pathologic coproporphyrinuria with isomer I increase and red cell PP (> 20 \'b5mol/l) are first signs for hepatic component in protoporphyria. This is the indication for starting UDCA treatment. The PP-reducing effect of UDCA may be due to mobilisation of accumulated PP crystals in liver cells and improved bile flow in cholestasis. A marked decrease of fecal PP excretion reflects PP induced progressive toxic liver injury leading to reduced clearance of PP from the liver. In these patients with protoporphyria-associated irreversible cholestatic cirrhosis liver transplantation is the therapy of choice.(Supported by the Hans-Fischer-Gesellschaft, Munich) Liver and bile ducts, 1: Liver transplantationLiver and bile ducts, 2: Bile formation, cholestasis }" "Cholestatic Liver Disease in Protoporphyria: Treatment with Cholic Acids and Liver Transplantation"

"P P 6 0157"P 6 0157 **Liver Transplantation (OLT) for Hepatocellular Carcinoma (HCC): Role of Selection and Chemotherapy**

*C. Marafin[1], G. Zanus[2], P. Burra[1], S. Targhetta[1], F. Farinati[1], U. Cillo[2], U. Tedeschi[2], R. Naccarato[1], S. Fagiuoli[1]

[1] Divisione di Gastroenterologia, Universit\'e0 di Padova

[2] Clinica Chirurgica I, Universit\'e0 di PadovaThe role of OLT for patients with HCC is still controversial because of high disease recurrence. The aim of our study was to evaluate if careful pre-OLT selection and multimodal chemotherapy could improve the results after OLT. Twelve out 108 patients transplanted at our unit were affected by HCC. Our policy is to to transplant only the patients in which a diagnosis of HCC is obtained while already on the waiting list. In 5 out of 12 the diagnosis of HCC was incidental. One case, a 24 year old patient, with a 15 cm unresctable HCC in HBV-related chronic hepatitis, was an exception to the rule. Pathologic TNM staging was T1 in 9 patients, T3 in 2 (both incidental HCC) and T4 in the last. Seven patients received pre-OLTx lipiodol-mediated arterial chemoembolization with adryamicin plus at least three courses of systemic chemotherapy (5-fluorouracil, folinic acid, carboplatin). After OLTx the patients received systemic chemotherapy weekly for a total of 24 cycles. The same treatment was administered in 3 patients with incidental HCC. Two patients with incidental HCC refused chemotherapy. In one patient a severe HCV-related hepatitis contraindicated the chemotherapeutic regimen. Therefore, a total of 9 patients underwent post-OLTx chemotherapy. Mean follow up is presently 24 months (range 4–46 months). One patient died for HBV-related cirrhosis at 44 months after OLTx, free of HCC recurrence. Overall and disease-free survivals are 100% and 92% at 36 months, respectively. The only recurrence was observed 3 months after OLTx in one incidental HCC who did not receive adjuvant chemotherapy. *Conclusion:* 1) patients with small HCC are good candidates for OLT if proper selection is adopted; 2) once a patient with HCC is selected for OLTx, or once HCC is an incidental finding at OLTx, also multimodal chemotherapy can improve the results in terms of overall and disease-free survival

"P P 6 0158"P 6 0158 **Liver Transplantation in Patents with Cirrhosis and Hepatocellular Carcinomas**

*P.H. Bernard, J. Carles, V. De L\'e9dinghen, B. LeBail, M. Winnock, J. Saric, C. Balabaud, P. Bioulac Sage

Unit\'e9 Transpl. H\'e9p & Serv. Ana-Path, CHU Pellegrin

Lab Pathologie, GREF, Univ Bordeaux II, Bordeaux, FranceIt has been recently shown that liver transplantation (LT) is an effective treatment for small unresectable hepatocellular carcinoma (HCC) in patients with cirrhosis (NEJM 1996; 334: 693–9). In this study, we report our experience on LT for HCC. Between January 1987 and December 1995, 244 LT were undertaken for patients among which 152 had cirrhosis (except for secondary biliary cirrhosis). Among these 152 patients, 48 (31.6%) had an HCC. Retrospectively, the indication for LT was HCC (group A, n = 21), cirrhosis and HCC (group B, n = 13), and cirrhosis (group C, n = 14). In group C, HCC was incidentally discovered by pathological examination in resected livers not originally thought to contain tumors. As of May 1996, 29 patients (60.4%), with a mean age of 54.8 – 1.8 years (range, 28 to 68) were alive without apparent recurrence, with an overall survival of 33 – 3.9 months (range, 6 to 83). 14 patients (29.2%), with a mean age of 57.4 – 1.4 years had died after LT complications without apparent tumoral recurrence within 1.6 – 0.5 months (range, 0 to 7), whereas 5 patients (10.4%), with a mean age of 62.2 – 1.7 years (range, 56 to 66) had died of tumoral recurrence within 15.6 – 4.2 months. Group C had the highest survival rate (79%) compared to groups A and B (52% and 54%, respectively). Patients alive from Group C had tumors, at the time of LT, whose diameter never exceeded 1.7 cm. From 9 patients, of the three groups, with tumors > 5 cm, 6 died and 3 of them of tumoral recurrence. All the patients who died of tumoral recurrence belonged to group A; the diameter of the tumor exceeded 7 cm (3 out of 5), there were tumoral nodes in the hilum (1/5), or adherence of the tumor to the diaphragm (1/5) (lung metastasis after LT). Of seven patients, out of 11, who had more than 3 tumor masses < 5 cm, except for 1 tumor, are alive. Hepatic resection (three cases) nor chemoembolization (12 cases) before LT seem to be linked to mortality since all patients undergoing hepatic resection and 8 out 12 patients undergoing chemoembolization were alive. Among the 104 patients transplanted for cirrhosis without cancer, 76 were alive (73%) and 28 (27%) died. These patients had a mean of 50.8 – 1.1 (range, 27 to 69) and 51.4 – 3.6 (range 9 to 70) years, respectively, at the time of LT and had a survival time of 50.2 – 3.2 months (range 7 to 102) and 11 – 3.6 months (range 0 to 86).In conclusion, it seems reasonable to propose LT to cirrhotic patients with a single or multiple HCC < 5 cm without loco-regional spread. However, in this study, patients with cirrhosis and HCC presented a high rate of mortality, possibly linked to the age of patients at the time of LT. Liver and bile ducts, 1: Liver transplantation }" "Liver Transplantation in Patents with Cirrhosis and Hepatocellular Carcinomas"

"P P 6 0159"P 6 0159 **Diagnostic Accuracy of Sonography (US), Computed Tomography (CT) and Angiography in the Diagnosis of Hepatocellular Carcinoma (HCC): Comparison with Histopathological Findings in 169 Transplanted PatientsA. Veltri, M. Grosso, D. Regge, M.C. Martina, U. Soldano, J. Galli**

Istituto di Radiologia, Universit\'e0 di Torino, Italy*Purpose*To assess the diagnostic accuracy of US, CT, and angiography in the diagnosis of HCC based on histopathological examination of explanted livers.*Materials and Methods*The presence or absence of HCC based on US, CT, and angiography performed in 192 patients before liver transplantation was retrospectively reviewed. The radiological findings were compared to the histopathological studies.*Results*Histopathological examination detected 81 nodules of HCC in 58/192 patients, whose diameter ranged from 0.7 to 9.0 cm (mean 2.65 cm). US, performed in 188/192 patients, diagnosed 59/79 nodules with a sensitivity of 82.1% (46/56 true positive patients), specificity of 90.9% and diagnostic accuracy of 88.3%. In 152/192 patients, CT detected 35/54 nodules (29/40 true positive patients; sensitivity 72.5%), with a specificity of 95.5% and diagnostic accuracy of 89.5%. The sensitivity of integrated diagnostic imaging studies was 89.6% with a specificity of 84.3% and diagnostic accuracy of 86%.*Conclusions*Our study, which supports the findings reported in the literature on explanted livers, underlines the low sensitivity of CT in detecting HCC. The integration of US, CT, and angiography, indispensible in the presurgical assessment when newer imaging methods (helical CT, angio-MR) are not available, is more sensitive for the diagnosis and staging of HCC but has a slightly reduced specificity and diagnostic accuracy. Liver and bile ducts, 1: Chronic non viral hepatitisOncology, specific: Liver, biliaryRadiology and ultrasound: Diagnosis }" "Diagnostic Accuracy of Sonography (US), Computed Tomography (CT) and Angiography in the Diagnosis of Hepatocellular Carcinoma (HCC): Comparison with Histopathological Findings in 169 Transplanted Pati"

"P P 6 0160"P 6 0160 **Radiological Treatment of Hepatocellular Carcinoma (HCC): Review of Results in 58 Transplanted PatientsA. Veltri, M. Grosso, D. Regge, M.C. Martina, J. Galli, U. Soldano**

Istituto di Radiologia, Universit\'e0 di Torino, Italy*Purpose*To evaluate the results of radiological treatment performed in patients with HCC before liver transplantation*Materials and Methods*Fifty-eight transplanted patients with a total of 81 nodules of HCC, whose diameter ranged form 0.7 to 9.0 cm (mean 2.6 cm) were studied. 43 lesions in 34 patients were previously treated with transcatheter arterial chemoembolization (TACE) (24), percutaneous ethanol injection (PEI) (10), or combined TACE + PEI (9). On histopathological examination of the explanted livers, tumor necrosis was judged to be complete, partial, or absent. The percentage of recurrence after transplantation was also calculated.*Results*After TACE, necrosis was complete in 6/24 lesions (25%), partial in 6/24 lesions (25%) and absent in 12/24 (50%). After PEI, necrosis was complete in 8/10 (80%) and partial 2/10 (20%). After combined therapy, complete necrosis was obtained in 9/9 (100%). 4/34 patients (11.8%) had complications (2 vascular and 2 parenchymal) without significant consequences for transplantation. 4/34 (11.8%) treated patients had post-transplantation recurrence; theses patients had previously underwent only TACE and explanted livers showed no tumor necrosis.*Conclusions*TACE alone is ineffective in treating HCC. The high efficacy of combined radiological therapy and the low incidence of recurrence in treated patients suggests using this approach even before liver transplantation. "P P 8 0173"P 8 0173 **Ultrastructural Characteristic of Papilla Vateri's CarcinomaB. Damyanov, B. Vladimirov, S. Babourov**

Medical University, Sofia, BulgariaThe microscopic picture of carcinoma of papilla Vateri makes its endoscopic diagnostics comparatively easy. However, sometimes even ERCP and histomorphological differential diagnostics with chronic oditis is too hampered.*Aim* of this investigation was to define more accurately the ultrastructural characteristic of carcinoma through subcellular organelles features and hence the possibilities for electronmicroscopic examination in the differential tumor diagnostics of the papilla.*Material and methods.* Tumor material was received by clip biopsy during endoscopic duodenopapilloscopy and ERCP of 14 patients, with following electronmicroscopic exploration.*Results and discussion.* The tumor's cells general appearance was uncertain, but here and there with elements of altered cover epithelium of tubular organs. In the irregular in shape and magnitude intercellular spaces of the tumor clusters there were sometimes microvilles, even binding structures of the type tight junction. General characteristic of the nuclei of the tumor cells was the different pattern of the wavy course of the nuclear membrane, often with formations of deep canyon-like engravements, improving characteristic monstrous appearance of the nucleus. All such nuclei were with enlarged quantity and atypical perichromatic granules and with 2–3 or more hypertrophic nucleoluses. For patients with chronic oditis, preceding or accompanying the malignus growth all elements of expressed fibrosis have been observed.*Conclusion.* The monstrous hyperactive nuclei are the main features of the malignus carcinoma of papilla Vateri. The lack of such nuclei, especially at present fibrosis proves sooner a chronic oditis. Oncology, specific: Liver, biliary }" "Ultrastructural Characteristic of Papilla Vateri's Carcinoma"

"P P 8 0175"P 8 0175 **Analysis of p53 Abnormalities in a Serie of 34 Tumors of the Ampullary of Vater**

*B. Terris, F. Muzeau, A. Sauvanet, J. Belghiti, D. H\'e9nin, J.F. Fl\'e9jou

INSERM U410, Facult\'e9 Xavier Bichat, Paris, France

Services d'Anatomie Pathologique et de Chirurgie Digestive, Hospital Beaujon, Clichy, France*Background and Aims:* As described in colon, epithelial tumors of the ampulla of Vater (AV) develop through a filiation from adenoma to adenocarcinoma with increasing grade of dysplasia. The diagnosis between adenocarcinoma and epithelial dysplasia of the AV may be difficult on endoscopic biopsies. p53 protein immunostaining has been proposed as a new marker of malignancy. Because controversies exist on the relationship between p53 protein immunostaining and the stage of resected ampullary tumors, we have investigated the presence of p53 abnormalities in 34 tumors of the AV.*Methods:* We studied 29 invasive adenocarcinomas and 5 adenomas with foci of mild (n = 3) or severe (n = 2) dysplasia of the AV. Immunohistochemistry was performed on formalin fixed tissue with DO7 antibody. In 19 cases, DNA was extracted from frozen specimens or paraffin sections and analysed for mutations of the p53 gene (exon 5–8) by PCR/denaturant gradient gel electrophoresis (DGGE) and sequencing technique.*Results:* One of the 5 adenomas (20%) and 16 of the 29 adenocarcinomas (55%) were positive on immunohistochemistry for p53. This positivity was present through all stages of ampullary adenocarcinomas. No significant difference in p53 protein expression was observed between adenomas and adenocarcinomas. A mutation of the p53 gene was detected on DGGE and confirmed by sequencing in 6 cases with a good correlation with immunohistochemistry in all 19 cases but 2.*Conclusion:* p53 gene mutation appears as a common event in ampullary tumors. It can be detected in most cases by immunohistochemistry. However our serie suggest that its detection does not help to appreciate the stage of the tumors. "P P 8 0178"P 8 0178 **Surgical Treatment of Klatskin's Tumor: Our Experience**

*I. Zoricic, B. Bakula, Z. Pasini, Z. Perko

University Department of Surgery, Sveti Duh General Hospital, Zagreb, CroatiaBetween January 1991 and February 1996 we operated ten patients with primary cancer originating in the hepatic duct confluence (Klatskin tumor). We got six males and four females. Average age was 59.6 years. The tumors were Type I, Type II, Type IIIa and IIIb in two, one, six and two patients respectively. Three tumors were unresectabile: two Type IIIa and one Type IIIb. In these cases transtumor stents have been placed. Stent in right, left and the both (""Y"" prosthesis) hepatic ducts were placed in one case each. In this group the average postoperative survival was 11 months. At three patients with the tumor Type I and II, tumor excisions in hepatic parenchyma and reconstructions with hepatico-jejuno-anastomosis Roux-en-Y were done. In the last four patients with the tumor Type IIIa, liver resections were done. Right hepatectomy and left hepatectomies were done in three and one case, respectively. From this group of patients, one patient had liver cirrhosis and died twenty days after operation, because of liver insufficiency. Other patients did not have complications in the postoperative course. In this group, one patient died 2.5 years after the operation, and other patients are still alive. The longest postoperative survival has a patient who 3.5 years after operation has not signs of the tumor recidive. Other patients are alive and without any recidive disease among 0.5 and 2 years. Our experience supports an aggressive surgical approach in patients with Klatskin tumor, and enables longer survival rate, than when only transtumor stent is placed. Oncology, specific: Liver, biliaryClinical practice: Management strategy }" "Surgical Treatment of Klatskin's Tumor: Our Experience"

"P P 8 0179"P 8 0179 **Hepatic Intraarterial Chemotherapy in the Treatment of Pig Experimental Biliary Cancer: A Comparative Study**

*V. Dufek, J. Petrt\'fdl, P. Klener

1st Medical Department, Charles University, Prague, Czech Republic (CR)Human cholangiocarcinoma (CHC) is one of the most dismal biliary tree cancers to cure. In Central and Eastern Europe, resectability of CHC does not exceed 6%, in general. If untreated, the median survival is 99 days.*Aims:* This study was performed to assess the feasibility of hepatic intraarterial (HIA) chemotherapy by FUDR to experimental pig CHC in comparison with those by FUDR conjugate (FUDR-Cathepsin B-like).*Methods:* In 23 male pigs (strain BU) – weight 23 kg, a CHC was induced by intraportal application of a combination of aflatoxin B_1 and 4-methylcholantren. After the end of cancerogenesis (affected about 30% of the liver by US and CT) a HIA chemotherapy was started in 16 animals. Seven pigs were left without any treatment (control group).*Results:* In the *nil treated group,* the median survival was *67.5* days. Neither tumour mass regression in US or CT nor tumor necroses were observed during the autopsy. In the *FUDR group,* the median survival was *116.6* days; in US and CT, the reduction of tumour tissue was predicted in 3 and 5 pigs, respectively. In autopsy, partial necroses of CHC were observed in such an animals. In the *FUDR-Cathepsin B-like group,* the results of HIA chemotherapy were quite expressive. The median survival reached *205.7* days. Autopsy, the same as US and CT revealed a significant reduction of the tumour tissue. For surprise, no differences in the size of tumour necroses were found, between the FUDR and FUDR-Cathepsin B-like groups.*Conclusions:* FUDR-Cathepsin B-like conjugate seems to be much more potent drugs in the pig CHC palliation as FUDR alone. The same is possible to expect in human primary cholangiocarcinoma.Supported by grant 2227 of IGA MH CR Oncology, specific: Liver, biliaryOncology, general: Therapy }" "Hepatic Intraarterial Chemotherapy in the Treatment of Pig Experimental Biliary Cancer: A Comparative Study"

"P P 9 0182"P 9 0182 **Does Computed Tomography Have an Impact on the Management of Acute Diverticulitis?N. Siauve[1], A. Berger[2], C.A. Cu\'e9nod[1], P. Wind[2], N. Bely[1], M.P. Revel[1], P.H. Cugnenc[2], G. Frija[1]**

[1] Department of Radiology, Hopital Laennec, Paris

[2] Department of Radiology, Hopital Laennec, Paris*Purpose:* To analyze whether computed tomography (CT) could influence the therapeutic management of acute diverticulitis.*Material and Methods:* Thirty-seven of patients hospitalized with the clinical diagnosis of acute diverticulitis were retrospectively reviewed. Each of these patients underwent a CT scanner with water-soluble enema within the first hours after admission. CT scanners were analyzed for complications like abscess, fistula or peritoneal gas effusion. The initial therapeutic option based only on clinical data (medical treatment or immediate surgery) was compared to the final decision which took into account the CT findings.*Results:* Eleven patients demonstrated one of the following complications on CT: abscess (n = 6), fistula (n = 3), and peritoneal gas effusion (n = 2). The 2 cases with peritoneal gas effusion were not suspected clinically or on plain films, and leaded to immediate surgery after CT. CT did not influence the initial decision of medical treatment in 4 of the 6 cases with abscess: in 2 cases the percutaneous drainage was not technically possible, and in 2 cases the collection was very small. Only one abscess was drained percutaneously, while the last one required surgery because it was associated with peritoneal gas effusion. In the 3 cases with fistula, there was no change in the initial decision and the patients received medical treatment.*Conclusion:* In this series of acute diverticulitis the therapeutic strategy based solely on clinical data was modified only in 3 cases (8%) by the CT findings.

"P P 9 0184"P 9 0184 **Severe Colonic Ischemia in Chronic Hemodialysis Patients: CT Scan Allows an Early DiagnosisA. Berger[1], N. Siauve[2], M. Nseif[1], C.A. Cuenod[2], M. Zanoun[2], M.P. Revel[2], G. Frija[2], P.H. Cugnenc[1]**

[1] Department of Surgery, Hospital Laennec, Paris

[2] Department of Radiology, Hospital Laennec, ParisColonic ischemia may be related to chronic hemodialysis, causing a high mortality and morbidity. This ischemia is distinctive due to its non occlusive character and to the frequency of right colon involvement. Clinical diagnosis may be difficult since patients symptoms are usually non specific. We report retrospectively the value of CT scan for the diagnosis of severe colonic ischemia in hemodialysis patients.*Patients and methods:* Severe colonic ischemia was suspected in four chronic hemodialysis patients on clinical findings (mean age 59 years); symptoms were abdominal pain of variable intensity starting just after an hemodialysis session. CT scan with water soluble enema was performed within 12 hours after the onset of the symptoms.*Results:* In all cases, CT scan showed a ring thickening of the bowel wall located in the right colon (mean 17.5 mm; 10–20), measuring 55 mm in length (30–90). In 3 cases a parietal pneumatosis was observed. These features were exactly correlated with operative and histological findings. Parietal pneumatosis was predictive of colonic gangrene.*Conclusion:* CT scan allowed an early diagnosis of severe colonic ischemia in chronic hemodialysis patients. Parietal pneumatosis is the main finding reflecting colonic necrosis and indicates immediate surgery. Radiology and ultrasound: DiagnosisRadiology and ultrasound: Therapy }" "Severe Colonic Ischemia in Chronic Hemodialysis Patients: CT Scan Allows an Early Diagnosis"

"P P 9 0185"P 9 0185 **The Ischemic Bowel and Its Myoelectric Activity an Experimental and Clinical Studies**

*R. Sendur, P. Thor, W. Dutkiewicz, W.W. Pawlik

Univ. Med. Sch. Inst. Physiol. CMUJ Krakow, PolandEvaluation of the intestinal electrical control activity (ECA) has been proposed as a method for determining of the bowel viability. However its diagnostic value has not been definitively established. The purpose of the present investigations was to evaluate intestinal myoelectric activity in the normal and ischemic bowel in experimental animals and humans. Experiments were performed on 15 cats anesthetized with pentobarbital. After laparotomy total intestinal blood flow (BF) was measured in superior mesenteric artery (SMA) with ultrasonic blood flowmeter and microcirculatory blood flow with laser Doppler flowmetry (LD). Myoelectric bowel activity was recorded simultaneously with BF and LD using three monopolar silver electrodes implanted on the serosal surface of the jejunum and Dynograph Recorder R-611. Bowel ischemia was induced by perfusion of SMA with saline or by temporal occlusion of both SMA and/or superior mesenteric vein (SMV). In clinical studies ECA was analysed in 10 patients during abdominal surgery due to bowel ischemia, using EMG technique. In patients comparison was made between ECA in ischemic and normal bowel. Intestinal ischemia in experimental conditions induced reduction in amplitude and frequency of ECA by 50%, whereas in patients about 60% reduction in amplitude and frequency of ECA was observed. Most sensitive parameter appears to be phase lag of ECA which even in small degree of ischemic changes to the bowel was doubled. Most dramatic changes with reduction of amplitude and frequency were observed during simultaneous SMA and SMV occlusion. Our results indicate that amplitude, frequency and the coupling of ECA are sensitive myoelectric parameters which could be used in clinical assessement of bowel viability. Motility, specific: Small bowelIntestinal disorders: Splanchnic circulation, ischemia }" "The Ischemic Bowel and Its Myoelectric Activity an Experimental and Clinical Studies"

"P P 9 0186"P 9 0186 **Nitrate Reducing Bacteria in the Excluded Colon: A New Clue to Diversion Colitis?C. Neut,**

*F. Guillemot, E. Lederman, J.F. Colombel

Laboratoire de Bact\'e9riologie, Facult\'e9 de Pharmacie, Clinique des Maladies de l' Appareil Digestif, CH et U Lille, F 59037 Lille*Background/aim:* Arguments have accumulated favouring a pathogenic role of nitric oxide (NO) in intestinal inflammation. NO is metabolized in the colon in nitrite and nitrate which subsequent reduction implicates the colonic flora. There is no data about nitrate-reducing bacteria in the colon of patients with chronic inflammation. In this work, we evaluated the nitrate-reducing flora in patients with diversion colitis which is a model of inflammation with no exogenous nitrite or nitrate supply. *Patients and methods:* Thirty patients (17 M, 13 F, mean age 45 yrs) having an excluded colon for various reasons (inflammatory bowel disease, n = 15; colon cancer, n = 5; diverticulitis and abscess, n = 7; miscellaneous, n = 3) were studied. Presence of diversion colitis was assessed using endoscopic and histologic criteria. Fecal material was collected by rectal swabs. Bacteriological analysis was performed in anaerobic conditions. Results were compared to those of 30 healthy controls (11 M, 19 F, mean age 28 yrs). *Results:* The percentage of nitrate-reducers among the total count of subcultured bacteria was 46 – 41% (mean – SD) in patients with diversion colitis as compared to 19 – 24% in healthy controls ($p < 0.05$). In patients with diversion colitis, 75/254 (29.5%) different isolated bacterial strains were nitrate-reducers as compared to 61/294 (21%) ($p < 0.05$) in controls. Among the 75 nitrate-reducing strains isolated from patients with diversion colitis, 55 (73%) were aerobes as *Pseudomonas, Proteus, Providencia* and *Morganella.* In healthy controls, nitrate-reducing anaerobes were nearly as frequent as aerobes. *Conclusion:* The bacterial flora of patients with diversion colitis is characterized by a quantitative and qualitative enrichment in nitrate-reducing bacteria. NO synthase might produce a bacterial substrate increasing the growth of bacteria with a high pathogenic potential creating conditions for chronic inflammation in patients with an excluded colon. Intestinal disorders: Anorectal disordersImmunology and microbiology: Inflammation }" "Nitrate Reducing Bacteria in the Excluded Colon: A New Clue to Diversion Colitis?"

"P P 9 0187"P 9 0187 **Sodium Cromoglycate in the Treatment of Eosinophilic ColitisF. Hamsioglu, N. Bagatur, A. Dobrucali, A. \'c7elik, C. Davutoglu, K. Bal, M. Tuncer, I. Yurdakul, H. Uzunismail, E. Oktay**

Gastroenlerology Section, Internal Medicine, Cerrahpasa Medical Faculty, University of Istanbul, Istanbul, TurkeyEosinophilic colitis is (EC) an uncommon inflammatory process marked by colonic eosinophilic infiltration. Despite of the discrepancy in the treatment, Sodium cromoglycate (SCG) seems to be effective. We report 3 cases of eosinophilic colitis with good response to SCG treatment. *Patient 1:* N.Y 30 year old woman, with recurrent abdominal pain, bloody diarrhoea, tenesm, artralgia and weight loss for 3 years treated with Salazopyrine (SZP) because of the diagnosis of Ulcerative Colitis. Eosinophilia was observed. By rectosigmoidescopy, colitis with hyperemia, edema and friability was observed. Colonic biopsy showed severe colitis, remarkable infiltration of lamina propria with eosinophils: regular crypt structure with depletion of goblet cells. The disease was limited only to colon. The prick test was normal. After the diagnosis EC which developed during the SZP therapy, she was treated with SCG 300 mg twice daily. After 2 weeks of therapy, her symptoms and endoscopy findings improved. *Patients 2:* K.\'c7 33 year old woman with recurrent abdominal pain, diarrhoea, artralgia and weight loss for 14 months. By her admittance only IgE and IgG were elaveted. The colonoscopy showed edema, hyperemia, friability and ulcers in the entire colon including terminal ileum. Crohn disease was the first diagnosis. But the biopsy showed chronic colitis with significant infiltration of the mucosa with eosinophils, intraepitelial eosinophils and regular crypt structure, Like patient 1 the colitis was limited to the colon. By the time of the diagnosis she had also cholesystitis. The clinical condition of the patient including cholesystitis improved after 2 weeks therapy with SCG 400 mg twice daily. *Patient 3:* N.B 39 year old woman with bloody diarrhoea, nausea for 2 months. She had allergy to various food, animal products and polens. The prick test was positive. Eosinophilia was determined. We observed colitis with erosions at rectosigmoidescopy. The biopsy result was the same as the one of patient 1. Like the previous patients the disease was limited only to the colon and the patient responded well to SCG 300 mg daily after 2 weeks. The results provide evidence of SCG efficacy in the treatment of EC, suggests its application as a first choice of drug. Intestinal disorders, absorption: Malabsorption syndromesImmunology and microbiology: Inflammation }" "Sodium Cromoglycate in the Treatment of Eosinophilic Colitis"

"P P 9 0190"P 9 0190 **Intestinal Neurofibromas with von Recklinghausen's Disease: Report of a New Case**

*P. Kasapidis, V. Milonakis, V. Delis, V. Balatsos, A. Konstantinidis, N. Skandalis

Department of Gastroenterology of the Athens General Hospital, GreeceMultiple neurofibromas (MN), which may occur either on familial basis with autosomal dominant inheritance or sporadically, were first described by von Recklinghausen (vR) in 1882. MN is a mesodermal and ectodermal dysplasia with a broad spectrum of clinical and radiological findings. The gastrointestinal tract and in particular the small intestine is involved in 10%–20% of the cases with MN (vR disease). Intestinal neurofibromas (IN), with or without vR disease, are rare. Only 6% of benign tumors in the small intestine are of neurogenic origin.The index case is a 42 year old female, without familial disease, who was admitted to our Department with a lifelong history of melena. Three such episodes had occurred eight, ten and twelve years prior to admission, which were attributed to a duodenal ulcer. On physical examination there was a soft skin nodule on the left heel, measuring 3 cm, and multiple cafë-au-lait spots predominantly on the trunk. No abdominal masses were palpable. Gastroscopy and colonoscopy were normal. Enteroclysis revealed one unstable smooth filling defect in the central jejunum, while intestinal angiography of superior and inferior mesenteric artery showed an abnormal ringlike enhancement formed by congested veins in the distal part of the fourth branch of jejunal artery. The biopsy of the skin nodule on the heel revealed a neurofibroma and the diagnosis of vR disease was established. At laparotomy two extraluminal neurofibromas, 6 cm and 1 cm respectively, were found and the segment (8 cm) of the proximal jejunum, containing the lesions, was resected. Immunohistochemically some malignant cells showed a positive reaction to S-100 protein.Intestinal neurofibromas with neurofibromatosis are rare. Radiographic examination or enteroscopy reveals multiple smooth tumors predominantly in the distal part of the ileum. As the neurofibromas are hypervascular, angiography is useful in defining the number and extent of the lesions. Surgical resection is indicated because of the danger of: a) malignant degeneration of intestinal neurofibromas (15% of > 40 years patients), b) bleeding and c) other serious complications such as, intestinal or biliary obstruction, ischemic bowel perforation, intussusception and megacolon. Clinical practice: Management strategyOncology, specific: Small bowelOncology, general: Therapy }" "Intestinal Neurofibromas with von Recklinghausen's Disease: Report of a New Case"

"P P 9 0191"P 9 0191 **Dermatitis Herpetiformis Duhring in Long-Term Clinical Follow-Up**

*M. Dvor\'e1k, P. Fric

Department of Medicine, 1. Medical Faculty of Charles University, Prague, Czech RepublicDermatitis herpetiformis Duhring (DH) is nowadays considered one of the ways of clinical manifestation of gluten enteropathy. The frequency of this disease has been increasing considerably, affecting even younger persons and if its gastrointestinal symptoms remain hidden it may be source of serious complications. Group of 92 patients (52 men, 40 women) has been followed up for a long time, at the average follow-up time 7.4 years (2–24 yr). Even if 83% of patients have never had any digestive troubles and physical examinations have been normal in almost all of them, 16% had anaemia, 52% light signs of malabsorption and in 73% of them various degrees of jejunal mucosa damage was proved at the time of the first enterobiopsy. In patients on gluten-free diet with repeated biopsy (n = 44) the intestinal as well as skin changes have improved in 94% of persons. Malignant tumors occurred in 4 patients (2 died). Evaluation of the changes in jejunal mucosa is impossible by current laboratory findings or functional tests, but only using enterobiopsy. In patients with proved changes permanent gluten-free diet is necessary, with a view to the usual absence of difficulties, however, the motivation to observing it is markedly lower than in the coeliacs. The course of DH, complications and the risk of malignancy are the same as in coeliac disease and prove the necessity of steady follow-up by the gastroenterologist. Intestinal disorders, absorption: Gluten enteropathyIntestinal disorders, absorption: Malabsorption syndromes }" "Dermatitis Herpetiformis Duhring in Long-Term Clinical Follow-Up"

"P P 9 0192"P 9 0192 **Collagenous Colitis Versus Inflammation of Collagenous Type as Nosologic Entity Versus Reaction Form**

*B. Boga, A. Tak\'e1ts, G. Gero″[1], J. Penyige

\'dajpesti Hospital 3rd Dept. Int. Med., Budapest, Hungary

[1] Dept. Pathology, Budapest, HungaryIn years 1993–1996 we examined 1340 patients with colonoscopy. Among them we found 36 cases with mostly mild mucosal hyperaemia in macroscopic picture and with broad subepithelial collagenous band in histology, mainly in the sigma, in 6 cases in other part of colon. All of them presented only with moderate symptoms not with watery diarrhoea which is characteristic of collagenous colitis. 22 had abdominal pain, 16: diarrhoea, 6: diarrhoea/constipation, 3: constipation, 10: meteorism, 2: without any abdominal complaint. In history 13 had had chronic gastritis, 2 ulcerative colitis, 1 m. Crohn, 2 aspecific colitis. 3 had simultaneously colon erosions, 2 ulcers, 6 diverticulosis, 4 lactose intolerance, 2 starch intolerance, in 2 patients the collagen layer appeared in the subepithelial part of a polyp.14 were treated with Salazopyrin. We had opportunity to follow up 10 cases, in all the collagen disappeared within 3–6 months. In 4 cases we observed a transitional phase with fragmented collagen layer.*Conclusion:* on the basis of the data of the literature and our findings, we raise a hypothesis: it must be distinguished between1. a collagenous colitis as a pathologic and clinical entity *and*2. a collagenous inflammation reaction type which is manifested in certain person's colon to various stimuli (per analogiam: lupus erythematodes vs. lupoid reaction). "P P 10 0193"P 10 0193**Malabsorption of Lactose (25 G), Frucose (25 G) and Sorbitol (5 G) in Patients with Irritable Bowel Syndrome (IBS): Effect of Ethnic Origin, Sex and AgeD. Mishkin, L. Sablauskas, M. Yalovsky,**

*S. Mishkin

Faculties of Medicine and Management, McGill University and Division of Gastroenterology, Royal Victoria Hospital, Montreal, Quebec, CanadaThe aim of this study was to determine whether the prevalence of fructose (F) and sorbitol (S) malabsorption was dependent on ethnic origin as is the case for lactose (L). The effect of sex and age were also analysed. *Methods:* 520 ambulatory patients with IBS all underwent H_2 breath testing after challenges of L, F and S. Using criteria of {\'b3} 20 ppm H_2 rise for L and {\'b3} 10 ppm for F and S, 56.3%, 52.7% and 57.5% were malaborbers of L, F and S resp. *Results:* Tests for equality of prevalence for L malabsorption across 6 ethnic groups was significant at $p < 0.005$ with Northern Europeans ({ h} = 58) and French Canadians ({ h} = 92) clustered as one group with a prevalence < 35% compared to another group consisting of Arabs ({ h} = 35), Greeks ({ h} = 60), Italians ({ h} = 53) and Jews ({ h} = 167) with an average prevalence exceeding 60%. Equivalent testing among F and S malabsorbers was not significant. Prevalence of malabsorption for all ethnic groups ranged between 41.5–55.4% and 47.2–63.0% for F and S resp. L malabsorption was greater among males: 63.0% male vs 52.6% female -$p < 0.029$. Females predominated among F and S malabsorbers; 55.8% and 60.8% female vs 45.7% and 50.0% males resp. -$p < 0.033$. The effect of age could be analyzed among Jewish patients ({ h} = 167). 78.6% malabsorbed L, F and S in the age group 25–34 years. A progressive decline in L malabsorption was noted between 25–55 followed by a significant rise in later years. For F and S, prevalence progressively fell to 51.9% and 48.2% resp by 75–84 years. *Conclusions:* In contrast to L, ethnic origin does not influence F and S absorption in IBS patients. Malabsorption of L was more common among males, the reverse with F and S. While L malabsorption increased after 55 years, that for F and S fell progressively in the ethnic group analyzed. Intestinal disorders, absorption: Malabsorption syndromes }" "Malabsorption of Lactose (25 G), Frucose (25 G) and Sorbitol (5 G) in Patients with Irritable Bowel Syndrome (IBS): Effect of Ethnic Origin, Sex and Age"

Depts of Medicine and Public Health Sciences, University of Edinburgh, UK

Pentland Medical Centre, Currie, Midlothian, UK

Eastern General Hospital, Edinburgh, UKAlthough irritable bowel syndrome (IBS) is common, little is known about the quality of life (QOL) in IBS patients in the community.181 patients, aged 19–74 yrs, with a diagnosis of IBS were randomly selected from the lists of 3 general practices in Lothian. Patients were contacted by letter or telephone and invited to complete a postal questionnaire. Part 1 was the Mayo Bowel Questionnaire and part 2 was the Medical Outcome Survey SF36. A single reminder was sent to non-respondents. Responses were coded for analysis and results compared to known values for the general population, taken from a sample of 6212 residents of Lothian and a sample group of patients with angina pectoris.110 questionnaires were returned: a response rate of 61% of whom 53% were female. Symptoms fulfilling the Rome criteria for IBS were reported by 79 patients. These patients were classified by the severity, Group 1 with mild or moderate pain and symptoms (39 patients (23 F 16 M) mean age 41 yrs) and Group 2 with severe pain and symptoms (40 patients (30 F 10 M) mean age 43 yrs). The remaining 31 patients (10 F 21 M), mean age 49 yrs, no longer had active IBS and appeared to be largely symptom free.MOS questionnaires showed the symptom free IBS patients had a QOL similar to that of the general population. For the mild/moderate group, QOL was minimally affected whereas in the severe group, QOL was markedly affected.The severity of abdominal pain in patients with IBS living in the community is significantly associated with lower scores in all domains of the MOS. Even relatively well IBS patients have impaired QOL. Patients with severe abdominal pain have a reduction in QOL comparable to that observed in patients with angina pectoris. Clinical practice: Quality assuranceMotility, general: Functional GI disorders }" "Quality of Life (QOL) of Irritable Bowel Syndrome Patients in the Community"

"P P 10 0195"P 10 0195**Is There a Gender Difference in the Natural History of Irritable Bowel Syndrome (IBS)?**

*A.B. Thomson, I.J. Kerr, M.J. Ford, J. Forbes, R.C. Heading

Depts of Medicine and Public Health Sciences, University of Edinburgh, UK

Pentland Medical Centre, Currie, Midlothian, UK

Eastern General Hospital, Edinburgh, UKIBS is a common functional gastrointestinal disorder in both primary and secondary care, with a reported prevalence of 14–20%, incidence of 9% and a female predominance of 2:1. Little is known about the gender difference in relation to the progression and severity of the condition in the community.181 patients, aged 19–74 yrs, with a diagnosis of IBS in the last five years were randomly selected from the lists of 3 general practices in the Edinburgh area. Patients were contacted by telephone or letter and invited to complete the Mayo Bowel Questionnaire. A single reminder was sent to patients not responding. Questionnaires were coded for analysis.Of the 181 questionnaires sent out, 110 were returned (a response of 61%) of whom 53% were female and 47% male. Symptoms fulfilling the Rome criteria for IBS were reported by 79 patients (72% of responders, 53 F 26 M). The remaining 31 patients (mean age 49 yrs) appeared to be substantially symptom free. Of this group 10 were female, 21 male. The 79 patients with active IBS were classified according to the severity of their condition. Group 1 with mild/moderate pain and symptoms comprised 39 patients (23 F 16 M) mean age 41 yrs: Group 2 with severe pain and symptoms comprised 40 patients (30 F 10 M), mean age 43 yrs. There was a statistically significant association between female gender and symptom severity: $X^2 = 13.3$, $P < 0.01$.These data show that among patients in the community diagnosed as IBS, symptom resolution is more common in men than women. To our knowledge, this gender difference in the natural history of the disorder has not previously been reported and emphasises the importance of community-based population studies. Clinical practice: Epidemiology (non cancer)Motility, general: Functional GI disorders }" "Is There a Gender Difference in the Natural History of Irritable Bowel Syndrome (IBS)?"

"P P 10 0196"P 10 0196**Colonic and Extra-Colonic Symptoms of 1032 Patients with Irritable Bowel Syndrome**

*O. Chassany[1], H. Blondon[1], M. Billardon[2], B. Cleret[2]

[1] Service M\'e9dical d'Accueil, Hospital Lariboisiére, 75010 Paris

[2] Laboratoires Vedim (UCB-Pharma), 92003 Nanterre, FranceAim of this survey was to describe demographic and clinical features of patients complaining of irritable bowel syndrome (IBS) and consulting a non-hospital gastroenterologist.*Materials and methods.* Patients included had abdominal pain related to defaecation associated with altered bowel habit and/or bloating. From september 1994 to february 1995, 271 French gastroenterologists filled-in 1032 questionnaires during a consultation.*Results.* Average age of patients was 49 – 16 years, with a high percentage of women (sex ratio: 2, 3). Average duration of IBS was 11 – 11 years; for only 1% of patients, symptoms appeared less than one year before the study, but for 65% of patients, symptoms were present since more than 5 years. At the time of the study, 96% of patients had abdominal pain and 93% a bloating, both symptoms for which intensity was mostly scored 3 to 5 on a 6 point-scale, and 64% of patients had constipation. The frequency of onset of symptoms was at least once per week for 81% of patients; for 30% of them, symptoms occurred daily. Most of patients (93%) had at least an other digestive symptom such as excess of gas, borborygmus, flatulence, eructation or nausea. 65% of patients complained of one or several non-specific symptoms such as fatigue, insomnia or headache. 67% of patients described symptoms reflecting psychological disorders, mostly anxiety and depression. Number of consultations for IBS during the last 12 months was 3 – 3, but 19% of patients had more than 5 consultations. 7% of patients were out of work and 9% were hospitalized during the last year because of IBS. Rest and holidays alleviated symptoms for half of patients; stressful events, food, job and family worsened symptoms of a majority of patients. 83% of patients went under at least one diagnostic procedure, a colonoscopy most frequently. 90% of patients had already at least one digestive drug prescription and 34% a sedative or anti-depressant drug.*Conclusion.* IBS, expresses by many and frequent symptoms which occur during many years. IBS is associated with anxiety and depressive symptoms. Thus IBS is surely to impair quality of life.This research was funded by Laboratories Vedim (UCB-Pharma). Clinical practice: Epidemiology (non cancer)Clinical practice: Quality assuranceMotility, general: Functional GI disorders }" "Colonic and Extra-Colonic Symptoms of 1032 Patients with Irritable Bowel Syndrome"

[1] Service M\'e9dical d'Accueil, Hospital Lariboisiére, 75010 Paris

[2] Laboratoires Vedim (UCB-Pharma), 92003 Nanterre, FranceIrritable bowel syndrome (IBS), through its frequent, intense and chronic symptoms, affects the daily life of patients. This is not explored correctly by current clinical criteria such as abdominal pain. The aim of this survey was to evaluate health related quality of life in patients with IBS consulting a non-hospital gastroenterologist.*Methods.* Patients had to present abdominal pain related to defaecation and altered bowel habit and/or bloating. Self-questionnaire was filled-in in waiting-room. It consisted in 34 items reflecting different domains. Answer for each item was a 4-point Likert scale. This questionnaire has been developed specifically for this study, and it has not been validated for evaluative purpose in therapeutic trials.*Results.* Among 1032 patients included by 271 gastroenterologists, 1021 (99%) completed the questionnaire. 68% of patients are afraid about not knowing when the next bout of IBS will arise. 69 to 85% patients declare having difficulties in the different aspects of their daily life (daily activities, job, leisures, social, family, affective) because of IBS. There is a significant correlation ($p < 0.001$) between the severity of pain and bloating (but not for bowel habit) and the impact on the daily life, diet and health perception. 57% of patients consider their health to be good and 51% to be identical to other people. 81% of them are unsatisfied, anxious or afraid by their health. 66% of patients think that their health did worsen during the last years and 21% that it will worsen during the next years. They are only 23% to be convinced that IBS will improve in the next years. 83% of patients declare having sleeping disorders because of their health, 55% feel fatigue and 7% declare to be exhausted. 86% of patients judge their mind as medium to very bad and 65% of them take hypnotic or anxiolytic drugs. 75% of patients follow a diet, which is judged cumbersome or unbearable by 65% of them and not efficient by 49%.*Conclusion.* Quality of life is daily altered in patients with IBS, in terms of discomfort, poor health perception, unsatisfiedness and fear. For an optimal therapeutic management of patients with IBS, quality of life should be evaluated as well as symptoms.This research was funded by Laboratories Vedim (UCB-Pharma). Clinical practice: Epidemiology (non cancer)Clinical practice: Quality assuranceMotility, general: Functional GI disorders }"

[2] MAPI, 69003, Lyon

[3] Institut de Recherche Jouveinal, 94260 FresnesIn a validation study of a specific quality of life questionnaire in functional digestive disorders (FDD) (results presented elsewhere), patients from France, Great Britain and Germany were asked also to fill-in the general health status questionnaire SF-36. *Materials and methods.* From june to november 1995, 187 practitioners recruited 401 patients: 191 with dyspepsia, 210 with irritable bowel syndrome (IBS). Patients were asked to fill-in alone the questionnaire SF-36. SF-36 has been given also to 97 control patients: among them, 12% had hypertension, 19% arthrosis, 12% rheumatism, 9% insomnia. The SF-36 questionnaire consists of 36 items in 8 domains: physical functioning (PF), physical problems (RP), bodily pain (BP), general perception of health (GH), vitality (VT), social functioning (SF), emotional problems (RE), mental health (MH). Period recall is the last 4 weeks. For each domain, items answers are summed and transformed on to a scale from 0 (worse health) to 100 (best). *Results.* The acceptability of SF-36 is good, a missing data being found in 11.5% of questionnaires (IBS and french patients are less compliant). Median scores of each domain are significantly different between control group and patients, but not between dyspeptic and IBS:

Conclusion. Quality of life is impaired in patients with FDD, in comparison of a control group of patients having other chronic diseases. SF-36 is a useful general tool to compare health status between patients with different clinical conditions.This research was funded by Laboratoires Jouveinal. Clinical practice: Epidemiology (non cancer)Clinical practice: Quality assuranceMotility, general: Functional GI disorders }" "Health Status Survey Questionnaire (SF-36) in Dyspepsia and Irritable Bowel Syndrome"

"P P 10 0199"P 10 0199**European Psychometric Validation of a Specific Quality of Life Questionnaire in Functional Digestive Disorders**

*O. Chassany[1], P. Marquis[2], B. Fraitag[3], B. Scherrer[3], C. Sapede[2], B. Geneve[3]

[1] Service M\'e9dical d'Accueil, Hospital Lariboisiére, 75010 Paris

[2] MAPI, 69003, Lyon

[3] Institut de Recherche Jouveinal, 94260 FresnesThrough several studies, we developed a french specific quality of life questionnaire in functional digestive disorders, translated in english and german, consisting in a self-administered questionnaire of 68 items with answers on a five-point Likert scale, reflecting 12 domains. Aim of this study was to assess the final psychometric properties (acceptability, validity, reliability) of the questionnaire.*Materials and methods.* From june to november 1995, 187 general practitioners and specialists recruited 401 patients in France, Great Britain and Germany: 191 dyspeptic (D), 210 with irritable bowel syndrome (IBS). Patients were asked to fill-in alone the specific questionnaire and the general health survey questionnaire SF-36.*Results.* Average age of patients was 50 – 15 years, with 52% (D) and 70% (IBS) of women. For 80% (D) and 86% (IBS) of patients, symptoms were present since more than 1 year. Disease was severe as 53% (D) and 46% (IBS) of patients complained of more than 10 symptoms. Handicap scored by doctor was at moderate to huge for 59% (D) and 69% (IBS) of patients. Acceptability of our questionnaire is good and similar to the SF-36 as 1 missing data occurred in 10.9% of questionnaires. Construct validity was assessed by a factor analysis. It resulted through several multitrait scaling analysis in a reduction of the questionnaire to 43 items in 8 domains having a good convergent and divergent validity. Reliability is shown by the overall { a} Cronbach coefficient at 0.94. Clinical validity is good as ""food"", ""discomfort"" and ""stress"" domains discriminate dyspepsia from IBS patients. IBS patients and women report a lesser quality of life. There is a correlation between quality of life and the handicap scored by doctor, the number of symptoms and the duration of disease. Finally, correlation with SF-36 is high especially with the ""daily activities"" and ""coping"" domains of the specific questionnaire.*Conclusion.* The good psychometric properties of this specific quality of life questionnaire in functional digestive disorders, translated in french, english and german, allow to use it in comparative therapeutic trials.This research was funded by Laboratoires Jouveinal. Clinical practice: Epidemiology (non cancer)Clinical practice: Quality assuranceMotility, general: Functional GI disorders }" "European Psychometric Validation of a Specific Quality of Life Questionnaire in Functional Digestive Disorders"

"P P 10 0200"P 10 0200**Kruis Scoring System and Manning's Criteria in Diagnosis of Irritable Bowel Syndrome: Is It Better to Use Combined?**

*\'dc.B. Dogan, S. \'dcnal

Gazi University, Faculty of Medicine, Department of Gastroenterology, Ankara, TurkeyIrritable bowel syndrome (IBS) is characterized by abdominal pain and alteration of bowel habits. Manning et al. have reported that certain symptoms distinguished IBS from organic gastrointestinal disease (OGD); these were pain relieved by defecation, looser or more frequent stools at the onset of pain, abdominal distention, mucus, and a feeling of incomplete evacuation. Another simple scoring system for discriminating IBS from OGD that incorporated historical data, physical examination findings, and basic investigations was first devised by Kruis et al. In differential diagnosis of IBS from OGD, to evaluate the reliability of Manning's criteria and Kruis scoring system when used apart or combined; we studied 347 outpatients who completed a bowel disease questionnaire which objectively measured Manning's criteria and scoring system of Kruis. The group included 165 patients with IBS and 182 patients with OGD. The Manning's criteria discriminated IBS from OGD with a sensitivity of 90% and a specificity of 87% if three or more items were regarded as positive. Also the Kruis scoring system discriminated IBS from OGD with a sensitivity of 81% and a specificity of 91%. When used together, these systems discriminated IBS from OGD with a sensitivity of 80% and a specificity of 97%. Manning's criteria and Kruis scoring system had a strong correlation when compared in IBS, but not in OGD. Clinical practice: Epidemiology (non cancer) }" "Kruis Scoring System and Manning's Criteria in Diagnosis of Irritable Bowel Syndrome: Is It Better to Use Combined?"

"P P 10 0201"P 10 0201**Impaired Quality of Life in Irritable Bowel Syndrome as Compared to Inflammatory Bowel Disease**

*M. O'Sullivan[1], M. Mamhud[2], E. Lovett[3], C.A. O'Morain[1]

[1] Dept. Gastroenterology, Meath/Adelaide Hospitals, Trinity College, Dublin, Ireland

[2] Dept. Clinical Medicine, Trinity College, Dublin, Ireland

[3] Dept. Psychology, UCD, Dublin, Ireland*Introduction* Chronic bowel diseases such as IBD and IBS can have a profound effect on patients' Quality of Life (QoL). Poor QoL may be more pronounced in IBS than IBD. Disease and non-disease related factors can impact significantly on QoL and symptomology alone rarely gives the full clinical picture. *Methods* Adult patients with a clinically confirmed diagnosis of IBS and IBD were assessed using validated interview based and self administered questionnaires as follows: QoL using the Schedule for the Evaluation of Individual Quality of Life (SEIQoL); Somatic symptoms (Tally's-modified); Psychological – Hospital anxiety and depression scale (HAD); Disease Knowledge and support (visual analogue). *Results* 110 patients, IBS (n = 40), Ulcerative Colitis (UC) (n = 40), Crohn's Disease (CD) (n = 30) were studied. QoL (SEIQoL) was significantly (P < 0.01) poorer in IBS 51.56 as compared to CD (64.21) and UC (67.03). Anxiety, depression and somatic symptom scores were significantly (P < 0.01) greater in IBS. Disease knowledge and support were significantly (P < 0.01) poorer in the IBS group. Preliminary data suggests impaired IBS QoL is not directly associated with symptom severity. *Conclusion* QoL is significantly impaired in IBS as compared to IBD and does not appear to be directly associated with symptom severity alone. Other aspects such as psychological non-colonic symptoms and poor disease knowledge and support are likely to be important. Clinical practice: Quality assuranceIntestinal disorders: IBD diagnosis, monitoringMotility, general: Functional GI disorders }" "Impaired Quality of Life in Irritable Bowel Syndrome as Compared to Inflammatory Bowel Disease"

"P P 10 0202"P 10 0202**Symptoms and Colonic Transit Time in the Irritable Bowel Syndrome Treated with Psyllium and Cisapride or PlaceboR. Meier[1],**

*Ch. Beglinger[2], R. Brignoli[3], IBS-CIS study group

[1] Cantonal Hospital Liestal, Switzerland

[2] University Hospital Basle, Switzerland

[3] Janssen Research Foundation, Baar, SwitzerlandSince cisapride (CIS) has been reported to be efficacious in the treatment of constipation and of IBS, it was considered of interest to investigate whether the addition of CIS to Psyllium in pts. not responding to the bulk forming agent could improve the clinical and objective result.*Material and Methods:* IBS was defined as lower abdominal pain eventually relieved by defecation and {\'b3} 1 additional target symptom (see table). Adult pts. with an IBS since at least 6 months and who did respond to with Psyllium during at least 1 month, with a negative Barium-X-Ray or colonoscopy, were randomized to additionally receive either cisapride 5–10 mg tid or placebo tid. The treatment was continued for 12 weeks followed by 4 weeks of drug-free observation. The target symptoms were rated every 4 weeks (from absent = 0, to severe {inhibiting daily activities} = 3). Before and at the end of the treatment period Colonic Transit Time (CTT) was measured. Significance was accepted if two tailed $p < 0.05$.*Results:* 101 pts. were randomized but only 51 had 2 CTT determinations (26 CIS and 25 placebo) and are reported here. In both groups all target symptoms improved significantly during the study, however lower abdominal pain improved significantly more in the CIS treated pts. The CTT values were correlated to the constipation scores before and after treatment, but not with the treatment given nor with the other symptoms rated.Delta CTT and daily scores of Target Symptoms (Mean – S.D.) Parameter Placebo Cisapride IntergroupAbdominal pain 0.85 – 0.43 0.57 – 0.32 p < 0.01Flatulence/meteorism 0.77 – 0.37 0.76 – 0.52 n.s.Constipation 0.81 – 0.48 0.74 – 0.50 n.s.Urge to defecate 0.34 – 0.42 0.35 – 0.41 n.s.Incompl. evacuation 0.32 – 0.32 0.41 – 0.56 n.s.CTT (END-Start) hours { -}10.9 – 28.7 { -}9.2 – 24.4 n.s.*Conclusions:* The adjunction of CIS to Psyllium translated in a significantly larger pain relief. This effect can not be explained by an effect on colonic motility. }" "Symptoms and Colonic Transit Time in the Irritable Bowel Syndrome Treated with Psyllium and Cisapride or Placebo"

"P P 10 0203"P 10 0203**Experimental Gut Pain in Man**

*A.M. Drewes, L. Arendt-Nielsen, J.B. Hansen, H.B. Krarup, U. Tage-Jensen

Department of Medical Gastroenterology, Aalborg Hospital, DK-9000, Aalborg, Denmark

Laboratory for Experimental Pain Research, Aalborg University, DK-9000, Aalborg, DenmarkVisceral pain is a substantial clinical problem. Experimental pain stimuli may elucidate physiological aspects of the pain, but only few human models are ailable. In the current study the findings using electrical stimuli of the gut mucosa were evaluated in patients with ileo/sigmoidostomy.Nine patients participated. Four had an ileostomy and five had sigmoidostomy. In all subjects the stomy was normally functioning. A flexible catheter containing six stimulation electrodes separated by 4 mm was introduced into the stomy. The gut mucosa was stimulated by single, five repeated and continuous electrical stimuli. The sensation threshold, pain detection threshold (PDT) and pain tolerance threshold (PDT) was determined. Also the location and size of the referred pain area was characterized. Finally, brain potentials to single stimuli were measured.PDT and PTT to single stimuli were difficult to determine whereas these thresholds were easily found when repeated stimuli were used. The pain thresholds to single stimuli were twice as high as thresholds to repeated stimuli indicating the importance of central temporal summation in visceral pain. During continuous stimulation the pain intensity as well as the referred pain area gradually increased. Also the amplitude of the brain potentials increased for increasing pain intensity.In conclusion the model demonstrated the importance of repetitive stimuli for eliciting visceral pain. The brain potentials may be useful in the study of basic pain physiology. Visceral stimuli seems adequate to evoke referred pain with profiles similar to those found in patients with different gastrointestinal diseases. Motility, general: Receptors and signals }" "Experimental Gut Pain in Man"

"P P 10 0204"P 10 0204**Irritable Bowel Syndrome (IBS) Observatory: Clinical and Therapeutic Aspects in 1571 Patients Treated by Town GPs**

*J.M. Raymond[1], P. Michel[1], D. Jessueld[2], O. Plique[2], J. Westerloppe[2], M. Amouretti[1]

[2] IPSEN, Paris

[1] CHU du Haut L\'e9v\'eaque, Bordeaux, France*Purpose:* the prevalence of irritable bowel syndrome (IBS) among the general public is high. Similarly, it presents in a wide range of ways and is treated by various means. The objective of the present work was to describe the characteristics and symptoms of patients consulting a GP for symptoms suggesting IBS, and to measure developments in the medium term.*Methods:* a representative sample of GPs from the whole of France was randomly selected, and their patients consulting for IBS symptoms were included. The clinical and therapeutic data were collected at this consultation and a second time three months later. Prescription of treatment or further examinations was left to the GPs' discretion, and recorded.*Results:* between February 1995 and January 1996, 463 GPs recruited 1571 patients aged 15 to 88 (mean – SD: 53 – 14), with women predominating (64%). 49% of the patients were in employment. 36% had had their appendix removed, and 12% their gall bladder. The IBS had existed for a mean of 8.9 years, chronically in 40% of cases and intermittently in 54%. During the initial consultation, 94% of patients reported pain, for 30.2% on a daily basis. Stool frequency was > 3 per day in 10% of patients, and < 1 per three days in 10.6%. Stool consistency was considered normal in 18%, soft or liquid in 42%, and hard in 14%. 30% of patients alternated between diarrhoea and constipation, and 86% exhibited meteorism.At three months, the pain had disappeared in 13% of patients, and occured on a daily basis in only 8.8%. The intensity of pain had significantly decreased. Stool frequency anomalies previously noted now occured in 3.6% and 3.4% of patients. Stool consistency was considered normal in 48% soft or liquid in 46%, and hard in 8.4%. 12% of patients alternated between diarrhoea and constipation, and 58.9% exhibited meteorism.During the three months preceding the study, 93% of patients were already on a treatment and 62% on a diet for their IBS. At the end of the first consultation, 95% of the patients were prescribed a medical treatment and 84% a diet. The mean number of medicines prescribed was 2.38 before the consultation and 2.16 after; the reduction largely concerned prescriptions involving four or more medicines. The most commonly prescribed therapies were intestinal dressings (diosmectite), antispasmodics of the musculotropic (mebeverine) and non-anticholinergic (phloroglucinol) types, and modifiers of digestive motricity (trimebutine).*Conclusion:* the IBS observatory enabled a profile of patients consulting for IBS out-patient treatment to be established. Symptoms at three months were significantly improved. The therapy given, the patterns of disease development or even the conditions of observation could be responsible for this improvement. Intestinal disorders: ConstipationClinical practice: Epidemiology (non cancer)Clinical practice: Quality assurance }" "Irritable Bowel Syndrome (IBS) Observatory: Clinical and Therapeutic Aspects in 1571 Patients Treated by Town GPs"

[2] IPSEN, Paris

[1] CHU du Haut L\'e9v\'eaque, Bordeaux, FrancePurpose: irritable bowel syndrome (IBS) is a common, benign pathology. The economic impact of its treatment is not exactly known. The objective of the present work was to assess consultation for treatment of patients presenting with IBS under usual non-hospital practice.*Methods:* a representative sample of GPs from the whole of France was randomly selected, and their patients consulting for IBS symptoms were included. The entire medical consumption over the three months preceding the consultation was recorded as was any prescription of examinations or treatment during this and/or another consultation three months later.*Results:* 1571 patients were recruited over 12 months by 463 GPs. During the three months preceding the consultation, 1364 patients stated having consulted a GP and 335 a gastro-enterologist for IBS at least once out of respective totals of 3348 and 403 consultations (mean of 2.1 and 0.26 per patient per three months). 49 patients were hospitalised, four of which twice and one three times (mean stay in hospital 3.1 days). 94 patients were put on sick leave at least once over the same period for a mean of 8.7 days. 534 patients stated having had a least one extra examination. The examinations included 326 coloscopies, 90 abdominal echographies, 46 barium enemas, 6 rectoscopies, 5 abdominal scanners, 38 coprocultures and 6 thyroid check-ups. 1461 patients were on medical treatment (involving less than 4 medicines in 86.2% of cases) and 976 were on a diet.At the end of the first consultation, a medical treatment was prescribed to 1494 patients, with less than 4 medicines in 92.3% of cases, and combined with a diet in 1329 patients. Further examinations were prescribed for 93 patients. During the three months of the study, 1081 patients saw a GP and 98 a gastro-enterologist for a total of 2130 and 126 consultations. 18 patients were hospitalized for a mean of 3.3 days, and 39 were put on sick leave for 7.2 days.*Conclusion:* IBS treatment may be improved through an analysis of its various components, taking their corresponding cost: efficiency ratios into account. "P P 10 0206"P 10 0206**Analysis of the Effect of Irritable Bowel Syndrome (IBS) on the Well-Being of 1571 Patients Treated by Town GPs**

*J.M. Raymond[1], P. Michel[1], D. Jessueld[2], O. Plique[2], J. Westerloppe[2], M. Amouretti[1]

[2] IPSEN, Paris

[1] CHU du Haut L\'e9v\'eaque, Bordeaux, France*Purpose:* irritable bowel syndrome (IBS) is one of the most common pathological conditions encountered in day-to-day practice. The effect of colonopathy on patients' everyday life has rarely been examined. The objective of the present work was to estimate the physical well-being of patients consulting a GP for symptoms suggesting IBS and to measure its progress three months later.*Methods:* a representative sample of GPs from the whole of France was randomly selected, and their patients consulting for IBS were included. A questionnaire asking for answers formulated on a four-point scale (enormously, fairly, a little, not at all) and analogue visual scales (AVSs) were filled in by the doctor and patient during the first consultation and at a second one three months later. Prescription of treatment or further examinations was left to the GPs' discretion, and recorded.*Results:* Between February 1995 and January 1996, 463 GPs recruited 1571 patients aged 15 to 88 (mean – SD: 53 – 14), with women predominating (64%). The IBS was chronic in 40% of cases and intermittent in 54%, and caused discomfort in various aspects of the patients' lives; according to aspect, the IBS bothered the patients ""enormously"" in 7.4 to 19.5% of cases. It bothered 69.3% of patients ""fairly"" or ""enormously"" for social life, 63.1% for leisure, 62.6% for family life, 57.4% for domestic life, 43.9% for work, and 30.2% for sex. During the initial consultation, stress was accused of triggering abdominal pain by 80.5% of patients and transit disorders by 69.3%. At the end of the study, no matter what the aspect, less than 2% of patients were ""enormously"" bothered by IBS and over 72% ""a little"" or ""not at all"". Assessment of discomfort by AVS demonstrated that the results changed on average between the two consultations from 4.7 to 2.6 for pain, 5 to 2.7 for swelling, 3.3 to 1.7 for diarrhoea, 3.2 to 2 for constipation, and from 5.2 to 3 for an AVS assessing overall discomfort. Age, sex and patterns of disease development were not significantly associated with differences in disease stage at three months.*Conclusion:* measuring the effect of IBS by AVS and discreet-answer questions were in agreement. IBS deteriorated various aspects of physical well-being in day-to-life and, to improve care, must be taken into consideration. The improvements observed during the study could be due to the treatments given, but also to the patterns of disease development or even the conditions of observation.

"P P 10 0207"P 10 0207**Enterocyte Covering Agent Versus Intestinal Motility Inhibitor in the Irritable Bowell AuthorsA.L. Oproiu,**

*M. Diculescu, A. Iov, S. Calin, A. Dumitrescu, G. Calin, M. Manuc, D. Pitigoi

""Carol Davila"" University of Medicine, Bucharest Romania*Purpose.* Irritable bowell syndrome (IBS) is a rather frequent disease in adults, with a complex pathogenic mechanism. Our aim was to assess whether enterocytes are more involved than smooth muscle cells in IBS with accelerated bowell transit.*Methods:* Our study was a prospective monocentric study. We had 2 groups of patients: group D had 30 patients with IBS who were treated with diosmectite 9 g/day. Group L had 32 patients and was treated with loperamide 4 mg/day. Both groups were treated for 30 days and had a definite IBS diagnosis based on clinical data and laboratory exclusion of organic, infective or systemic diseases who could mimick IBS. All the 62 patients were evaluated at the beginning, and at days 10, 20, 30. Statistic analysis evaluate the median, maximal, and minimal values for quantitative variables, and Wilcoxon's test for qualitative variables.*Results.* The number of stools had reduced from 3.4 – 1.0 to 1.0 – 0.7 in the D group comparative with a reduction from 3.6 – 1.0 to 1.8 – 0.3 in the L group. The frequency of abdominal pain was reduced from 6.5 – 2.4 to 1.6 – 2.1 and from 5.8 – 1.8 to 2.9 – 2.2 respectively. Flatulence was absent in 16.7% before treatment and 83.3% after 30 days in group D compared with 21.9% and stil 37.5% in group L. Global efficacy at 10 days was 46.7% very good and 26.7% good in the D group compared with 31.25% and 18.75% in group L.*Conclusion* Global efficacy at 30 days was 96.7% with diosmectite and 62.5% with loperamide which may mean that usually in IBS smooth muscle hypermotility may be in some conditions more dependent upon the enterocyte and intraluminal status than upon the nervous system. "P PP0 0221"PP0 0221 **A Double-Blind, Randomized, Placebo-Controlled Study of Cisapride in Pediatric Gastroesophageal Reflux**

*R.B. Scott, C. Ferreira, L. Smith, A.B. Jones, H. Machida, M.J. Louhoues, C.C. Roy

Divisions of Pediatric Gastroenterology and Nutrition, Universities of Calgary and Montreal, CanadaGastroesophageal reflux is a common condition affecting infants and may lead to serious complications such as aspiration, apnea, esophagitis, stricture and failure to thrive. The present study was designed to assess the efficacy and safety of oral Cisapride suspension in the treatment of pediatric gastroesophageal reflux disease. A randomized, prospective, double-blind, placebo-controlled clinical trial was conducted at three study sites. After a one-week run-in period, 45 evaluable infants (aged 6 weeks–2 years) were randomized to receive a 6 week double-blind treatment with Cisapride (0.2 mg/kg q6h) or a placebo suspension. Efficacy was assessed with 24 h esophageal pH monitoring, esophageal manometry, esophageal biopsy before and after the treatment period. A diary was kept by parents of regurgitation frequency and severity, and global evaluation by parents and physician were performed at every visit. Safety was assessed by means of adverse event monitoring and standard laboratory measurements. Compared with placebo, Cisapride significantly ($p < 0.05$) reduced the mean duration of upright and supine reflux episodes by the end of the trial. Compared to baseline, Cisapride significantly reduced the duration of the longest reflux episode, and placebo increased the number of reflux episodes > 5 minutes. Cisapride was not significantly different from placebo for the following measurements: % total time pH < 4, number of reflux episodes, lower esophageal sphincter pressure, swallow pressure, regurgitation frequency or global evaluation scores. The incidence of adverse events was comparable in both groups. No serious adverse events were reported during the study. Cisapride is a safe, well-tolerated prokinetic agent which improves some parameters of 24 h pH measurements in children with GERD under the age of 2 years. It may be effective in reducing secondary complications of GER in pediatric patients. "P PP0 0222"PP0 0222 **Reflux Esophagitis: A Complication of Helicobacter Pylori (HP) Eradication Therapy?**

*N. Sacc\'e0, A. De Medici, S. Rodin\'f2, M. De Siena, A. Giglio

Servizio di Endoscopia Digestiva, Ospedale Ciaccio, Catanzaro, ItaliaRecently some authors reported in a preliminary study an high incidence of reflux esophagitis in patients after HP eradication therapy. Aim of our study was to evaluate this phenomenon in our endoscopical population.*Methods:* 276 patients affected by peptic ulcer and HP infection were treated with different therapeutic regimens (various antisecretory drugs: Omeprazole or Ranitidine and various antibiotics: Clarytromicine (C) + Tinidazole, C + Metronydazole (M), Amoxycillin (A) + Bismuth, A + M. The patients were investigated clinically and endoscopically at 1–6 months after therapy and when dyspeptic symptoms occurred. HP status was assessed by urease test and histology in antrum and body of the stomach and in third inferior of esophagus as well.*Results:* 169 (61.2%) were eradicated at 6 months after therapy: 24 of them developed an endoscopically proven reflux esophagitis which was mild (grade I) in all patients.*Conclusions:* our study confirmed the evidence of reflux esophagitis development in patients treated for Hp infection. Such evidence can be explained by differents theory: changed eating and drinking habits that can reduce lower esophageal sphincter pressure or the interruption of a chronic therapy with antisecretory drugs for peptic disease. Any evidence of HP has been found in esophagus as and in stomach as well. We believe that this phenomenon isn't casual finding in patients without previous evidence of reflux esophagitis and that further studies are needed to clarify this phenomenon. "P PP0 0223"PP0 0223 **Treatment of Candida Esophagitis in the Acquired Immunodeficiency Syndrome: Evaluation of Long-Term Therapeutic Efficacy of Fluconazole and Itraconazole**

*G. Barbaro, G. Barbarini[1], W. Calderon[1], B. Grisorio[2], P. Alcini[3], G. Di Lorenzo, Candida Esophagitis Multicenter Italian Study (C.E.M.I.S.)-Group

Department of Emergency Medicine and Infectious Diseases, University ""La Sapienza"", Rome, Italy

[1] Department of Emergency Medicine and Infectious Diseases, University of Pavia, Italy

[2] Division of Infectious Diseases, General Hospital, Foggia, Italy

[3] Department of Clinical Pharmacology, University of Pavia, Italy*Introduction.* Little information is actually available regarding the long-term response of Candida esophagitis to antifungal therapy. Aim of the study has been to assess the long-term therapeutic efficacy of fluconazole and itraconazole in the treatment of Candida esophagitis in a selected population of HIV-positive patients.*Methods.* The study has considered 2213 HIV-positive patients at first episode of esophageal candidiasis diagnosed by endoscopy; 1105 received fluconazole (100 mg b.i.d.), 1108 received itraconazole (100 mg b.i.d.) for 2 week. The patients who presented, after 2 weeks of treatment a partial endoscopic response (Kodsi's grade I), even if asymptomatic, continued the pharmacological treatment up to week 5. At week 5 they underwent endoscopic examination and only the patients with endoscopic cure were considered for long-term follow-up. The other patients were withdrawn from the study. Beginning from week 5, clinical examination was performed every week up to month 3, every two weeks up to month 6 and then every month up to the end of follow-up (month 12); endoscopic examination was performed at months 3, 6 and 12. Endoscopic examination could be performed also if relapses of esophageal symptoms were observed during the follow-up period, in order to assess if Candida infection was responsible or not for symptomatic relapse.*Results.* At week 2, endoscopic cure occurred in 81.2% of patients treated with fluconazole and in 65.6% of patients treated with itraconazole (relative risk: 1.23; 95% C.I.: 1.08–133; $p < 0.001$). Clinical cure was observed in 81.5% of patients treated with fluconazole and in 75.2% of patients treated with itraconazole (relative risk: 1.08; 95% C.I.: 0.95–1.18; $p < 0.001$). A total of 2158 patients were clinically and endoscopically evaluable at week 5 and were considered for long-term follow-up. At the end of follow-up, endoscopic and clinical cure cure were observed in 96.2% of patients treated with fluconazole and in 96% of patients treated with itraconazole (relative risk: 1.00; 95% C.I.: 0.87–1.08; $p = 0.816$). By intention-to-treat analysis endoscopic and clinical cure were observed in 93.6% of patients treated with fluconazole and in 93.3% of patients treated with itraconazole (relative risk: 1.00; 95% C.I.: 0.87–1.08; $p = 0.857$). Symptomatic relapses of endoscopically-demonstrated esophageal candidiasis were observed in 6% of fluconazole-treated patients and in 6.5% of itraconazole-treated patients presenting endoscopic and clinical cure at week 5 (relative risk: 0.92; 95% C.I.: 0.79–0.99; $p = 0.650$).*Conclusions.* Both fluconazole and itraconazole are provided with a good long-term therapeutic efficacy in the treatment of Candida esophagitis in HIV-positive patients. Fluconazole is associated with a higher rate of endoscopic and clinical cure than itraconazole in short-term treatment. Immunology and microbiology: GI infections in

"P PP0 0227"PP0 0227 **TP53 Gene and MTS1 Gene Alterations in Oesophageal Squamous Carcinomas**

*M.A. Giroux, M.P. Audr\'e9zet, J.P. Metges, J.B. Nousbaum, B. Mercier, C. F\'e9rec, H. Gou\'e9rou, M. Robaszkiewicz

CHU de la Cavale Blanche, 29609 Brest cedex, FranceThe TP53 gene is the most commonly mutated gene in human cancers. Another tumor suppressor gene called MTS1 encoding for p16 protein is frequently mutated in melanoma cell lines. Recent data have reported homozygous and heterozygous deletions involving 9p21. The aims of this study were: 1) to establish the prevalence of TP53 gene mutations, 2) to analyze the rate of deletions of 9p21 and 3) to detect MTS1 mutations in a large series of oesophageal squamous cell carcinomas (SCC).*Material and Methods:* One-hundred tumors were studied. TP53 mutations were identified using a GC clamp Denaturing Gradient Gel Electrophoresis (DGGE) and DNA sequencing. Deletion mapping of 9p21 was performed using microsatellites. MTS1 mutations were identified using DGGE and DNA sequencing.*Results:* TP53 gene mutations were detected in 78 patients (78%). The mutations identified were transitions (48.5%), transversions (34.8%) and frameshift mutations (16.7%). Five patients had a germline mutation of the TP53 gene. Loss of heterozygosity of 9p21 was investigated in 82 samples. Allelic loss involving at least one of the 2 microsatellites was detected in 11 of 75 informative cases (14.7%). We found 6 somatic mutations in exon 2; 3 consisted in deletions of 5, 10, and 33 base pairs and an identical missense mutation (A140T) was detected in the 3 other cases. Two patients had a genomic point mutation identical to that found in somatic DNA, and a loss of the other allele in the tumour.*Conclusion:* this study shows that TP53 gene alterations occur frequently in oesophageal SCC. On the other hand, somatic mutations of MTS1 gene are rare during oesophageal tumorigenesis. "P PP0 0228"PP0 0228 **Sensory Nervous Fibers and CGRP in Gastric Adaptation to Stress**

*A. Dembinski, Z. Warzecha, T. Brzozowski, D. Drozdowicz, S.J. Konturek

Institute of Physiology, Collegium Medicum, Jagiellonian University, Krak\'f3w, PolandGastric mucosa is capable to adapt to ulcerogenic action of stress but the mechanism of this phenomenon is unclear. Stimulation of capsaicin-sensitive sensory nerves and calcitonin gene-related peptide (CGRP) exhibit protective effects against mucosal damage in various models of gastric lesions, and for this reason, we investigated the influence of sensory nerves and sensory neuropeptide such as CGRP on gastric adaptation to stress. Acute gastric lesions were produced by water immersion and restrain stress (WRS) in rats. WRS was applied either once or repeatedly every other day for up to 8 days in animals with intact or capsaicin deactivated sensory nerves. It was found that WRS applied once produced multiple gastric erosions (19.0 – 0.9 per rat) accompanied by an increase in basal gastric acid secretion (– 30%), a decrease in gastric blood flow (determinated by laser Doppler technique) by about 50% and a reduction of DNA synthesis by 57% as compared to intact rats without WRS. Repeated WRS insults resulted in a significant reduction of number of gastric lesions. This adaptation to stress ulcerogenesis was accompanied by a gradual decrease in gastric acid secretion, an increase in gastric blood flow and a return of mucosal DNA synthesis to the control value. Capsaicin-induced deactivation of sensory nerves eliminated gastric adaptation to WRS as manifested by a failure to decline of gastric lesions after repeated WRS and sustained decrease in GBF. Pretreatment with CGRP in capsaicin denervated rats prevented the formation of acute gastric mucosa lesions by WRS. One exposure to WRS in CGRP-pretreated rats resulted in a decrease of gastric lesions number to the value similar to that observed after gastric adaptation to stress but repeated WRS insults did not result in any additional significant reduction of gastric lesions. We conclude that the stomach is able to adapt to repeated stress insults due to enhancement of GBF and mucosal cell proliferation, and this adaptation dependents upon the activity of sensory nerves and probably the release of CGRP.

"P PP0 0229"PP0 0229 **Clinical Guidelines for Dyspepsia in Primary Care**

*K. Bodger, M.J. Daly, R.V. Heatley

St James's University Hospital, Leeds, England*Background* Clinical guidelines have been suggested as a means of improving the quality and uniformity of patient care, though are easier to produce than to implement successfully. We have developed local consensus-based management guidelines for dyspepsia in co-operation with local general practitioners (GPs), and report a prospective audit of their implementation in a primary care setting.*Methods* A heterogeneous group of 9 GPs from 3 practices were recruited to pilot the guidelines. Consecutive consultations for dyspepsia were recorded on a *dyspepsia management record* (DMR), kept in each patient's casenotes. The DMR was designed to summarise clinical information, facilitate guideline compliance, and simplify audit.*Results* 217 DMR's were completed, relating to 396 consultations for dyspepsia. Prescribing patterns (%), and guideline compliance, are summarised for selected dyspepsia sub-groups (274 consultations):[N = consultations. Nil = no prescription; Ant = antacid; Mot = motility agent; H2R = H2-antagonist; PPI = proton pump inhibitor; HpE = *H. pylori* eradication; % PP = % prescriptions per protocol; parentheses ""(n)"" = prescriptions outside protocol; ""empirical"" = uninvestigated patients] Sub-group N Nil Ant Mot H2R PPI HpE % PPNew patient 29 7 48 3 38 (24) 3 (3) 0 73Past dyspepsia, ""empirical"" 47 4 30 4 38 23 (11) 0 89Past reflux, ""empirical"" 37 3 46 0 19 32 0 100Non-ulcer dyspepsia 42 2 5 14 43 29 (24) 5 (5) 71Reflux (-ve investigations) 32 3 16 0 38 44 0 100Reflux oesophagitis 37 0 5 0 22 (3) 68 5 (5) 92Duodenal ulcer disease 50 4 2 0 62 (36) 8 (4) 24 60*Conclusions* Although dyspepsia guidelines were well received by GPs, with overall compliance relatively good, some therapeutic agents were still used ""inappropriately"", and *H. pylori* eradication therapy was under-prescribed in DU disease. Even when guidelines are introduced under ""ideal"" conditions, with ongoing audit, prescribing practice may prove difficult to modify. Continuing medical education, targeted at specific aspects of disease management, is vital, particularly if guidelines are to be viable on a larger scale. "P PP0 0230"PP0 0230 **Ultrastructural Evidence of H. Pylori Penetration into the Gastric CellsJ.N. Giannios,**

*J.A. Karagiannis

Gastroenterology Unit, St. Savvas Anticancer Hospital, Athens, GreeceH. Pylori is considered as exerting its damaging effects to the gastric mucosa by adhering to the gastric mucosa cells without invading them. Aim of the study was to examine intrastructurally the sequence of H. Pylori interaction with the gastric mucosa. Twenty-eight patients with active chronic gastritis and peptic ulcer disease were diagnosed to have been infected with H. pylori, by ^{13}C-urea breath test, histology, culture and rapid urease test (CLO-test). Biopsy specimens from these patients were randomly selected and were fixed in 2.5% glutaraldehyde sodium cacodylate and then post-fixed in osmium tetroxide. After dehydration and gold coating, samples were examined under a Scanning Electron Microscope (SEM). A second set of biopsies were embedded in epoxy resin and cut to ultrathin sections which were stained with uranyl acetate and lead citrate for enhancing electron scattering for Transmission Electron Microscopy (TEM) analysis. Both SEM and TEM showed that, initially, bacteria adhere to the glycocalyx layer of microvilli, destroying them. Then the bacteria attach directly via filamentous material to the gastric cell surface, where the phospholipase A_2 activity of H. pylori degradate the external phospholipid membrane of gastric cells especially around the areas of tight junctions. Subsequently, the bacteria penetrated into the cytoplasmic region of the gastric cells where bacterial VacA toxin induces formation of large cytoplasmic vacuoles leading to cellular disintegration. Some bacteria were still adhered to cytoplasmic parts and granules which were floating free in the gastric milieu. Furthermore, generation of complement products and cytokines released after urease induction activated the chemotaxis of polymorphonuclear leucocytes which migrated through the epithelium into the gastric lumen, phagocytosing H. pylori and inducing inflammation to the gastric tissue. H. pylori strains having the GagA gene detected by Western Blotting showed greater polymorphonuclear leucocyte infiltration of the gastric tissue and hence induced more severe inflammation. The above observations reveal the ultrastructural mechanism under which H. pylori causes gastritis and peptic ulcer disease by actually invading the gastric cells. Oesophageal gastric duodenal disorders: Helicobacter Pylori }" "Ultrastructural Evidence of H. Pylori Penetration into the Gastric Cells"

*F. Luzza, M. Imeneo, M. Maletta, G. Paluccio, A. Giancotti[1], F. Perticone, P. Graziano, A. Foca'[1], F. Pallone

Dipartimento di Medicina Sperimentale, Universita' di R. Calabria, Catanzaro, Italy

[1] Cattedra di Microbiologia, Universita' di R. Calabria, Catanzaro, Italy*Background:* Recent studies showed that the age-specific prevalence of *H. pylori* infection parallels Hepatitis A (HAV) suggesting similar modes of transmission. *Aim:* To investigate risk factors for *H. pylori* and HAV and the possibility that the two infections could be associated. *Methods:* Between January and September 1995, a random sample of 705 resident subjects who attended the outpatient medical center of the rural county of Ciro' (11.000 inhabitants, Southern Italy) for blood testing were recruited. All subjects completed a questionnaire for general demographic details, height, weight, current and childhood socio-economic circumstances, history of cardiovascular diseases, diabetes, dyspepsia, smoking and alcohol. Serum sample was drawn from each subject and stored at { -}20\'b0C. Blood pressure was measured. All sera were assayed for *H. pylori* specific IgG by an in-house ELISA using a crude *H. pylori* sonicate as antigen (sensitivity and specificity 97% and 91%). In 466 subjects, antibodies to HAV were detected by means of a commercial ELISA kit (Behring, USA). In subsets of subjects, serum fasting cholesterol, triglycerides and glucose were also measured. Data were analysed by multiple logistic regression analysis, Spearman's test, { k} statistic and expressed also as odds ratio (OR) and 95% confidence intervals (CI). *Results:* Of the 705 (273 M, 468 F; age range 1–87, median 50) subjects, 446 (63%) were positive for *H. pylori.* Among the 466 (163 M, 303 F; age range 1–87, median 49) subjects screened for HAV, 291 (62%) were positive for *H. pylori* and 407 (87%) for HAV. Cross-tabulation of this data showed that 275 (59%) were positive and 43 (9%) negative for both *H. pylori* and HAV, 16 (3%) were positive only for *H. pylori* and 132 (28%) were positive only for HAV (OR = 5.6, CI: 3–10). There was an age-specific increase in the prevalence of the two infections and a fair correlation (r = 0.287) whereas the association was more weak ({ k} = 0.21) or not significant ({ k} = { -}0.064) when assessed in the first two decades. In multivariate analysis, current and childhood socio-economic features were differently associated with *H. pylori* [dyspepsia (OR = 1.6, CI: 1.1–2.3), occupation (OR = 0.7, CI: 0.6–0.9)] and HAV [n. of siblings (OR = 1.3, CI: 1.05–1.7), refrigerator (OR = 5.6, CI: 1.3–24)]. *Conclusion:* The correlation between *H. pylori* and HAV reflects the age-specific high seroprevalence of both infections more than a true association. The fecal-oral spread of *H. pylori* is unlikely. Clinical practice: Epidemiology (non cancer)Oesophageal gastric duodenal disorders: Helicobacter Pylori }" "Seroepidemiology of H. Pylori Infection and Hepatitis A in a Rural Area. Evidence Against a Common Mode of Transmission"

"P PP0 0233"PP0 0233 **Regression of Lymphoid Follicles in Gastric Mucosa of Helicobacter Pylori Infected Patients 12 Months after Eradication**

*G. Battaglia, P.E. Lecis, P.M. Donisi[1], G.A. Grasso, M.E. Benvenuti, G. Leandro[2], M. Pasquino, M. Bergamasco[3], F. Di Mario[4]

Unit of Gastroenterology, Venezia, Italy

[1] Unit of Pathology, Venezia, Italy

[3] Unit of Microbiology Venezia, Italy

[2] Unit of Castellana Grotte, Italy

[4] Division of Gastroenterology of Padova, Italy*Introduction.* Only few studies, on small samples, demonstrated that eradication of Helicobacter pylori (Hp) infection causes a decrease of number of lymphoid follicles (LF) and a regression of low grade B cell gastric MALToma. *Aim.* To verify whether the cure of Hp infection could determine the regression of LF in the gastric mucosa. *Methods.* 100 patients (59 M, 41 F, mean age 59) with Hp infection and treated with either double, triple or quadruple therapy for 7–14 days entered the study. Hp colonization was confirmed by histology of 4 biopsies (Hematossilin-eosin and Giemsa modified stain), CLO test and colture. Pathologists were blinded as regards either therapy carried out or clinical results. An endoscopy was performed at baseline, three and twelve months after the end of eradication therapy. Patients with active lesion undergone a further endoscopy after 1 month. *Statistic.* Mc Nemar test of simmetry. *Results.* 55 patients were proven to have LF at baseline endoscopy (Group A) while 45 did not (Group B). After three months 46/55 subjects of the Group A were proven to be Hp negative and the follicles were still present in 20 (36%); 22 out of the Group B patients were revaluated 1 month after the immission and 11 (50%) were found to have LF, while after 3 months the presence was in 18/45 (40%): eradication was obtained in 36/45 (80%). 44 patients were evaluated after 12 months: LF were detected in 8/24 patients of Group A (3 Hp+ve, 5 Hp{ -}ve) and were absent in 16 (1 Hp+ve, 15 Hp{ -}ve) while in Group B LF were present only in 1/20 patients; all the patients of this group were Hp{ -}ve. The differences between baseline and long-term check-up were proven statistically significant (p = 0.0022 after 3 months and p = 0.0003 after 12). *Conclusion.* The cure of Hp infection significantly reduces the presence of LF in the gastric mucosa. }" "Regression of Lymphoid Follicles in Gastric Mucosa of Helicobacter Pylori Infected Patients 12 Months after Eradication"

"P PP0 0234"PP0 0234 **Helicobacter Pylori Infection and Antral Intestinal Metaplasia: One Year Follow-up after Eradication**

*M. Ravizza, P. Dusio, R. Navone, D. Mazzucco[1], R. Suriani[1]

Servizio di Endoscopia Digestiva, Ospedale Evangelico Valdese, Torino (I)

[1] Servizio di Endoscopia Digestiva Ospedale degli Infermi di Rivoli, Torino (I)*Purpose of the study:* To evaluate Helicobacter Pylori (HP) significance in development of intestinal metaplasia (IM) and how HP eradication modifies IM evolution.*Methods:* In 99 consecutive IM histological diagnosis in specimens obtained during upper endoscopic investigation we performed four biopsies, two from angular mucosa and two from fundic mucosa and detected HP presence histologically by Giemsa stain. All patients were endoscopically reinvestigated one year later. The group of patients presenting IM and HP positivity underwent eradication therapy immediately after diagnosis. Statistical analysis was performed by chi-square method.*Results:* 82 (82.8%) out of 99 patients resulted HP positive and 17 (17.2%) were HP negative. All IM and HP positive patients underwent eradication by triple therapy (omeprazole 20 mg daily for one month, amoxycillin 1 g twice a day for one week, clarytromicin 250 mg twice a day for one week). 69 patients out of 82 resulted eradicated by immunological method two months after therapy. After 12 months 98 patients out of 99 underwent endoscopic control; one patient IM positive and HP negative dropped out of the study. 14 (87.5%) out of 16 patients (87.5%) IM positive and HP negative at time 0 showed IM in histological specimen and one of them was HP positive to Giemsa stain. At the same time only 53 (64.5%) patients out of 82 treated demonstrated intestinal metaplasia on histological specimen; 40 patients out of 53 were HP negative and 13 resulted HP positive. Among 29 patients IM positive at time 0 and IM negative twelve months later 27 were HP negative and 2 HP positive to Giemsa stain. Comparing the IM and HP positive patients before and after eradication, data analysis by chi-square method shows statistical significance ($P < 0.005$).*Conclusions:* 82.8% patients affected from IM is HP positive. HP eradication allows regression of histological intestinal metaplasia in 30% cases one year after eradication. According to Correa's gastric carcinogenesis model, eradicating HP positive patients with proven IM. could be suggestable. "P PP0 0236"PP0 0236 **Cost-Impact of Clarithromycin Plus Omeprazole Compared to Traditional Therapies for Treatment of *H. Pylori* Associated Duodenal UlcersA. Sonnenberg**

VA Medical Center, Albuquerque, NM USA and The Gastrointestinal Utilization Trial Study Group*Introduction:* The NIH Consensus Development Conference recommended a comprehensive economic analysis of the impact of treating or not treating *H. pylori* (HP) associated ulcers. Patients were enrolled in a multicenter (n = 132), controlled clinical trial to determine cost savings of eradicating HP with clarithromycin plus omeprazole (C + O) versus conventional anti-ulcer therapy (omeprazole (O) or ranitidine (R) alone). *Methods:* Adult patients with HP and active duodenal ulcer were randomized to double-blinded treatment (Rx): 1) C 500 mg TID + O 40 mg QD for 14 days followed by O 20 mg QD for 14 days; 2) O 20 mg QD for 28 days; or 3) R 150 mg BID for 28 days. Visits were performed at pre-Rx (EGD + biopsy), post-Rx (safety), and 4–6 weeks post-Rx (eradication). After the third protocol directed visit, investigators followed patients for one year by monthly telephone calls to assess ulcer symptoms and collect economic data. Additional management was to be ""standard of care"" for that investigational site. *Results:* Of the 819 patients enrolled, 750 patients were eligible (confirmed ulcer and HP infection) for economic analysis. The demographics of the three groups were similar. Analysis of health resource utilization is given in the table below: Resource utilization C + O O R(beyond protocol) (n = 253) (n = 255) (n = 242)EGDs 31 76 69Ulcer related clinic visits 84 136 161Ulcer days lost from work 116 122 787All hospitalizations 26 47 42Ulcer related hospitalizations 0 5 6All hospital days 158 318 205Ulcer hospital days 0 24 37*Conclusion:* Ours is the first prospective study to show that using antibiotics to eradicate *H. pylori* in patients with duodenal ulcer results in decreased utilization of health care resources, overall and ulcer related, when compared to conventional anti-ulcer therapy with omeprazole or ranitidine. "P PP0 0237"PP0 0237 **A Management Plan for Upper Gastrointestinal (GI) Disease in Primary CareJ. Brun, S.A. Brunton, F. Carelli, H. Haslbauer, P. Heyse, H. Maurer, P. O'Connor, W. Peterz, K. R\'fcdy,**

*M.J. Whitaker

International Gastro Primary Care GroupThe International Gastro Primary Care Group (IGPCG) was formed in May 1994 and includes primary care physicians from seven European countries, the USA and Australia. Based on their collective clinical and research experience, they devised a practical guide for the management of upper gastrointestinal (GI) disease.In the absence of alarm symptoms or use of Non Steroidal Anti-inflammatory Drugs (NSAIDs) the IGPCG management plan allocates patients based on predominant symptoms into three subcategories: motility disorder likely (bloating, abdominal discomfort, early satiety, fullness and nausea), ulcer disease likely (localised epigastric pain), gastro-oesophageal reflux disease (GORD) likely (heartburn, regurgitation).For each sub category particular management is recommended. The motility group is treated with a prokinetic. In the ulcer group the Helicobacter pylori (Hp) status is checked: Patients positive for Hp are referred for endoscopy and receive eradication treatment if an ulcer is confirmed. For GORD patients a step-up approach is recommended, starting with a prokinetic or and H2 antagonist. Treatment failures receive proton pump inhibitors (PPIs) or combination therapy or are referred.A pilot project in the form of a survey was set up to test the practical application of the IGPCG upper GI management plan in primary care. The age range was < 20 to over 80 [mean 45 years] and the male/female ratio was close to 50:50. Of the 58 patients included, 25 (44%) were allocated to the motility group, 22 (40%) to the ulcer group and 12 (21%) to the GORD group. Only three patients (5%) could not be placed into a specific group. Overall a satisfactory response was obtained in 34/58 (59%) patients, [21/25 (84%) in the motility group, 9/22 (41%) in the ulcer group and in 5/12 (42%) in the GORD group].The IGPCG protocol postulates the use of predominant symptom in primary care management. This is contrary to symptom clustering which has been shown to be impractical in the management of upper GI disease. However, prospective validation of this plan is required to evaluate its cost-effectiveness. Clinical practice: Management strategy }" "A Management Plan for Upper Gastrointestinal (GI) Disease in Primary Care"

"P PP0 0239"PP0 0239 **Has Spiral Computed Tomography Improved the Staging of Patients with Gastric Carcinoma?**

*J. Davies, A.G. Chalmers, J. May, G.V. Miller, H.M. Sue-Ling, D. Johnston

Centre for Digestive Diseases, Leeds General Infirmary, EnglandMuch controversy exists as to the value of computed tomography (CT) in the pre-operative staging of gastric cancer, due to its limited ability to correctly identify lymph node (LN) metastases, adjacent organ invasion and peritoneal metastases. The third generation of spiral CT scanners has a number of potential advantages including; minimal respiratory misregistration, image reconstruction smaller than scan collimation and optimization of intravenous contrast enhancement.The aim of this study was to assess the sensitivity and specificity of spiral CT, compared with both a formal operative staging and the final pathological (TNM 1987) staging.105 consecutive patients who underwent both spiral CT and operative assessment were reviewed, median age 71 years (range 33–91 years). A single radiologist reviewed all scans which were assessed for LN metastases, adjacent organ invasion and hepatic and peritoneal disease. A similar assessment was made at the time of surgery. Both were then compared with the final histological staging.*Results:* Spiral CT staging Operative staging Sensitivity Specificity Sensitivity SpecificityN1 nodes 24% 100% 94% 63%N2 nodes 43% 100% 84% 74%Mesocolon 76% 95% 94% 95%Pancreatic 50% 99% 100% 98%Hepatic 57% 100% 100% 99%Peritoneal 70% 93% 100% 100%There has been some improvement in spiral CT ability to detect both adjacent organ invasion (mesocolon) and peritoneal disease. Moderate sensitivity with high specificity in detecting spread means that a positive spiral CT result can be relied upon. Spiral CT has the potential to identify those patients who would be suitable for neo-adjuvant chemotherapy before surgery. Oncology, specific: StomachRadiology and ultrasound: Diagnosis }" "Has Spiral Computed Tomography Improved the Staging of Patients with Gastric Carcinoma?"

"P PP0 0240"PP0 0240 **Incidence of Inflammatory Bowel Disease Across Europe: Is There a Difference between North and South?**

*S. Shivananda, EC-IBD study group

University Hospital Maastricht, The Netherlands*Background:* It has been suggested that the incidence of inflammatory bowel disease (IBD), including ulcerative colitis (UC) and Crohn's disease (CD), is higher in the North than in the South of Europe. The aim of this European Collaborative study was to investigate the hypothesis of the North-South gradient.*Methods:* Over 2 years (1 Oct. 1991 to 30 Sept. 1993) all new patients with IBD were identified in 20 European centres according to a standard protocol for case ascertainment and definition.*Findings:* 2201 patients aged 15 years or more were identified, of whom 1379 were diagnosed as UC (including proctitis), 706 as CD and 116 as inderterminate. The overall incidence per 100,000 at ages 15–64 years (standardised for age and sex) of UC was 10.4 (95% confidence interval (CI): 7.6–13.1) and of CD was 5.6 (95% CI: 2.8–8.3). Rates of UC in northern centres were 40% higher than those in the South (rate ratio (RR) = 1.4, 95% CI: 1.2–1.5) and for CD they were 80% higher (RR = 1.8, 95% CI: 1.5–2.1). For UC, the highest incidence was in Iceland (24.5) and for CD, in Maastricht (The Netherlands) (9.2) and Amiens (NW France) (9.2). The lowest incidence of UC was in Almada (S. Portugal) (1.6) and of CD in Loannina (NW Greece) (0.9). An unexpected finding was that in UC the incidence in women but not in men declined with age. The higher incidence rates in northern centres was not explained by differences in tobacco consumption or education.*Conclusions:* The magnitude of the North-South difference for both conditions was less than expected which may reflect recent increases in the incidence of IBD in southern Europe. Nevertheless there are substantial differences in incidence of UC and CD across Europe which are not readily explained by differences in case ascertainment. Intestinal disorders: IBD, basicIntestinal disorders: IBD, etiology and genetics }" "Incidence of Inflammatory Bowel Disease Across Europe: Is There a Difference between North and South?"

"P PP0 0241"PP0 0241 **Inhibition of Cytokine Formation by the Novel Thiol Modulating Agent OR-1384**

*P. Aho, E. Serkkola, K. Haasio, I.-B. Lind\'e9n

Orion Pharma Research, Espoo, FinlandElevated levels of proinflammatory cytokines, (IL-1, IL-8 and TNF-{ a}), have been associated with the pathogenesis of inflammatory bowel disease (IBD). The key regulatory proteins in the signalling cascade leading to the induction of cytokine genes are thiol sensitive. OR-1384 (3-[[4-(methylsulfonyl)phenyl]methylene]-2,4-pentanedione) is a novel thiol modulating agent, which forms reversible adducts with thiol groups. The aim of this study was to evaluate the effect of OR-1384 on the formation of the major proinflammatory cytokines. We also tested the efficacy of OR-1384 in experimental colitis induced by a hapten, TNBS.*Methods:* Isolated human monocytes were used for the *in vitro* cytokine studies. The monocytes were stimulated with lipopoly-saccharide (50 ng/ml) and incubated with different concentrations of OR-1384. IL-1{ b}, TNF-{ a} and IL-8 were measured from the incubation medium by specific ELISAs. Colitis was induced in mice and in rats by a single intracolonic administration (i. col.) of 5 and 15 mg of TNBS, respectively. In rats, 3–30 mg/kg of OR-1384 was administered i. col. once daily for 5 days and in mice 30 mg/kg was given i. col. 24 and 1 h before TNBS. The rats were killed 96 h and the mice 4, 8, 16, 24, 48 or 72 h after the induction of colitis. Colonic inflammation was assessed by macroscopic and histological scorings and by measurement of tissue myeloperoxidase (MPO) activity. In mice, IL-1{ a}, IL-1{ b} and TNF-{ a} were measured in mucosal homogenates of the colon.*Results:* OR-1384 inhibited the formation of IL-1{ b}, TNF-{ a} and IL-8 in human monocytes the IC_{50} values being below 10 \'b5M. In rats, OR-1384 protected against TNBS-induced injuries and decreased the MPO activity significantly and dose-dependently, maximally by more than 70%. In mice, the colonic injuries were visible already 4 h after TNBS, but they were most severe at 48 h. Colonic cytokine levels, IL-1{ a}, IL-1{ b}, and TNF-{ a} were increased several fold reaching the maximum at 16 h. OR-1384 inhibited the formation of these cytokines and protected against the lesions and inflammation.*Conclusion:* OR-1384 was shown to effectively protect against hapten-induced colonic injuries and inflammation. The marked suppression of the key inflammatory mediators IL-1, IL-8 and TNF-{ a} suggests the anti-inflammatory activity of OR-1384 to be cytokine mediated. The locally acting OR-1384 offers a new alternative for the treatment of IBD.

"P PP0 0242"PP0 0242 **Interleukin-8 in Inflammatory Bowel Disease**

*T. Yamaguchi, K. Ina, M. Shinoda, H. Yamamoto, T. Matsuura, A. Imada, T. Hosokawa, M. Ohsuga, K. Kusugami

First Department of Internal Medicine, Nagoya University School of Medicine, Nagoya, Japan*Background and purpose:* Increasing evidence points to various pathogenic roles for cytokines in inflammatory bowel disease (IBD). Interleukin-8 (IL-8) is a major cytokine for recruitment and activation of neutrophils. Neutrophils play a central role in the active stages of IBD. This study aimed to characterize secretion of IL-8 by mucosa in vitro and to visualize its distribution and its positive cell types in the affected intestine of patients with IBD.*Materials and methods:* Biopsies or resected segment were obtained from 12 patients with active Crohn's disease (CD) and 18 with active ulcerative colitis (UC). In 11 patients, macroscopically normal portion was obtained from large bowel resected because of colorectal carcinoma. IL-8 content of organ culture supernatants was determined by enzymed linked immunosorbent assay, and IL-8 gene expression was analyzed by in situ hybridization with IL-8 DNA probes.*Results:* The secretion of IL-8 (ng/mg biopsy protein) in 24 hours from inflamed mucosa of patients with CD (median 135.4, range 52.4–352.4) or UC (median 179.5, range 57.4–385.8) was significantly higher than that from normal mucosa (median 51.9, range 35.3–107.9: $p = 0.0006$ vs. CD, $p = 0.0001$ vs. UC), and correlated with the number of neutrophils infiltrating in the affected intestinal mucosa of IBD ($r = 0.760$). In situ hybridization with IL-8 DNA probes revealed strong signals in the involved mucosa. The number of cells expressing IL-8 mRNA correlated with histological grades of disease activity. Most of IL-8 mRNA producing cells were focally distributed in erosive or ulcerative intestine of patients with CD, whereas they were diffusely distributed over the entire inflamed mucosa in patients with UC. IL-8 mRNA was mainly expressed by macrophages, neutrophils, and epithelial cells in the involved intestine of IBD.*Conclusion:* The results of this study suggest that IL-8 play an important role in the pathogenesis of IBD. The distinct distribution of IL-8 gene in CD and UC may indicate that there exists a difference of inflammatory responses between these two forms of IBD. "P PP0 0243"PP0 0243 **Intestinal Cytotoxic CD4+ TH1-Like Cells in Crohn's DiseaseA. Bachetoni, P. Mariani, M. D'Alessandro, D. Lomanto, P. Mazzocchi, G. Dalsasso, L. Strolighi, V. Speranza**

2\'b0 Cl. Chirurgica, Univ. La Sapienza, Roma, ItalyCytotoxic function of isolated lamina propria T lymphocytes (LP-CTL) in inflammatory conditions is not well established. Our previous results show that LP-CTL, mediated by TCR-CD3, is slightly increased in Crohn's disease (CD). Aim of our study is to evaluate which kind TH subset is involved in inflammatory conditions. We have examined the toxic function and cytokine profile (IFN-{ g}, IL4 and IL5) of CD4+ enriched or CD4{ -} depleted LPL, from terminal ileum of CD pts (n = 10) and controls (n = 10). LPL are isolated using DTT-EDTA-Collagenase digestion followed by discontinuous Percoll density gradients and CD4+ cells were purified by Dynabeads. The cytotoxic activity of freshly isolated LPL is assessed against the NK-resistant B7 P815 cell line; anti-CD3 (5 mcg/ml, TR66), anti-CD2 ($T11_{2,3}$) or PHAp (1 mcg/ml) were added to effector and target cells, ratio of 50:1, and incubated for 6 hrs at 37\'b0C. The results are:

*Contr vs Crohn p = 0.03; \'b0CD4+ vs CD4{ -} p = 0.02The present data unexpectedly indicate that CD4+ have cytotoxic activity and TH1 profile ({ g}-IFN concentration 6 ng/ml). The CD4+ function is significantly arisen from tissues of all Crohn's pts by TCR/CD3 engagement. Furthermore showing that both CD4+ and CD4{ -} mediated lysis are independent from costimulatory signal. Therefore, the present findings could be of interest because they point out the relevance of activated CD4+ subset with an inflammatory function in the pathogenesis of CD. "P PP0 0244"PP0 0244 **High Validity of Transabdominal Bowel Sonography for Detection of Complications in Crohn's Disease**

*C. Gasche, G. Moser, T. Krutt, G. Oberhuber, P. Moeschl

Depts. of Gastroenterology, Pathology and Surgery, Univ. of Vienna, Austria*Aim:* Transmural bowel inflammation with alteration of the echoarchitecture of the bowel wall and luminal narrowing in Crohn's disease (CD) can be located and visualized by transabdominal bowel sonography (TABS). The significance of these findings has been demonstrated in previous studies regarding the diagnosis of CD (Eur J Gastroent Hepatol 1992, 4: 173–182). Since TABS is a noninvasive, radiation-free method that is well tolerated by the patients, repeated investigations can be easily performed during the follow-up. This study was initiated to investigate the validity of TABS in detection of disease specific complications in CD. *Methods:* Between 1994 and 1996 repeated TABS were performed by two investigators (GC, MG) using 3.5 and 7.5 MHz transducers (Ultramark 9, ATL Inc.) in the follow-up of 213 CD patients. In this study all patients who underwent bowel resection were evaluated (n = 25). The presence and location of intraabdominal fistulas, abscesses or bowel obstruction was assessed by TABS and compared with results obtained by surgery and by histopathology. *Results:* Peri-intestinal hypoechoic lesions were considered to be fistulas and with a diameter > 2 cm to be abscesses. Bowel obstruction was defined by luminal narrowing and evidence of prestenotic dilatation. TABS turned out to have a high validity in detection of such complications: In 14/17 patients, fistulisation was correctly detected by TABS (sensitivity 82%). 7/8 patients were identified to have no fistulas (specificity 88%). Intraabdominal abscesses were detected in 6/6 patients (sensitivity 100%) and excluded in 17/19 patients (89% specificity). Intestinal obstruction was detected in 19/19 and excluded in 6/6 patients (sensitivity and specificity 100%). *Conclusion:* TABS is a valid method to detect specific intraabdominal complications in patients with CD. We therefore recommend TABS for monitoring patients with CD. "P PP0 0245"PP0 0245 **Maintenance Therapy May be Discontinued in Ulcerative Colitis Patients in Remission for Over 2 Years with Salicylates**

*S. Ardizzone, V. Imbesi, R. Cerutti[1], S. Desideri, G. Bianchi Porro

Gastrointestinal Unit, ""L. Sacco"" Hospital, Milan, Italy

[1] Bracco S.p.A, Milan, Italy*Aims* To compare the efficacy of a delayed-release 5-ASA (ASACOL) against placebo in patients with ulcerative colitis (UC) in remission and to verify if duration of disease remission affects the relapse rate.*Patients and methods* 112 patients (66 M, mean age 35), with intermittent chronic UC in clinical and endoscopic remission with salicylates for at least one year, were treated in a double-blind, double-dummy, randomized fashion, with 5-ASA (1.2 g/daily) versus placebo (Pl), for a follow-up period of one year. Assuming that a minor duration of remission may be associated to higher relapsing risk, the patients were stratified according to the length of their disease remission, in groups (A) (5-ASA 26, Pl 35, in remission from 12 to 24 months) and (B) (5-ASA 28, Pl 23, in remission over 2 years, median 4 years). Clinical, endoscopic and histologic findings were assessed every 6 months. ""End point"" of the study was considered the finding of clinical and endoscopic relapse. A Kaplan-Meier life table analysis was used to calculate the relapse rate. Cox model was used to identify predictive factors of relapse.*Results* Fifty-four patients were treated with 5-ASA and 58 with Pl. The relapse rate was similar in both groups after 6 months (5-ASA 8/54 (15%), Pl 14/58 (24%), p = 0.15, IC95 0.23 + 0.05), while a statistically significant difference was found after 12 months of therapy (5-ASA 11/54 (20%), Pl 23/58 (40%), p = 0.016 IC95 -0.35–0.02). 5-ASA was significantly more effective than Pl in preventing relapse at 12 months in group A (5-ASA 6/26 (23%), Pl 17/35 (49%), p = 0.037, IC95 { -}0.48–0.02). In contrast, no statistically significant difference was observed between the two treatments, either at 6 months (5-ASA 3/28 (11%, Pl 5/23 (22%), p = 0.24, IC95 0.31 – 0.09) or 12 months (5/28 (18%), Pl 6/23 (26%), p = 0.37, IC95 0.31 – 0.14) of follow up, in group B. Patients in group B are older and have had the disease longer than those in group A. The probability of relapse was independently affected by the 5-ASA treatment and remission duration of disease. In contrast, the relapse rate was not affected by age, sex, age at onset of symptoms, duration of disease, extent of disease, familial aggregation.*Conclusions* This study shows that 5-ASA prophylaxis is really necessary for preventing UC relapses in patients in remission for less than 2 years, and may be discontinued in those with a remission duration longer than 2 years. }" "Maintenance Therapy May be Discontinued in Ulcerative Colitis Patients in Remission for Over 2 Years with Salicylates"

"P PP0 0246"PP0 0246 **Efficacy of 5-ASA Suppositories (Pentasa') 1 g Three Times a Week to Prevent Relapse of Ulcerative Proctitis. A Double Blind, Randomised, Placebo Controlled, Multicentre Trial**

*P. Marteau, J. Crand, M. Foucault, J.C. Rambaud

Gastroenterology Unit, Saint-Lazare Hospital, Paris

Ferring SA, Gentilly, FranceThe efficacy of daily administration of oral or rectal formulations of 5-aminosalicylic acid (5-ASA) in the prevention of recurrence in patients with ulcerative colitis is well established. *Our aim* was to compare the efficacy of 5-ASA suppositories (Pentasa' 1 g, 3 times per week) versus placebo (Pl) to maintain remission in patients with cryptogenetic proctitis. *Subjects and methods:* 95 patients (44 M, 51 F, mean age 41 yr.) with cryptogenetic proctitis were randomised immediately after remission (clinical remission + endoscopy score 0 or 1) to receive for 1 year or till relapse 3 suppositories per week of either 1 g 5-ASA or Pl. Follow up was performed at 1, 3, 6, 9 and 12 months or in case of relapse. The major end point was the finding of relapse. Data were analysed in intention to treat using ANOVA, Chi2 tests and Kaplan-Meier life table analysis. In case of relapse, the patients received blindly 1 sup/d till remission. *Results:* comparable demographic and proctitis severity variables existed between the 2 groups. The figure depicts survival curves for time to relapse (log rank: p = 0.06). A significant reduction of the recurrence risk was observed for the following time intervals: 0–90 d (19% relapse in the 5-ASA group vs 38%, p = 0.035), 0–180 d (29% vs 54%, p = 0.017), 0–270 d (38% vs 60%, p–0.031). The risk of recurrence was not influenced by the endoscopy score at entry. Treatment of relapse was significantly better in the group treated with pentasa' 1 g/d: 61% of the pts had benefit vs. 8% with Pl (p = 0.001).

Adverse events were reported in 12% and 10% of the 5-ASA and placebo group respectively. *Conclusion:* 5-ASA suppositories 1 g 3 times per week are effective for preventing relapses of cryptogenetic proctitis, and well tolerated. Pentasa' 1 g/d is effective in the majority of subjects who relapse with the 3 per week schedule. "P PP0 0247"PP0 0247 **Gut Permeability Test in Subjects with and without Exercise-Induced Gastrointestinal Symptoms**

*M.A. Van Nieuwenhoven[1], B.J. Geerling[2], N.E.P. Deutz[3], F. Brouns[1], R.-J.M. Brummer[2]

[1] Dept. of Human Biology, University of Maastricht, the Netherlands

[2] Dept. of Gastroenterology, University of Maastricht, the Netherlands

[3] Dept. of Surgery, University of Maastricht, the Netherlands*Introduction:* Up to 30% of endurance athletes suffer from gastrointestinal symptoms during physical exercise. Splanchnic blood flow drastically decreases during exercise, and may lead to gut hypoxia or ischemia. The aim of this study was to investigate whether the permeability of the gut changes as a result of strenuous exercise.*Methods:* After an overnight fast, 5 well-trained subjects with exercise-induced intestinal symptoms, and 5 well-trained controls ingested a test solution on 3 different occasions; at rest, during a 90 min. running period on a treadmill at 70% of their previously determined Vmax, and 24 h post-exercise, respectively. The test solution consisted of 10 gram lactulose (L) and 1 gram rhamnose (R) in 65 ml water. Before the solution was ingested, the subjects emptied their bladder. Urine was collected for 5 h, and during this period the subjects were not allowed to eat or drink. The L and R excretion was determined by a validated, sensitive, newly developed fluorescent detection HPLC system. Glucose excretion was determined as well. Data are presented as mean – SEM. Statistical analysis was performed by using a two-way ANOVA (time and group).*Results:* During exercise, both the L and the R recoveries were increased, compared to pre-and post-exercise (L: pre = 0.15 – 0.05%, exc. = 0.21 – 0.04% and post = 0.14 – 0.04%, R: pre = 8.9 – 1.2%, exc. = 12.2 – 1.0%, post = 8.4 – 1.0%). R recovery shows a significant difference ($p = 0.033$) between the three periods. Comparing these periods, no significant difference was found in the L/R ratio. The increase of the R recovery was higher ($p = 0.04$) in subjects with exercise-induced symptoms. This increase was related to urinary glucose excretion ($p = 0.008$).*Conclusion:* Alterations in gut permeability seem not to occur during strenuous exercise on a treadmill in our experiment. Rise in rhamnose recovery coincides with an increased glucose excretion. Whether this observation is related to fluid balance differences in these subjects remains to be established.Supported by grantss of Sandoz Nutrition and the Dutch Olympic Committee Intestinal disorders, absorption: Epithelial transportIntestinal disorders, absorption: Pathophysiology of diarrheaMotility, general: Functional GI disorders }"

"P PP0 0248"PP0 0248 **The Influence of Small Bowel Bacterial Overgrowth in Patients after Total Gastrectomy**

*R. Br\'e4gelmann[1], U. Armbrecht[2], D. Rosemeyer[3], B. Schneider[4], W. Zilly[5], R.W. Stockbr\'fcgger[1]

[1] University Hospital, NL-Maastricht

[2] Bad Kissingen

[3] Bad Driburg

[4] Medizinische Hochschule Hannover

[5] Bad Br\'fcckenau*Purpose:* To elucidate whether small bowel bacterial overgrowth (SBBO) after total gastrectomy influences abdominal symptoms, nutrient assimilation, and/or medico-social functioning. *Methods:* 127 consecutive patients (f = 47, m = 80; mean age 56.9 (95% confidence interval (CI) 55.1 to 58.7) years) after potentially curative total gastrectomy for gastric malignancy 573 days earlier (mean; CI 364 to 782) were evaluated for abdominal symptoms (reflux, dysphagia, dyspepsia, early satiety, vomiting, dumping, meteorism), objective signs of malassimilation (haematological and biochemical values, body mass index, weight loss since operation, calorie intake per kg body weight, bowel habits, faecal mass, faecal fat excretion, fat assimilation), Karnofsk index, and the degree of medico-social functioning (Edinburgh Rehabilitation Status Scale, (ERSS), range 0 to 28, best to worst). Patients without SBBO as assessed with a radiographically controlled H_2-breath test (n = 80) were compared with patients with SBBO (n = 47). *Results:* Mean time since operation was significantly shorter in patients with SBBO (370 days, CI 96 to 645) than in patients without SBBO (687 days, CI 397 to 976) ($p < 0.01$). Controlling for the difference in the time span since operation, there were no significant differences between the subgroups regarding basic parameters, the haematological and biochemical evaluation, the frequency of abdominal symptoms, the bowel habits, the different factors of nutrient assimilation, and the Karnofski index. However, the mean ERSS on admission was significantly lower in patients without SBBO (3.7 (2.2–5.2)) compared in patients with SBBO (5.1 (3.0–7.0)) ($p < 0.05$). *Conclusions:* In 127 patients after total gastrectomy, the frequency of SBBO decreased with time past operation. Although patients without SBBO did not differ from patients with SBBO concerning abdominal symptoms, biochemistry, or nutrient assimilation, medico-social functioning is significantly impaired in the latter. "P PP0 0249"PP0 0249 **B-Cell Primary Gastrointestinal Lymphomas (PGIL) (188 Cases)**

*P. S\'e1nchez-Fayos, J.M. Castrillo, J. S\'e1nchez Fayos, C. Montalban, A. Gonz\'e1lez Guirado, C. Rivas, J.C. Porres

Dept. of Gastroenterology, Fundaci\'f3n Jim\'e9nez D\'edaz, Universidad Aut\'f3noma of Madrid, Spain*Aims.*- To analyse B-PGIL (PGL 143 cases, PIL 45 cases) with the purpose of: 1) differentiate behaviours between themselves and between ""low grade"" (LG) and ""high grade"" (HG) forms and 2) identify prognostic factors.*Methods.*- 1) Records review; 2) histopathological reclassification after immunophenotyping (Isaacson); 3) staging (Ann Arbor/Musshoff); and 4) conventional statistical analysis (X^2, log-rank test, etc.).*Results.*- The significantly more common features in LG PGL (84 cases) were male sex, infiltrative endoscopic/pathologic aspect and localised stages (IE-IIE1) and in HG PGL (51 cases) they were weight loss, vegetative endoscopic/pathologic aspect, serosa invasion and an advanced stage (IIE2-IV). The following were favourable prognostic factors: LG character, localised stages, normal LDH, complete surgical resection (cSR) and achieving a complete remmision (CR). The significantly more common features in LG PIL (20 cases) were a long pre-diagnostic history, diarrhoea/steatorrhoea, finger clubbing, malabsorption, hypoproteinaemia/oedema, multisegment involvement and a nodular radiologic pattern and in HG PIL (25 cases) they were a palpable mass, surgical emergencies, ileo-coecal involvement and a high PC10-positive cell rate. Favourable risk factors were: female sex, normal LDH, unicentric tumour, lowPC10-positive cell rate, use of polychemotherapy (+/{ -} cSR) and achieving a CR.*Conclusions.*- B-PGL and B-PIL show different clinico-pathological features between themselves and when compared with their nodal counterparts. The different behaviour of the LG and HG seems to translate unequal biological entities, nonetheless united by the mixed histology forms (LG/HG) which are more proximal to HG in PGL and to LG in PIL. Finally, in the group with PIL a small patient subgroup was discovered suffering a form of lymphoma which ressembled the so-called ""immunoproliferative small bowel disease"". "P PP0 0250"PP0 0250 **Bone Mineral Density in Adult Coeliac Disease**

*A. Calabr\'f2, M.T. Passaleva, M.L. De Feo[1], O. Tarantino, M.L. Brandi, C. Surrenti

GI Unit, Department of Clinical Pathophysiology, University of Florence, Florence, Italy

[1] Endocrinology Unit, Department of Clinical Pathophysiology, University of Florence, Florence, ItalyThe association between overt coeliac disease (CD) and clinical bone disease has long been recognized. However, evidence is mounting that bone demineralization may occur even in relatively young patients with latent gluten sensitivity. We examined bone mineral density (BMD) and biochemical markers of bone metabolism in a group of otherwise healthy, treated, adult CD patients, and compared these results with those obtained in untreated CD patients. *Subjects and methods:* 36 CD patients (31 F, 5 M) diagnosed in adult life and already established on a gluten free diet participated in the study. The average age of the men was 28.2 yr (range 20–40 yr) and that of the women was 37.9 yr (range 20–74 yr). Thirty-six coeliac patients (30 F, 6 M) who had been recently diagnosed, or who were not receiving a gluten free diet formed the group of newly diagnosed/untreated patients. The average age of the men was 36.5 yr (range 23–65 yr) and that of the women 36.8 yr (range 20–68 yr). BMD of total skeleton was measured by dual energy x-ray absorptiometry (DEXA), and serum and urinary parameters of mineral metabolism (serum and urinary calcium and phosphate, 25-OH vitamin D_3, alkaline phosphatase, PTH, osteocalcin, and urinary deoxypyridinoline) were determined by standard methods. BMD was expressed both in terms of absolute values (g/cm^2) and as the Z-score, calculated from age- and sex-matched control subjects. *Results:* 20 out of 36 (55%) asymptomatic CD patients on a gluten free diet had reduced values of BMD, defined as a Z score < { -} 1 SD; of note, severe osteopenia, defined as a BMD > 2 SD below mean normal values for sex and age, was found in 4 young patients (3 F, 1 M) aged 20–26 yr. Overall, reduced BMD was found in 29 out of 36 (80.5%) newly diagnosed/untreated patients; however, while 23 out of 25 (92%) symptomatic patients presented osteopenia, reduced BMD was found only in 6 of 11 (54%) symptomatic patients. No difference in BMD was found between treated and asymptomatic untreated CD patients. Serum and urinary markers of bone metabolism did not show conclusive abnormalities. *Conclusions:* our findings provides evidence that osteopenia is common in adult CD, even in treated asymptomatic patients, and emphasize the importance of early diagnosis and treatment. Intestinal disorders, absorption: Gluten enteropathy }" "Bone Mineral Density in Adult Coeliac Disease"

"P PP0 0251"PP0 0251 **Evaluation of the Effects of 2 \lquoteSpasmolytic\rquote Agents on Gut Motility Using Prolonged Ambulant Small Bowel Manometry (PSBM)X.Y. Qin, D.F. Evans,**

*D.L. Wingate, S. Allouche[1]

GI Science Research Unit, St. Bart's and the Royal London Medical School, London, UK

[1] Laboratoire Jouveinal, Paris, FranceSmall bowel motility can be evaluated by PSBM during waking and sleeping, during fasting and after food, at rest and under mental or physical stress, and in response to medication; its precision is increased by computer analysis. In the past, PSBM has shown that oral medications do not always have the effects predicted from *in vitro* studies or ""bolust"" i.v. administration. We have previously shown that the \lquoteprokinetic\rquote cisapride does not alter the amplitude and incidence of contractions, and the main action of trimebutine, a gut-selective enkephalinergic agonist, is the preservation of normal motility during exposure to stress.We used PSBM to study the effect of 2 \lquotespasmolytic\rquote medications – alverine citrate 60 mgm and phloroglucinol 80 mgm – on small bowel motility in healthy volunteers. PSBM was carried out twice for 24 hrs in 6 subjects, once with twice daily dosing with one drug, and again with twice daily dosing with the other. After intubation on Day 1 of each study, recording started at mid-day. Subjects were freely ambulant and went home after an evening meal. On Day 2 they were exposed to 2 2-hr periods of mental stressors separated by a 1-hr rest period before extubation. Efficacy of stressors was monitored by serial measurements of heart rate and blood pressure. After computer analysis, motility variables were compared for the 2 drugs against established control values.Stress significantly increased heart rate ($p < 0.001$). Neither agent had any effect on the incidence or amplitude of contractions. No effects of phloroglucinol on any aspect of motor activity were detected. Alverine blocked the effect of stress on migrating motor complexes (MMC) ($p < 0.05$) and on blood pressure ($p < 0.001$); it also blocked ($p = 0.02$) the normal diurnal lengthening of the MMC cycle. These findings are not consistent with an effect of either agent on gut smooth muscle; the effects of alverine are best explained by blockade of the central modulation of gut motility during CNS arousal in waking and under stress. "P PP0 0252"PP0 0252 **Discrimination of Irritable Bowel Syndrome by Nonlinear Analysis of 24 H Jejunal Motility**

*R. Wackerbauer[1], T. Schmidt, A. Pfeiffer, G. Morfill[1], H. Kaess

[1] Max-Planck-Institute for Extraterrestrial Physics, Garching, Germany

Department of Gastroenterology, Hospital Bogenhausen, Munich, Germany*Background:* Conventional analysis of ambulatory long-term manometry of the small intestine has revealed an abnormal result in only 43% of patients with the irritable bowel syndrome (Gastroenterology 1995; 108: A605), mainly during phase 2. The aim was to use methods from nonlinear dynamics to discriminate motility in IBS from healthy subjects.*Methods:* Ambulatory 24 h jejunal motility was obtained with digital data logger and catheter-mounted pressure transducers under standardized caloric intake in 30 diarrhea-predominant IBS patients and 30 controls. The variability and dynamics of the amplitudes of successive phasic contractions during phase 2 was described as a symbolic dynamical system, which means that the dynamics of a system is represented by a sequence of symbols. The sequence was quantified with the entropy, a specific complexity measure, which characterizes the degree of randomness inherent in the time series. For a completely regular process the entropy is 0, for a purely random process the entropy takes the maximum value of 1.*Results:* Phase 2 motility was characterized by two parameters, the mean value of amplitudes and the entropy. In 19 IBS patients (63%), but only 1 control subject (3%), mean amplitudes exceeding 22 mm Hg and entropies greater than 0.976 were found. Lower contraction amplitudes and entropies > 0.976 were present in 17 controls (57%) and 6 IBS patients (20%). Entropies below 0.976, independent of mean contraction amplitudes, were identified in 12 controls (40%) and 5 patients (17%). A diagnostic accuracy of 80% was obtained.*Conclusion:* In diarrhea-predominant IBS, phase 2 contractions exhibit a more random dynamics than in healthy subjects. Symbolic dynamics seems to be a promising new method for the analysis of long-term motility data of the small intestine. Motility, general: Functional GI disordersMotility, specific: Small bowel }" "Discrimination of Irritable Bowel Syndrome by Nonlinear Analysis of 24 H Jejunal Motility"

"P PP0 0253"PP0 0253 **Diagnosing Whipple's Disease in Feces**

*M. Gross, Ch. Jung, W.G. Zoller

Medizinische Poliklinik, University of Munich, GermanyWhipple's disease is caused by the bacteria *Tropheryma whippelii* that still cannot be cultured. The diagnosis is based on the examination of a duodenal biopsy. Part of the bacterial 16S rRNA gene sequence is known. We investigated the possibility to diagnose Whipple's disease non-invasively by analysing bacterial DNA isolated from feces.DNA was extracted from stool of an untreated patient with Whipple's disease and from 18 healthy control subjects. Since the known sequence of *T. whippelii* shows a high homology to other bacteria, we increased both sensitivity and specificity by performing three subsequent PCRs with nested primers: P52: 5{\'a2}-AGA GAT ACG CCC CCC GCA A (position 965 of the TWRG16S sequence in the EMBL GenBank), P53: 5{\'a2}-ATT CGC TCC ACC TTG CGA (position 1214), P54: 5{\'a2}-CCG CAA CGA GCG CAA CCC TC (1046), P55: 5{\'a2}-ACG CGT GAA GCC CAA GAC CG (1163), P56: 5{\'a2}-CGT CCT GTG TTG CCA GCG CG (1065), P57: 5{\'a2}-CCC AAG ACC GAA GGG GCA TG (1153). The annealing temperatures were 55\'b0C (P52-P53), 52\'b0C (P54-P55) and 58\'b0C (P56-P57).After the third PCR, the product was analysed by gel electrophoresis. A single strong band was visible using DNA extracted from the patient's stool and in 10/18 samples from control subjects. Sequencing the PCR product of the patient resulted in the known *T. whippelii* sequence. In control samples superposing sequences were seen representing DNA from various bacteria.This result shows that Whipple's disease can be diagnosed by detection of DNA of *T. whippelii* in the stool. As long as only part of a highly conserved gene of this bacteria is known, the PCR product has to be sequenced to confirm the diagnosis. However, as soon as more specific sequences of the bacteria are known, the diagnosis can be based on PCR with DNA from stool and subsequent specific tests such as restriction analysis or dot blot tests to exclude amplification of DNA of other bacteria. Intestinal disorders, absorption: Malabsorption syndromesImmunology and microbiology: GI infections in adults }" "Diagnosing Whipple's Disease in Feces"

"P PP0 0254"PP0 0254 **Multicenter Double Blind Randomized Placebo Controlled Study to Assess the Effect of Sucralfate in Prevention of Acute Enteric Toxicity Secondary to Pelvic IrradiationA. Valls, I. Pestchen, C. Prats, J. Pera, G. Arag\'f3n, M. Vidarte**

Hospital de l'Esperan\'e7a, Barcelona

Hospital La Fe, Valencia

Instituto Valenciano de Oncolog\'eda, Valencia

Ciutat Sanitaria i Univ. de Bellvitge, Barcelona

Cl\'ednica Puerta de Hierro, Madrid

Hospital Virgen del Rocio, Sevilla1. *Purpose of the study:* To demonstrate the efficacy of Sucralfate in the prevention of the acute enteric toxicity induced by pelvic irradiation with linear accelerator in patients with primary diagnosis of gynaecologic (cervix and endometrium), prostate or urinary bladder neoplasia, compared with placebo.2. *Methods:* 120 patients (without metastasized neoplasia) between 18 and 80 years old, with a Karnofsky index {\'b3} 80% and usual defecation range (3–10 defecations/week) undergoing whole pelvic irradiation, were included. The whole duration of the study was 7 weeks, following weekly controls. The first week all the patients received placebo. In the second week the patients were randomized into two groups: Sucralfate (61 patients, 2 gr/tid p.o. before meals) and placebo (59 patients). The pelvic radiotherapy started in the beginning of the third week after the patient inclusion and lasted until the end of the study. All patients received 45–50 Gy total dose (1.8–2 Gy/day, 5 days/week) with the ""box technique"". The principal variable was percentage of diarrhoeal stools per week. The statistical analysis of the clinical records was carried out by means of a two way analysis of variance with a repeated measurements design over the principal variable between the groups Sucralfate and placebo.3. *Results:* Intention to treat analysis of the main variable studied showed a statistical significance in favour of Sucralfate vs placebo ($p = 0.03$) concerning the evolution of this study variable from the baseline (first week) to the finalization of the pelvic radiotherapy treatment (seventh week). Per protocol analysis also showed a statistical significance in favor of Sucralfate vs placebo group ($p < 0.03$) in this study variable.4. *Conclusion:* Sucralfate is effective in the prevention of acute enteric toxicity induced by pelvic irradiation with linear accelerator compared to placebo. "P PP0 0256"PP0 0256 **Microsatellite Instability in Sporadic Colorectal Carcinomas**

*P. Lage, M. Cravo, C. Albuquerque, I. Claro, A. Suspiro, P. Chaves, P. Fidalgo, C. Nobre Leit\'e3o, F. Costa Mira

Servi\'e7o de Gastrenterologia, Instituto Portugu\'eas de Oncologia, Lisbon, Portugal*Background:* Microsatellite instability (MIN) has been observed in the large majority of tumors from patients with Hereditary Non Polyposis Colorectal Cancer (HNPCC) as well as in 10 to 15% of sporadic colorectal carcinoma (CRC). *Aims:* To evaluate the prevalence of MIN tumors in a series of sporadic CRC as well as to analyse their clinical and pathologic characteristics. *Patients and Methods:* Sixty three patients with sporadic CRC were included in the present study. Mean age was 64 (36–83) years, 36 were male and 27 were female. MIN was detected by evaluating the length of CA repeats sequences at 7 loci: D1S216, D2S118, D3S1611, D5S404, D8S260, D17S783, D22S282. DNA was amplified in a radioactive PCR, the products were run in a 6% polyacrylamide denaturing gel and autoradiography was performed. MIN was defined as the presence of an extra band in one or in the two alleles in DNA from tumor as compared to DNA from normal colonic mucosa. *Results:* MIN in one or more loci was found in 15 (24%) patients, while 7 (11%) patients dysplayed MIN in at least 2 markers. We found that among patients with MIN+ tumors, familial history was more prevalent (33% vs 11%) although not significantly and these tumors were more frequently located on the right side of the colon (P = 0.01). From a pathological point of view, MIN+ tumors were more frequently mucinous (29% vs 17%) and a higher percentage of them presented at an earlier stage (TNM staging stage II: 57% vs 30%). When considering solely patients with right sided neoplasms, the differences were even more striking. Patients with MIN+ tumors were younger (59 – 11.4 vs 70 – 8.5); familial history was found in 50% of the cases as compared to 0% in patients with MIN{ -} tumors. Also, right sided MIN{ -} tumors relapsed in 50% cases but no relapses were detected in those MIN+. *Conclusions:* MIN seems to identify a subset of patients in whom familial history is more prevalent, tumors are more frequently located on the right colon and despite a more aggressive morphology, they seem to have a better prognosis. Mutation analysis of the mismatch repair genes are needed to elucidate whether these patients are part of the HNPCC syndrome.

"P PP0 0259"PP0 0259 **Non Specific Anal and Complex Fistulae: Results of MRI in the Diagnosis and Follow-UpJ.P. Grandjean,**

*L. Henry, O. Daville, O. Tissot, B. Milox, H. Damon, P.J. Valette

Clinique Sainte Marie Th\'e9rése, 1 rue Laborde 69500, Bron, France*Purpose:* to assess the interest of MRI in the surgical management of problematical anal fistulae in ano and in the follow-up of the cases treated by long term seton drainage with two or three stage fistulotomy.*Method:* (1) 24 patients, crohn disease excluded, with recurrent high trans-sphincteric or supra-sphincteric fistula (n = 13) and/or important anal or rectal sclerosis (n = 11) and/or active suppuration (n = 5) were prospectively assessed with MRI before treatment [*pre-op MRI*]. Surgery consisted in excision (n = 24) eventfully completed by fistulotomy and long term seton drainage (n = 14).(2) In the later cases a second MRI [*post-op MRI*] was systematically performed in order to assess the result of the drainage (n = 14).(3) Long term (> 6 months) overall results were obtained in 20 patients (18 month mean follow-up).*Results:* (1) [*pre-op MRI*]: the systematic comparison with surgical findings showed an overall accuracy of 84% for the visualization of internal opening, primary and secondary tracts, and 100% for the detection of horse-shoe fistula tracts (7/7)(2) [*post-op MRI*]: in 5 cases, MRI modified the planed treatment indicating the necessity of a prolonged seton drainage or a new surgical excision by demonstrating the evidence of persistant infection.(3) Long term clinical follow-up showed no evidence of recurrence for 19/20 patients (96%)*Conclusion:* MRI accurately demonstrates the extension of high complex fistulae in ano and is helpfull to assess the healing in cases treated with seton drainage and two or three stage fistulotomy. Therefore it appears to be usefull in the conservative surgical management of fistulae in ano. "P PP0 0260"PP0 0260 **Immunohistochemical Study About the Neuronal Intestinal Dysplasia Type B in Whole Mounts of the Human ColonH.-J. Krammer,**

*F. Krieger, W. Meier-Ruge[1], M.V. Singer

Dept. of Med. IV, Univ. Hosp. of Heidelberg at Mannheim, Germany

[1] Dept. of Pathology, Univ. of Basel, SwitzerlandNeuronal intestinal dysplasia (NID) is well known, but its definition is a topic of debate. The histopathological diagnosis of NID is based on traditional enzyme-histochemical methods such as the acetylcholinesterase and lactate-dehydrogenase reaction on native sections. In this study, we have investigated the enteric nervous system in whole- mount preparations of resected intestinal segments affected by NID of the plexus submucosus (type B). The plexuses of the tunica mucosa and tunica submucosa were visualized by immunohistochemical methods using a polyclonal antibody to protein gene product 9.5 (PGP 9.5). PGP 9.5 is a novel general cytoplasmatic marker specific for the nervous system. The morphology of the plexuses is revealed in full, making possible changes easily discernible. Known pathological findings of the NID can be identified and judged more precisely with this method. Numerous enlarged nerve trunks run within the tunica submucosa and tunica mucosa. Hyperplastic ganglia with an unusually high nerve cell number in the tunica submucosa can be demonstrated as well as heterotopic nerve cells in the tunica mucosa.In the present study is shown that PGP 9.5 immunostaining overcomes many problems observed with other neuronal and glial markers. It has been possible to demonstrate the histopathological features of NID with PGP 9.5 in whole mount preparations.Sponsored by DFG Kr 1257/2-1 Motility, general: InnervationMotility, specific: Colon, anorectum }" "Immunohistochemical Study About the Neuronal Intestinal Dysplasia Type B in Whole Mounts of the Human Colon"

[7] Hospital de la Source, Orl\'e9ans, Saint-Etienne, France

[8] Centre Hospitalier du Havre, Paris, France

[9] Laboratoires Houd\'e9, Paris, France*Introduction:* O.V.S. may result in ulcers which may cause severe bleeding or delay further sclerosant injection. A study was conducted to determine if lansoprazole could prevent ulcers or accelerate their healing.*Methods:* 98 cirrhotic patients with active (n = 74) or recent (n = 24) variceal h&aellig;morrhage and starting an O.V.S. protocol (sessions performed on days 1, 7, 14, 28, 49 and 70 with 10–70 cc of 1% polidocanol) were randomly allocated to lansoprazole 30 mg o.a.d. (gp 1, n = 50) or placebo (gp 2, n = 48) in a double-blind 70-day study. At each session, ulcers severity was assessed by a 1–5 index taking into account height and % of &eolig;sophageal circumference. It was planned to compare the % of patients with at least one ulcer of index {\'b3} 2, D14 being the main endpoint. The biological safety was assessed at each session.*Results:* The two groups were comparable for age, sex, Child's score, % of active bleeding at inclusion and total dose of injected sclerosant at each visit. 39 patients (19 in gp 1 and 20 in gp 2) were withdrawn before D70 mainly due to complications of the underlying disease. % of patients with at least one ulcer of index 2 on D14 were 31.7% (13/41) in gp 1 and 23.1% (9/39) in gp 2 (p = 0.38). At D7 this criteria was: gp 1 = 0% (0/45) vs gp 2 = 14.6% (6/41); p = 0.008. At D28, D49 and D70 no significant difference was found between groups. 12 and 14 severe adverse events were declared in groups 1 and 2 respectively. One of them was related to treatment in each group (2 cases of ulcer bleeding). For each liver and kidney function test, % of patients with a clinically relevant change was similar in the two groups. 6/33 (gp 1) and 3/30 (gp 2) patients had a gastrin level > 2 N at the end of the treatment.*Conclusion:* Anti-secretory treatment is not likely to prevent or accelerate healing of O.V.S.-induced ulcers after the 2nd sclerosis session. In cirrhotics, clinical and biological safety of lansoprazole was excellent. "P PP0 0264"PP0 0264 **Percutaneous Microwave Coagulation Therapy for Liver Cancer**

*T. Seki, T. Nakagawa, M. Wakabayashi, M. Imamura, T. Tamai, A. Nishimura, K. Inoue

The Third Dept. of Internal Medicine Kansai Medical University, Osaka 570, Japan*Aim:* Percutaneous ethanol injection therapy (PEIT) is widely performed as a percutaneous local treatment for liver cancer. It has been reported by many that the effects of PEIT were satisfactory. However, PEIT is occasionally ineffective for intracapsular or extracapsular invasion of cancer cells. In some cases, injected ethanol flows into the vessels around the tumors, instead of causing tumor necrosis. There is therefore a need for a more effective technique to destroying liver cancer.We designed ultrasonically guided percutaneous microwave coagulation therapy (PMCT) as a new method of percutaneous local treatment for liver cancer. In this presentation, we introduce the technique of PMCT and report the effect of PMCT comparing with that of PEIT for liver cancer.*Subjects and Method:* Percutaneous local treatments were performed for the 94 patients having a single liver cancer (tumor size {\'a3} 3 cm) between Ja. 1990 and Ap. 1996. There were 46 patients treated by PMCT alone (Group M) and 48 who were treated by PEIT alone (Group E).The microwave electrode (2.0 mm in thickness, 25 cm in length) was inserted through a guide needle (13G) to be placed in the tumor area which was then irradiated with microwave. PEIT was performed conventionally with a 21G-fine needle. The therapeutic results of these two groups were evaluated on the basis of survival rate, disease free survival rate, pattern of recurrences, and kind of re-treatment for recurrent cases.*Results:* For Group M and E, the 5 yr-survival rates (4 yr-disease free survival rate) were 62% (39%) and 30% (17%), respectively. The recurrent rate of Group M and Group E at treated subsegment area within one year after treatment was 4% (2 cases) and 13% (6 cases), respectively. In recurrent cases of Group M and E, TAE was performed for 3 cases and for 8 cases, respectively.*Conclusion:* Compared with PEIT, PMCT is an effective for liver cancer in producing local necrosis. "P PP0 0265"PP0 0265 **Long Term Ganciclovir Therapy for Hepatitis B Virus Infection after Liver TransplantationB. Roche,**

*D. Samuel, C. F\'e9ray, M. Gigou, M.F. David, M. Reynes, H. Bismuth

Hepato-Biliary and Liver Transplantation Center, Paul Brousse Hospital, Villejuif, FranceHBV infection of liver graft is characterized by a severe outcome leading to graft failure and is associated with high level of HBV replication. It has been suggested that GANCICLOVIR (Roche-Syntex, USA) is active against HBV. We have studied the efficacy of long term IV GANCICLOVIR therapy for HBV infection on liver graft. 17 patients (pts): 12 with HBV reinfection and 5 with de novo HBV infection were studied. HBV DNA was positive in all pts, HBeAg in 8. Pts received IV GANCICLOVIR 10 mg/kg/day for 14 days, 5 mg/kg/day for 30 days then 5 mg/kg 3 to 5 times a week for a mean of 8.6 months (0.5–34). HBsAg and HBV DNA (Digene Hybrid Capture System; Murex, France), were tested for every month. At time of onset of treatment, mean HBV DNA titer was 756 pg/ml (12–2000), liver graft histology showed no specific changes (n = 1), acute hepatitis (n = 5), chronic active hepatitis (n = 8), cirrhosis (n = 3). GANCICLOVIR was well tolerated. During therapy, HBV DNA negativation (complete response (CR)) was observed in 11 pts, decrease of more than 50% of initial HBV DNA values (partial response) in 3 and absence of response in 3. Among the 11 complete responders, 4 pts relapsed under (n = 3) or after (n = 1) therapy. This last pt presented a CR after a second course of GANCICLOVIR. HBsAg clearance occurred in 3 pts. A dramatic clinical improvement was observed in 4 pts. Last histology showed cirrhosis in 6 pts, CAH in 3 and submassive hepatitis in 2 who were retransplanted. One pt died from variceal rupture. Among the 3 partial responders, none died or was retransplanted, last histology showed cirrhosis in 2 and CAH in 1. Among the 3 non responders, 1 was retransplanted for HBV related graft failure and 2 developed chronic active hepatitis.*Conclusion:* GANCICLOVIR is effective to inhibit HBV replication after LT and is well tolerated. Despite HBV DNA negativation and clinical improvement, an histological deterioration may be observed. }" "Long Term Ganciclovir Therapy for Hepatitis B Virus Infection after Liver Transplantation"

"P PP0 0266"PP0 0266 **Prevention of Hepatitis B Reinfection after Liver Transplantation by Post Transplant Long-Term Administration of Ganciclovir IV and Anti-HBs Immunoprophylaxis in Patients at High Risk of Viral RecurrenceB. Roche,**

*D. Samuel, C. F\'e9ray, M. Gigou, J.L. Arulnaden, M.F. David, A. Bismuth, M. Reynes, H. Bismuth

Hepato-Biliary and Liver Transplantation Center, Paul Brousse Hospital, Villejuif, FranceThe risk of HBV recurrence after liver transplantation (LT) is high in patients (pts) with HBV replication despite use of long-term anti-HBs immunoprophylaxis even associated with preLT Interferon (IFN). The aim of this study was, in HBV DNA positive pts, to associate pretransplant antiviral therapy with post-LT long-term administration of anti-HBs immunoglobulins and GANCICLOVIR IV (Roche-Syntex, USA). 9 pts (8 M, 1 F, mean age 45.8 yrs), HBs Ag and HBV DNA positive were included. The initial diagnosis was: HBV recurrence on first graft (4), acquired HBV infection post-transplant (1), HBV cirrhosis (3), and subacute HBV hepatitis (1). Each patient received antiviral therapy prior to LT: ARA AMP then GANCICLOVIR (4), GANCICLOVIR (2), IFN (2), ARA AMP then IFN (1). After LT, all pts received long-term anti-HBs immuno-prophylaxis to achieve anti-HBs Ab titer above 500 IU/l and IV GANCICLOVIR 10 mg/kg/d for 2 weeks then 5 mg/kg 3 times/week for a mean of 11.9 months (3–24). HBsAg was tested every month, HBV DNA (Digene Hybrid Capture System, Murex, France) was detected every 3 months. Pre-LT negativation of HBV DNA occurred in 7/9 pts, a mean of 2.7 months before LT. After LT, recurrent HBV infection was diagnosed in 1 pt at 3 months which leads to cirrhosis on the graft. 8 pts remained HBs Ag and HBV DNA negative – a mean of 20.5 months (11–36) after LT. Graft histology was available in 7 pts at 1 year and was normal. Tissue antigen detection of HBsAg and HBcAg was negative. One pt died at 2 years of carcinoma unrelated to HBV infection.*Conclusion:* This open study demontrates the efficacy of a combination of post-transplant long-term anti-HBs immunoprophylaxis and IV GANCICLOVIR in pts at high risk of HBV recurrence. }" "Prevention of Hepatitis B Reinfection after Liver Transplantation by Post Transplant Long-Term Administration of Ganciclovir IV and Anti-HBs Immunoprophylaxis in Patients at High Risk of Viral Recurre"

"P PP0 0267"PP0 0267 **Hepatitis G Virus Infection in France: Preliminary Epidemiologic Data and Analysis of Viral Tropism**

*N. Agoli, P. Chossegros, P. Berthillon, G. Inchausp\'e9, C. Trepo

INSERM U271, Lyon, France*Goal:* The two main goals of the present study are: 1) to evaluate the prevalence of the newly discovered hepatitis GB virus type C (GBV-C) in different groups of French patients 2) to analyze, in the patient group displaying the highest prevalence, the cellular tropism of GBV-C viruses.*Methods:* Prevalence of infection was assessed by means of RT-PCR-amplification of viral sequences from the NS3 region (nested amplification) using degenerated primers (adapted from Simons et al., Nature Medicine 1995) as well as using non-degenerated primers from the 5{\'a2}non-coding region (single PCR followed by Southern Blot detection). The following samples, obtained from 10 positive patients are being analyzed for the presence of both the positive and negative strand viral RNA: 1) sera, 2) liver biopsies, 3) PBMC (peripheral blood mononuclear cells) 4) T and B cells and 5) monocyte/macrophages. PBMC cellular subpopulations have been purified using specific monoclonal antibodies after immunomagnetic separation. Techniques for the detection of either genomic sequences have been validated, both quantitatively and qualitatively, using synthetic templates.*Results:* NS3-derived GBV-C sequences were detected in 36% (23:64), 21% (4:19), 15% (3:20) and 5% (3:59) of respectively IVDU (all co-infected with hepatitis C virus (HCV)), Hemophiliacs, HCV chronic carriers and non-A, non-E hepatitis patients (all with sustained elevated ALT). Detection of viral sequences using 5{\'a2}NCR-derived primers was less efficient, since only 81% of patients positive using the NS3-based PCR were detected with this assay.*Conclusions:* Prevalence of GBV-C virus appears the highest when associated with parenteral transmission, in particular in HCV-co-infected populations while prevalence of infection is very minor in cases of hepatitis from unknown etiology. Data will be presented on the cellular tropism of GBV-C viruses in the different cell populations indicated above. Clinical practice: Epidemiology (non cancer)Liver and bile ducts, 1: Hepatitis viral, diagnosis }" "Hepatitis G Virus Infection in France: Preliminary Epidemiologic Data and Analysis of Viral Tropism"

"P PP0 0268"PP0 0268 **HGV (GB-C) and HCV Coinfections in French Intravenous Drug Users: Prevalence and Histological Impact**

*V. Thiers[1], S. Pol[3], P. Berthelot[3], B. Nalpas[3], C. Br\'e9chot

[1] Hybridotest, CBMS, Institut Pasteur, 75724 Paris cedex 15, France

[2] Inserm U370, CHU Necker, 75730 Paris cedex 15, France

[3] Hepatology Unit, Necker Hospital Paris FranceWe have analyzed 77 anti-HCV positive intravenous drug users (IVDU) to 1) define on a large series the actual prevalence of HGV (GB-C) coinfections in this population and 2) evaluate the impact of these coinfections on liver biological tests and histology.*Patients and methods:* 77 anti-HCV positive French IVDU (63 males and 14 females), aged 32 – 5 years, including 24 anti-HIV positive. Serum HCV RNA was tested by PCR in 5{\'a2}NCR and HGV (GB-C) RNA was tested by PCR with NS3 (GB-C) and NS5 (HGV) sequences.*Results:HCV:* HCV RNA was detected in 67/77 and HCV typing showed genotypes 1a (22), 1b (9), 3a (16) and 4/5 (15).*HGV (GB-C):* HGV (GB-C) RNA was detected in 16/77 (20.7%), 14 males and 2 women. Four of these 16 were infected by HIV. HGV (GB-C) RNA positive and negative individuals showed similar duration of drug abuse (11.5 and 10.2 years, respectively).There was no significant differences between HGV (GB-C) RNA positive and negative patients for ALAT/AST and GGT levels nor histology Knodell scores (5.1 – 3.2 vs. 5.2 – 3.2) (NS), respectively. Finally HCV genotypes distribution did not differ in the 2 groups.*Conclusions:* Our study 1) demonstrates a high prevalence of HCV/HGV (GB-C) coinfections in French IVDU, whether or not coinfected by HIV1 and 2) shows no evidence for worsening of liver lesions due to these coinfections. Liver and bile ducts, 1: Hepatitis viral, diagnosis }" "HGV (GB-C) and HCV Coinfections in French Intravenous Drug Users: Prevalence and Histological Impact"

"P PP0 0269"PP0 0269 **Is Interferon Alpha Atherogenic?P. Kuder, A. Abergel, P. Jouanel[1], C. Bonny, J. Boulant, C. Henquell[2], H. Brun, H. Lafeuille[2], M. Dapoigny, G. Bommelaer**

Service d'H\'e9patogastroent\'e9rologie, Clermont Ferrand

[1] Laboratoire de Biochimie, Clermont Ferrand

[2] Laboratoire de Virologie, Clermont FerrandInterferon-a (IFN) is the treatment of choice for Chronic Hepatitis C (CHC). Recent report has suggested that serum triglycerides (TG), cholesterol (XOL), cardiac risk indexes (XOL-LDL/XOL-HDL, Apo B/Apo A1) increased during IFN therapy (Malaguarnera M., Hepatology 1995, A50). *Aim:* This study was performed to determine the effect of IFN on serum TG, XOL, XOL-HDL, XOL-LDL, Apo A1 and Apo B in adults with CHC. *Methods:* 33 patients were evaluated (mean age 48 + 2.8 years; 46% were male). All had (+) anti-HCV by third generation antibody assay and RIBA-4, ({ -}) serologies for all other causes of chronic hepatitis, and liver histology compatible with CHC. All patients were treated with 3–6 MU of IFN TIW for six months. The following parameters were determined and monitored using routine laboratory tests before and during treatment (3 to 6 months): Serum XOL, TG, XOL-HDL. XOL-LDL was determined by friedwald's formula; Apo A1 and Apo B using the nephelometric method. The Apo B/Apo A1, XOL-LDL/XOL-HDL ratios were considered. Statistical analysis was conducted using Student's test for paired data. *Results:* Mean serum Apo A1 and HDL decreased from respectively 1.30 – 0.2 g/l to 1.11 – 0.18 g/l ($p < 0.001$) and 1.26 – 0.3 mmol/l to 1.02 – 0.22 mmol/l ($p < 0.001$). No statistical difference was found for serum Apo B, XOL, XOL-LDL. Mean serum TG increased from 1.11 – 0.50 to 1.93 – 2.8 mmol/l ($p = 0.06$ NS). Apo B/Apo A1 and XOL-LDL/XOL-HDL cardiac risk indexes increased respectively from 0.71 – 0.26 to 0.85 – 0.24 ($p < 0.005$) and from 2.63 – 1.1 to 3.1 – 1.1 ($p < 0.005$). *Conclusion:* 1) Serun TG increase and Apo A1 decrease during IFN therapy, the mechanism of which is unknown. 2) Three hypothesis should be explored: A) *inhibition* of endothelial lipolysis by reduction of *lipoprotein-lipase (LPL) activity.* A) an *increase of TG hepatic* synthesis by IFN and/or C) a *decrease of Apo A1 hepatic* synthesis 4) *In the future patients* with basal increase of *cardiac risk index* must be considered *carefully regarding IFN therapy.* Liver and bile ducts, 1: Hepatitis, viral, treatmentNutrition: Metabolism }" "Is Interferon Alpha Atherogenic?"

"P PP0 0272"PP0 0272 **Can Preoperative Variables Predict Symptomatic Outcome after Cholecystectomy?I.B. Andersen, L. Bardram, L. Borly, E. Christensen, H. Kehlet, L. Paloheimo,**

*L. H\'f8jgaard

Department of Surgical Gastroenterology and Clinical Physiology and Nuclear Medicine, Hvidovre Hospital, University of Copenhagen, Denmark

Medical Department B, Bispebjerg Hospital, University of Copenhagen, Denmark

Department of Clinical Biochemistry, Rigshospitalet, University of Copenhagen, DenmarkCholecystectomy for symptomatic gallstone disease results in pain relief in most of the patients, but for 20–30% abdominal pain is present also after the operation, as the so-called postcholecystectomy syndrome.*The aim* of this study was to investigate whether preoperative variables could predict the symptomatic outcome after cholecystectomy.*Methods:* 102 patients were referred to elective cholecystectomy in a two year prospective study. Median age was 45 years, range 20–81. A preoperative questionnaire on pain, symptoms, history etc. was completed, and the questions on pain and symptoms were repeated postoperatively after 6 weeks and one year. Preoperative cholescintigraphy and sonography evaluated gallbladder motility, gallstones and gallbladder volume. CCK-profile was measured after meal stimulation. Bile, gallbladder and stones were analysed after the operation. Preoperative variables in patients with or without pain were compared statistically and significant variables were combined in a logistic regression model to predict the postoperative outcome.*Results:* 80 patients completed all questionnaires. Of the 80 patients 21 had abdominal pain after the operation, whereas 59 had no pain postoperatively. Patients with pain one year after cholecystectomy were characterized by preoperative presence of a high dyspepsia score, ""irritating"" abdominal pain and an introvert personality. Further by absence of ""agonizing"" pain and absence of symptoms coinciding with pain. $\{ ?\}^2 = 47$, d.f. 5, $p < 0.000001$. Of 18 patients predicted as having postoperative pain, 15 had this (PVpos = 0.83). Of 62 patients predicted as having no pain postoperatively, 56 had this (PVneg = 0.90). Overall 88.7% of the patients were classified correctly according to this reclassification.*Conclusion:* In this prospective study on postoperative outcome after cholecystectomy preoperative symptoms were able to predict abdominal pain after cholecystectomy. Since reclassification gives too optimistic results, the model should be validated in independent patients. }" "Can Preoperative Variables Predict Symptomatic Outcome after Cholecystectomy?"

"P PP0 0274"PP0 0274 **A New Multimodal Therapy to Extend the Resectability of Advanced Klatskin-Tumors**

*R.E. Hintze, A. Adler, W. Veltzke, T. Vogl, J. Balzer, J. Dette, R. Felix, P. Neuhaus

Depts. of Gastroenterology, Central Interdisciplinary Endoscopy and Surgery, Virchow-Klinikum, Humboldt-University of Berlin, Germany*Therapeutic concept and aim of the study:* 1. Endoscopic decompression of the tumorfree lobe of the liver by internal drainage. 2. Embolisation of the tumor-invaded lobe of the liver for its degeneration and at the same time compensatory hyperplasia of the tumorfree part of the liver. 3. Hemihepatectomy of the embolised part of the liver. *Material and Methods:* In this prospective randomised study 12 patients with primary inoperable Klatskin-tumors of the classification III of Bismuth were included. The mean age of the patients was 61 years, 4 male, 8 female. In 6 patients initially due to a filiforme tumorstenosis on both sides with obstructive jaundice an endoscopic decompression of tumorfree parts of the liver by endoscopic drainage was indicated. In all 12 patients preoperatively an embolisation was performed. 4 to 12 coils with a diameter up to 5 mm with a length of 35 to 55 mm were used. Pre- and post embolisation the volume of the whole liver and of the left lobe of the liver was measured with spiral computed tomography. *Results:* In 6 out of 12 patients existed a highgrade obstructive jaundice due to tumorgrowth. As first step of therapy in these patients an internal drainage in tumorfree areas of the liver lobe contralateral to the lobe with the main tumor mass could be placed successfully. In those as well as the 6 without obstructive jaundice an embolisation of the liver lobe with the main tumor mass was performed, thereof 11{\'b4} arterial, 1{\'b4} venous via portal vein. 11 of the 12 patients in the mean after 44 days (min 27 – max 75 days) underwent abdominal surgery: 9 patients could be hemihepatectomised after embolisation. Volumetric follow-up observations with imaging techniques showed in the following weeks a reduction of the tumor infiltrated liver lobe of 10% (min 2 – max 33%) and an augmentation of the drained resp. tumorfree liver lobe of 37% (min 11 – max 68%). *Conclusions:* The first results of our study demonstrate that primary technical inoperable Klatskin-tumors can be changed to a status for resective surgery. This is possible by preoperative decompression of the lobe that will be preservated and embolisation of the contralateral tumor invaded liver lobe that will be resected. Clinical practice: Management strategyOncology, specific: Liver, biliaryEndoscopy, specific: Biliary }" "A New Multimodal Therapy to Extend the Resectability of Advanced Klatskin-Tumors"

"P PP0 0277"PP0 0277 **Transforming Growth Factor { b}1 (TGF{ b}1) and Epidermal Growth Factor (EGF) in Caerulein-Induced Pancreatitis in Rat**

*P.C. Konturek, A. Dembinski[1], Z. Warzecha[1], S.J. Konturek[1], E.G. Hahn

Dept. Med I, Univ Erlangen, Germany

[1] Inst. Physiol. Jagiell. Univ. Med. Sch. Krakow, Poland*Background:* TGF{ b}1 is considered as the multifunctional cytokine which modulates the expression of several constituents of extracellular matrix (ECM) resulting in the formation of fibrosis and tissue repair. EGF was shown to promote cellular growth and the regeneration of pancreatic tissue but the influence of TGF{ b}1 and EGF on the course of acute pancreatitis has not been studied. In the present study we investigated the changes TGF{ b}1 and EGF gene expression as well DNA synthesis, pancreatic blood flow (PBF), protein content and plasma amylase concentration in the course of hormonally induced acute pancreatitis. *Methods:* Wistar rats weighing 200–250 g were infused with supramaximal dose of cearulein (10 mg/kg/h s.c.) for 5 h to induce pancreatitis. Rats infused with saline served as a control. Animals were killed at 1, 2, 3, 4 and 5 h after the start of infusion. The PBF was measured using laser Doppler flowmeter and blood was collected to determine serum amylase concentration. The pancreatic tissue was removed and biopsy samples were taken for measurement of the protein content, DNA synthesis (by incorporation of ^{3}H thymidine) and histological assessment of pancreatitis. Expression of TGF{ b}1 and EGF mRNA was studied by reverse-transcriptase polymerase chain reaction (RT-PCR) and assessed semiquantitatively as undetectable ({ -}), minimally expressed (+) or strongly expressed (++). *Results:* Caerulein infused at 1, 2, 3, 4 and 5 h caused a time-dependent decrease in DNA synthesis as compared to vehicle-controls, by 11%, 15%, 45%, 49%, and 54%, respectively. This was accompanied by gradual decrease of PBF by 29%, 36%, 43%, 50%, and by 54% respectively, and a significant increase in pancreatic weight reaching after 3–5 h, 157%, 163% and 173% of control value, respectively. The protein content and plasma amylase concentration showed progressive increase with the peak achieved after 5 h of cerulein infusion. Histology revealed oedema of pancreatic tissue, strong cell vacuolisation and prominent leukocyte infiltration starting after 3 of cearuleuin infusion. Following the development of pancreatitis, TGF{ b}1 mRNA was strongly expressed at each time interval beginning from the 1 h after the start of cerulein infusion. By contrast, EGF mRNA was first detected at 5 h after induction of pancreatitis. *Conclusions:* 1) During the development of pancreatitis is observed an inhibition of pancreatic tissue growth and PBF accompanied by enhanced expression of TGF{ b}1. 2) The expression of EGF at the end of the pancreatitis development may indicate the initiation of pancreatic repair. 3) TGF{ b}1 seems to leed to sequential induction of EGF that stimulates the regeneration of injured pancreas. "P PP0 0278"PP0 0278 **The Role of TGF-{ b}1 and IL-6 in Pancreas Regeneration**

*T. Tak\'e1cs, Gy. Farkas Jr., Y. M\'e1ndy[1], K. J\'e1rmay, J. Lonovics

First Department of Medicine, Albert Szent-Gy\'f6rgyi Medical University, Szeged, Hungary

[1] Department of Microbiology, Albert Szent-Gy\'f6rgyi Medical University, Szeged, HungarySome reports suggest that low doses of cholecystokinin octapeptide (CCK-8) promote the regeneration of the pancreas. We aimed to investigate whether changes occur in the serum TGF-{ b}1 and IL-6 levels during the regeneration, and whether there is a connection between their levels and the rate of regeneration in rats. *Methods.* Distal pancreas resection (75%) was performed. CCK-8 was administered subcutaneously in a dose of 250 ng/kg 3 times per day to the investigated group, while the control animals received the same amount of saline. The rats were examined 3, 7, 14 and 28 days after the first injection. Serum TGF-{ b}1 levels were determined by ELISA, IL-6 levels by bioassay, DNA content by Giles & Meyers method. *Results.* The weights of the residual pancreas were increased in both groups on day 3. At subsequent times the weights decreased in the controls but increased continuously in the CCK-8-treated group. There was significant difference between the two groups on day 14. The pancreas weight almost doubled in the CCK-8 group, whereas it decreased to the normal level in the controls on day 28. The DNA contents of the pancreas were higher in the treated than in the control group, but the difference proved to be significant only on day 28 (1800 – 350 vs. 780 – 240 { g}/pancreas). The protein content reached its highest level on day 28 in the CCK-8-treated group, but the levels did not differ significantly to those of controls. A significantly higher level of IL-6 was measured on day 7 vs. the control (250 – 70 vs. 50 – 30 pg/ml). Significantly different TGF-{ b}1 levels were measured in the treated group on day 7 and 14 (290 – 40 vs. 275 – 10 vs. 180 – 65 ng/ml, respectively). Both cytokines returned to the normal level by day 28. No significant changes in the amylase levels were observed; they remained at a normal level (4.8 – 0.8 U/ml). This indicates that the increase in the pancreas weight was not caused by pancreatitis. *Conclusion.* Our results reveal that regular low dose of CCK-8 resulted in pancreas regeneration following 75% distal resection. This was indicated by increases in the pancreas weight, and in the DNA and protein contents of the pancreas. Significantly elevated serum TGF-{ b}1 and IL-6 levels were also detected up to day 14. These data suggest that TGF-{ b}1 and IL-6 might play a stimulatory effect in the process of pancreas regeneration.This work was supported by grants from the National Scientific Research Fund (T-017235) and the Ministry of Social Welfare 609/1993/02. "P PP0 0282"PP0 0282 **RET Proto-Oncogene and Endothelin B Receptor (EDNRB) Gene Mutation in Hirschsprung Disease**

*R. Salomon, J. Amiel, T. Atti\'e9, A. Munnich, S. Lyonnet, C. Ricour, Nihoul C. F\'e9k\'e9t\'e9

Hospital des Enfants Malades, 149 rue de Sévres 75743 Paris C\'e9dex 15Hirschsprung disease (HSCR) is a common congenital malformation, regarded as a multigenic neurocristopathy. Two susceptibility loci have been identified in HSCR namely the *RET* proto-oncogene and the endothelin B receptor (*EDNRB*) gene. We have studied the prevalence of the *RET* and *EDNRB* mutations in a large series of HSCR patients.The mutations were detected by a combination of denaturing gradient gel electrophoresis (DGGE) and single strand conformation polymorphism (SSCP), after extraction of the DNA from blood samples.Mutant genotypes at the *RET* locus were identified in 50% of the familial forms as compared to 17% in sporadic cases, with a large proportion of *de novo* mutations. Regarding the length of the aganglionic segment, we found no phenotype-genotype correlation. Finally the penetrance of *RET* mutant alleles in familial HSCR was significantly higher in males (72%) than in females (51%).On the other hand, homozygous mutations of the *EDNRB* gene have been identified in consanguineous HSCR families presenting with other malformations of neural-crest derived cells (Shah-Waardenburg syndrome). In our series, we have identified heterozygous *EDNRB* mutations in only 4 isolated HSCR patients.Thus, genetic heterogeneity of HSCR is confirmed by the presence of mutations on *RET* and *EDNRB* gene, with a higher frequency for *RET* mutants. However, the mutations of *RET* and *EDNRB* account for a minority of the patients studied.While mutations in the non coding regions of *RET* and *EDNRB* have not yet been studied, our data suggest that other genes are involved in HSCR. "P PP0 0283"PP0 0283 **Overexpression of ICAM-1, VCAM-1 and ELAM-1 in Colorectal Carcinomas**

*Ch.A. Maurer, H. Friess, B. Kretschmann, M. Schilling, J. Deflorin, M. Korc[1], A. Zimmermann, M.W. B\'fcchler

Dept. of Visceral and Transplantation Surgery and Institute of Pathology, University of Berne, Switzerland

[1] Dept. of Medicine and Biological Chemistry, University of California, Irvine, USA*Purpose of the Study:* The pathogenesis of colorectal cancer and the mechanisms which contribute to metastases are still poorly understood. Adhesion molecules are cell-surface-bound glycoproteins which are important in cell-to-cell attachment. Changes in the expression of adhesion molecules may increase the risk for local invasion and hematogenic metastases of colonic cancer cells.*Patients and Methods:* Cancerous tissue samples were obtained from 5 female and 19 male patients with a mean age of 67 years (range 46–84 years) undergoing colonic resection due to carcinoma of the colon or rectum. Tumors were classified according to the TNM-system (UICC): 5 stage I, 10 stage II, 1 stage III and 8 stage IV. Normal colonic tissues from the same patients served as controls. Tissues destined for RNA extraction were frozen in liquid nitrogen immediately upon surgical removal. In addition, freshly removed tissue samples were fixed in Bouin solution and paraffin embedded for histological analysis. Expression of ICAM-1, VCAM-1 and ELAM-1 was analyzed by Northern blot analysis using specific cRNA probes. In addition, immunhistochemical analysis using specific monoclonal antibodies was performed.*Results:* By Northern blot analysis ICAM-1, VCAM-1 and ELAM-1 mRNA were increased in 16/24 (67%), 12/21 (57%) and 15/24 (63%) carcinomas, respectively in comparison with the normal tissue samples. Densitometric analysis of the Northern blots revealed a 2.1-fold increase of ICAM-1 ($p < 0.006$), a 3.4-fold increase of VCAM-1 ($p < 0.02$) and a 2.2-fold increase of ELAM-1 ($p < 0.002$) in cancerous tissues compared to controls. Linear regression analysis showed co-expression between ICAM-1 and VCAM-1 ($r = 0.8$) and ICAM-1 and ELAM-1 ($r = 0.7$). Immunhistochemical analysis revealed enhanced ICAM-1-, VCAM-1- and ELAM-1-immunoreactivity in endothelial cells of cancer blood vessels. Furthermore, the intercellular matrix of cancer samples exhibited more intense ICAM-1-immunostaining than the stroma of controls.*Conclusion:* Our findings suggest a role of adhesion molecules in tumor pathogenesis and disease progression. The overexpression of these factors might increase the ability of colonic cancer cells to attach in blood vessels and distant organs and thereby contribute to tumor invasion and metastasis. [3] Dept. of Medicine, Columbia University, New York, NY

[4] Dept. of Epidemiology, Columbia University, New York, NY

[5] Div. of Medicine, St. Luke's-Roosevelt Hospital Center, Columbia University, New York, NYCyclin D1 is a cell cycle regulator essential for G1 phase progression. Our laboratory has shown that: a. Cyclin D1 is amplified in about 30% of esophageal squamous cell carcinomas, b. A cyclin D1 antisense construct introduced into human esophageal and colon cancer cell lines reduced their tumorigenesis. To further determine the importance of cyclin D1 in gastrointestinal carcinogenesis cyclin D1 expression was determined from nuclear immunoreactivity in 719 samples. Organ Normal Inflammation Adenoma CarcinomaEsophagus 0/94[@] 0/39 31/69 (46)* 26/37 (67)[#]Stomach 0/87 0/32 – 16/33 (48)Small bowel 0/61 – 10/28 (36) 14/31 (45)Large bowel 0/88 – 12/35 (34) 8/27 (30)Pancreas 0/35 0/15 – 6/17 (35)[@]Number of positive/total (%), *Barrett's esophagus, [#]Both squamous and adenocarcinomas.Cyclin D1 immunoreactivity was not seen in hyperplastic polyps nor in inflammatory tissues and did not correlate with the mitotic index; implying that cyclin D1 expression is not merely a marker of increased proliferation. Cytoplasmic immunostaining was seen in about 25% of the tissues, sometimes without nuclear staining, possibly representing a novel role of cyclin D1. Increased expression was associated with advanced age, well differentiated tumors and smoking status. Cyclin D1 overexpression was found in 70% of the intestinal type of gastric cancers and only 8% of the diffuse type. it was also significantly higher in the left colon then the right colon (48% and 11% respectively).We conclude that increased nuclear expression of cyclin D1 occurs in many gastrointestinal tumors; as an early event during the multistage process of carcinogenesis since it was also seen in adenomatous polyps and Barrett's esophagus. Increased expression of cyclin D1 may perturb cell cycle control and thereby enhance tumor progression. These findings suggest that cyclin D1 may be a useful target in cancer therapy. Oncology, general: Molecular biology, geneticsOncology, general: Proliferation, carcinogenesis }" "Overexpression of Cyclin D1 is a Common, Important and Early Event in Gastrointestinal Tumorigenesis Process"

"P PP0 0285"PP0 0285 **Increased Retinoblastoma Protein (pRb) Expression Occurs Throughout the Adeno-Carcinoma Sequence in the Colon, and is Associated with, but does Not Parallel Increased Proliferation**

*H. Lemass, E. Ryan, P. MacMathuna, J. Crowe, J.C. O'Keane

Departments of Gastroenterology & Pathology, Mater Hospital, DublinIn colonic mucosa, as in other normal tissues, pRb expression in G0 and G1 is believed to mediate growth inhibition. In tumors, deregulation is typically associated with a decrease in pRb expression. In colorectal carcinomal (CRC) pRb expression is increased. We investigated the hypothesis that pre-invasive adenoma epithelium is associated with increased pRb expression, thus confirming increased pRb expression as a feature of the entire adenoma-carcinoma sequence in CRC.To evaluate pRb expression in colorectal adenomas and correlate this with proliferation.Normal colorectal mucosa, 11 hyperplastic polyps, 52 adenomas (31 low grade dysplasia (LGD), 21 high grade dysplasia (HGD), (30 tubular, 22 villous)) were immunostained using monoclonal antibodies to pRb and PCNA, by standard immunoperoxidase techniques.In normal mucosa, pRb and PCNA expression is confined to the proliferative compartments of colonic crypts (< 10% cells staining). In hyperplastic polyps 10/11 (91%) showed < 10% pRb expression in a pattern resembling that seen in normal crypts. 45/52 (87%) of adenomas showed increased pRb expression throughout the epithelium, (mean 45, { s} 25, range 10–90%). 32–52 (62%) of adenomas showed increased PCNA expression throughout the epithelium, (mean 50, { s} 22 range 10–90%). In individual adenomas, pRb expression did not correlate with increased PCNA expression and discordant percentage of expression was seen in 46/52 (89%) cases. Increased pRb expression does correlate with the grade of dysplasia, but does not correlate with growth patterns.Increased pRb expression (1) occurs in the earliest stages and throughout the adenoma-carcinoma sequence in CRC from tubular adenomas to large villous adenomas; (2) is not a feature of hyperplastic polyps; (3) shows increased pRb expression in HGD compared with LGD; (4) is associated with, but does not parallel increased proliferation. Oncology, general: Molecular biology, geneticsOncology, general: Proliferation, carcinogenesis }" "Increased Retinoblastoma Protein (pRb) Expression Occurs Throughout the Adeno-Carcinoma Sequence in the Colon, and is Associated with, but does Not Parallel Increased Proliferation"

"P PP0 0286"PP0 0286 **Deregulated Apoptosis Contributes to the Developments of Human Colon Cancer**

*K.B. Hahm, H. Yim, S.J. Hong, K.J. Lee, J.H. Kim, S.W. Cho, J.K. Youn[1]

Dept. of Gastroenerol. Pathol., Ajou University School of Medicine, Suwon, Korea

[1] Dept. of Anat. Pathol., Ajou Inst. for Medical Science, Ajou University School of Medicine, Suwon, KoreaIt has been shown that cells of the luminal surface epithelium exhibit fragmentation of their DNA, suggesting that programmed cell death, apoptosis, is involved in the superficial loss of intestinal cells. Normal tissue homeostasis requires the physiologic deletion of cells by activation of apoptosis. Inhibition of apoptosis by the deregulation of certain oncogenes results in clonal expansion. The progressive accumulation of genetic alterations (e.g., APC, p53, DCC, MCC, and Ras) governs the transition of normal colorectal epithelium to adenoma or carcinoma. This study was designed to know the contribution of apoptosis mechanism in preventing the accumulation of abnormal, deranged cells in colon carcinogenesis. Apoptotic cells were detected *in situ* by TdT-mediated biotin-dUTP nick end-lebelling (TUNEL) in histopathological section of colorectal tissue. Immunohistochemical analysis of bcl-2 protein expression was done in nomal colonic mucosa, colonic polyp, and colorectal carcinoma. The sections were incubated with monoclonal mouse antihuman Bcl-2 (DAKO 124, USA). Western analysis of bcl-2 and p53 proteins were also performed using bcl-2 Ab and p53 (Transduction Laboratories, USA). Detection of genomic fragmentation by TUNEL resulted in an intense nuclear staining of apoptotic cells and apoptotic bodies. Distinct patterns of apoptotic cell death emerged in normal mucosa mostly, whereas rarely in some polyps and colon cancers. Bcl-2 expressions were more prominent in homogenates of colon cancer as compared to nomal colonic mucosa. the expressions of bcl-2 in colonic polyp were intermediate between normal and colon cancer. Immunohistochemical staining of bcl-2 showed intense increment in the whole layer of colonic tumors whereas positive staining was noted in the base of normal colonic crypts. It seems to be that progressive inhibition of apoptosis will relate to the development of colorectal cancer by the accumulation of abnormal and mutated cells. Oncology, general: Proliferation, carcinogenesis }" "Deregulated Apoptosis Contributes to the Developments of Human Colon Cancer"

"P PP0 0287"PP0 0287 ***In Vivo* Imaging of Liver-Directed Gene Transfer of Human LDL-Receptor in the Rabbit Model of LDL-Receptor Deficiency**

*H.H.-J. Schmidt, W. Burchert, G. Cichon, C. B\'fcttner, M. Dogar, P. Gielow, A. Schneider, K. B\'f6ker, C. Olbricht, M. Strauss, M.P. Manns

Depts. of Gastroenterology and Hepatology, Nuclear Medicine, and Nephrology, Medizinische Hochschule Hannover, D-30623 Hannover, Germany

Dept. of Molecular Medicine, Max-Planck-Institute, D-13125 Berlin, GermanyFamilial hypercholesterolemia (FH) is associated with early death due to myocardial infarction. The underlying defect is the deficiency of the LDL-receptor, which is primarily found within the liver. Therefore FH is an excellent model for developing liver-directed gene therapy strategies. To monitor the gene transfer of the LDL-receptor, we developed an external *in vivo* scanning technique. Gene transfer was performed using Adenovirus containing the human CMV promoter and the human LDL-receptor. Adenovirus containing { b}-galactosidase served as the negative control. The low density lipoprotein (LDL) fraction was isolated from human, radiolabelled with Indium, and injected into Watanabe Heritable Hyperlipidemic rabbits (the animal model of FH). Scans were obtained at different time points before and after gene transfer (human LDL-receptor versus { b}-galactosidase). The increased uptake of human LDL after transfer of the human LDL-receptor was easily detectable with our scans. We confirmed the successful gene transfer by measuring total cholesterol in plasma and performing human LDL turnover studies before and after gene transfer. In addition we were able to confirm the specific uptake of LDL by hepatocytes in contrast to non-parenchymal liver cells using cell separation techniques. *In conclusion,* we have developed an extremely sensitive external imaging technique to monitor the gene transfer of the LDL-receptor in the animal model of FH. This powerful method may also be used in humans to monitor cell membrane receptor mediated gene transfer. In addition it may serve as a new diagnostic tool to detect LDL-receptor deficiency in human. First Dept. of Surg., Nippon Medical School, Tokyo, Japan

[1] 2nd Dept. of Pathol., Nippon Medical School, Tokyo, JapanColorectal neuroendocrine carcinoma (NEC) is unusual and its biological behavior is still unclear. This tumor has clinically aggressive characteristics and its prognosis is poor. At the 4th UEGW (1995), we have reported the establishment of human rectal adenocarcinoid in nude mice xenograft. Here we examined the effect of a somatostatin analog, octreotide acetate (OA), and 5-fluorouracil (5-FU) on the growth of this tumor.*Materials and Method:* Tumors of a 3 mm cube were implanted bilaterally into the flank of nude mice. Mice were randomly divided into 4 groups (n = 10 mice/group) and agents were intraperitoneally administered for 2 weeks as followed; group 1: saline, group 2: OA (300 \'b5g/kg), group 3:5-Fu (10 mg/kg), group 4:OA + 5-Fu (OA 300 \'b5g/kg + 5-Fu 10 mg/kg). The bodyweight of mice and tumor size were measured weekly.*Results:* 1) Both OA and 5-Fu, administered as single agents, inhibited the tumor growth compared with control group, and 5-Fu was more effective than OA; however, after stopped administration of these agents, tumors had grown as well as the control group. 2) OA and 5-Fu treated in combination, most significantly inhibited tumor growth, and inhibition continued to the time of killing. 3) There were no difference in body weight of mice between the experimental groups and control group.*Conclusion:* OA and 5-Fu inhibited growth of NEC in nude mice. This tumor will be a useful experimental model to elucidate the biological behavior of human NEC and further study of various therapeutic agents on this tumor is important. Oncology, general: TherapyOncology, specific: Colon, rectum }" "Effect of Octreotide Acetate and 5-Fluorouracil on the Human Rectal Neuroendocrine Carcinoma (Adenocarcinoid) Xenograft in Nude Mice"

"P PP0 0289"PP0 0289 **Importance of the Cystic Fibrosis Transmembrane Conductance Regulator (CFTR) in Duodenal Secretion**

*D.L. Hogan, D.L. Crombie[1], J.I. Isenberg[2], P. Svendsen[1], O.B. Schaffalitzky de Muckadell[1], M.A. Ainsworth[1]

[1] Dept. of Gastroenterology, Odense University, Denmark

[2] Dept. of Gastroenterology, UC San Diego Medical Center, CA, USASurface epithelial bicarbonate is an important factor in preventing acid-peptic injury, as well as facilitating pancreatic enzyme function. HCO_3{ ¯} is likely transported with Cl{ ¯} by CFTR. However, the role of CFTR in duodenal secretion has been ignored. Thus, our aims were to determine if CFTR regulates basal and acid-stimulated HCO_3{ ¯} transport, as well as cAMP- and Ca^{2+}-mediated secretion. The cystic fibrosis (CF) murine model (*cftr*^{m1UNC}) was used with genotyping confirmed by PCR. Normal littermates (25–46 d, 17 – 3 g) were compared to CF [CFTR ({ -}/{ -})] mice (22–39 d, 13 – 3 g). Anesthesia was induced and maintained with hypnorm/midazolam (i.p.); animals (37\'b0C) were hydrated with saline. The proximal duodenum (4–7 mm) was canulated and perfused with 154 mM NaCl (0.17 ml/min). Stimulation was accomplished with either intrasegmental perfusion of HCl (10 mM, 5 min), PGE_2 (10{ ¯6}–10{ ¯4} M), forskolin (10{ ¯6}–10{ ¯4} M), carbachol (10{ ¯6}–10{ ¯3} M), or VIP (5 pmol/g, i.p.) to activate either cAMP- or Ca^{2+}-stimulated secretion; N {\'b3} 4 for each series. [HCO_3{ ¯}] was measured by a validated micro-back titration method. Initial studies demonstrated that animals could be maintained under these conditions for > 3 h (stable basal HCO_3{ ¯} secretion, respiration rate, plasma [HCO_3{ ¯}]). Basal HCO_3{ ¯} secretion was diminished significantly (P < 0.001) in CFTR ({ -}/{ -}) vs. normal, 2.8 – 1.1 vs. 5.1 – 1.6 \'b5mol/cm-h. Moreover, in CFTR ({ -}/{ -}), HCO_3{ ¯} secretion was significantly (P < 0.01) impaired in response to all secretagogues (Figs). Furthermore, normal littermates demonstrated net fluid secretion during basal which increased in response to stimulation, whereas CFTR ({ -}/{ -}) expressed net absorption (P < 0.05 vs. normal) and was largely unresponsive to agonists. We conclude that CFTR plays a key role in regulating epithelial bicarbonate transport, as well as duodenal secretion, processes likely mediated by cAMP.

"P P 12 0290"P 12 0290**Pantoprazole Versus Famotidine in the Treatment of Acute Duodenal Ulcer Disease**

*E.G. Hahn, H.G. Dammann, G. Adler, M. Schlander

Erlangen, Hamburg, Ulm and Konstanz, Germany*Objective:* Pantoprazole is a new, precise proton pump inhibitor. It was the aim of the present clinical study was to compare the efficacy and tolerability of pantoprazole (40 mg) and famotidine (40 mg) in outpatients with acute duodenal ulcer under the conditions of routine gastroenterological practice.*Methods and patients:* Open, 2:1 randomized, controlled, multicenter study. 456 Outpatients with acute and uncomplicated duodenal ulcer (diameter 3–20 mm) were recruited by 72 investigators to receive either pantoprazole (n = 307) 40 mg o.a.d. (morning) or famotidine (n = 149) 40 mg o.a.d. (evening) for 2 weeks, or 4 weeks if endoscopic healing was incomplete by 2 weeks. Demographic data and ulcer size were comparable in both treatment groups.*Results:* Endoscopically proven healing rates (primary study end-point, *intent-to-treat* analysis [per protocol]): 2 weeks 4 weeksPantoprazole 82% [87%] 93% [98%]Famotidine 68% [76%] 88% [94%] $p < 0.001$ [$p < 0.05$] $p = 0.07$ [$p = 0.07$]Among the patients with pain prior to treatment, complete freedom of pain after 2 weeks was achieved in 87% of the patients in the pantoprazole group and in 72% of the patients in the famotidine group ($p < 0.01$). Both drugs were well tolerated.*Conclusions:* Pantoprazole (40 mg o.a.d.) was highly effective and well tolerated in the acute treatment of duodenal ulcer. Clinically relevant superiority of pantoprazole over famotidine was achieved with respect to healing and pain relief, while the tolerability of both drugs was comparable. "P P 12 0293"P 12 0293**Pantoprazole in Long-Term Management of H_2-Blocker Refractory Acid-Peptic Disease**

*G. Brunner, U. Harke, A. Schneider[1], R. Fischer[1]

Medical University, Hanover, FRG

[1] Byk Gulden, Constance, FRG*Aim:* The efficacy and tolerability of the H^+,K^+-ATPase inhibitor pantoprazole (PAN) in H_2-blocker refractory acid-peptic disease was investigated.*Methods:* Patients with acute reflux esophagitis or peptic ulcer refractory to extended high-dose H_2-blockers were treated with 40–120 mg PAN daily for 4–12 weeks, depending on healing, in an open-label trial. Healed patients were admitted to maintenance treatment for up to 5 years. Upper GI endoscopy was performed at admission, every 4 weeks during the healing phase, and every 6 months during long-term treatment. Intermediate results are presented.*Results:* Healing of the acute lesions was achieved in 129/141 patients (91.5%) after 4 weeks and 140 (99.3%) after 12 weeks. In one patient with severe esophagitis, the lesion took more than 6 months to heal. By the time of this analysis, 115 patients were on maintenance treatment for at least one year, 89 for 2 years, 60 for 3 years, 27 for 4 years, and 9 for 5 years. Most patients were kept in remission with 40–80 mg PAN daily; 20 patients required higher doses up to 320 mg. Most frequent possibly treatment-related adverse events were pruritus and tiredness (in two patients each). Four patients with reflux disease and full-blown liver cirrhosis tolerated this treatment without any side-effects up to five years. Routine laboratory tests remained without significant changes throughout the entire period of treatment. Median serum gastrin levels were already elevated at baseline due to pretreatment with H_2-blockers (72 pg/ml, 68% range 41–191) and increased to 120.0 pg/ml (68–280) after one year of maintenance treatment without any further consistent increase thereafter. Median ECL cell density in the oxyntic mucosa increased slightly from 0.3% to 0.5% after 3 years.*Conclusions:* The data demonstrate that pantoprazole is highly effective and safe in acute healing and long-term treatment of H_2-blocker refractory peptic ulcer and reflux esophagitis and also in patients with advanced liver disease. "P P 12 0294"P 12 0294**No Pharmacokinetic and Pharmacodynamic Interaction between Pantoprazole and Glibenclamide****I. Walter-Sack, H. Bliesath, F. St\'f6tzer, R. Huber[1], V.W. Steinijans[1], W. Wurst[1]**

University Heidelberg

[1] Byk Gulden Konstanz, FRGThe new H^+/K^+-ATPase inhibitor pantoprazole is metabolized in the liver by CYP2C19 and CYP3A4. As substituted benzimidazoles can interact with the cytochrome P450 system, the interaction between pantoprazole and the sulfonyl urea glibenclamide was investigated. Glibenclamide is used in the treatment of diabetes mellitus and is metabolized in the liver by CYP3A.20 healthy male volunteers completed a randomized single-blind cross-over study. They received 40 mg pantoprazole (Test) or placebo (Reference) sid for 5 days and concomitantly 3.5 mg glibenclamide on day 5. Glibenclamide, pantoprazole, glucose and insulin serum concentrations were measured on day 5 of each period. Lack of interaction was considered as an equivalence problem. The following pharmacokinetic characteristics were observed: Parameters Test: Ref.: Eq. Ratio (Test/Ref.) Geometric mean Point est. 90% CI Glibenclamide (G) with P without PAUC (\'b5g {\'b4} h/l) 616 588 1.05 0.98–1.12C_{max} (\'b5g/l) 193 185 1.04 0.89–1.22 Pantoprazole (P) with G without GAUC (mg {\'b4} h/l) 4.23 4.29 0.98 0.93–1.04C_{max} (mg/l) 4.62 4.78 0.97 0.89–1.06The 90%-confidence intervals (CI) of the ratios of AUC and C_{max} were entirely within the equivalence range of 0.8–1.25. Additionally, the pharmacodynamic profiles of glucose and insulin were comparable in both periods. No interaction between pantoprazole and glibenclamide was concluded. No dose adjustment is required during concomitant treatment. "P P 12 0295"P 12 0295**Rabeprazole Effectively Inhibits 24 Hr H^+ Activity and Nocturnal Acid Secretion in Healthy Subjects**

*H.G. Dammann[1], F. Burkhardt[1], N.E. Bell[2], T. Bjaaland[2]

[1] Institute for Clinical Research, Hamburg, Germany

[2] Eisai Europe, London, UKIn humans rabeprazole has produced a dose-dependent, potent and long lasting inhibition of acid secretion. No significant incremental effect was noted with doses greater than 20 mg.*Purpose:* The purpose of this study was to determine the effect of an oral dose of rabeprazole 20 mg on 24 hr intragastric pH, 24 hr H^+ activity and nocturnal acid secretion in healthy subjects following a 14 day dosing period.*Methods:* 12 young healthy male subjects (mean age 27.5 Yrs) were investigated in this single centre, double-blind, randomised, 2-period-crossover comparison of rabeprazole 20 mg and placebo given orally once in the morning for 14 days. On Day 7 24 hr intragastric pH was monitored and nocturnal acid secretion measured by continuous aspiration (00.00 to 06.00 hrs) and titration of gastric contents. The pH measurements were extended for a 72 hr period after the last dose of medication (Days 14, 15 and 16). pH measurements were collected using a Synectics Mk II system and a nasogastric tube with pH electrode.*Results:* In comparison to placebo, rabeprazole 20 mg significantly inhibited 24 hr H^+ activity (table) and nocturnal acid secretion (36.6 – 6 vs 6 – 2 mmol/00.00–06.00 hrs).24 hr H^+ activity ($AUC_{0–24}$) mmol.h/L (means – SE) Placebo Rabeprazole Inhibition (%)Day 7 503 – 71 72 – 27 86Day 14 343 – 102 44 – 12 87Day 15 501 – 121 126 – 31 75Day 16 379 – 74 146 – 29 61*Conclusions:* Rabeprazole 20 mg produced a significant and long lasting inhibition of acid secretion. Inhibition of up to 87% was observed. The half-life for recovery of acid secretion was longer than 72 hours. Based on published data rabeprazole 20 mg appears to be at least as potent and as long acting as omeprazole and lansoprazole. "P P 12 0297"P 12 0297**Drug-Drug Interaction Evaluation of Rabeprazole Sodium: A Clean/Expected Slate?**

*T.J. Humphries, R.V. Nardi, J.D. Lazar, S.A. Spanyers

Eisai Corporation of North America, Teaneck, NJ, USA

Pharmaco International, Austin, TX, USAAs was the case with the early members of the family of H_2 receptor antagonist, drug-drug interactions mediated by CYP-450 isoenzymes were demonstrated with omeprazole the first proton pump inhibitor (PPI) as were interactions based on the profound antisecretory effect of the PPI class with drugs for which absorption is dependent on intragastric pH.The potential for rabeprazole sodium (RAB) to interact with co-administered diazepam, theophylline, phenytoin, warfarin, ketoconazole and digoxin has been evaluated. The diazepam interaction was studied in Japanese patients (high incidence of PM) while all other studies were conducted in US subjects. Standard PK parameters, including C_{max}, T_{max}, T 1/2 and AUC were measured. The results of this group of studies are shown in the table below: Drug InteractionDiazepam NoTheophylline NoPhenytoin NoWarfarin NoKetoconazole Yes ({\'af} AUC and C_{max})Digoxin Yes ({\'ad} AUC, C_{max}, and T 1/2)*Conclusions:* Based on an extensive battery of studies, RAB shows no potential for major CYP-450 interactions, and predictably effects blood levels of ketoconazole and digoxin based on its antisecretory effect. When planning to co-administer ketoconazole with RAB, consideration should be given to discontinue RAB. With respect to digoxin, although co-administered RAB results in a modest (20%) increase in trough digoxin levels, monitoring of digoxin levels is suggested when RAB therapy is initiated in patients taking digoxin. *S.M.A. Bastaki, M.Y. Hasan, I. Chandranath, A. Garner

Faculty of Medicine & Health Sciences, United Arab Emirates University, Al Ain, U.A.E.*Purpose:* PD-136,450 is a selective ligand for the CCK-B receptor in vitro with binding affinity for mouse cortex – 500-fold greater than for rat pancreatic CCK-A receptors. This study characterises gastric acid and pancreatic bicarbonate secretions together with anxiolytic activity of PD-136,450 in the rat. *Methods:* Gastric and pancreatic secretions were measured by titration at 10 min intervals. Basal acid output and secretion stimulated by s.c. injection of 32 \'b5g/kg gastrin-17 or 10 mg/kg dimaprit were determined in anaesthetised rats or conscious animals fitted with indwelling fistulae. Pancreatic secretions were collected via a catheter inserted into the main duct of anaesthetised rats. Anxiolytic activity was assessed by a standard black and white two-compartment activity assay.*Results:* As anticipated, PD-136,450 inhibited gastrin-stimulated acid output in anaesthetised or conscious rats (IC-50 of 1 mg/kg s.c.). Doses up to 10-fold higher had no effect on dimaprit-induced acid output (255 \'b5mol/hr before and 243 \'b5mol/hr after PD 136,450). Of note, PD-136,450 increased pancreatic secretion. At a dose of 4.5 mg/kg it showed similar efficacy to CCK-8 with bicarbonate output rising from 36 to 207 \'b5mol/hr 60 min after s.c. dosing and remaining elevated for > 3 hr. This action was inhibited by 75% after pretreatment with the CCK-B antagonist L-364,718 (bicarbonate output 55 \'b5mol/hr) but was not effected by the CCK-B antagonist L-365,60 (output 211 \'b5mol/hr). Time spent in the dark compartment by rats pretreated with 10 mg/kg PD-136,450 was reduced 36% compared with control ($p < 0.01$, $n = 6$). This response was similar to the effect of 5 mg/kg daizepam (41% inhibition). Latency for movement from the light to the dark compartments increased similarly with PD-136,450 and diazepam.*Conclusions:* PD-136,450 is a selective inhibitor of gastrin-stimulated acid secretion in vivo. The drug also stimulates pancreatic bicarbonate secretion and displays anxiolytic activity comparable to diazepam. While PD-136,450 has weak antisecretory activity compared with H_2 blockers or PPIs, it may have utility as an adjunct therapy in peptic ulcer disease by countering the actions of gastrin and increasing acid neutralization. "P P 12 0301"P 12 0301**Evaluation of the Antisecretory Activity of Pantoprazole in Duodenal Ulcer Patients by Continuous 24-Hour pH Monitoring**

*V. Savarino, G.S. Mela, P. Zentilin, M.R. Mele, T. Santagada[1], M. Ballabio[1]

DI.M.I., Universit\'e0 di Genova, Italy

[1] Byk Gulden Italia, Cormano (Mi), ItalyThe extent and duration of acid suppression are considered of critical importance for healing of acid-related disorders and optimizing activity of antimicrobial drugs in H. pylori eradication. Pantoprazole (Pan) is a novel proton pump inhibitor, acting by selective binding to H^+/K^+-ATPase of gastric parietal cells. Its main distinctive features are represented by minimized potential for interactions with human cytochrome P450 enzyme system, the stability and lack of activation in neutral environment and a predictable pharmacokinetic profile. The aim of our study was to evaluate the effects of Pan on 24-h intragastric acidity in duodenal ulcer (DU).Pan 40 mg mane was orally administered for 5–7 days to 20 patients with DU in clinical remission. 18 out of them were H. pylori positive.Continuous 24-h intragastric pH-metry was performed in basal conditions and after treatment, according to well established procedures. Mean 24-h, nighttime and daytime pH values, and mean times spent above pH thresholds of 3.0, 4.0 and 5.0 have been evaluated as acidity indexes. Two-way ANOVA was used for statistical analysis.A significant reduction of gastric acidity was induced by Pan compared to basal levels ($p < 0.001$), in terms of both mean pH in the different time intervals and times spent above several pH thresholds (see Table). Basal Pan 40 mgMean (SD) 24-hour pH (17:00–16:59) 1.34 (0.22) 5.13 (1.11)Nighttime pH (20:00–07:59) 1.16 (0.25) 4.80 (1.35)Daytime pH (08:00–19:59) 1.53 (0.30) 5.47 (1.12)Mean (SD) hrs. > pH 3.0 1:33 (1:02) 19:20 (4:43)pH 4.0 0:40 (0:30) 17:30 (5:29)pH 5.0 0:10 (0:14) 14:43 (6:04)Our results show that pantoprazole represents an optimal antisecretory treatment in acid-related diseases inducing a pronounced and long-lasting suppression of acid secretion. The pharmacodynamic effect is more evident during the daytime than during the nighttime and this confirms a peculiar feature of proton pump inhibitors. "P P 12 0302"P 12 0302**Comparison of Intravenous Famotidine and Ranitidine in Suppressing Gastric Acid Secretion in Reflux Esophagitis and Duodenal Ulcer Bleeding**

*M. Tuncer, A. Dobrucali, I. Yurdakul, C. Davutoglu, N. Bagatur, F. Hamsioglu, A. \'c7elik, E. Oktay

Gastroenterology Department of Cerrahpasa Medical Faculty of Istanbul University, Istanbul, Turkey*Purpose:* We investigated the efficacy of H_2-receptor blockers in raising gastric pH to above 4 in patients with Reflux esophagitis and duodenal ulcer bleeding and we compared the efficacy of intravenous famotidine and ranitidine in this subject.*Methods:* 44 patients with endoscopically proven Reflux esophagitis (grade II, III Savary-Miller classification) and duodenal ulcer bleeding, 44 patients (28 males, 16 female, 28–68 yrs) were assigned randomly to receive intravenous bolus doses of either famotidine 20 mg every 12 hours (n = 22) or ranitidine 50 mg every 8 hours (n = 22) for mean 5 days. Gastric juice was aspirated before the start of treatment (base-line) and six times during each 24 hour period; pH was measured by a pH meter.*Results:* Measured base-line pH was not significantly different between the two groups. Famotidine raised gastric pH to higher level than did ranitidine, reaching statistical significance ($p < 0.05$) for 28 of 44 collection periods.*In Conclusion;* When given by intermittent intravenous bolus, famotidine 20 mg every 12 hours is more effective than ranitidine 50 mg every 8 hours in raising gastric pH to above 4 in reflux esophagitis and duodenal ulcer bleeding. [2] FISA Group's Medical Departament, Barcelona, Spain

[3] Hospital Virgen de las Nieves, Granada, Spain

[4] Hospital Juan XXIII, Tarragona, Spain

[5] Hospital Cruz Roja, Barcelona, Spain*Purpose.* To assess the efficacy of Ebrotidine 400 mg compared with Ranitidine 300 mg nocte, in the treatment of benign gastric ulcer.*Methods.* A randomized phase III parallel double-blind trial. 104 patients from 4 hospitals were enrolled in the study. 98 of them (94.23%) completed the treatment and were evaluated. Patients gathering the entry criteria were randomized to receive Ebrotidine or Ranitidine until the endoscopic cure of ulcer, or until a maximum of 12 weeks of treatment. Basal endoscopy was repeated after 6 9 and 12 weeks of treatment. The chi-square test was used to compare the number of patients with a complete remission of the ulcus, and the ANCOVA test was used to compare reduction in the size of the ulcer.*Results.* Both groups were homogeneous and without differences for the basal parameters studied. In the intention to treat analysis Ebrotidine was effective in 88.2% of the patients and Ranitidine in 78.7% (N.S). There were significant differences ($p = 0.017$) concerning the size of the ulcer at six weeks of treatment (95% CI, 0.5589 mm to 1.8724 mm for Ebrotidine and 1.6337 mm to 4.9621 mm for Ranitidine). Adverse events were absent in both groups of patients.*Conclusions.* Ebrotidine appears to be significantly faster than Ranitidine in the healing of the benign gastric ulcer. Ebrotidine is a new drug with anti-secretory profile, anti-H2 and gastroprotective activity, thus conferring a significant advantage versus Ranitidine and possibly versus other types of antisecretors drugs. "P P 12 0306"P 12 0306**Role of { b}-Adrenoceptors and Nitric Oxide in the Circulatory, Metabolic and Protective Effects of Epidermal Growth Factor (EGF) in the Stomach**

*W.W. Pawlik, R. Sendur, K. Czarnobilski, J. Biernat, T. Brzozowski, S.J. Konturek

Univ. Med. Sch. Inst. Physiol. CMUJ Krakow, PolandEGF is considered to play an important role in the maintenance of gastrointestinal mucosal integrity. The evidence existed has pointed to the trophic and vascular effects of EGF in the mechanism of its gastroprotective activity. The aim of this study was to investigate the involvement of betha adrenergic receptors in the vascular and protective actions of EGF in the stomach. Two series of dogs and rats were performed. In anesthetized dogs with fundic flap preparation, total gastric blood flow (GBF) was determined ultrasonically and mucosal blood flow (MBF by laser Doppler flowmetry. Gastric oxygen consumption (GVO_2) and systemic arterial pressure (AP) were also determined. EGF administered i.a. at dose 2.0 mg/kg increased GBF, MBF, GVO_2 by 58 – 9, 123 – 16 and 37 – 8% respectively, not change AP. Pretreatment with propranolol (5 mg/kg i.v.) significantly reduced above and metabolic responses induced by EGF. In rats acute gastric lesions were induced by 100% ethanol. Mucosal blood flow (LDF) was measured by laser Doppler technique area was also determined in mm. Ethanol induced mean lesion was 110 – 12 mm and reduction in LDF by 75%. Pretreatment with EGF (100 mg/kg-h s.c.) decreased the lesion area by 86 – 10% ($p < 0.05$) and increased LDF by 72 – 8% ($p < 0.05$). Pretreatment of animals with propranolol (5 mg/kg i.p.) abolished the protective effect of EGF. Propranolol alone was without any effect on the ethanol induced gastric damage. These data provide evidence that EGF is a potent vasodilator of gastric circulation and modulator of gastric tissue oxygenation. This peptide possess also protective properties which, at least in part, may depend on its dilatory activity. Both, vascular and protective effects of EGF appear to be mediated by betha adrenergic receptors. Hormones and receptors: Receptor characterizationIntestinal disorders: Splanchnic circulation, ischemia }" "Role of ß-Adrenoceptors and Nitric Oxide in the Circulatory, Metabolic and Protective Effects of Epidermal Growth Factor (EGF) in the Stomach"

"P P 12 0307"P 12 0307**Inhibition of the Gastric H,K ATPase and Acid Secretion by a New Anti-Ulcer Drug**

*W.A. Simon, R. Boer, C. von B\'fcdingen, K. Munson[1], G. Sachs[1]

Byk Gulden, Konstanz, Germany

[1] UCLA, Los Angeles, USA*Background:* A new anti-ulcer drug, the imidazo 1,2{ a} pyridine BY841, that inhibits gastric acid secretion, is in clinical trial for treatment of acid related diseases.*Aims:* To correlate the binding of the drug with inhibition of the gastric H,K ATPase and to determine the relative efficacy of this inhibitor compared to a H2 receptor antagonist.*Methods:* Purified hog gastric vesicles were used to compare inhibition of the ATPase with binding of ^{3}H-BY841 and determine K competition with BY841. Isolated rabbit gastric glands were used to compare the effects of ranitidine and BY841.*Results:* The K_l for inhibition of the ATPase by BY841 was 6 nM and the K_d for binding was 4.4 nM. K displaced BY841 in intact cytoplasmic side out gastric vesicles only when K was able to penetrate the vesicle interior by the H,K exchange ionophore, nigericin, with a K_{app} of 1 mM, similar to the concentration required for ATPase activation. The IC_{50} value for inhibition of acid secretion in gastric glands by BY841 was 60 nM compared to 3 \'b5M for ranitidine and BY841 inhibited basal as well was stimulated aminopyrine accumulation, in contrast to ranitidine.*Conclusions:* BY841 is a potent and effective inhibitor of gastric acid secretion by the parietal cell by binding to an extracytoplasmic site on the gastric H,K ATPase in a K competitive manner. Its mode of action and efficacy in vitro translates into effective inhibition of gastric acid secretion in vivo.

"P P 12 0308"P 12 0308**Deposition of Bismuth from Different Compounds. An Advantage in Using Ranitidine Bismuth Citrate (RBC)?**

*J. Canena, J. Reis, A. Pinto, A.M. Santos, J. Leit\'e3o, T. Pinheiro, M.G. Quina

Cl\'ednica Universit\'e1ria de Medicina Interna e Gastrenterologia, Hospital de Pulido Valente, Lisbon, Portugal*Purpose:* To determine if treatment of rats with bismuth compounds can lead to its deposition in several organs after therapy, 30 days after stopping treatment and to see if this is affected by gastric pH.*Methods:* 48 male wistar rats were gavaged twice daily, during 15 days, with placebo (PL, n = 14), bismuth subcitrate alone (B, n = 14)-13.7 mg/Kg/day, or in association with ranitidine (8.6 mg/Kg/day)-(BR, n = 8) and with RBC, (n = 12)-22.8 mg/Kg/day. After 2 weeks 8 rats of PL, B, BS and 6 of RBC groups were euthanized and samples of blood, liver, kidney, brain and lung were removed. After 30 days, remaining rats were killed and organs were collected. Intragastric pH was assessed at the 10th day with a glass electrode connected to a pH measuring device. Bismuth was assessed by Particle Induced X-ray Emission and concentrations are expressed in \'b5g/g of dry weight. *Results:* Intragastric pH levels were: PL-1.7 – 0.2, B-2.3 – 0.1, BR-3.6 – 0.2, RBC-3.5 – 0.1. In PL group all analysed samples had bismuth levels below detection limit (2 \'b5g/g). After 15 days bismuth concentration was: B BR RBCBrain 4.77 – 0.97 (50%) 3.12 – 1.31 (100%) < 2 \'b5g/g (100%)Lung 4.07 – 1.92 (100%) 2.95 – 0.66 (100%) 3.20 – 0.39 (33%)Liver 2.36 – 0.29 (100%) 2.38 – 0.37 (100%) 2.17 – 0.63 (33%)Kidney 30.81 – 8.59 (100%) 32.44 – 13.1 (100%) 4.24 – 1.75 (100%)** p < 0.001 (t-student). Blood values above 2 \'b5g/g were found in 75% of B group, in 35.7% of BR group and in 83% of RBC group. After 30 days all rats had values below 2 \'b5g/g. *Conclusions:* Treatment with bismuth can lead to its deposition in several organs and it is not influenced by gastric pH. Bismuth deposition was lower in brain and blood levels correlate poorly with organ deposition. One month after stopping therapy bismuth deposition was not detectable. There is a clear advantage in using RBC as far as organ deposition is concerned. }"

"P P 12 0309"P 12 0309**Safety and Efficacy on Symptom Relief of Pantoprazole: Interim Analysis of a French Prospective Study**

*H. Licht, G. Giret-d'Orsay, R. Samoyeau, Eupantol study group

H\'f4p. Delafontaine 93 St Denis-Lab. Byk France 77 Le M\'e9e/Seine*Objective:* Pantoprazole is a potent inhibitor of acid secretion which binds precisely to the key cysteins of the gastric H+/K+-ATPase. This trial was conducted to assess the safety and efficacy on symptoms relief of pantoprazole 40 mg/day given for the acute treatment of acid-related diseases.*Methods:* Open, prospective, multicentric trial. The general practitioners (n = 900) selected the patients and the gastroenterologists (n = 300) included them after the endoscopic evidence of ulcer or esophagitis. Patients were treated for 1 or 2 months.*Results:* In duodenal ulcer patients (n = 166), the most frequently reported symptoms at entrance were characteristic ulcer pain (70%) and nausea and vomiting (46%). 89% of patients with characteristic ulcer pain and 97% of patients with nausea and vomiting were free of symptoms at day 7. Smokers, age under 50 and male gender seem to be predictive factors for rapid symptom relief.Gerd patients (n = 620) were classified as follows: stage I: 56%, stage II: 30%, stage III: 8%, stage IV: 6%. The most frequently reported symptoms at entrance were: heartburn (78%), acid regurgitations (73%), non characteristic epigastric pain (35%), dysphagia (23%). 87% of patients with characteristic Gerd symptoms were asymptomatic at day 7. The median time to be free of symptoms without intake of antacid was 4 days independently of the original stage. Non smoker status, age over 50, and the male gender seem to be predictive factors for a rapid pain relief.Safety was analysed on 1020 patients. The adverse events possibly or certainly related to the test medication were: diarrhea (2.4%), headache (2.3%), abdominal pain (1.8%), dizziness, asthenia. These rates correspond to those described with the other PPI*s.Conclusion:* On a large population representative of acid-related disease patients, pantoprazole is effective on symptoms relief. The tolerability was excellent. These results have to be confirmed by the final analysis. Oesophageal gastric duodenal disorders: EG RefluxOesophageal gastric duodenal disorders: GD disorders, acid peptic }" "Safety and Efficacy on Symptom Relief of Pantoprazole: Interim Analysis of a French Prospective Study"

"P P 12 0310"P 12 0310**Influence of the H^+,K^+-ATPase Inhibitor Pantoprazole on Blood Ethanol Levels in Healthy Humans**

*S. Teyssen, M.V. Singer, H. Heinze[1], R. Pf\'fctzer, H. Harder, R. Huber[1], F. Stephan, A. Schneider, R. Fischer[1]

Dept. of Med. IV, Univ. Hosp. of Heidelberg at Mannheim, Germany

[1] Byk Gulden, Constance, Germany*Background:* Alteration in gastric first pass metabolism of ethanol during administration of several H_2 receptor antagonists has been previously reported. In the H^+,K^+-ATPase inhibitor omeprazole inter-action was not detected. *Aim:* To study the effect of the H^+,K^+-ATPase inhibitor pantoprazole on blood ethanol levels after taking a moderate dose of ethanol in healthy humans. *Methods:* 16 healthy volunteers (12 male, 4 female; mean age 27 years) received either 40 mg pantoprazole or placebo orally at 8.00 AM for seven days in a double blind, randomized cross over design, separated by a 14 day wash out. On day 7 a standardized breakfast was given at 8.00 AM, directly after administration of pantoprazole. At 10.00 AM, 200 ml of orange juice, containing 0.5 g/kg body weight pure ethanol, were given within 5 min. Blood samples were taken at 10–30 min intervals for 4 h and then hourly until 6.00 PM. Ethanol concentrations were determined by a modified ADH enzymatic assay (ALC, Du Pont). For confirmative analysis the area under the curve (AUC) of blood ethanol levels over 8 hours (10.00 AM–6.00 PM) was calculated. Lack of interaction was handled as an equivalence problem (Steinijans et al. 1991). *Results:* The seven day administration of pantoprazole caused no significant change in peak ethanol concentration (Cmax, %) and in 8 h integrated (AUC) blood ethanol levels (% {\'b4} h) after ingestion of 0.5 mg/kg ethanol as compared to placebo. Independent from the sequence of treatment regimens, no side effects were reported.Table: Peak ethanol concentration (Cmax, %) and 8 h integrated (AUC) blood ethanol levels (% {\'b4} h) *after ingestion of 0.5 mg/kg ethanol.* Pantoprazole PlaceboAUC (% {\'b4} h) 1.127 (0.855–1.485) 1.113 (0.862–1.436)C_{max} (%) 0.435 (0.339–0.558) 0.427 (0.322–0.565)Values are geometric means and 68% ranges; the 90% confidence intervals of the pantoprazole/placebo ratio (AUC: 0.91–1.12; Cmax: 0.94–1.11) were within the equivalence range (0.8–1.25).*Conclusions:* 1.) A therapeutic dose of pantoprazole does not alter the pharmacokinetics of orally administered pure ethanol (0.5 g/kg body weight). 2.) Sporadic intake of ethanol does not influence the safety and tolerability of pantoprazole when concomitantly taken. "P P 13 0311"P 13 0311**Activity of { g}-Glutamyl-Transferaze ({ g}-GT) in Blood Serum and Mucosa in Helicobacter Pylori Infected SubjectsGrazyna Klupinska**

Dept. of Infectious Diseases and Gastroenterology MMA, Kniaziewicza 1/5, 91-347 Lodz, Poland{ g}-Glutamyl -transferaze ({ g}-GT) is a heterogenic enzyme. In physiologic environment hepatic fractions (iso-enzymes) make only about 40% of the whole activity of this enzyme and the remaining part comes from other organs. The increase { g}-GT is assumed to be a sensitive factor of tissue damage and neoplasia. The purpose of his study was estimation of { g}-GT activity in serum and gastric mucosa in Hp-infected subjects. The studies were performed in 26 men, aged 42–66 years, whose histopathological diagnosis showed active, chronic gastritis. Hp infection was confirmed by microscopy and enzymatic examination (urease test). Other diseases particularly of liver and pancreas were excluded. The patients were not administered any drugs or alcohol. Before and six weeks after treatment (famotidine + amoxycyline + metronidazol) { g}-GT was determined in serum according to kinetic method and in fundic and atrial mucosa – by method of Cormay { g}-GT – TRIS no cat. 1-033 acc. to F. Hoffmann-La Roche. The following results were obtained: { g}-GT Before treatment After treatmentSerum (U/l) 77.8 – 7.3 61.3 – 8.2Stomach (mU/mg protein)– fundic 14.3 – 5.2 9.1 – 5.4– antrum 16.7 – 8.0 10.4 – 5.9It has been concluded that, Hp infection is the reason of the increase of { g}-GT activity in gastric mucosa and serum. The role of Hp infection in gastritis pathogenesis also proves the necessity of antibacterial treatment. Istituti di Medicina Interna e Geriatria, Roma, Italy

[1] Patologia Chirurgica, Universit\'e0 Cattolica, Roma, Italy

[2] Laboratorio di Immunologia ENEA-CRE. Roma, ItalyIn organ specific infections the significance of local immune reactivity can be different from that of peripheral blood lymphocytes (PBL). The organ draining blood could represent an intermediate compartment between the mucosa associated and the systemic immunity.Aim of our study was to investigate if the PBL were able to proliferate to Hp CagA protein and if this assay had any specificity in Hp infected patients. Moreover we compared the data with those obtained testing the lymphocytes isolated from gastric vein blood (GVBL). Patients supposed to undergo abdominal surgery (not for neoplastic diseases) underwent a thorough study for Hp infection. During the surgical intervention blood samples were obtained by puncture of the gastric draining veins and the antecubital vein. Lymphocytes were purified and cultured in the presence of several mitogenic stimuli (anti-CD3, anti-CD28, PHA, Hp CagA protein) and the proliferative response was measured by means of tritiated thymidine uptake. Hp CagA protein induced lymphocyte proliferative response in a high percentage of Hp infected subjects (71.5% GVBL and 57% PBL) while it did not in the Hp negative patients. Comparing the Hp positive and negative groups the mean lymphocyte proliferative response to CagA was significantly higher in the GVBL ($p < 0.05$) while no difference was detected for the other mitogenic stimuli. Analysing the patients as a whole, GVBL showed a significantly higher response to PHA than PBL.It is known that the Hp CagA protein can induce a humoral immune response. We have detected a different functional behaviour of GVBL compared to PBL. We have demonstrated that T lymphocytes from Hp infected subjects specifically proliferate when challenged with this antigen and that GVBL of such patients show a more frequent and higher response. "P P 13 0313"P 13 0313**Detection of Cytotoxin Associated Gene a (*CagA*) as Serodiagnostic Marker in Diagnosis and Treatment of Duodenal Ulcer (DU) and Non-Ulcer Dyspepsia (NUD)**

*E. Karczewska, A. Bobrzynski, S.J. Konturek, H. Keanthous

Inst Physiol, Univ Sch Med, Krakow, Poland

OraVax Inc, Cambridge, MA, USA*Purpose:* It has been proposed that about 60% of *Helicobacter pylori* (Hp) isolates express *CagA* and that this protein induces serum IgG antibodies. Infection with Hp expressing *CagA* was suggested to increase the risk of DU but no comparative studies have been made regarding the expression of *CagA* in DU and NUD during anti-Hp therapy.*Methods:* This study included 50 Hp-positive (by ^{14}C-UBT, CLO, histology and culture of gastric biopsy) DU patients with active ulcers, 50 symptomatic NUD patients and 25 Hp-negative healthy control. Serum samples were obtained at day of initial endoscopy, 2 wk after triple therapy (omeprazole 20 mg bd, amoxicillin 750 mg bd and metronidazole 500 mg bd) and 4 wk after completion of this therapy. The presence of serum IgG antibodies to Hp was determined by ELISA using EIAGEN HP IgG test. Antibodies to *CagA* sera were detected by ELISA using recombinant *CagA* (ORV220) as antigen.*Summary of results:* All tested Hp-positive DU and NUD patients but none of healthy controls had positive serology for IgG. Serum IgG antibodies to *CagA* were positive in 80% of DU, in 40% of NUD but in none of healthy controls. After 2 and 6 wk of anti-Hp therapy, which succeeded in 95% eradication of Hp both in DU and NUD and complete ulcer healing in DU, there was significantly gradual decrease in IgG and *CagA* titre both in DU and NUD, reaching – 80% of patients.*Conclusions:* 1. Expression of *CagA* is strongly associated with Hp infection and is about twice higher in DU than in NUD patients suggesting that *CagA* expression increases the risk of DU and may serve as serodiagnostic marker to implement anti-Hp therapy, 2. gradual decrease in serum IgG and *CagA* titre may be useful in documentation of the progress in DU healing. Oesophageal gastric duodenal disorders: GD disorders, acid pepticImmunology and microbiology: GI infections in adults }" "Detection of Cytotoxin Associated Gene a (CagA) as Serodiagnostic Marker in Diagnosis and Treatment of Duodenal Ulcer (DU) and Non-Ulcer Dyspepsia (NUD)"

"P P 13 0314"P 13 0314**Suppression by Sulglycotide of H. Pylori Protease Activity towards PDGF and TGF{ b}**

*B.L. Slomiany, J. Piotrowski, J. Majka, E. Piotrowski, A. Slomiany

Res Ctr., UMDNJ, Newark, NJ USASulglycotide, a chemically sulfated derivative of duodenal mucin, is a potent cytoprotective agent also recognized for its remarkable inhibitory activity towards Helicobacter pylori (HP). Since, HP is known to undermine the gastric mucosal integrity through a variety of enzymes capable of rapid destruction of gastric mucosal defense potential, in this study we assessed the effect of sulglycotide on the susceptibility of PDGF and TGF{ b} to HP protease. The experiments were carried out with HP, strain ATCC 43504. The plates with grown colonies were washed with 0.9% NaCl, filtered (0.2 \'b5m) to retain the bacteria, and the filtrate was used as an enzyme source. The incubation mixtures for HP protease assays consisted of ^{125}I-labeled PDGF or TGF{ b}, enzyme protein (50–100 \'b5g), sulglycotide (0–100 \'b5g) and 0.22 ml phosphate buffer, pH 7.0. After 1 h incubation at 37\'b0C, the incubates were chromatographed on a Bio-Gel P-2 column and the produced ^{125}I-labeled peptide fragments were measured in a gamma counter. The results of analysis of the eluted fragments revealed that HP protease caused extensive degradation of growth factors. Under the assay conditions HP protease evoked a 61.7% degradation of PDGF and a 62.3% degradation of TGF{ b}. Introduction of sulglycotide to the reaction assay system caused a dose dependent inhibition in PDGF and TGF{ b} proteolysis by HP enzyme. The maximal inhibitory effect was obtained with sulglycotide at 100 \'b5g/ml, at which dose an 84.4% decrease in PDGF and 88.3% decrease in TGF{ b} degradation was achieved. These results demonstrate that sulglycotide by exerting a strong inhibitory activity on the HP protease towards PDGF and TGF{ b} is capable of promoting the proliferative action of these peptides in mucosal repair process. "P P 13 0316"P 13 0316**Emerging Patterns of Helicobacter Pylori (*H. Pylori*) Antimicrobial Susceptibility in Europe -Q.N. Karim[1], R.P.H. Logan[2], GlaxoWellcome *H. pylori* Study Group**

[1] St Mary's Hospital, Paddington

[2] University Hospital, Nottingham*Introduction:* H. pylori antimicrobial susceptibility is an important determinant of the efficacy of eradication therapies [1]. The prevalence of antimicrobial resistance varies within Europe and is likely to increase given the diverse number of regimens and dosages currently used. This multicentre study assesses the prevalence of *H. pylori* antimicrobial resistance in the United Kingdom.*Methods: H. pylori* was isolated from antral biopsies of patients undergoing routine endoscopy and cultured according to standard microbiological methods (blood/chocolate agar in a microaerophilic environment, incubated for up to 10 days). Antimicrobial resistance was determined using ""E-tests"" or disc tests (tinidazole only) and breakpoints were taken from previous studies.*Results: H. pylori* has been isolated from 32% (1222/3823) of biopsies and antimicrobial susceptibility determined in 90% (1077/1222) of isolates. The percentage national average resistances (and ranges) for the most widely used antimicrobials are as shown in the table below: Metronidazole Tinidazole Clarithromycin Tetracycline38.6 (14.6–65.2) 28.2 (7.2–41.5) 4.8 (1.3–12.5) 2.2 (0.7–6.3)The prevalence of resistance to metronidazole was greater in isolates from inner city centres (45.1%, n = 488) compared with rural centres (17.7%, n = 273). The same was shown with resistance to clarithromycin (4.8% vs. 1.7%). Nineteen isolates showed resistance to both clarithromycin and metronidazole. Multiple resistance was therefore seen in 5.3% of isolates.*Discussion/Conclusion:* The results demonstrate the wide variation of antimicrobial resistance to *H. pylori.* In the UK metronidazole resistant *H. pylori* is endemic. Multiple antimicrobial resistance seen in approximately 5% of *H. pylori* positive isolates, underlines the importance of establishing local patterns of antimicrobial resistance.

"P P 13 0317"P 13 0317**Nitric Oxide Synthase Activity in Gastric Mucosa: Influence of Helicobacter Pylori Colonization and NSAID AdministrationJ. Esteban[1],**

*M.A. Rodr\'edguez[1], P. Hergueta[2], F. Pellicer[2], D. Delgado[2], J.M. Herrer\'edas[2]

[1] Servicio Central de Investigaci\'f3n en Ciencias de la Salud. Universidad de C\'e1diz

[2] Servicio de Aparato Digestivo. Hospital Universitario ""Virgen Macarena"", Universidad de Sevilla*Purpose:* Nitric oxide (NO) is related to several gastric processes including protective and agressive effects. In this sense, NO synthezised by constitutive enzyme has protective effects such as an increase of mucus production and a major proliferative index of epithelial cells. These effects are mediated by cGMP. As oppossed to this, NO released by inductible enzyme is related to appearance and maintenance of inflammatory processes. On the other hand, Helicobacter pylori (Hp) and NSAID administration have the ability to induce gastric damage by different mechanisms: Hp increases agressive factors and NSAID decreases protective effects. In this sense, we have studied the influence of Hp colonization and NSAID administration on the NOS activity and the cGMP levels in gastric mucosa. *Methods:* Determination of NOSi and NOSc activity by measuring ^{14}C-L-citrulline formation (pmol.g of tissue$^{\{ -}$1}.min$^{\{ -}$1} and cGMP levels (pmol.g of tissue$^{\{ -}$1}) in gastric biopsies of 78 patients of Gastroenterological Service of Virgen Macarena Hospital, Sevilla. The sample studied was composed by 11 normal subject, 7 patients with NSAID-induced gastric damage, 35 with gastritis Hp+, 6 patients with gastritis Hp{ -}, and 19 patients Hp+ and with duodenal ulcer. *Results:* NOS activity, both constitutive and inductible are not significantly different when normal, and gastritic patients (Hp+ and Hp{ -}) were contrasted (normal NOSc: 17.21 – 4.24 and NOSi: 20.89 – 3.81; gastritic patients Hp+ NOSc: 13.42 – 5.16 and NOSi: 35.67 – 12.26 and gastritic patients Hp{ -} NOSc: 14.34 – 11.23 and NOSi: 31.24 – 6.27). Similarly there were no significant differences when cGMP gastric levels were compared (normal: 100.55 – 27.35; gastritic patiens Hp+: 76.59 – 21.85; and gastritic patientes Hp{ -}: 81.57 – 14.28). On the contrary, the NOSi activity in patients with duodenal ulcers was significantly increased in comparison with normal and gastritic patients (NOSi: 67.34 – 15.43). The cGMP concentration is similar to normal. In patients with NSAID-induced gastric damage, the NOSc activity is significantly lower than normal (NOSc: 2.75 – 1.27). The same result was observed when cGMP was determined (22.08 – 5.24). *Conclusions:* NO can be related to gastrolesive ability of Hp through the NOSi activation and perpetuation of inflammatory proccesses. On the contrary, the NSAID-induced gastric injury can be related with a fall in NOSc activity and decrease of cGMO levels in gastric mucosa. This last results is in concordance with others experimetal results obtained in rats. Oesophageal gastric duodenal disorders: Helicobacter PyloriOesophageal gastric duodenal disorders: GD disorders, acid peptic }" "Nitric Oxide Synthase Activity in Gastric Mucosa: Influence of Helicobacter Pylori Colonization and NSAID Administration"

"P P 13 0318"P 13 0318**Effect of Helicobacter Pylori Infection on Gastric Endocrine Cell Behavior of Duodenal Ulcer Patients**

*Hagiwara Eiitirou, Kashiwagi Hideyuki, Chen Gang, Ishibashi Yoshirou, Omura Nobuo, Moriya Yusuke, Aoki Teruaki

Department of Surgery (II), The Jikei University School of Medicine, Tokyo, Japan*Aim.* This study investigated the influence of H. pylori infection on gastrin-immunoreactive cell (G-cell) and histamine-immunoreactive cell numbers in stomachs of duodenal ulcer patients.*Method.* Endoscopic biopsy specimens from antrums of 22 duodenal ulcer patients were fixed by Carnoy's fluid and immuno-stained using antibodies of gastrin and H. pylori. Another specimens from gastric bodies were fixed by 4% [1-ethyl-3 (3-dimethyl-amino-propyl) carbodimide] (EDCDI) and 4% paraformaldehyde (PEA), and they were immuno-stained using antibodies of histamine. The numbers of gastrin cell and histamine cell were counted. The degree of H. pylori infection was classified to three groups according to the ratio of the numbers of gastric pits where H. pylori exist in 50 pits at random.*Result.* The G-cell numbers in middle-infected group were more than those in low-infected groups, but they were significantly decreased in high-infected group. The histamine cell numbers had a tendency to increase according to the degree of H. pylori infection.*Conclusion.* This result suggests that H. pylori infections has a stimulatory effect on gastrin cell numbers, but the severe infection in antrum seemed to induce the damage and decrease of gastrin cells. And histamine cell numbers were also increased according to the degree of H. pylori infection. The increase of histamine-immunostained cell in gastric body should be considered not only the increase of enterochromaffine-like cells but also those of mucosal mast cell. "P P 13 0319"P 13 0319**Induction of Gastric Epithelial Apoptosis by H. Pylori Lipopolysaccharide and Its Suppression by SucralfateJ. Piotrowski, E. Piotrowski, D. Skrodzka, A. Slomiany,**

*B.L. Slomiany

Res. Ctr., UMDNJ, Newark, NJ USAThe preservation of gastric mucosal homeostasis is a highly complex biological process that involves the programmed cell death. Under normal physiological conditions the mucosal integrity is maintained by a dynamic equilibrium of cell loss by apoptosis with that of cellular proliferation, while the enhanced cell apoptosis is a prominent feature in HP-associated gastritis. In this study we assessed the effect of HP lipopolysaccharide (LPS) on the induction of gastric epithelial cell apoptosis. The experiments were conducted with rats subjected to intragastric surface epithelial treatment with a dose of 50 \'b5g HP LPS or LPS preincubated with 100 \'b5g sucralfate. The animals were sacrificed 2 days following the treatment and their stomachs subjected to quantification of apoptotic epithelial cells. The cells undergoing apoptosis were identified using terminal deoxynucleotidyl transferase-mediated dUTP-digoxigenin nick end labeling assay. The slides were developed with diaminobenzene reagent and counterstained with methyl green. The sections were subjected to counting and the number of positive cells was expressed as the apoptotic index (AI %). The results of microscopic assessment revealed only occasional presence of apoptotic cells in the surface epithelium from the control group (AI 2.6%), while in the LPS group a numerous apoptotic cells were identified not only in the superficial epithelium but also deeper in the glands (AI 51.5%). Preincubation of HP LPS with sucralfate prior to animal treatment led to a marked reduction in the epithelial cell apoptosis (AI 4.9%). The findings demonstrate that HP induces apoptosis through its cell wall LPS and that sucralfate is capable of suppressing this untoward effect of HP. "P P 13 0320"P 13 0320**Corporal Lymphoid Follicles (LF) Do Not Discriminate Autoimmune or H. Pylori Related Chronic Atrophic Gastritis (CAG)**

*M. Marignani, P. Caruana[1], B. Annibale, S. Angeletti, C. Bordi[1], G. Delle Fave

Dept. Gastroenterology, University ""La Sapienza"" Roma, Italy

[1] Dept. Pathology, University ""La Sapienza"" Parma, ItalyCAG is a condition characterized by atrophy of oxyntic mucosa hypo/achlorhydria and fasting hypergastrinemia. It has been considered an autoimmune condition, usually associated with latent or overt pernicious anemia (PA), but it has recently been observed that a small proportion of CAG patients are Hp infected. However, since the progression of corporal gastritis is accompanied by disappearance of H. pylori, the persistence of immunological memory, expressed by the presence of IgG to Hp, could indicate past exposure to the bacterium. Presence of LF in gastric biopsy specimens have been described as a constant feature of H. pylori-associated gastritis. Aim of this study was to investigate in a consecutive series of newly diagnosed CAG patients, the prevalence of present or past infection and the presence of LF as a histological marker of H. pylori infection. 104 consecutive hypergastrinemic CAG patients (84 F, 20 M aged 22–81) were divided in three groups as follows: Histo{ -} = histology, colture, IgG negative. Histo+ = histology, colture, Ig G; at least two of these tests positive. IgG+ = histology and colture negative, only IgG positive (> 40 U/l; Elisa, Biorad). Corporal atrophy was defined as focal or complete replacement of oxyntic glands by metaplastic pyloric or intestinal glands. LF were defined as intramucosal, basally located lymphoid aggregates with or without germinal centers. % Positive lymphoid folliclesCAG groups Antrum CorpusHisto{ -} (n = 58; 55.8%) 16.7 52.8Histo+ (n = 25; 24%) 50* 70IgG+ (n = 21; 20.2%) 5.9 61.9*Results:* In a consecutive, newly diagnosed series of CAG patients, autoimmunity accounts for 55.8%, whereas active or past H. pylori infection for 44.2%. Corporal LF are widely present but do not discriminate the two different ethiologic causes. In the antrum of Histo+ pts, LF are present in the 50%, being significantly higher than the other two groups (* Fisher test $p < 0.005$) *Conclusions:* These data show that 44.2% of CAG pts have been infected H. pylori and that corporal LF are not exclusive markers for the presence of the infection. "P P 13 0321"P 13 0321**Helicobacter Pylori Biotypes in Patients with Peptic Ulcers**

*T. Kawai, T. Ueda, H. Mutukawa, M. Takase, M. Nakagawa, Y. Nishizati[1], T. Saito[2]

[1] Department of Gastroenterology, Hachioji Medical Hospital, Tokyo Medical College

[2] The Fourth Department of Internal Medicine, Tokyo Medical College*Objectives:* We isolated Helicobacter pylori from the collected gastric mucosa in patients with peptic ulcers. The obtained strains were classified into biotypes according to the presence or absence of activity of some enzymes, and the differences of these biotypes among peptic ulcers was investigated.*Methods:* The subjects were 164 patients with peptic ulcers, who had undergone endoscopic examination including H. pylori. They consisted of 82 with gastric ulcer, 61 with duodenal ulcer and 21 with gastroduodenal ulcer. In upper gastrointestinal endoscopy, gastric mucosal samples were collected from the greater curvatures of the antrum and the gastric body incubated under microaerophilic conditions (5% O_2, 10% CO_2 and 85% N_2) for 5–7 days. The produced colonies were allowed to grow with blood agar medium for 3–7 days. A bacterial solution was used for experiments using API ZYM Kit (Bio Meriux S.A., France) for determination of H. pylori biotype. H. pylori was classified into biotypes I, II and III according to Kung's classification.*Results:* Investigation of the clinical isolates from 164 patients with peptic ulcers showed that 154 (94%) were positive for incubation (with Squiraud medium). Biotypes I, II and III were revealed in 7, 48 and 46 cases, respectively. There were some patients who showed different biotypes in the antrum and the gastric body of the same patient. This type was designated as mixed type. The patients who showed such mixed types consisted of one with mixed type I + II, one with mixed type I + N.D. (non-differentiated), and 18 patients with mixed type II + III. As a result of assessment of biotypes according to each disease, the frequencies of biotypes II and III were high in each peptic ulcer. There was no significant difference between disease and biotype using the chi-square test of independence.*Conclusions:* The frequencies of Kung's types II and III were high on the evaluation of H. pylori biotypes in patients with peptic ulcers. There were some patients who showed different H. pylori biotypes in the stomach of the same patient. There were no significant relationships between various peptic ulcers and biotypes.

*K. Hibi, W. Koizumi, S. Tanabe, H. Imaizumi, S. Noguchi, M. Kida, M. Ohida, T. Mitsuhashi, K. Saigenji[1], H. Mitomi, S. Kuwao, I. Okayasu[2]

[1] Department of Internal Medicine, Kitasato University, Sagamihara, Kanagawa, Japan

[2] Department of Pathology, Kitasato University, Sagamihara, Kanagawa, Japan*Aims:* The purpose is to evaluate whether the increased risk of gastric carcinoma development due to *Helicobacter pylori (H. pylori)* infection might be linked with elevated cell proliferative activity and oncoprotein overexpression. *Subjects:* Forty-eight patient undergoing therapy for *H. pylori* positive gastroduodenal ulcer were separated into not eradicated (NE;23 cases) and eradicated (E;25 cases) group 6 months after the treatment.*Methods:* Histological change in the gastric corpus and the antrum, assessed according to modified Sydney System, as well as epithelial cell kinetics (mitosis, Ki 67, PCNA), and expression of oncoproteins (p53, *bcl*-2) were examined before and at 3 months and 6 months after treatment for *H. pylori. Results:* Chronic persistent *H. pylori* infection was associated with increased inflammation and activity score, as well as elevated proliferation, as evidenced by the Ki67 and PCNA labeling indices and the mitotic index in NE group. Overexpression of p53 protein continued to be observed in the NE group after treatment but was significantly decreased in the E cases. *Conclusions:* Persistent *H. pylori* infection causes gastritis, with epithelial degeneration and regeneration that result in accentuation of epithelial cell proliferation and overexpression of p53 protein, this presumably heightening the risk of gastric carcinoma development. "P P 13 0323"P 13 0323**Effect of Helicobacter Pylori (HP) Infection on Oxygen Metabolism in Gastric MucosaGrazyna Klupinska**

Dept. of Infectious Diseases and Gastroenterology MMA, Kniaziewicza 1/5, 91-347 Lodz, PolandIn pathogenesis of gastrointestinal tract diseases more and more often the role of active forms of oxygen is taken into consideration especially as they cause the direct damage to mucosa. The overproduction of free oxygen radicals is stimulated by many pathologic factors which include also Hp infection. The aim of this study was the estimation of selected parameters of aerobic metabolism in subjects with Hp dependent gastritis before and after infection eradication. Investigations were carried out in 30 subjects, aged 38–73 years, with histopathological diagnosis of chronic gastritis. Hp infection was confirmed by urease test and histological examination. In gastric mucosa bioptate frozen to { -}70\'b0C, there were determined: – malonic dialdehyde (MDA) – by Yagi method; – glutathione peroxidase (Gpx) -by Paglia and Valentine method; superoxide dismutase (SOD) -by Minami and Joshicara method. The tests were performed before and six weeks after the successful anti-bacterial treatment (famotidine + amoxycyline + metronidazol). The following results were obtained: Before treatment After eradicationMDA (nmol/mg protein) 0.976 – 0.239 0.985 – 0.250Gpx (U/mg protein) 0.0369 – 0.0173 0.0249 – 0.024SOD (\'b5g/mg protein) 6.61 – 2.11 4.29 – 1.25*Conclusions:*- the decrease in SOD activity in gastric mucosa after Hp eradication indicates the bacterial origin this enzyme- lack of simultaneous significant decrease in MDA activity proves that short-term treatment may result in clinical improvement but does not restore metabolic balance- after Hp eradication the anti-inflammatory treatment ought to be continued, particullary in its antioxidant form, in order to decrease oxygen radicals generation. Oesophageal gastric duodenal disorders: Helicobacter Pylori }" "Effect of Helicobacter Pylori (HP) Infection on Oxygen Metabolism in Gastric Mucosa"

"P P 13 0324"P 13 0324**Helicobacter Pylori (Hp), Gastric Mucus and Endocrine Cells in Duodenal Ulcer**

*E.V. Bespalova, Y.A. Gaidar, E.V. Stepanova

Ukrainian Scientific Research Institute of Gastroenterology, Dnepropetrovsk, UkraineThe aim of the study was to investigate the interrelation between Hp and gastric mucusproducing, gastrin- and somatostat in producing cells in patients with duodenal ulcer (DU).*Material and Methods:* 94 patients with DU were observed. Hp-infection was revealed in 86% cases. The estimate of gastric mucusproduction based on quantitative and qualitative analysis of intracellular mucus in surface epithelium and mucus in gastric juice using biochemical, histochemical and morphometric methods. The condition of G- and D-cells was determined by immunomorphologic method and electron microscopy. The generally accepted methods of statistic analysis were used.*Results:* It was determined, that persistence of Hp in patients with DU was accompanied by considerable decrease of intracellular mucus quantity in surface epithelium ($p < 0.01$) with simultaneous increase of mucoprotein concentration in basal gastric juice ($p < 0.03$). That testified to intensive mucus exstrusion. These changes were increased in correlation with the increase of Hp-infection degree ($r = 0.62$). The conciderable decrease of fucose and sialic acids testified to qualitative changes of mucus. The morphologic confirmation of direct contact of Hp with G-cells was received. The different degree of G-cells hyperplasia accompanied with D-cells hyperplasia was noted in 23% patients with DU associated with Hp.*Conclusion:* The obtained data testify to the modulating action of Hp on protective mechanisms and neuroendocrine function of the stomach in DU. "P P 13 0325"P 13 0325**Immunohistochemical Study in Gastric Mucosa of *Helicobacter Pylori*-Positive Duodenal Ulcer**

*T. Shimizu, T. Ando, T. Yamaguchi, M. Sakakibara, M. Shinoda, T. Konagaya, K. Kyokane, M. Ohsuga, N. Kasuga, K. Kusugami

First Department of Internal Medicine, Nagoya University School of Medicine, Nagoya, Japan*Purpose:* In *Helicobacter pylori (H. pylori)* infected gastric mucosa, there is an increase in the number of polymorphonuclear neutrophils (PMN) and mononuclear cells (MNC). *H. pylori* is known to stimulate the production of chemokines involved in recruitment of PMN and MNC. This study aimed to evaluate infiltrating cells and chemokine activity (IL-8 and GRO-{ a}) in *H. pylori* infected gastric mucosa.*Materials and Method:* Ten duodenal ulcer patients were studied before and after 1 week eradication therapy with omeprazole, metronidazole, and clarithromycin. *H. pylori* infection was confirmed by bacterial culture, histology, CLO, and urea breath test before the treatment. Three mucosal biopsies were taken from the antrum and body, respectively: one was for immunohistochemical staining with the antibody against *H. pylori,* myeloperoxidase (MPO), CD11b, CD68, IL-8, and GRO-{ a}, one for HE staining to assess according to the Sydney system, and one for 24-hr organ cultures.*Results: H. pylori* eradication was achieved in all 10 cases (100%). Before eradication, there was a significant increase of mucosal PMN and MNC especially in the antrum. Most MPO-positive PMN were also positive for CD11b. After eradication, the number of MPO-positive PMN (antrum, 108.4 – 25.2 vs. 5.1 – 2.0/mm^2: body, 56.8 – 23.1 vs. 1.0 – 1.0/mm^2) and MNC was significantly decreased. The infiltrating IL-8 and GRO-{ a}-positive cells were mostly CD68-positive macrophages and their number decreased after eradication (IL-8, 59.6 – 12.8 vs. 14.7 – 6.9/mm^2: GRO-{ a}, 43.4 – 9.2 vs. 10.6 – 5.3/mm^2 in the antrum). Before eradication, the gastric epithelial cells were also positive for IL-8 and GRO-{ a}. In the organ culture supernatant, IL-8 and GRO-{ a} activity decreased significantly after eradication.*Conclusion:* Mucosal chemokines may play an important role in the pathogenesis of *H. pylori*-infected gastric mucosa. "P P 13 0326"P 13 0326**Salivary and Gastric Epidermal Growth Factor (EGF) and Gastric Mucosal EGF Expression in Duodenal Ulcer (DU) Patients before and after Eradication of Helicobacter Pylori (Hp)**

*P.C. Konturek[1], A. Bobrzynski[2], H. Ernst, S.J. Konturek[2], G. Faller[3], Ch. Klingler[1], T. Kirchner[3], E.G. Hahn[1]

Dept. Med. I, Univ. Erlangen, Germany

[3] Inst. Pathol., Univ. Erlangen, Germany

[1] Dept. Med. I and Inst. Pathol., Univ. Erlangen, Germany

[2] Inst. Physiol. Jagiell. Univ. Med. Sch. Krakow, PolandEGF is released mainly by salivary glands and promotes gastric mucosal growth and repair but the influence of Hp infection on EGF release and its mucosal expression have not been evaluated. In this study, basal and pentagastrin-induced salivary and gastric luminal release of EGF (radioimmunoassay) as well as gastric mucosal expression of EGF (immunohistochemistry and RT-PCR) have been examined. 10 Hp-negative (by ^{14}C-urea breath test) controls and 20 Hp-positive active duodenal ulcer (DU) patients were tested before and 4 weeks after 2 week triple therapy (amoxicillin 500 mg qd, metronidazole 500 mg bd and omeprazole 20 mg bd). There was no difference in basal salivary and gastric luminal EGF contents between healthy controls and DU patients. Infusion of pentagastrin (2 mg/kg-h) raised by 3 folds salivary and gastric luminal concentrations and outputs of EGF both in control and DU subjects but following successful eradication of gastric Hp (confirmed by histology and culture of endoscopic biopsy samples) and complete healing of DU, there was 3–4 fold higher gastric EGF release in basal state and after pentagastrin than before the triple therapy. Salivary basal and pentagastrin-stimulated EGF was not significantly affected by the triple therapy and Hp was detected in gingival pockets in 18 out of 20 DU patients using Hp culture and PCR technique. Gastric mucosal EGF expression was negligible in healthy controls but was 2–4 times higher in DU patients and triple therapy had no influence on this enhanced expression. We conclude that (1) the stomach itself is capable to release large amounts of EGF that is augmented by pentagastrin, (2) gastric Hp eradication by triple therapy results in DU healing and further increase in gastric luminal EGF release and mucosal EGF expression but does not affect salivary EGF release possibly due to the failure to eradicate oral Hp. Oesophageal gastric duodenal disorders: Helicobacter PyloriHormones and receptors: Growth factors }" "Salivary and Gastric Epidermal Growth Factor (EGF) and Gastric Mucosal EGF Expression in Duodenal Ulcer (DU) Patients before and after Eradication of Helicobacter Pylori (Hp)"

"P P 13 0327"P 13 0327**Is there a Correlation between the Mean Values of IgG and IgA Specific Antibodies Against *H. Pylori* and Severity of Chronic Active Gastritis?**

*C. Mart\'edn de Argila, D. Boixeda, C. Redondo, I.A. Baleriola, C. Arocena, J.P. Gisbert, V. Moreira

Gastroenterology and Pathology Departments, ""Ram\'f3n y Cajal"" Hospital, Madrid, Spain*Aim:* To evaluate the correlation between specific IgG and IgA values to *H. pylori* according to the severity of chronic active gastritis.*Methods:* A total of 400 patients attended at the Endoscopy Unit because of symptoms attributable to the upper gastrointestinal tract were studied. At endoscopy, multiple biopsies from gastric antrum, gastric body, and gastric fundus were obtained for histology and *H. pylori* culture.The severity of chronic active gastritis was graded as mild, moderate and severe on the basis of polymorphonuclear leukocyte infiltration of gastric mucosa. It was not possible to determine the severity of chronic active gastritis in 7 patients. At endoscopy serum samples were obtained for serological testing. Specific IgG and IgA antibodies against *H. pylori* were determined by a quantitative commercial IgG ELISA (Helico G, Porton, Cambridge, UK) and a semiquantitative comercial IgA ELISA (G.A.P. Test IgA. Bio-Rad, Italy), respectively. *H. pylori* infection was diagnosed if culture was positive in at least one of the biopsy samples obtained.*Results:* 355 out of 400 (89%) patients were diagnosed with histological chronic gastritis involving some of the portion stomach. A total of 337 out of 355 (95%) patients with histological chronic gastritis were infected by *H. pylori* (demonstrated by culture). Mean values of IgG and IgA specific antibodies against *H. pylori* in relationship to the chronic gastritis activity and the severity of gastritis in patients with gastritis yielded the following results: Chronic gastritis IgG (U/ml) IgA (U/ml)Without activity 69 – 38.6* 19 – 13.4Mild activity 77.4 – 44.5* 20.5 – 10.5Moderate activity 89 – 38.1 27.8 – 22.3Severe activity 105.8 – 30.8 53 – 69.1p < 0.05 in all comparisons between the different groups, with the exception of the comparison signed with ""*"".*Conclusions:* IgG and IgA specific antibodies against *H. pylori* mean values are clearly higher in patients with chronic gastritis with moderate and severe activity than those with chronic gastritis without activity. Moreover, mean values of IgG and particularly IgA specific antibodies against *H. pylori* *H. pylori* infection increased with increasing severity of chronic gastritis. Oesophageal gastric duodenal disorders: Helicobacter PyloriOesophageal gastric duodenal disorders: GD disorders, acid pepticImmunology and microbiology: Inflammation }" "Is there a Correlation between the Mean Values of IgG and IgA Specific Antibodies Against H. "P P 13 0328"P 13 0328**Correlation between Helicobacter Pylori Gastric Infection and Plasma Levels of Fibrinogen, Plasminogen Activator Inhibitor (PAI) and Von Willebrand Factor (vWF) AntigenL. Bierti,**

*C. Cernuschi, C. Abbiati, G. Beccari, R. Di Battista, R. Marchi, A. Federici[1], B. Bottasso[1], N. Di Rocco[1], R. de Franchis, P.M. Mannucci[1]

Gastroenterology Service, Institute of Internal Medicine, University of Milan, Italy

[1] A. Bianchi Bonomi Hemophilia and Thrombosis Centre, Institute of Internal Medicine, University of Milan, ItalyThere is evidence suggesting that patients at risk for coronary heart disease (CHD) are more likely to suffer from Helicobacter Pylori (HP) gastric infection than controls. In addition, preliminary data suggest that patients with HP infection may have high levels of plasma fibrinogen. *Aim:* to determine whether HP infection is associated with increased plasma levels of fibrinogen and other risk factors for CHD such as PAI and vWF antigen. *Methods:* consecutive patients undergoing upper gastrointestinal endoscopy at our Institute were studied. HP infection was diagnosed by the histological (modified Giemsa) and biochemical (CLO-test) methods. Concomitant inflammatory conditions were excluded by clinical examination and by measuring ESR, WBC, PCR, alpha-1-acid-glicoprotein. Fibrinogen levels were measured by Clauss' technique, while vWF antigen and PAI were assayed by ELISA. Statistical analysis was carried out by means of Student's t test. *Results:* 130 patients (66 HP positive and 64 HP negative) were enrolled. There was no difference between the two groups in sex, age, smoking history, hormonal therapy in females, arterial hypertension, dyslipidaemia, values of acute phase reactants, family history of CHD. Plasma fibrinogen levels (mg/dl) were 318 – 76 in the HP+ group vs 291 – 65 in the HP{ -} group; plasma PAI levels (ng/dl) were 41.2 – 29 in the HP+ and 35.8 – 24 in the HP{ -} patients; vWF antigen levels (U/dl) were 138 – 53 in the HP+ group vs 114 – 52 in the HP{ -} group. Differences between the two groups were statistically significant for vWF plasma levels p = 0.01 and fibrinogen plasma levels p = 0.037. *Conclusion:* Plasma levels of vWF and fibrinogen were significantly higher in HP+ than in HP{ -} patients, PAI levels were also increased in HP+ patients although the difference did not reach statistical significance. Further studies on larger patients populations are required to clarify whether HP+ patients are indeed at higher risk for CHD. Oesophageal gastric duodenal disorders: Helicobacter Pylori }" "Correlation between Helicobacter Pylori Gastric Infection and Plasma Levels of Fibrinogen, Plasminogen Activator Inhibitor (PAI) and Von Willebrand Factor (vWF) Antigen"

"P P 13 0329"P 13 0329**Helicobacter Pylori Infection and Serum Pepsinogen I Concnetration**

*S.M. Park, J.W. Park, B.C. Yoo

Dept of Med, Chung-Ang University Hospital, Seoul, Korea*Purpose:* In order to clarify the relationship between H. pylori (Hp) infection and pepsinogen I (PGI), we have compared fasting serum PGI levels before and after the eradication of Hp infection in patients with peptic ulcer. *Methods:* Serum PGI levels were measured by RIA in 511 Hp (+) and 225 Hp ({ -}) patients. 110 out of 511 Hp (+) patients were given TDB, metronidazole, ranitidine, and antacid. 97 Hp (+) and 54 Hp ({ -}) patients were treated only with ranitidine and antacid. *Results:* Fasting serum PGI levels were significantly higher in infected patients (124.3 – 46.9 vs 77.9 – 25.8 ng/ml, $p < 0.001$). Hp was eradicated in all the patients who received 4-week antibacterial therapy and serum PGI were significantly decreased from 129.8 – 43.0 to 82.4 – 24.0 ng/ml ($p < 0.001$). Pre- and post-eradication PGI levels of both Hp (+) patients, not receiving antibacterial therapy, (120.8 – 40.9 vs 126.3 – 40.4 ng/ml) and Hp ({ -}) patients (75.1 – 8.0 vs 77.3 – 24.5 ng/ml) were not changed. *Conclusion:* We have confirmed that Hp infection causes increased PGI secretion and eradication of Hp results in significant fall in PGI levels. }" "Helicobacter Pylori Infection and Serum Pepsinogen I Concnetration"

"P P 13 0330"P 13 0330**Serum *CagA* IgG Antibodies in Korean Patients with *Helicobacter Pylori* Infection and their Relation to Gastric Pathology and Serum Pepsinogen**

*K.C. Kim, H.J. Park, K.S. Lee, S.I. Lee, I.S. Park

Department of Internal Medicine, Yonsei University College of Medicine, Seoul, Korea*Purpose:* To examine serum IgG response to *CagA* protein of Helicobacter pylori (HP) in HP+ Korean patients with functional dyspepsia (FD) and peptic ulcer disease and evaluate its effect on gastric pathology and biochemical changes (changes of serum gastrin and pepsinogen (PG) concentrations).*Methods:* Sera from 74 patients with FD (n = 50), gastric ulcer (GU, n = 12) and duodenal ulcer (DU, n = 12), all of whom were HP+ by histology and rapid urease (CLO) test, were assayed by ELISA for *CagA* IgG antibodies using a recombinant fragment (50 kDa) of *CagA* as antigen. The cut-off level for seropositivity was determined as 2 standard deviations above the mean reactivity of Western blot negative sera. The degree of gastric inflammation was studied in patients with FD using gastric inflammatory scores (modified method of Marshall et al. and Rugger et al., total score 0–8). The serum levels of gastrin, PG I, PG II were also studied in patients with FD using radioimmunoassay kits.*Results:* Percentage *CagA* seropositivity in HP+ patients with DU, GU and FD was 92%, 83% and 77% respectively ($p = 0.28$). The magnitude of *CagA* IgG response was higher in patients with DU than those with GU and FD, but the difference was not statistically significant (mean optical density (OD) ratios; 0.41 – 0.25 *vs* 0.26 – 0.18 *vs* 0.28 – 0.21, $p = 0.12$). The IgG titers (OD ratios) of *CagA* in patients with FD (n = 32) correlated well with the degree of gastric inflammation (r = 0.6558, $p < 0.001$). The mean inflammatory score was 5.67 – 1.61 in *CagA*+ patients and 2.25 – 2.19 in *CagA*{ -} patients ($p < 0.01$). The IgG titers of *CagA* in patients with FD (n = 48) also correlated with serum PG II level (r = 0.3133, $p < 0.05$) and PGI/II ratio (r = { -}0.4056, $p < 0.05$), but not with serum levels of gastrin or PG I.*Conclusions:* Levels of *CagA* seropositivity in HP+ ulcer patients and HP+ FD patients did not differ in this Korean population and may not be useful to predict peptic ulceration. However IgG titers of *CagA* correlated well with gastric inflammation and serum PG II level. Oesophageal gastric duodenal disorders: Helicobacter Pylori }" "Serum CagA IgG Antibodies in Korean Patients with Helicobacter Pylori Infection and their Relation to Gastric Pathology and Serum Pepsinogen"

"P P 13 0333"P 13 0333**Decrease in Basal and Stimulated Gastrin and Pepsinogen I Levels after Eradication of *H. pylori.* A One-Year Follow-Up Study**

*J.P. Gisbert, D. Boixeda, T. Vila, A. Al-Mostafa, Mart\'edn C. de Argila, F. Bermejo

Ram\'f3n y Cajal Hospital, Madrid, Spain*Purpose:* To demonstrate the influence of *H. pylori* eradication on basal and stimulated gastrin (G) and pepsinogen I (PG) levels in duodenal ulcer patients, at an early stage and for a one-year follow-up period.*Methods:* Twenty-six patients (81% males, mean age 51 – 12 years) with a duodenal ulcer and successful *H. pylori* eradication were studied. In all patients biopsy (H&E) and a C^{13}-urea breath test were performed both at diagnosis and 1 month after completing therapy (triple therapy with bismuth, or omeprazole plus one or two antibiotics). Serum samples were obtained at diagnosis and at 1 month, 6 months and 1 year, to measure basal and stimulated G (10 and 20 min) and PG (30 and 60 min) levels after ingestion of beef cubes (Oxo Ltd. McColl et al, Lancet 1989) and injection of pentagastrin (6 \'b5gr/kg), respectively.*Results:* A significant histologic improvement both in the antrum and body ($p < 0.001$) was observed after finishing treatment. Decreases in G and PG levels after eradication are summarized in the table. G 0 m G 10 m G 20 m PG 0 m PG 30 m PG 60 mInitial 45 – 12* 94 – 48* 92 – 40* 101 – 30* 108 – 33* 118 – 36*1 mth 40 – 10* 62 – 22* 62 – 21* 83 – 23* 86 – 27* 95 – 29*6 mth 38 – 10 60 – 26 60 – 24 75 – 24* 77 – 25* 86 – 26*1 year 39 – 80 66 – 27 62 – 22 74 – 26 77 – 27 87 – 30m: minutes; *$p < 0.05$G levels decreased immediately after eradication (at 1 month), and remained unchanged afterwards (for the 1-year follow-up) (Wilcoxon test for paired data). However, decrease in PG occurred progressively during the 6 months following eradication (they fell down at 1 month, and again at 6 months). Finally, the values remained unchanged at 1 year.*Conclusions: H. pylori* eradication in duodenal ulcer patients was associated with a significant decrease in basal and stimulated G levels, that was detected immediately (one month) after finishing treatment, and remained unchanged for one-year. However, decrease in basal and stimulated PG levels occurred progressively during the six months following eradication, although such levels also remained unchanged afterwards.

"P P 13 0336"P 13 0336**H. Pylori Colonization of Gastric Metaplasia in Proximal Duodenum (DGM) Is Not an Obligatory Condition for a Duodenal Ulcer (DU) Development and a Preferentially One**

*D. Pospai, C. Vissuzaine, M. Merrouche, S. Forestier, M. Joubert-Collin, M. Mignon

Bichat, Cl. Bernard Hospital, Paris, FranceAccording to the accepted cascade of pathophysiological events in DU disease, H. pylori colonizes DGM resulting in active duodenitis and ulceration. In fact DGM is a pre-existing obligatory condition for DU development independent of any associated risk factor (Gastroenterology 1996; 110, 4: A 232). In contrast Hp is inconstantly found in DGM areas. To establish duodenal Hp prevalence and location in DGM areas, and determinants of duodenal Hp colonization, 55 active DU pts with Hp positive gastritis were evaluated prospectively. *Methods:* Duodenal Hp was detected by histology and immunohistochemistry (IHC) (antibody-DACO B0471) from multiple biopsies (4–8 quadrantic in 1st duodenum and 3 on DU margins). PAS (DGM prevalence and extent [as % of total epithelial surface measured in biopsies] and HPS [grading of gastritis (in 6 Sydney system biopsies) and duodenitis] stains were performed. *Results: Prevalence:* Duodenal Hp was detected in 17/55 (30.9%): Hp was detected by histology and IHC in 13 cases and by IHC only in 4 cases. *Location:* In all pts with Hp detected in duodenum, Hp was located on DGM areas harbouring the niches (100%) and concomitantly in DGM areas outside the ulcer in 23% only. In Hp+ve DGM areas, active duodenitis was present in 100% on ulcer margins and 50% in extra ulcer DGM areas. *Determinants* of the preferential duodenal Hp colonization: *a)* larger extent of Hp colonized DGM vs non colonized DGM: % median (range): 85 (70–100) vs 50 (10–100) respectively p = 0.03. *b)* significantly higher association with Hp pangastritis in duodenal Hp+ve (12/17) vs duodenal Hp{ -}ve (11/38) pts p = 0.03. *c)* significantly higher association with antral atrophic gastritis and intestinal metaplasia in duodenal Hp+ve (7/17) vs duodenal HP{ -}ve (5/38) pts p = 0.02. No other significant differences were observed concerning age, sex, familial history, smoking, number of relapses, location and type of ulcer or previous treatment between duodenal Hp+ve vs. Hp{ -}ve group. *Conclusion:* In DU pts Hp colonization of DGM was found in only 31%, located in the most extended areas of DGM and preferentially in patients presenting with both Hp pangastritis, antral atrophic gastritis and intestinal metaplasia. Oesophageal gastric duodenal disorders: Helicobacter PyloriEndoscopy, specific: Stomach, duodenum }" "H. Pylori Colonization of Gastric Metaplasia in Proximal Duodenum (DGM) Is Not an Obligatory Condition for a Duodenal Ulcer (DU) Development and a Preferentially One"

"P P 13 0338"P 13 0338**Structure of Gastric Mucous Membrane When an Ulcer Disease is Present Associated with Helicobacter Pylori (HP)M.I. Dauletbakova, B.K. Nurgalieva**

Almaty state medical institute, Almaty, Kazakhstan*The purpose:* study of the role HP colonization in progression of structural changes of gastric mucosae.*Materials and methods:* There were 162 patients observed with Ulcer disease, including 94 with gastric Ulcers and 68 with duodenal ulcers. Endoscopy with biopsy and histologic examination of gastric mucosal biopsies were performed as well as detection of HP. Cytologic smears and the presence of HP in them were studied also.*Results:* Endoscopic gastritis was diagnosed in 87% of gastric Ulcers, and 95% of duodenal ulcers. In histologic examination gastritis was found in 100% of the patients, surface gastritis in 13.6%, atrophic gastritis in 23.4%, atrophic gastritis with intestinal metaplasia in 38.8%, athrophic-hyperplastic in 6.2%, erosive gastritis 8%, diffuse gastritis in 10.5%. The cytologic picture was characterized by marked cell changes: there were signs of inflammation and proliferation in 100%, dysplasia in 85%, dystrophy in 53%, intestinal metaplasia in 65% and infiltration by lymphocytes in 38.8% of all cases. In all investigated smears, neutrophil infiltration was revealed. Cell dysplasia was characterized by expressed proliferation, illegible borders, polymorphic cells, changes of a nucleo-cytoplasmatic ratio. Dysplasia of the first degree was revealed in 9%, second degree in 55.6%, and third degree in 20.4% of all cases. The results listed above testify the significant structural changes of gastric mucosae in HP colonization. HP was detected by Standard histilogic method in gastric ulcers in 66%, and in duodenal ulcers at 87% of the time. In cytologic smears HP was detected in 67% of gastric Ulcers and in 89.8% of duodenal ulcers. *Conclusions:* The degree of HP colonization correlates with structural changes of gastric mucosae. It also correlates with the length of time needed for healing from ulcer damage. Structural changes and time for healing seem to be closely related. "P P 13 0339"P 13 0339**Helicobacter Pylori (HP) and Free Oxygen Radicals**

*N. Yen&idot;ce, N. Aksoy, M. Y\'fcksel, M. K\'fc\'e7\'fck, G. Haklar, S. Yal\'e7in

SSK Okmeydani Education Hospital & Marmara University Fac. of Medicine, Istanbul-TurkeyFree radicals (FR) can easily intake and give out electrons from molecules around them due to the fact that they contain in the last orbit only one electron. These radicals come into the being either during normal cell functions which are toxic, or materials produced by defence cells. They cause the degeneration and dead of the cell membrane or loss of organs function and tissue. The aim of our work was searching the relation between the action of HP on gastric mucosa inflammation caused by FR and to know the condition by patients given omeprazole (om.) or om. + amoxicillin (amox.) before or after treatment in the basis of FR.The study has begun with 20 female, 27 male (totally 47) patients. In our clinic with peptic complaints, who had taken no medicine for last 1 month. (Age range 16–63, average 35.9 years). Endoscopic results have shown duodenal ulcus 10, antral gastritis 25, bulbitis 7, bulbitis + gastritis 5 cases. The patients have been divided into two groups at random. *Group IA:* (n: 16), HP (+), omep. *Group IB:* (n: 24), HP (+), om. + amox. Another group was built up of HP ({ -})'s; *Group II:* (n: 7), HP ({ -}), om. Omeprazole was given. 40 mg/day orally every morning by hungery for 1 month, amox. 500 mg/day for 10 days orally. From each case 9 biopsies have been taken from antrum on days 0 and 30. HP searched by Clo test, FR were searched through chemiluminescense method. For H_2O_2, $OH^{\{-}$}, hypoclorit and peroxynitrite *""Luminal""*, for $O_2^{\{-}$} *""Lucigenin""* are used. The results are given as in the tableTable Luminal (Cpm/mg-tissue) Lucigenin 0. Day 30. Day 0. Day 30. DayGroup IA 2.25 1.57 2.40 1.61HP (+), Omep. p: 0.03 p: 0.008Group IB 1.65 0.32 1.96 0.49HP (+), Omep + Amox. p: < 0.001 p: < 0.001Group II 0.60 0.30 0.82 0.64HP ({ -}), Omep. p: 0.11 (NS) p: 0.02 (St. t test)*Conclusion:* * The FR level before the treatment in both HP (+) and HP ({ -}) were considerably high. This indicates that HP is increasing of the gastric mucosa inflammation through the FR. * By single or combined treatment a considerable decrease of FR has been observed. (Those decreases are more obvious by the patients who take om. + amox. related to the patients who take only om. So the treatment of peptic diseases causes to decrease of FR and consequently the decreasing of destructive action of HP. Oesophageal gastric duodenal disorders: Helicobacter Pylori }" "Helicobacter Pylori (HP) and Free Oxygen Radicals"

"P P 13 0340"P 13 0340**Condition of Hormonal System and Mucosal Immune Response of Antral Secion in Women of Different Age Categories with Helicobacter Pulori: — Associated Duodenal Ulcer**

*R.R. Gazizova, A.N. Novikova, M.A. Vinogradova, F. Kamilov, L.N. Mingazetdinova, N.A. Vinogradov, E.G. Mutalova

Bashkir Medical University, Ufa, Russia*Aim:* To investigate the relationship between the hormonal system and the local immune response of the gastric mucosa (GM) in women of the reproductive and postmenapausal age groups with duodenal ulcer (DU) associated with Helicobacter pulori (H.p.).*Methods:* Basal Levels of pituitary (F SH, LH, STH, ACTH, TSH) and peripheral hormones (estradiol, progesterone, testosterone, cortisol, T3, T4, gastrin, C-peptide, insulin) in 98 women with DU in both phases of their menstrual cycle plus 20 control subjects and also in 76 elderly women as well as 16 comparable controls were assessed by RIA. In antral biopsies the number of Ig A, M, G-producing cells and T-helpers (T-h), and T-suppressors (T-s) — by the indirect immunofluorescent method with the aid of monoclonal antibodies. H.p. was detected according to L. Walters et al.*Results:* It has been found that DU distorts the feedback between the central and the peripheral parts of the endocrine system. The prevalence of confirmed H.p. was 98.2%, the number of H.p. bacteria in the pits was 15.44 – 0.54 against 10.29 – 0.14 in younger women ({\'b4} 900 magnification). Elderly women manifested a statistically reliable decline in the number of IGA-producing cells ($p < 0.01$) and T-h. Their immunoregulatory index was reduced to 0.71 against 0.81 in younger women. Women of the reproductive age group had a high correlation between the amount of protesterone and IGM in the first phase of the menstrual cycle, such correlation disappeared in the second phase; in elderly women there was a positive correlation between IgG and STH and a negative correlation with the number of H.p. ($R = 0.74$, $D = 0.55$).*Conclusion:* Depending upon their age and phase of the menstrual cucle, women suffering from DU associated with H.p. display marked differences in the relationship between the hormonal system and the local immune response of GM. "P P 13 0341"P 13 0341**Gastric Mucosa Lymphoid Hiperplasia in Helicobacter Pylori (H P) Infections****C. Hajdu, G. Simu, S. Bataga[1], L. Bancu[1], C. Copotoiu[2]**

Department of Pathology, Clinical Contry Hospital Tg Mures, Romania

[1] Department of Gastroenterology, Clinical Contry Hospital Tg Mures, Romania

[2] Depart. of Surgery, Clinical Contry Hospital Tg Mures, RomaniaA long time infection with H P can evolve in some people from diffuse lymphoid hiperplasia towards malignant lymphoma, although the lymphoid tissue is not extremely abundant in the gastric mucosa.Were studied 54 surgical removed stomachs, 46 from patients with complicated gastric ulcer and 8 from patients with endoscopic aspect as lobulated, polypoid mass in the distal half of the stomach. We made slides from gastric mucus and stained them with Giemsa for HP; the removal pieces were embeded in paraphin and stained with hematoxiline eosine and PAS hematoxiline. We also applied imunohistochimic methods.39 cronic gastric ulcers associated with cronic gastritis and H P infections have been found. In 7 cases the gastric ulcer was accompanied by a diffuse mucosal and submucosal inflamatory hiperplasia with the presence of clearly reactive germinal centers throughout the lesions. In the gastric mucus H P was present. One case was a marginal extranodal lymphoma with small cleaved cells, accompanied with cronic diffuse gastritia with active foci and a high H P infection. We found also 2 large polymorphous B cell lymphoma and 4 cases were mixed diffuse form, small and large B cell limphoma. In the 2 cases of large cell lymphoms in the gastric mucus microbian flora was polymorph and HP was absent. Interesting was the case of an undiferentiated gastric carcinoma accompanied with a high diffuse lymphoid hiperplasia, HP being also present.Our observation sugest that the H P infection could develop an important lymphoid hiperplasia, sometimes liable to turn into lymphoma. The establishment of policlonal or monoclonal nature of the lymphoid hiperplasia by imunohistochemical methods is essential in finding out the reactive or neoplasic aspect of this hiperplasia. "P P 13 0342"P 13 0342**DNA Fingerprinting of Helicobacter Pylori Isolated from Patients with Peptic Ulcer**

*C.S. Shim, Y.H. Lee, Y.D. Cho, H.K. Bong, J.O. Kim, J.Y. Cho, Y.S. Kim, J.S. Lee, M.S. Lee, S.G. Hwang, S.J. Hong

Institute for Digestive Research, Division of Gastroenterology, Soon Chun Hyang University, Seoul, KoreaThe gastric pathogen, Helicobacter pylori establishes long-term chronic infection that can lead to gastritis, peptic ulcer, and gastric cancer. Urease might allow the survival of the bacteria in an acidic environment, a prerequisite for colonization. Helicobacter pylori is cytotoxic to cultured human gastric epithelial cells and this toxicity is due in part to ammonia produced by hydrolysis of urea. In a previous study by Foxall et al., they suggested that Hae III digest patterns of PCR-amplified UreA and UreB genes might serve as a sensitive epidemiological tool for the typing of clinical isolates of Helicobacter pylori. We obtained the PCR-amplified UreA and UreB genes from the 18 clinical isolates in Korean and analyzed the Hae III digest patterns. In methods, clinical isolates of Helicobacter pylori were obtained by endoscopic biopsy from 18 patients with gastric or duodenal ulcer. Biopsy tissues were inoculated onto blood agar plates containing 5% horse serum and skirrow's supplement, and the plates were cultured for 3 days at 37 \'b0C under microaerobic conditions. Chromosomal DNA of Helicobacter pylori were extracted from harvested colonies and PCR amplification were performed to amplify the urease structural subunit genes, UreA and UreB (Labigne A, et al. J. Bacteriology, 1991). PCR products, digested with Hae III, were run on 1.5% agarose gels. In results, the 2.4 kb PCR products were amplified from all 18 Helicobacter pylori isolates. From the restriction enzyme digestion of these PCR products, we could classify on the basis of RFLP patterns by Hae III restriction endonuclease digestion produced 11 distinct patterns on agarose gel, with five patterns occurring within two or three isolates. In conclusion, the urease genes of Helicobacter pylori had genetic heterogeneity, therefore it could be of considerable tool for epidemiological studies. Oesophageal gastric duodenal disorders: Helicobacter PyloriImmunology and microbiology: GI infections in adults }" "DNA Fingerprinting of Helicobacter Pylori Isolated from Patients with Peptic Ulcer"

"P P 13 0343"P 13 0343**Low Gastric Glutathione and Glutathione S-Transferase Levels in Patients Infected with Helicobacter Pylori**

*M.L. Verhulst, A.H.A.M. v Oijen, H.M.J. Roelofs, W.H.M. Peters, J.B.M.J. Jansen

Department of Gastroenterology, University Hospital Nijmegen. The Netherlands*Introduction:* Infection with Helicobacter pylori (HP) is strongly associated with peptic ulcer disease. In addition, chronic infection with HP may increase the risk of gastric cancer. The mechanism of carcinogenesis, however, is not yet clarified.Glutathione (GSH) and glutathione S-transferases (GSTs) represent an important detoxification system in epithelial cells of the gastrointestinal tract. Toxins or carcinogens are inactivated by conjugation with GSH, catalyzed by GSTs. High levels of GSH and GST have been correlated with a low risk of developing gastrointestinal cancers.*Methods:* GST and GSH levels were measured in biopsies taken from the gastric antrum of 1) patients with gastric complaints without HP infection (n = 57; age 43.1 – 13.5 yrs), 2) patients who became HP negative after eradication of HP (n = 22; age 49.4 – 2.3 yrs) and 3) patients with proven HP infection (n = 24; age 49.5 – 2.6 yrs). Results are given as means – SD and were tested for significant differences with the Wilcoxon rank sum test.*Results:* GSH and GST levels in both groups of patients negative for HP (groups 1 and 2) did not differ and were 32.8 – 10.8 vs. 27.2 – 11.1 nmol/mg protein, and 775 – 291 vs. 860 – 208 nmol/min. mg protein, respectively. GSH and GST values in the HP positive patients (11.6 – 11.8 nmol/mg protein and 591 – 176 nmol/min. mg protein, respectively) were significantly lower as compared to values in both groups of HP negative patients (all p-values < 0.01).*Conclusion:* The antral mucosa of patients infected with HP contains significantly lower amounts of GSH and GST, which results in a decreased capacity to detoxify toxins and carcinogens. This finding may contribute to the increased risk of development of adenocarcinomas in these patients. "P P 13 0345"P 13 0345**Degradation of Growth Factors by Helicobacter Pylori: Effect of Sucralfate**

*B.L. Slomiany, J. Piotrowski, A. Slomiany

Res. Ctr., UMDNJ, Newark, NJ USAInfection with Helicobacter pylori (HP) is now recognized as a major factor in the pathogenesis of gastric disease, and the bacterium is known to elaborate a number of enzymes capable of rapid compromise of gastric mucosal homeostasis and the repair mechanisms. Among the factors implicated in the control of mucosal repair are bioactive peptides that exert their effects by activating specific cell surface receptors which often contain an intrinsic tyrosine kinase activity. The purpose of this study was to assess the susceptibility of EGF, bFGF TGF{ b} and PDGF to degradation by HP protease. The effect of an antiulcer agent, sucralfate on this pathogenic activity of HP was also investigated. The experiments were carried out with HP protease obtained from the filtrates of saline washes of the bacterium cultures. The incubation assays for growth factors susceptibility to HP protease consisted of ^{125}I-labeled EGF, bFGF, TGF{ b} or PDGF, enzyme protein (50 \'b5g), sucralfate (0–200 \'b5g), and 0.22 ml of phosphate buffer, pH 7.0. The reaction mixtures were maintained at 37\'b0C for 1 h, and then subjected to chromatography on Bio-Gel P-2 column and the produced ^{125}I-labeled peptide fragments were quantitated by counting in a gamma counter. The results established that under the assay conditions HP caused only 5–7% degradation of EGF and bFGF. However, the HP protease evoked a 61.7% degradation of PDGF and a 62.3% degradation of TGF{ b}. Introduction of sucralfate to the assay system caused the inhibition in the extent of growth factors proteolysis by HP enzyme. This inhibitory effect of sucralfate was dose dependent and reached a maximum value at 200 \'b5g/ml sucralfate, at which concentration a 79.7% decrease in PDGF and 82.7% decrease in TGF{ b} degradation occurred. The results provide strong evidence for the effectiveness of sucralfate in the protection of gastric mucosal growth factor pool against degradation by HP. "P P 13 0346"P 13 0346**Increasing Surface Hydrophobicity in Transformation to the Coccoid Form of Helicobacter Pylori. A Pathogenic Factor?D. Risberg, H. Enroth, L. Engstrand, A. Uribe**

Department of Medicine, Karolinska Institute, Danderyd Hospital, Stockholm, Sweden

Department of Microbiology, University Hospital, Uppsala, SwedenIt has been suggested that the coccoid form of H. pylori facilitate the survival of the microorganism in the stomach. This may contribute to the relapses of infection following eradication therapy. Our aim was to examine the contact angles during transformation of H. pylori to the coccoid form, to estimate potential changes in surface hydrophobicity which could affect bacterial attachment and the protection of the microorganism in an acidic environment.*Methods: H. pylori* strains 88–23, A5 and knock-out mutants lacking vac A cytotoxic protein (A5 vac A), the urease-negative strain 4, and the mutant strain 69 A lacking flagellae were investigated. All strains were cultured on agar from 2 up to 15 days. Samples of viable bacteria were obtained at regular intervals, and evenly spread on glass covers. After 30 minutes of drying, a droplet of saline was applied and the contact angle was measured using a goniometer.*Results:* In all examined strains the contact angle was significantly increased from day 2–3 and on, compared to control values ($p < 0.001$). Thus, the contact angle of the strain 88–23 was 50% higher after 14 days, the maximal increment for the urease negative strain was 46.15% and for the flagellae-negative mutant 28.3%, respectively. Similarly, an increment in contact angle of 37% and 21.5% were observed in the A5 and the A5 vac A strains, respectively.*Conclusions:* Development of coccoid forms of H. pylori is associated with increased surface hydrophobicity, which may facilitate the attachment of the microorganism to the gastric mucosa. Possibly, it may also act as a protective mechanism against hydrophylic agents such as gastric acid. Oesophageal gastric duodenal disorders: Helicobacter PyloriImmunology and microbiology: GI infections in adultsImmunology and microbiology: Host defense mechanisms }" "Increasing Surface Hydrophobicity in Transformation to the Coccoid Form of Helicobacter Pylori. "P P 13 0347"P 13 0347**Gastric Production of Inflammatory Cytokines in Patients with Helicobacter Pylori Infection with and without Duodenal Ulcer**

*C. Abbiati, M. Pomati[1], G. Meucci, G. Beccari, C. Calabresi, R. Di Battista, M. Vecchi, L. Bierti, R. de Franchis

Institute of Internal Medicine, University of Milan, Milan, Italy

[1] Institute of Medical Sciences, University of Milan, Italy

IRCCS Ospedale Policlinico, Milan, ItalyAn enhanced mucosal production of interleukins 8 (IL-8) and 6 (IL-6) has been observed in Helicobacter pylori (Hp) infection, while fewer data are available on interferon gamma ({ g}INF) and IL-4. However, the correlation between cytokines levels and presence of duodenal ulcer (DU) is unknown.*Aim:* to study gastric mucosal production of IL-8, IL-6, IL-4 and { g}INF in patients with Hp infection with DU or nonulcer dyspepsia (NUD).*Methods:* we studied 13 patients with Hp+ DU, 8 with Hp+ NUD and 4 with Hp{ -} NUD. 10 DU patients underwent repeat endoscopy after treatment. Hp was assayed by rapid urease test and histology. IL-8, IL-6, IL-4 and { g}INF concentrations were measured in the homogenate supernatant of 2 antral biopsies by commercially available ELISA kits. *Results:* (see table) IL-8 was detectable in 0/4 patients with Hp{ -} NUD, in 5/8 Hp+ NUD and in 12/13 untreated DU. IL-8 levels were higher in Hp+ than in Hp{ -} patients (p = 0.013). After treatment, IL-8 was detectable in 0/4 eradicated and in 5/6 noneradicated DU patients. IL-6 was detectable in 7/13 untreated DU but in 0/12 NUD, regardless of Hp status (p = 0.026), and remained delectable in most DU patients after ulcer healing and/or Hp eradication. { g}INF levels were higher in Hp+ NUD and UD than in Hp{ -} NUD, reaching statistical significance (p = 0.046) only for Hp+ NUD; IL-4 was detected only in 1 patient with DU. Cytokine Hp+ Hp{ -} Hp + DU DU after treatmentmean NUD NUD Baseline healed Hp{ -} healed Hp+ unhealed(pg/mg) n = 8 n = 4 n = 13 n = 4 n = 2 n = 4IL-8 26.7 0 39.8 0 21.0 18.8IL-6 0 0 1.4 2.0 0 0.8{ g}INF 10.0 0 7.1 3.1 0 0*Conclusions:* Our data confirm a strong correlation between IL-8 production and Hp infection, regardless of the presence of DU. A weaker correlation exists between Hp positivity and { g}INF levels. IL-6, by contrast, appears to be produced only in patients with DU, either active or healed. "P P 13 0348"P 13 0348**Antral G-Cell and D-Cell Numbers in Helicobacter Pylori Infection**

*S.M. Park, H.R. Lee, H.S. Park[1]

Dept of Med, ChungAng Univ. Hospital, Seoul, Korea

[1] Dept of Pathology, National Medical Center, Seoul, Korea*Purpose:* It has been recognized that H. pylori infection induced abnormal regulation of serum gastrin secretion. We examined whether there was a relationship between H. pylori infection and G- and D-cell numbers. *Methods:* The numbers of antral G- and D-cells and serum gastrin levels were compared between 37 peptic ulcer patients infected with H. pylori and 33 patients without infection. G- and D-cells in antral mucosa were examined immunohistochemically using antibodies specific for the gastrin and somatostatin. *Results:* While the number of G-cells per gastric gland was similar in infected and uninfected patients (7.1 – 3.1 vs 7.3 – 3.9), that of D-cells was significantly less in infected patients (1.3 – 0.4 vs 2.5 – 1.6, $p < 0.001$, G/D-cell ratio: 5.7 – 2.7/1.0 vs 3.5 – 19./1.0, $p < 0.001$). Serum gastrin level was also significantly higher in infected patients (80.3 – 23.5 vs 47.6 – 14.1 ng/ml, $p < 0.001$). *Conclusion:* These results suggest that H. pylori-associated increased secretion of gastrin appear to be related to relative G-cell hyperfunction resulted from reduced number of D-cells. }" "Antral G-Cell and D-Cell Numbers in Helicobacter Pylori Infection"

"P P 13 0349"P 13 0349**Helicobacter Pylori (Hp) and Domestic Cats**

*D. Bets, J. Ferwerda, W. Dekker

Department of internal medicine, EG Haarlem and Comprehensive Cancer Centre Amsterdam, The NetherlandsHandt et al isolated (Infection and Immunitity 62: 2376–2374) Helicobacter pylori from domestic cats in 1994. Because the exact mode of transmission is not fully understood we speculated that patients who had been living in close contact with cats in child- and/or adulthood may have a higher infection rate of Hp.From 200 consecutive patients who attended the endoscopy unit for diagnostic oral endoscopy 5 biopsies were taken from their stomach, independent of whatever endoscopic diagnosis was made. Two from antrum and corpus for histology and one for the CLO-test from antrum to determine if they were infected with Hp. These patients were asked if they had been in close contact with cats in child-and/or adulthood and whether they were born and lived in the Netherlands. The same questionnaire was handed out to patients who visited the department for colonoscopy. Excluded from this study were patients who were treated recently for eradication of Hp, had undergone gastric surgery, were suffering from bleeding during examination or came for an acute endoscopy. We decided that a patient was Hp positive if both CLO-test and histology turned out to be positive. Likewise a patient was free of Hp. if both assys didn't show Hp.In a period of 4 months 185 patients were enrolled in this study. In 25 of the cases the CLO-test outcome was not equal to histology. From the remaining 160 patients 38 were Hp positive (23.8%) and 122 negative. From the 40 patients who never had cats 11 (28%) were contaminated with Hp. The ""ever"" group is a combination of people who had cats all their lives 10.7% (3/28) or only in child- or adulthood resp. 28.1% (9/32) and 22.2% (6/27) were Hp positive. The overall Hp positive status of Dutch patients in our study turned out to be 22.8% (29/127). The patients who came for colonoscopy showed an eqal behavior in owning cats as the gastroscopy group.With only 22.8% of our patients suffering from Hp, the incidence in our patient group is low compared to the 30–50% which is the average nation-wide. In our material we didn't find over-presentation of Hp positive patients whom were in close contact compared to the ""never"" group. Although the group of people who were in close contact with cats all their lives is small with only 28 patients, this group shows a remarkable low percentage of 10.7% infected patients.So in our patient group we couldn't find support for our speculation that owning a cat leads to a higher rate of Hp. Clinical practice: Epidemiology (non cancer) }" "Helicobacter Pylori (Hp) and Domestic Cats"

"P P 13 0350"P 13 0350**Inhibition of Gastric Mucosal Somatostatin Receptor by H. Pylori Lipopolysaccharide: Effect of Ebrotidine****J. Piotrowski, A. Slomiany,**

*B.L. Slomiany

Res. Ctr., UMDNJ, Newark, NJ USAAmong the consequences of Helicobacter pylori (HP) infection is the loss of inhibition of gastrin release and subsequent hypergastrinemia. This apparent pathological effect of HP has been linked to the impairment in feedback inhibition by somatostatin. Recently, we provided evidence that HP through its cell wall lipopolysaccharide inhibits the binding of somatostatin to its mucosal cell membrane receptor (Biochem. Mol. Biol. Int. 1995: 36; 491). The purpose of this study was to assess whether an antiulcer agent, ebrotidine, is capable of countering this untoward effect of HP. The study was conducted with rat gastric mucosa. The somatostatin receptor was prepared from the solubilized gastric epithelial cell membranes by affinity chromatography on a column consisting of covalently coupled D-Tryp^{8}-SRIF-14 to Affi-Gel 10. The receptor protein displayed on SDS-PAGE a band of 61 kDa and showed specific affinity towards ^{125}I-labeled somatostatin. The binding of somatostatin to the isolated mucosal somatostatin receptor was inhibited by HP lipopolysaccharide and reached a maximum of 94.1% inhibition at 50 \'b5g/ml. Preincubation of HP lipopolysaccharide with ebrotidine caused a dose-dependent reversal of HP inhibitory effect, and at the optimal concentration of 20 \'b5g/ml ebrotidine produced an 84% restoration in somatostatin-mucosal receptor binding. The interference by HP lipopolysaccharide with the receptor binding site for somatostatin could account for the observed deficiency of negative feedback from D-cells to G-cells with HP infection. Further, our results demonstrate that ebrotidine possesses the ability to counteract HP interference with somatostatin acid secretion regulatory effects. Hence, ebrotidine offers a new potent choice in ulcer therapy. "P P 13 0351"P 13 0351**Inducible Nitric Oxide (NO) Synthase in *Helicobacter Pylori* Associated Gastritis in Duodenal Ulcer Patients**

*J. Stachura, J.W. Konturek, E. Karczewska, W. Domschke, S.J. Konturek

Inst Physiol & Pathomorphol Univ Sch Med Krakow

Dept Med B, Univ Muenster, FRG*Purpose:* Previous studies showed the presence of constitutive NO synthase (NOS) in gastric epithelial and endothelial cells and NO was found to mediate mild irritant-induced gastroprotection and mucosal hyperemia in rats but no study was undertaken to identify the role of inducible NOS (iNOS) in mucosal damage associated with *Helicobacter pylori* (Hp) infection in men.*Methods:* The immunohistochemistry, which selectively stains iNOS has been used to detect the iNOS in the antral mucosa obtained by endoscopic biopsy from Hp positive (^{14}C-urea breath test, histology and culture) duodenal ulcer (DU) patients and in the Hp isolated from the culture of antral mucosa. These bacteria were checked that they are members of the group of Gram-negative, spirally curved microaerophylic, oxidase-positive rods. A sterile swab harvested all culture from previously prepared subculture plates. The density of bacteria suspended in saline was – 10^9 colony forming units and 30 \'b5l of this suspension was smeared on glass and air dried. The immunoreactivity of iNOS was examined using primary antibody (Santa Cruz Biotechnology Inc, Santa Cruz, CA) diluted at 1:50. The reaction was completed with APAAP Dako kit (Dako, Copenhagen) using fast red as chromogen.*Summary of results:* The iNOS immunoreactivity was found in the antral mucosa obtained during gastroscopy from 50 active DU patients who were Hp-positive (with ^{14}C-urea breath test, CLO-test and culture). The iNOS was detected in histiocytic cells and in mucosal microvessel cells. The epithelial cells in the pits and glands were negative. The isolated bacteria from these DU patients were strongly stained by the antibody used in all tested samples.*Conclusions:* Hp is capable of expressing iNOS and NO produced in excess in gastric mucosa by this enzyme may contribute to the pathogenesis of Hp-associated gastritis Oesophageal gastric duodenal disorders: Helicobacter PyloriOesophageal gastric duodenal disorders: GD disorders, acid peptic }" "Inducible Nitric Oxide (NO) Synthase in Helicobacter Pylori Associated Gastritis in Duodenal Ulcer Patients"

"P P 13 0352"P 13 0352**Helicobacter Pylori (Hp) and Gastrin-Somatostatin (S-S) Link in Duodenal Ulcer (DU) Patients**

*J.W. Konturek, W. Bielanski, S.J. Konturek, W. Domschke

Dept. of Medicine, University of M\'fcnster, M\'fcnster, Germany

Institute of Physiology, Jagiellonian University School of Medicine, Krak\'f3w, PolandHp infection is associated with DU in over 90% of patients and accompanied by increased release of gastrin and deficiency of S-S but the mechanisms of these changes in patients after eradication of Hp have little been studied. Cholecystokinin (CCK) has been implicated in the feedback control of gastric acid secretion in healthy subjects but its contribution to secretory disorders and delay of ulcer healing in DU patients have not much been examined. This study, therefore, investigated whether CCK participates in the impairment of postprandial gastrin release and gastric acid secretion in active DU patients. Tests were undertaken in 10 DU patients without or with elimination of the action of endogenous CCK using loxiglumide (LOX), a selective CCK-A receptor antagonist, before and 4 wks after eradication of Hp with triple therapy (omeprazole, amoxycillin and bismuth). In Hp positive DU patients, the postprandial acid secretion (measured by continuous intragastric pH monitoring) was accompanied by a pronounced increment in plasma gastrin with negligible increase of intraluminal release of S-S. The administration of LOX in these patients did not affect significantly the postprandial pH profile and the rise in plasma gastrin. After eradication of Hp the median postprandial intragastric pH increased to about 4.3 (compared to 3.5 before Hp eradication); the postprandial gastrin concentration was reduced by about 40%, while luminal release of S-S was increased about 2 fold. The administration of LOX resulted in significantly greater decrease in median pH (3.1) and higher rise in postprandial plasma gastrin in these patients. Also the postprandial plasma S-S showed a small, but significant decline (by about 25%) as compared to that in placebo treated patients. This study provides evidence that: (1) Hp infection in DU patients is accompanied by enhanced gastrin release and reduction in luminal release of S-S; (2) The failure of LOX to affect gastric secretion and plasma gastrin in Hp infected DU patients could be attributed, at least in part, to the failure of endogenous CCK to control gastric acid secretion via release of S-S; (3) Hp infected patients appear to exhibit a deficiency of S-S release that can be reversed by the eradication of Hp indicating that both CCK and S-S may contribute to the acceleration of ulcer healing following Hp eradication in DU patients; (4) Testing with LOX and gastric luminal S-S assay may be useful in identification of Hp positive DU patients with CCK-mediated impaired feedback control of gastric secretion and deficiency of S-S caused by Hp infection. Oesophageal gastric duodenal disorders: Helicobacter PyloriOesophageal gastric duodenal disorders: GD disorders, acid pepticOesophageal gastric duodenal disorders: Secretion: mechanism, regulation }" "Helicobacter Pylori (Hp) and Gastrin-Somatostatin (S-S) Link in Duodenal Ulcer (DU) Patients"

"P P 13 0353"P 13 0353**Health Care Workers and *Helicobacter Pylori* Infection**

*C. Mart\'edn de Argila, S. Sainz[1], R. Sainz[2], D. Boixeda, J. Mon\'e9s[1]

Department of Gastroenterology, ""Ram\'f3n y Cajal"" Hospital, Madrid, Spain

[1] Department of Gastroenterology, Santa Creu i Sant Pau Hospital, Barcelona, Spain

[2] Department of Gastroenterology, Hospital Cl\'ednico, Zaragoza, SpainAn oral-to-oral route of transmission of *H. pylori* infection has been postulated, which is supported by the observation that *H. pylori* is present in saliva, gastric juice and dental plaque. On the basis of this assumption, an increased risk for *H. pylori* infection among health care workers was postulated.*Aim:* To determine the prevalence of *H. pylori* infection among a wide group of health care workers compared with a control group and its possible relationship with inherent endoscopy risks.*Materials and Methods:* A group of 224 medical workers (48 females; mean age: 41. – 8 yrs; range: 25–70 yrs) and a control group of 84 persons (36 females; mean age: 36.3 – 10.4 yrs; range: 19–62 yrs) -not working in health area- were studied. Subjects with history of previous peptic ulcer or digestive disease were excluded. All health care workers were asked for their relationship with gastroenterology and endoscopy activities. In all subjects *H. pylori* status was assesed by the ^{13}C-urea breath test following the European Standard Protocol. A positive result was defined as an excess of { d}$^{13}CO_2$ excretion > 5%.*Results:* The overall (medical and non health care workers) *H. pylori* prevalence was 50%.The measurement of ^{13}C-urea breath test in different groups yielded the following distribution: Control group 37/84 (44%)Medical workers 118/224 (53%)Non Gastroenterologists 22/44 (50%) p > 0.05Gastroenterologists 96/180 (53%)Endoscopists 23/43 (55%) p > 0.05Non endoscopists 73/137 (53%)No significant differences were observed comparing *H. pylori* prevalence in the control group with other groups.*Conclusions:* 1) The overall *H. pylori* prevalence was in agreement with that observed in other western countries. 2) Health care workers had not a higher prevalence of *H. pylori* infection than the control group. 3) Performing gastrointestinal endoscopies and the gastroenterology specialty itself are not associated with a higher risk for developing *H. pylori* infection in Spain. "P P 13 0354"P 13 0354**Does Helicobacter Pylori Infection Have a Role in Primary Sj\'f6gren's Syndrome?N. Erdem, G. Ers\'f6z,**

*A. Aydin, U.S. Akarca, E. Doganavsargil, \'c7. B\'fcke, T. Akalin, Y. Batur

Rheumatology, Gastroenterology, Microbiology and Pathology Depts, Ege University, Izmir, T\'fcrkiyeTo investigate a possible relationship between primary Sj\'f6gren's syndrome (pSs), an autoimmune disease of unknown etiology, and Helicobacter pylori (Hp) infection 14 patients with pSs (13 women and 1 men, mean age: 48 – 13.2) were studied. The diagnosis of pSs was based on Sen Diego criteria. Hp infection was assessed by histology, urease test and culture of gastric biopsies and detection of IgG antibodies for Hp. All cases were treated with omeprazole 20 mg b.i.d. for 1 month and amoxicillin 1 g b.i.d, and tinidazole 500 mg b.i.d. between 16–30 days. Clinic and endoscopic examinations were repeated one month after completion of the therapy. Hp eradication was defined by negativity of all these tests, except anti-Hp IgG.Active Hp infection was diagnosed in 11 (78.4%) cases. In 2 (14.3%) patients anti-Hp IgG was positive alone. Hp eradication was achieved in all cases. After Hp eradication xerostomia disappeared in 8 (57.1%). But, xerostomia was not improved in any of 3 Hp ({ -}) cases, given the same therapy. Mean serum IgG level decreased from 2036.5 – 726.2 mg/dl to 1817.9 – 597.6 (p = 0.06) and Chisholm score, showing the degree of mononuclear cell infiltration on lip mucosal biopsy, from 3.45 – 0.9 to 2.7 – 1.3 (p = 0.1). Shrimer's test improved from 6.0 – 5.4 mm to 13.9 – 9.4 (p = 0.0006). In Hp ({ -}) 3 cases, given the same therapy, mean IgG level changed from 2584.6 – 1084.2 mg/dl to 2023.6 – 896.7 and Chisholm score from 3.0 – 1.7 to 2.3 – 1.5. Shrimer's test also increased from 11.3 – 8.1 mm to 14.0 – 7.9 (Because of small number of patients statistical evaluation could not be performed).*Conclusions:* 1. The prevalence of Hp is high in patients with pSs. 2. Hp eradication results in a significant improvement in the signs and symptoms of pSs. 3. It seems that Hp infection may have a role in the pathogenesis of pSs. 4. Probable beneficial effect of the therapy should be tried in more Hp ({ -}) patients. Oesophageal gastric duodenal disorders: Helicobacter Pylori }" "Does Helicobacter Pylori Infection Have a Role in Primary Sjögren's Syndrome?"

"P P 13 0356"P 13 0356**DNA Typing of HLA Class II Genes in Japanese Patients with *Helicobacter Pylori* Infection**

*S. Yoshitake, M. Okada[1], T. Sasazuki[2]

[1] First Department of Internal Medicine, Fukuoka Univ.

[2] Department of Genetics, Medical Institute of Bioregulation, Kyushu Univ.*Purpose:* The aim of this study is to investigate the HLA-linked genetic predisposing factors in *H. pylori* infection.*Subjects and Methods:* The study group consisted of 58 Japanese patients with *H. pylori* positive gastric ulcer and 44 Japanese patients with *H. pylori* positive duodenal ulcer and 44 Japanese patients with *H. pylori* positive gastritis. Control subjects were 36 without *H. pylori* infection. The biopsy specimens taken from the antrum and the body were used for the bacterial culture. We compared HLA class II genes between control and patients groups. HLA class II genes was analyzed by the PCR-SSOP typing of each group.*Results:* 1) The allele frequencies of DRB1*1502, DPA1*0201 and DPB1*0901 were significantly higher in *H. pylori* positive gastric ulcer patients than in controls, whereas those of DRB1*1501, DQA1*01021 and DQB1*0601 were significantly lower in *H. pylori* positive gastric ulcer patients than in controls. The same results were observed between *H. pylori* positive gastritis patients and controls, except for DPA1*0201. 2) The allele frequencies of DRB1*0405 and DQB1*0401 were significantly higher in *H. pylori* positive duodenal ulcer patients than controls, whereas those of DRB1*1501, DQA1*01021 and DQB1*0601 were significantly lower in *H. pylori* positive duodenal ulcer patients than in controls. 3) There were no significant differences in the allele frequencies between *H. pylori* positive gastric ulcer patients and *H. pylori* positive gastritis patients. 4) The allele frequency of DRB1*0901 was significantly lower in *H. pylori* positive duodenal ulcer patients than in *H. pylori* positive gastritis patients.*Conclusions:* These observations suggest that *H. pylori* infection is associated with HLA class II genes and the HLA class II genes are involved in the pathogenesis of peptic ulcer and gastritis via different mechanisms. "P P 13 0358"P 13 0358**Cytokines Gene Expression on Helicobacter Pylori Infected Gastric Epithelial Cells**

*N. Nakajima[1], H. Kuwayama[2], Y. Ito[1], S. Yamaguchi[1], T. Imai[2], T. Ohtani[1], E. Kogure[1], A. Iwasaki[1], Y. Arakawa[1]

[1] Dept. of Medicine, Nihon University School of Medicine, Tokyo, Japan

[2] Dept. of Medicine, Tokyo Women's Medical College, Tokyo, JapanInfection of *Helicobacter pylori (H. pylori)* activates infectious response on gastric epithelial mucosa by monocytes and neutrophils. This cellular response probably represents a primary immune defense mechanism against a microbial pathogen. *H. pylori* produces various factors which will attract or activate neutrophils. Infection with *H. pylori* also results in increased gastric mucosal production of cytokines, interleukin-6 and -8, which is a potent activator and chemotactic agent for neutrophils. As gastric epithelial cells express interleukin-6 and -8, they may have an important role in regulating primary host defense mechanisms and be functionally involved in the neutrophils response to *H. pylori* infection. In this study, we analyzed IL-6 and -8 gene expression by reverse transcription-PCR of human gastric epithelial cells, Kato-III, to *H. pylori* infection with special reference to neutrophil modification. Human IL-6 and -8 specific mRNA was detected when Kato-III cells were incubated with neutrophils or *H. pylori. H. pylori* itself did not express IL-6 and -8 mRNA, whereas Kato-III cells and neutrophils showed expression of IL-6 and -8 mRNAs. IL-8 mRNA expression by Kato-III cells was further enhanced when they were co-incubated with both *H. pylori* and neutrophils compared to those with neutrophils only. We conclude that human gastric epithelial cells, Kato-III expresses IL-6 and -8 mRNA which can be further enhanced by neutrophils. These results indicate that neutrophil may upregulate IL-8 mRNA expression in *H. pylori*-infected gastric epithelial cells. "P P 14 0359"P 14 0359**Familial Occurrence of Helicobacter Pylori Infections- Contribution to the Studies of Treatment FailuresK. Wasowska-Kr\'f3likowska, E. Toporowska-Kowalska, E. Kowalska**

I Children Clinic, Medical University of L\'f3dz, PolandIn children with persistent complains associated with the alimentary tract it is necessary to look for Helicobacter pylori (Hp) infection, also in their family environment. The study was carried out in a group of 50 children with suspected inflammation of the upper alimentary tract mucosa.*Methods:* 1/Endoscopic examination of upper portion of the alimentary tract; 2/Histopathological evaluation of mucous membrane of the stomach and duodenum (according to the Sydney Classification); 3/Quantitative determination of anti-Hp antibodies performed by means of immunoenzymatic tests (Boehring) in all the children and members of the families of patients with Hp infection confirmed by means of histopathological or immunological techniques.In the investigated group it was demonstrated that among 50 children with suspected inflammation of the upper alimentary tract mucosa on the basis of endoscopy suggesting Hp etiology the coincidence was confirmed histopathological in 44 children. In 26/50 children there was a positive result demonstrating the anti-Hp antibodies (range 24–245); simultaneous presence of serological and histopathological markers of Hp infection were observed in 22 out of 50 patients. In the investigated group infection markers were present in 34 family environments, including 16 cases in which anti-Hp antibodies were detected in more than one member of the family, more frequently in parents than in brothers or sisters.).The above observations may indicate horizontal transmission in the family environment and make a contribution to the studies of the causes of failures of the currently recommended alternatives of the therapy in the infected patients. Oesophageal gastric duodenal disorders: Helicobacter PyloriEndoscopy, general: Endoscopy: children }" "Familial Occurrence of Helicobacter Pylori Infections- Contribution to the Studies of Treatment Failures"

"P P 14 0360"P 14 0360**The Seroprevalence of Helicobacter Pylori in Instituted Intellectually Disabled and Employees****C.J.M. B\'f6hmer, E.C. Klinkenberg-Knol[2], M.C. Niezen-de Boer[1], H. Schreuder[3], S.G.M. Meuwissen[2]**

[1] Bartim\'e9us, Zeist, the Netherlands

[2] Free Univ Hosp, Amsterdam, the Netherlands

[3] Hosp. Eemland, Amersfoort, the NetherlandsIn instituted intellectually disabled an acquisition rate of *Helicobacter pylori* infection (HpI) of 60%–75% is indicated (Berkowitz, 1987/Lambert 1995), while in the normal Dutch population a prevalence from 5–50% is found. Therefore we analysed the seroprevalence of HpI in 2 institutes with 1997 inhabitants and 1404 employees. Randomly, in 338 intellectually disabled HpI was assessed by retrospective analysis of sera with an EIA-g test (Orion), and after voluntary venapunction in 254 employees. A level of > 300 IU was defined as evidence of HpI. Subjects with HpI were defined as patients and compared with the total Dutch population evaluated by Loffeld (thesis 1989).In 280 (82.8%, mean age 51 yrs) intellectually disabled HpI was found, compared with 51.4% in the total normal intellectual Dutch population (mean age: 55 yrs; p < 0.0001). Riskfactors in intellectually disabled for developing HpI were: male gender, the duration of institutionalisation, an IQ < 50, rumination, and a history of upper abdominal symptoms. 75 (29.5%, mean age: 29.5 yrs) employees showed HpI, compared with 25% (mean age: 30.5 yrs) in the total Dutch population (ns). Employees with intensive physical contact with the intellectually disabled, with a long duration of employment, and with upper abdominal symptoms had HpI more frequently.*In conclusion:* instituted intellectually disabled have a higher frequency of HpI, especially if they are male, with a long stay in an institute, with an IQ < 50, with rumination or with a history of upper abdominal symptoms. Employees with intensive physical contact with intellectually disabled, and after longer duration of employment are at higher risk for HpI. "P P 14 0361"P 14 0361**H. Pylori Gastritis and Intestinal Metaplasia in Polynesian and European Inhabitants of New Zealand**

*J.R. Jass, S.-L. Peng, A.G. Fraser

University of Auckland, School of Medicine, Auckland, New ZealandThere is up to a fivefold excess of gastric cancer in Polynesian (Maori and Pacific Island) versus European inhabitants of New Zealand (NZ). The aim of the study was to determine the frequency of H. pylori (HP) gastritis and intestinal metaplasia (IM) within these ethnic groups.A prospective series of 92 Polynesians (mean age 51.6 years) and 66 Europeans (mean age 59.5 years) was referred for routine gastroscopy and showed the following distribution of endoscopic diagnoses: gastric ulcer (18.4%), duodenal ulcer (21.5%), oesophagitis (11.4%), gastric carcinoma (0.6%) and normal (48.1%). HP gastritis was diagnosed when two of the following were positive: histology, CLO test and urease breath test. Six biopsies were obtained from prepylorus (2), antrum (2) and body (2).HP gastritis was detected in 88% of Polynesians (mean age 51 years) and 47% Europeans (mean age 61 years) (p = 0.0001). IM was found in 60% Polynesians (mean age 53 years) and 29% Europeans (mean age 65 years) (p = 0.0006). IM was more extensive and inflammation more severe in Polynesians. Eight Polynesians (8.7%) had type III IM at a mean age of 51 years. Three Europeans (4.5%) had type III IM at a mean age of 72 years. No dysplasia was seen.These data suggest that Polynesians develop HP gastritis, IM and type III IM with greater frequency and/or severity and at an earlier age than European inhabitants of NZ. The findings are consistent with the view that HP gastritis is a major risk factor in the aetiology of gastric cancer. Oncology, specific: StomachOncology, general: EpidemiologyEndoscopy, specific: Stomach, duodenum }"

"P P 14 0362"P 14 0362**Is Helicobacter Pylori Infection an Occupational Hazard for Medical Staff?**

*R. Kosik, H. Kordecki, D. Pilecka

Dept. of Gastroenterology, M. Curie Hospital, Szczecin, PolandThe epidemiology and the way of transmission of Helicobacter pylori (H.p.) are still unclear. The way from person to person is generally accepted. In this way of transmission helical bacillary forms play an essential role. But because besides of these forms also coccoidal forms of H.p. have been discovered the way of transmission through secretions and excretions could be also possible.*The aim* of our study was to analyse if medical personnel who are in contact with human excretions and secretions are at higher risk to acquire H.p. infection. We analysed the incidence rate of H.p. antibodies in medical and laboratory staff. We diagnosed it by using ""Helisal"" test produced by ""Cortecs Diagnostics UK"". This method evaluates IgG antibodies in diluted capillary blood.We examed 14 persons who work in Endoscopic Unit in our department and perform endoscopical examinations (endoscopists and nurses), 14 persons who work in the Department of Cardiology and 15 persons who work in the Laboratory in our hospital. These groups were similar according to age and dyspeptic symptoms.*Results:* No. of pers. % of H.p. positive % of H.p. negativeEndoscopical pers. 14 86% 14%Cardiological pers. 14 36% 64%Laboratory person. 15 80% 20%*Conclusions:*1. H.p. infection appears more frequently in persons working in Endoscopic Unit and Laboratory who are in contact with human secretions and excretions as compared with those carring out cardiological treatment.2. Due to high frequency of H.p. antibodies in these groups of medical personnel this infection should be consider as occupational hazard. Clinical practice: Epidemiology (non cancer)Oesophageal gastric duodenal disorders: Helicobacter PyloriEndoscopy, general: Complications }" "Is Helicobacter Pylori Infection an Occupational Hazard for Medical Staff?"

"P P 14 0363"P 14 0363**Role of *Helicobacter Pylori* in the Pathogenesis of Gastroduodenal Lesions in Patients with Cirrhosis: A Prospective Evaluation**

*L. Prigent-Delecourt, D. Lamarque, F. Roudot-Thoraval, R. Akremi, M.T. Chaumette, J.P. Richardet, J.C. Delchier

Hopital Henri Mondor, 94000 Cr\'e9teil, FranceAlthough gastroduodenal ulcerated mucosal lesions in patients with cirrhosis are common, their pathogenesis remains unclear. The aim of this prospective study was to determine the pathogenic factors associated with gastroduodenal mucosal lesions in patients with cirrhosis and especially to assess the role of *Helicobacter pylori (Hp).*Patients with histologically proven cirrhosis and not recently treated by antibiotics, antisecretory or anti-inflammatory drugs, were enrolled and referred for upper gastrointestinal endoscopy. Upper digestive tract bleeding within the last week was an exclusion criteria. Age, gender, smoking habit, recent alcohol intake, etiology of cirrhosis, Child-Pugh grade were recorded and basal gastrinemia was determined. Esophageal varices were graded from 0 to 3. Severity of hypertensive gastropathy in the body and the antrum was graded from 0 to 3 for erythema, edema and snake-skin mosaic pattern (maximum score: 18). *Helicobacter pylori* status was determined from rapid urease test and histology on biopsy samples or 13-C urea breath test when biopsies were impossible.Sixty four patients were included. There were 52 males and 12 females, mean age – SD: 55 – 11 years. Cirrhosis was alcoholic in 47, grade A, B and C in the Child-Pugh classification in 19, 21 and 24 respectively. Thirty five (55%) were *Hp* positive. One or several mucosal lesions were present in 24 patients (37%): gastric ulcer in 8, duodenal ulcer in 7, gastric erosions in 9, duodenal erosions in 4. Univariate analysis showed that mucosal lesions were not significantly related with age, gender, smoking habit, etiology of cirrhosis, Child-Pugh grade, esophageal varices grade, *Hp* positivity (12/24 *vs* 23/40, $p = 0.74$), and basal gastrinemia. Univariate and multivariate analysis showed that they were significantly related to a recent alcohol ingestion (62.5% vs 27.5%, $p < 0.006$) and to a high hypertensive gastropathy score (10.9 – 4.4 *vs* 7.4 – 5.3, $p < 0.02$).*Conclusion:* Ulcerated lesions in cirrhotics are unrelated to *Hp* despite high prevalence of infection. They are significantly and independently related to recent ingestion of alcohol and to hypertensive gastropathy severity. Oesophageal gastric duodenal disorders: GD disorders, acid pepticOesophageal gastric duodenal disorders: Helicobacter PyloriLiver and bile ducts, 1: Cirrhosis: portal hypertension }" "Role of Helicobacter Pylori in the Pathogenesis of Gastroduodenal Lesions in Patients with Cirrhosis: A Prospective Evaluation"

"P P 14 0364"P 14 0364**Variation in Immunoblot Patterns According to Geographical Origin of Patients Infected by *Helicobacter Pylori (Hp)***

*D. Lamarque[1], T. Gilbert[1], F. Roudot-Thoraval[1], L. Deforges[1], R. Ferrero[2], A. Labigne[2], J.C. Delchier[1]

[1] CHU H. Mondor, Cr\'e9teil, Paris

[2] INSERM U389, Institut Pasteur, Paris*Hp* infection is generally acquired early in childhood. The antigenic pattern of *Hp* may be related to the geographical area of origin. The aim of this study was to compare, by using *Hp* serological test by Western Blot (Helico Blot 2.0 ’, Genelabs), the different antibodies present in patients according to the area of birth and childhood.*Hp* infection was found in 136 patients by mean of positive culture, histology or 13C urea breath-test and positive *Hp* Elisa serological test. Country and rural/urban area at birth and childhood were recorded. Countries were distinguished as France and Southern country (Southern Europe and Africa). By using Western Blot serology, the presence of antibodies against different molecular weight antigens (19.5, 26.5, 30 or 35 kD) or against VacA (89 kD) and CagA (116 kD) was compared in the different groups.Fifty-eight percent of patients were born or spent their childhood in France and 30% in rural area. Antibodies against antigens of 19.5, 26.5, 30, 35, 89, 116 kD were found in 46, 88, 61, 63, 45 and 67% respectively. Antigens of 26.5, 35 kD were significantly more frequent in patient born or who spent their childhood in Southern country than in France (97% vs 81%; $P < 0.03$; and 74% vs 53%; $P < 0.05$, respectively). By contrast, 89 kD (Vac-A) was more frequent in patient born in France (53% vs 25%; $P < 0.03$). Antibodies against antigens of 19.5 and 89 kD (Vac-A) were more frequent in patients issued from urban area (51% vs 28%, $P < 0.02$ and 49% vs 32%, $P < 0.05$ respectively). Cag-A was found similarly whatever the patient origin (66% in France vs 61%; 67% in urban area vs 68%).Western Blot patterns suggest that the antibodies directed against antigens of 26.5, 35 kD are more frequent in South of Europe and in Africa than in France. By contrast Vac A seems more frequent in France and in urban areas. These results evoke that differencies in *Hp* strain are associated with geographical origin of patients. Oesophageal gastric duodenal disorders: Helicobacter Pylori }" "Variation in Immunoblot Patterns According to Geographical Origin of Patients Infected by Helicobacter Pylori (Hp)"

"P P 14 0365"P 14 0365**Serological Assessment H. Pylori Infection in Children and Adults with Chronic Gastritis and Gastroduodenitis**

*E. Czkwianianc, M. Chmiela, M. Lawnik, T. Rechcinski, L. Bak-Romaniszyn, I. Planeta-Malecka, W. Rudnicka

Dep. of Pediatrics, Polish Mother's Memorial Hospital, Military Medical University, Dep. of Infectioctious Biology, University, Dep. of Internal Medicine, K. Jonsher's Hospital, L\'f3dz, PolandDespite of available commercial serologic tests for H. pylori (Hp.) the diagnostic value of this method is still controversial.The aim of the study was to assess the serologic exponents of Hp. in children and adults. 27 and 23 dyspetic children and adults with chronic gastritis or gastroduodenitis (diagnosed endoscopicaly and pathomorfologicaly according to ""Sydney System"") with Hp. infection (confirmed by urease test, histologic and microbiologic methods) and 14 adult volunteers as well as 13 children excluded of Hp. were examined by serologic methods. The sera were tested for presence of IgG, IgM and IgA specific antibodies to the surface acid-glycine extract (GE) obtained from cells of the reference Hp. strain (CCUG 17874) and cagA antigen of Hp.In 70% of children and in all adults with Hp. but only in 9% of uninfected children and in 40% of adult volunteers IgG antiGE antibodies were found. In contrast anticagA IgG were detected only in 30% infected children and in 55% adults with Hp. The highest frequency of IgM antiGE was found in infected adults (70%), but anticagA IgM only in 25% individuals of this group were seen. IgA antibodies were detected only in 2 (7%) children, while in adults they were present in 52% with Hp. and in 30% of the volunteers. Also titres of these antibodies were much higher in adults.The presence of IgG antibodies (in high titres) against the surface extract antigens of Hp. in both infected groups irrespective of age was seen. Lower frequency of the antibodies to cagA suggests the possibility of cross reactions with other bacterial antigens and rather exludes monitoring Hp. infection by only serologic tests alone. Serologic test IgA of Hp. has no much usefulness in children. Oesophageal gastric duodenal disorders: GD disorders, acid pepticOesophageal gastric duodenal disorders: Helicobacter PyloriImmunology and microbiology: GI infection, children }" "Serological Assessment H. "P P 14 0366"P 14 0366**An Audit of the Management of *Helicobacter Pylori* Infection in a District General Hospital**

*N. Coleman, C. Grimley, P. Ramsell, C. Nwokolo, D. Loft

Department of Gastroenterology, Walsgrave NHS Trust, Clifford Bridge Road, CoventryCarefully controlled clinical trials indicate *Helicobacter pylori* (HP) eradication rates of 80–90% but it is important to know whether there rates are translated to clinical practice on an intention to treat basis.*Aims of Audit:* 1. Is HP eradication being used appropriately? 2. What method is used for HP diagnosis pre-treatment. 3. Which treatment regimes are being used and evaluate their efficacy. 4. To check the timing of follow up breath tests.*Method:* Information was collected prospectively over a 14 month period. Subjects who attended for a post eradication ^{13}C UBT to confirm the success of eradication were included. The original diagnosis, the initial method used to confirm HP infection, the HP eradication regime used and the timing to the follow-up breath test after completing eradication therapy were noted.*Results:* There were 92 post-eradication breath tests in the study period in 85 patients. The overall eradication rate was 85%. The initial diagnosis was gastric or duodenal ulcer in 91% of cases but eradication was also offered to subjects with NUD (5%), oesophagitis (1%) and gastritis (1%). The CLO test was used most frequently to make the diagnosis of HP infection pre-treatment. Five eradication regimes were used in the period. The best results were obtained with omeprazole (O) 20 mg bd, Clarithromycin (C) 250 mg bd and metronidazole 400 mg bd with an eradication rate of 96% (n = 25). Dual therapy with O 20 mg bd and C 250 mg tds was second at 93% (n = 27) and traditional triple therapy regimes gave a rate of 80% (n = 25). 96% of post eradication breath tests were done more than 4 weeks after completing treatment.*Conclusion:* In the DGH setting on the basis of intention to treat with no exclusion criteria, eradication rates were comparable to those of randomised controlled trials. Most patients received HP eradication for PUD but 7% were treated inappropriately. The best results were achieved with low dose OCM (cost 29.88 \'a3). The CLO test was used most frequently to make the initial diagnosis and the timing of a follow-up breath test was appropriate in 96% of cases. "P P 14 0367"P 14 0367**Seroconversion of Helicobacter Pylori: A Five Years Follow-Up in Asymptomatic Donors Living in a Western Country**

*M. Menegatti, F. Landi, D. Palli, B. Massardi, C. Ricci, J. Holton, A. Al\'ec, S. Farinelli, F. Mucci, C. Saieva, M. Miglioli, D. Vaira

Ist Medical Clinic, Bologna, Center for Oncology Study and Prevention, Florence, Italy

Microbiology Dept, University College London Hospital, London, UK*Purpose:* Infection rate for Helicobacter pylori (H pylori) in Western countries is reported to be very low: 0.5–2%/year. We aimed to assess the infection rate, as determined by seroconversion from H pylori IgG seronegative to H pylori IgG seropositive, in asymptomatic blood donors resident in an urban area in the North of Italy over a follow-up period of 5 years (1990–95).*Methods:* From a blood donors population screened for H pylori in 1990–91 (N = 1010; M/F: 556/454, age: range 18–65, mean 44 years) a total of 588 (58%) tested as seronegative and were invited for a new IgG antibodies assessment in 1995–96. Specific anti-H pylori antibody were evaluated in duplicate by an ""in house"" ELISA assay validated in endoscoped patients (sensitivity and specificity of 94%). For each participant a repeat ELISA on the original serum sample (stored at { -}20\'b0C) was also carried out.*Results:* Until now 324 donors have been re-evaluated (M/F: 191/133, age: range 23–65, mean 42 years). At the repeat assessment of original serum a total of 19/324 (6%) were found to be seropositive, and confirmed seropositive at follow-up. The remaining 305/324 (94%) were confirmed as seronegative. A total of 5/305 (1.6%) were found to have seroconverted to seropositive at the follow-up sample. The table shows the results at repeated assay compared to previous results (+/{ -}ve = positive/negative). 1995: +ve 1995: { -}ve1990: +ve (n = 19) 19 –1990: { -}ve (n = 305) 5 300Assuming the seroconversion at mid point of the considered period, for the 305 seronegative donors have been considered more than 1500 years-person of follow-up, the mean follow-up period was 5.2 years (range 4.9–5.8 years) with a seroconversion rate of 0.33%/year (95% CI = 0.1–0.8).*Conclusion:* Our preliminary results confirm an extremely low seroconversion rate for H pylori infection in asymptomatic populations living in a Western country. "P P 14 0368"P 14 0368**Household Members and *Helicobacter Pylori* Infected Patients**

*C. Mart\'edn de Argila, D. Boixeda, R. Cant\'f3n, N. Valdezate, F. Bermejo, J.P. Gisbert, A. Garc\'edaPlaza

Gastroenterology and Microbiology Departments, ""Ram\'f3n y Cajal"" Hospital, Madrid, SpainReports on the epidemiology of *Helicobacter pylori* infection are scarce, and the source and spread of this organism are still relevant unanswered questions.*Aim:* The aim of this study was to evaluate *Helicobacter pylori* infection among first- and second- degree relatives and spouses of duodenal ulcer patients with previously demonstrated *Helicobacter pylori* infection to provide further information on the potential spread of this microorganism mediated by a close personal contact.*Materials and Methods:* Sixty-two close personal contacts of 19 patients with duodenal ulcer in whom *Helicobacter pylori* had been cultured from gastric biopsies (18 spouses, 11 siblings, 29 children, and 4 parents) and 272 controls from the same environment and with similar age were studied. *Helicobacter pylori*-specific IgG antibodies were detected by an enzyme-linked immunosorbent assay (ELISA). Subjects were considered positive when titers were > 10 U/ml.*Results:* The antibodies were positive in 81% of the household contacts of the index patients and in 49% of the controls ($p < 0.001$). In all families there was at least one member infected. Parents (100%) and siblings (100%) were more likely to be infected than spouses (78%) and children (72%) ($p < 0.001$).*Conclusions:* Clustering of *Helicobacter pylori* infection within household contacts suggests that a person-to-person spread of these microorganisms or a common source exposure. This fact might account for some therapeutic failures in patients living together with infected household contacts. "P P 14 0369"P 14 0369**Infection of Partners: Is It a Risk Factor for Helicobacter Pylori Reinfection?**

*J.P. Gisbert, D. Boixeda, C. Mart\'edn de Argila, R. B\'e1rcena, T. P\'e9rez, L. Moreno, A. Garc\'eda Plaza

""Ram\'f3n v Cajal"" Hospital, Madrid, Spain*Purpose:* At present it is unknown whether *H. pylori* status of spouses plays a role in reinfection after successful eradication. Our purpose was to study the incidence of reinfection in a one-year follow-up period after eradication of *H. pylori* and to describe the prevalence of infection in spouses of these patients.*Methods:* Thirty-three patients (mean age: 49 – 12 yrs, 79% males) with duodenal ulcer in whom *H. pylori* had been succesfully eradicated (with bismuth triple therapy, or omeprazol plus one or two antibiotics) were prospectively studied. Endoscopy with biopsies (H & E), and C^{13}-urea breath test were performed 1 month after completing therapy. Eradication was defined as the absence of *H. pylori* by both methods. C^{13}-urea breath was repeated at 6 and 12 months. At the 1-year follow-up visit, a breath test was also performed to respective partners.*Results:* At the 6-month control, all patients were *H. pylori*-negative. At 1-year, two patients become reinfected (52 and 63 years old, respectively), which represents an incidence of reinfection of 6% (CI95%: 1.7–20%). The mean age of spouses was 49 – 13 yrs, and their prevalence of *H. pylori* infection was 82% (n = 27) (higher than the corresponding prevalence in similar age-population), with a mean { d}$^{13}CO_2$ level of 35 – 27. The mean time of living together was 24 – 1 yrs. None had a previous history of peptic ulcer, and only two (6%) complained from ulcer-like symptoms. Reinfection ocurred in 7.4% (2.1–23%) of patients when the spouse was infected, and in 0% if the spouse was *H. pylori*-negative (a non-significant difference; the power of the study was only 10%). Thus, even if the spouse is infected, 92.6% of patients persist uninfected one year after eradication.*Conclusion:* These preliminary results suggest that further studies are needed to assess a possible role of spouses infection in the reinfection rate after *H. pylori* eradication. It seems that reinfection is uncommon even if partners are *H. pylori*+. However, if a role is demonstrated, therapy against the organism could be recommended also in infected spouses.

*Ahmet Aydin, Galip Ers\'f6z, \'d6mer \'d6z\'fctem&idot;z, M\'fcge Tun\'e7y\'fcrek, Hanefi \'c7avusoglu

Depts. of Gastroenterology and Pathology, Ege University, Izmir, T\'fcrk&idot;yeEradication of Helicobacter pylori (Hp) leads to regression of gastric inflammation, and reduction of ulcer recurrence. But, reinfection is thought to be a serious problem, especially in developing countries where the sanitation conditions are inadequate.To investigate the reinfection rate of Hp infection in T\'fcrkiye, a developing country, 59 cases (31 women and 28 men, with a mean age of 41.4 – 11.5 yr) in whom Hp was eradicated 12–36 (14.2 – 6.2) months ago were studied. Pretreatment diagnoses were duodenal ulcer (DU) and non ulcer dyspepsia (NUD) in 18 and 41 of them, respectively. All cases underwent upper GI endoscopy and 6 gastric biopsies (2 for histologic examination and 1 for urease test from both antrum and corpus) were taken. A case was regarded as Hp negative, if all of the biopsies were found to be negative on both the diagnostic methods.Only 2 (3.4%) of the cases (1 DU and 1 NUD) were found to be Hp positive. In both cases, histological findings of active chronic gastritis were also present. Histological examination showed normal gastric mucosa in 50 (87.7%), focal inflammatory cell infiltration in 3 (5.3%), chronic only gastritis in 2 (3.5%), and chronic atrophic gastritis in 2 (3.5%) cases. None of the DU cases who remained Hp negative described any symptoms suggesting an ulcer recurrence. Their endoscopic examinations also showed no ulcer recurrence. But, the symptoms of the DU patient who was found Hp (+) were going on. Her endoscopic examination also demonstrated the presence of a DU.The result of this study shows that, reinfection rate of Hp infection is not high in T\'fcrkiye. Low reinfection rate, despite the high prevalence of Hp infection in our population, suggests that Hp colonization is not common in adulthood. It seems more reasonable to think that the infection is generally acquired in early ages when gastric acid production is inadequate due to immaturity of the parietal cells. Oesophageal gastric duodenal disorders: Helicobacter Pylori }"

*A. Hackelsberger, T. G\'fcnther[1], V. Schultze, U. Platzer, P. Malfertheiner

Dept. for Gastroenterology, University of Magdeburg, Germany

[1] Dept. of Pathology, University of Magdeburg, Germany*Aim:* Helicobacter pylori (HP) according to current knowledge predilects colonization of the gastric antrum. As the cardiac glands resemble pyloric glands a similar colonization pattern could be expected. We investigated the prevalence of HP colonization (HPC) and gastritis in the cardia (CA) in relation to gastric antrum (A) and corpus (CO) in a sample of unselected+ patients.*Methods:* Two biopsies of each A, CO and CA (within 1 cm below squamocolumnar junction) from 269 consecutive pats. without previous attempts at H. pylori eradication, or esophageal varices+ were obtained. In addition a rapid-urease test (HUT-Test, Astra) was performed. Histologic gastritis grading followed the Sydney system (modif. Giemsa, if necessary Warthin-Starry). We used a 4 pt. scale (0 to 3) for activity (ACT), degree (DG), HPC, intestinal metaplasia (IM) and atrophy (AT). Mean rank gradings were compared for A, CO and CA (Friedman two way ANOVA, SPSS, $p < 0.05$). Expression of gastritis in the CA for different clinical diagnoses was evaluated.*Results:* Endoscopy revealed the following diagnoses: Normal aspect: 9.3%, signs of gastritis 45%, DU 14.6%, GU 6%, GERD 8.6%, others 16.5%. 132 pats (49.1% of the sample) showed HP+ve active gastritis in histology and/or urease-test. 120 pats. (90.1%) thereof had HP+ve gastritis in A, 112 pats (84.5%) in CO, 93 pats (70.4%) in CA. The table gives mean rank gradings only for HP+ve pats. No correlation of the macroscopic diagnoses with HP+ve gastritis in the Cardia was found. n = 132 ACT DG HPC IM ATAntrum 1.47 2.05 1.31 0.21 0.20Corpus 1.22 1.68 1.27 0.14 0.11Cardia 1.15 1.69 0.98 0.19 0.05A/CA p = **< 0.01 ***< 0.001 ***< 0.001 0.855 0.345*Conclusion:* About 70% of pats. with HP detected in A have HPC of the cardia region also. However ACT and DG of cardia gastritis are lower compared to the antrum. HP+ve gastritis in the cardia region shows no positive correlation to patients clinical diagnoses. "P P 14 0372"P 14 0372**Chronic *Helicobacter Pylori* Gastritis: A Lifelong Progressive Inflammation?**

*A. Hackelsberger, V. Schultze, T. G\'fcnther[1], U. Platzer, E. Bayerd\'f6rffer, P. Malfertheiner

Dept. of Gastroenterology, University of Magdeburg, Germany

[1] Department of Pathology, University of Magdeburg, Germany*Aim: Helicobacter pylori* (HP) gastritis is a lifelong infection of the gastric mucosa, mostly aquired in childhood, predominantly in the antrum and expanding in a pylorocardial direction over decades. If so, we suspect there could be a different histological expression of gastritis in antrum, corpus and cardia in different age groups. We therefore investigated the age dependence of the histological features of gastritis.*Methods:* 218 carefully selected patients with mere gastritis, (no circumscript lesions) were included. Two biopsies of each antral, corpus and cardiac gastric mucosa were obtained for histology. In addition a rapid urease test (HUT test, Astra) was performed. Histology was graded by the Sydney system with modified Giemsa- and if necessary Warthin-Starry. A four point scale (0–3) was used for grading of activity (A), degree (D), HP-colonization (HPC), intestinal metaplasia (IM) and mucosal atrophy (AT). According to patients age quartiles were formed (I-21–43 ys, II-44–55 ys, III-56–64 ys, IV- 65–85 ys). Statistical tests (T-test, ANOVA) were performed (SPSS, 6.1).*Results:* 107 pats. showed HP+ve gastritis; only their data are reported herein. Means of histological A and D only showed an increase from age group I to II in the antrum and cardia (*$p < 0.05$), but not in the corpus. In contrast a slight continous increase in HPC showed in the antrum and cardia for all age groups, but was expressed significantly* only in the corpus mucosa. No age dependent differences for AT were shown. IM decreased significantly* in antral mucosa from age group II to III, but remained stable in corpus and cardiac mucosa.*Conclusion:* The data suggest, that the inflammatory responses to HP infection and intestinal metaplasia in the antrum are marked in younger and middle-aged subjects but decrease in the elderly. This happens in spite of a trend towards higher HPC with age.

"P P 14 0373"P 14 0373***Helicobacter Pylori* Antibodies Against CAG A and VAC A in Patients with Chronic Gastritis, Duodenal and Gastric UlcerM. Nilius, G. Illies, U. Platzer, U. Schmidt-Wittig, A. Hackelsberger, P. Malfertheiner**

Dept. Gastroenterology, Hepatology and Infect. Diseases Otto-von-Guericke-University Magdeburg, Germany*Background:* Serological studies have shown that Cag A producing strains of *H. pylori* are associated with duodenal ulcer. Antibody titers against Cag A correlate with severity of disease. Vac A always is coexpressed with Cag A.Aim of the study was to investigate the antibody reaction against Cag A and Vac A of patients with chronic gastritis (CG) and gastric (GU) and duodenal ulcer (DU).*Methods:* 133 patients undergoing upper gastrointestinal endoscopy were included. *H. pylori* infection was determined by urease test (HUT), histology and IgG-ELISA (Bio Whittaker). Patients were considered *HP*-positive if they were positive in 2 of these reference methods. Antibody response to specific *H. pylori* antigens was tested by a commercially available Immunoblot-System (BAG-Pylori-Blot).*Results:* 116 from 133 patients had a positive Immunoblot (DU: 21/28 (75%); GU: 23/32 (71.9%); CG: 72/73 (98.6%). Antibody reactions against the different antigens are summarized in the following table: Antigen DU GU CG116 kd (Cag A) 23/28 (82.1%) 24/32 (75%) 53/72 (73.6%)89 kD (Vac A) 11/28 (39.2%) 12/32 (37.5%) 38/72 (52.8%)30 kD (Ure A) 17/28 (60.7%) 17/32 (53.1%) 45/72 (62.5%)26.5 kD 24/28 (85.7%) 17/32 (53.1%) 56/72 (77.8%)19.5 kD 13/28 (46.4%) 15/32 (46.9%) 33/72 (35.8%)*Conclusion:*Whereas the serological profile to CagA and all other antigens was not significantly different between DU, GU and CG patients, serological profile to VacA was significantly associated with CG. }" "Helicobacter Pylori Antibodies Against CAG A and VAC A in Patients with Chronic Gastritis, Duodenal and Gastric Ulcer"

"P P 14 0374"P 14 0374***Helicobacter Pylori,* Gastric Ulcer and Non-Steroidal Anti-Inflammatory DrugsD. Boixeda,**

*J.P. Gisbert, F. Bermejo, Baleriola I. Alvarez, R. Cant\'f3n, R. Aller, Mart\'edn C. de Argila

""Ram\'f3n y Cajal"" Hospital, Madrid, Spain*Purpose:* To describe the prevalence of *H. pylori* infection in gastric ulcer (GU) patients and to study its relationship with non-steroidal anti-inflammatory drug (NSAID) administration.*Methods:* 161 patients with active GU were studied (mean age: 54 years, 70% males). In all patients 3 biopsy specimens were taken from both gastric antrum and body (H&E stain, Gram stain and culture).*Results: H. pylori* was found in 83% (95% CI = 77–89%) of patients. In non-NSAID users *H. pylori* infection reached 87% (95% CI = 81–93%), while in NSAID users the corresponding figure was 63% (CI = 43–79%) (p = 0.008). The percentage of GU patients without *H. pylori* infection not taking NSAIDs was 11% (CI = 6–16%). In multiple logistic regression analysis NSAID administration was the only variable which correlated with *H. pylori* infection (odds ratio = 0.25; 95% CI = 0.09–0.66; chi^2 model = 7.27; p = 0.007). Additional variables (age, sex, smoking, alcohol, and GU location) were not correlated with *H. pylori* infection. Chronic gastritis percentages were higher in *H. pylori*+ than in *H. pylori{ -}* patients (97% vs 67% at antrum, and 78% vs 42% at body) (p < 0.001).*Conclusion:* The overall prevalence of *H. pylori* infection in GU patients was 83%; this prevalence increased up to 87% when only non-NSAID users were considered. The percentage of GU patients without *H. pylori* infection not taking NSAIDs was only 11%, which suggests that both factors (*H. pylori* and NSAIDs) are the most relevant in GU disease, the emergence of GU without them being uncommon. "P P 14 0375"P 14 0375**A Survey on Management of *H. Pylori* by Dutch Specialists in 1995**

*P.J. Boekema[1], G.P. VanBerge-Henegouwen[1], R.A. Veenendaal[2]

[1] Department of Gastroenterology, University Hospital Utrecht, The Netherlands

[2] Department of Gastroenterology-Hepatology, Leiden University Hospital, The NetherlandsIn order to conduct a survey of the management of *Helicobacter pylori* infection by Dutch specialists a postal questionnaire was sent to 420 members of the Dutch Society of Gastroenterology in June 1995.Of the 226 respondents (response rate 54%) all but two treated patients for *H. pylori* infection. From the survey it could be estimated that at least one out of thousand Dutch inhabitants was treated for *H. pylori* infection in 1995. Accepted indications for treatment of *H. pylori* infection were duodenal ulcer (98%), gastric ulcer (91%), low-grade B cell MALT lymphoma (56%), pre-malignant gastric mucosal changes (33%), non-ulcer dyspepsia (32%), and chronic use of proton pump inhibitors (30%). The diagnostic methods mainly used by the respondents were histology (93%), urease test (60%), and culture (46%). Most physicians (82%) used a combination of tests to detect *H. pylori.* Non-invasive diagnostic tests were only used by a minority of respondents. Triple therapy was used for treatment by 54% of the respondents but the ""classical"" bismuth triple therapy (14%) has been surpassed as the treatment of choice by proton pump inhibitor based triple therapy combinations (40%). The relatively new quadruple therapy combinations were already used by 26% of the respondents. After treatment the eradication of *H. pylori* was routinely confirmed by diagnostic tests by 42% of the respondents, while 48% only did so when confirmation of eradication was considered clinically relevant. Confirmation of eradication was assessed at least 4 weeks after treatment. 72% of the respondents waited 8–12 weeks before testing for eradication.It was concluded that, medio 1995, treatment of *H. pylori* was almost generally accepted by Dutch specialists in case of associated ulcer disease. An association of *H. pylori* with other upper gastrointestinal diseases was not unanimously accepted. Biopsy-based diagnostic methods were generally preferred. Treatment regimens differed widely.Sponsored by the Dutch Society of Gastroenterology

"P P 14 0376"P 14 0376**Serum Lipids, Body-Indices, Age at Menarche, and Helicobacter Pylori Infection in 1,756 Danish Women**

*S.J. Rosenstock, L.P. Andersen, O. Bonnevie, T. J\'f8rgensen

Dept. of Surgery K, Bispebjerg Hospital, the Copenhagen Hospital Corporation, the Glostrup Population Studies, University of Copenhagen, 2400 NV Denmark*Aim:* To assess the association between the seroprevalence of IgG antibodies to *H. pylori,* serum lipids, body-indices, and age at menarche in women.*Methods:* A random sample of 3,589 adult Danes entered a population study in 1982–1983. A total of 1,756 women were eligible for the present study. Seroprevalences of circulating IgG antibodies to *H. pylori* were assessed with an in-house ELISA assay. IgG antibody levels were categorized as sero-negative, border-line, or sero-positive. Information on life-style factors and age at menarche was ascertained from a questionnaire. Height and weight was measured and body mass index (BMI) calculated. High-density-lipoprotein (HDL), triglyceride, and cholesterole levels in serum were measured. Age, life-style factors, and socioeconomic status was included as possible confounders in multivariate logistic regression analyses using IgG seropositivity as the dependent variable.*Results:* The likelihood of seropositivity for IgG antibodies to *H. pylori* was increased in women with upper quartile HDL values (OR 1.7 [1.1–2.6]), upper quartile weights (OR 1.6 [1.1–2.3]), and upper quartile BMIs (OR 1.4 [0.9–2.0]). Women with upper quartile heights (OR 0.7 [0.5–1.0]) were less likely than women with lower quartile heights to be seropositive for IgG antibodies to *H. pylori.* The likelihood of *H. pylori* infection increased with age at menarche with 12 per cent/year (OR 1.12 [1.02–1.20]). Serum triglyceride and serum cholesterole levels were not associated with *H. pylori* infection.*Conclusion: Helicobacter pylori* infection relates to late menarche in Danish women. This finding may explain the relationship between decreased height in women in this study and the association with impaired pubertal growth spurt earlier reported. Increased HDL values may be found more often in women with *H. pylori* infection. Oesophageal gastric duodenal disorders: Helicobacter PyloriClinical practice: Epidemiology (non cancer) }" "Serum Lipids, Body-Indices, Age at Menarche, and Helicobacter Pylori Infection in 1,756 Danish Women"

"P P 14 0377"P 14 0377**CagA Hp Infection: Its Association with Gastroduodenal DiseaseB. Orsini, G. Macr\'ec, S. Milani, G. Ciancio, E. Surrenti, M.R. Biagini, P.C. Ballo, A. Covacci[1], C. Surrenti**

Gastroenterology Unit, University of Florence, Italy

[1] IRIS, Siena, ItalyHelicobacter Pylori (Hp) is believed to have a pathophysiologic role in chronic active gastritis and peptic ulcer disease. *Aim:* To investigate whether these alterations might be related with specific Hp strains, expressing the cytotoxin associated gene product (CagA). *Methods:* We recruited 135 Hp+ve subjects: 42 non ulcer dispepsia (NUD), 65 duodenal ulcer (DU) and 28 gastric ulcer (GU). All patients were assessed by hystology and rapid urease test. Sera from these subjects were assayed by anti-Hp ELISA and EIA for CagA-IgG. *Results:* A high prevalence of anti-CagA was found associated with DU (56/65, 86.1%) and GU (27/28, 96.4%) patients, while NUD patients showed anti-CagA seropositivity in 22/42 (52.4%). No significant difference was observed in seropositivity rates between DU and GU patients. Besides, in chronic active gastritis patients (CAG), 76/102 (74.5%) were anti-CagA+ve. The prevalence raised to 95% (19/20) in patients with chronic active atrophic gastritis (CAAG) and was 76.9% (10/13) in subjects with CAAG +intestinal metaplasia (IM). Among CAG, a high prevalence of anti-CagA was found associated with DU (46/53, 86.8%) and with GU (13/14, 92.8%), while NUD patients showed anti-CagA in 17/35 (48.6%). *Conclusions:* 1) Anti-CagA seropositivity is strongly associated with peptic ulcer disease but there is no significant difference between DU and GU. 2) The presence of endoscopic lesions in a small number of anti-CagA{ -}ve patients suggests that CagA is not essential for the development of the ulcer disease. On the other side, the evidence of a marked number of NUD anti-CagA+ve patients implies that CagA is not sufficient to induce ulcerative lesions. 3) Anti-CagA seropositivity is strongly correlated with all the forms of chronic gastritis, although the absence of anti-CagA in a reasonable number of NUD with CAG suggests that some Hp strains induce CAG independently from the production of CagA. Immunology and microbiology: GI infections in adults }" "CagA Hp Infection: Its Association with Gastroduodenal Disease"

"P P 14 0378"P 14 0378**High Incidence of H Pylori Seropositivity in Young Patients with Coronary Artery DiseaseS.D.H. Malnick, K. Adlan, S. Goland, D.D. Bass,**

*M. Beergabel, A. Fink, D. Geltner, O. Eisenberg, M. Fogel, A. Caspi, Z.M. Sthoeger

Division of Internal Medicine, Kaplan Hospital, Rehovot, IsraelH pylori infection is now clearly linked with peptic ulcer disease. In addition H pylori infection appears to be associated with gastric carcinoma and MALT-lymphoma of the stomach.Peptic ulcer disease has been shown to be associated with coronary artery disease (CAD) and evidence is accumulating linking H pylori infection with CAD.We investigated young (< 50 years) patients who were survivors of a myocardial infarction or who had angiographically-proven CAD. H pylori seropositivity was determined by a 2nd generation ELISA (Roche) in sera from the study patients and an age- and gender-matched control population.43 patients have been examined, 32 males and 6 females. The mean age is 45 – 6.15 years. 31 (81.6%) patients were H pylori seropositive and 7 (18.4%) seronegative. Of the 31 seropositive patients 28 were male and 3 female and of the 7 seronegative patients 4 were male and 3 female.In 33 control patients H pylori seropositivety was seen in 21 (63.6%) and 12 (37.4%) were seronegative ({ ?}^{2} test, $p < 0.001$).Anti-cardiolipin antibodies (ACA), which have been linked to CAD, were also examined by a solid-phase ELISA. ACA were detected in 2 of 38 (5.3%) study patients and in none of the control patients.In summary, we have shown a high (81.6%) incidence of H pylori seropositivity in young patients with CAD. This is much higher than seen in a control population and also much higher than the incidence of ACA. Further work is needed to investigate whether this relationship is causal and if there is an effect of H pylori eradication on these patients.(Supported by a grant from Abic Ltd.) "P P 14 0379"P 14 0379**High Prevalence of *Helicobacter Pylori* Infection in Coronary Heart Disease Demonstrated by the ^{13}C-Urea Breath Test**

*C. Mart\'edn de Argila, D. Boixeda, A. Fuertes, R. Aller, C. Arocena, J.P. Gisbert, R. Cant\'f3n, A. Garc\'eda Plaza

Gastroenterology and Cardiology Departments, ""Ram\'f3n y Cajal"" Hospital, Madrid, SpainPrevious studies have reported an association between coronary heart disease (CHD) and *H. pylori* infection, but all of them have used serological tests to confirm infection.*Aim:* To determine the prevalence of *H. pylori* infection in a large group patients with CHD and its relationship with different conventional CHD risk factors.*Materials and Methods:* One hundred and twelve consecutive patients (95 males and 17 females, Mean age: 59.1 – 11.9 yrs) were studied with documented CHD admitted at the Coronary Care Unit in our Hospital. Patients with previous history of peptic ulcer disease or digestive conditions were excluded. Information was inquired on the presence of conventional risk factors for cardiovascular disease (diabetes, hyperlipidemia, smoking, and arterial hypertension). Eighty-three healthy persons (24 males and 59 females; mean age: 51.5 – 10.7 yrs) comprised the control group. IgG antibodies to *H. pylori* were measured in all persons by means of a serological ELISA method (Helico-G, Porton, Cambridge, UK). All persons with CHD underwent also a ^{13}C-urea breath test (^{13}C-UBT) to study *H. pylori* infection.*Results:* Ninety-one (81.3%) of 112 patientes with CHD had a positive serology for *H. pylori* (> 10 U/ml) compared with 53 (63.8%) persons out of the 83 in the control group ($p < 0.01$). In 90/112 (80.4%) of patients with CHD the ^{13}C-UBT was positive ({ d}CO_2 > 5/1000). No association was observed between *H. pylori* infection and the different risk factors for CHD: Characteristic Yes Nohistory of: *H. pylori* + *H. pylori* { -} *H. pylori* + *H. pylori* { -}Smoking 43 (82.7) 9 (17.3) 47 (78.3) 13 (21.7)Hyperlipidemia 33 (76.7) 10 (23.3) 57 (82.6) 12 (17.4)Diabetes 19 (82.6) 4 (17.4) 71 (79.8) 18 (20.2)Hypertension 40 (76.9) 12 (23) 50 (83.3) 10 (16.7)p > 0.05 in all comparisons between the different groups.*Conclusions:* Patients with CHD had a high prevalence of *H. pylori* infection, significantly higher than that observed among healthy persons. The absence of an association between conventional risk factors for CHD and *H. pylori* infection suggests an independent action of *H. pylori* in its possible involvement in CHD. "P P 14 0380"P 14 0380**Lack of Association between *Helicobacter Pylori* Infection and Angiographically Documented Coronary Heart Disease****F. Maier, A. Auricchio[1], M. Nilius, J.-E. Dominguez-Munoz, H. Klein[1], P. Malfertheiner**

Dept. Gastroenterology, Hepatology and Infectious Diseases, Otto-von-Guericke-University Magdeburg, Germany

[1] Dept. Cardiology, Angiology and Pulmonology, Otto-von-Guericke-University Magdeburg, Germany*Background:* Recent data have linked chronic infection with *Helicobacter pylori* (*HP*) to coronary heart disease (CHD). Since symptoms like angina, palpitation or chest pain as well as non-invasive testing are less sensitive and specific for detection of CHD, the gold standard for assessing CHD remains coronary angiography. The aim of this study was to evaluate the incidence of *HP* infection in patients undergoing routine coronary angiography.*Methods:* 257 consecutive patients undergoing routine coronary angiography with known or suspected CHD, valvular defects or electrophysiological abnormalities were screened for antibodies by *HP*-IgG-ELISA. Laboratory investigations for well known risk factors of CHD, such as arterial hypertension, diabetes mellitus, adipositas, cholesterol, triglycerides uric acid, fibrinogen as well as acute phase reactants (C-reactive protein, ESR, WBC) were performed. Further, smoking history, family history, sex, age and history of gastric symptoms has been investigated. Patients were devided in a group with angiographically documented CHD and in a second group without morphological evidence of CHD. Statistical analysis was performed with unconditional multivariate stepwise logistic regression analysis.*Results:* The patient groups were comparable in age and sex. No significant difference was seen in prevalence of *H. pylori* infection and between men and women in patients with and without CHD. Both groups had a comparable mean age (61.88 (CHD+) vs. 58.04 (CHD{ -}). Whereas no significant correlation for CHD was found with *HP* infection, multivariable analysis resulted in a very significant correlation with well known risk factors like cholesterol, triglyceride concentration, smoking and age.*Conclusion:* The results of our study clearly show that there is no significant link between CHD and *H. pylori* infection as hypothesized by others. "P P 14 0381"P 14 0381**Relation between *H. Pylori*-Gastritis and GERD**

*A. Hackelsberger, V. Schultze, T. G\'fcnther[1], P. Malfertheiner

Dept. of Gastroenterology, University of Magdeburg, Germany

[1] Dept. of Pathology, University of Magdeburg, Germany*Aim:* Few data on the relation between chronic H. pylori (HP)-gastritis and gastroesophageal reflux (GERD) exist. We compared the histologic pattern of gastritis in the cardia from patients with erosive GERD to that of patients with chronic gastritis.*Methods:* Two endoscopic biopsies of antrum, body and cardia mucosa (within 1 cm below the squamocolumnar junction) were obtained in 450 consecutive pats. Gastritis (modified Giemsa, HE, AB-PAS) was graded by the Sydney System on four pt. scale (0 to 3) for activity, degree, HP colonization (HPC), atrophy and intestinal metaplasia (IM). To assess HP-status histology and rapid urease test, if necessary additional Warthin Starry stain, 13-CUBT, culture, and serology were performed. At endoscopy 61 pats showed erosive lesions in the esophagus, forming the GERD group. As controls 212 pats. with mere gastritis, without ulcers, erosive lesions and GERD symptoms were selected. Mean gastritis gradings were compared (SPSS, win 6.1: Mann-Whitney-U-test, Wilcoxon rank sum test)*Results:* 26 out of 61 GERD pats. were HP+ve (42%), 35 were HP{ -}ve (58%). Of 212 pats. with gastritis 104 were HP+ve (49.1%), 108 were HP{ -}ve (50.9%). Age and sex were equally distributed. No differences were found between GERD and gastritis in HP{ -}ve pats. Histology in gastric antrum and corpus did not differ between HP+ve GERD and gastritis patients. activity degree HP-C atrophy IMHP+ve GERDCardia 0.846 1.538 0.538 0.077 0.154HP+ve GastritisCardia 1.135* 1.731 0.99 ** 0.058 0.173 p < 0.05 p < 0.01*Conclusion:* A causal link between chronic HP+ve gastritis and GERD is unlikely. Reflux may however create a hostile environment for HP, as the activity of gastritis and density of HPC in the cardia are decreased in HP+ve pats. with GERD. Oesophageal gastric duodenal disorders: Helicobacter PyloriOesophageal gastric duodenal disorders: GD disorders, acid pepticOesophageal gastric duodenal disorders: EG Reflux }" "Relation between H. Pylori-Gastritis and GERD"

"P P 14 0382"P 14 0382**Delayed Gastric Emptying Unchanged after Cure of H. Pylori Infection (HP) in Functional Dyspepsia (FD)**

*U. Peitz, S. Blaudszun, B. Tillenburg, S. Aygen[1], O. Hennemann[1], M. Stolte[2], G. B\'f6rsch, J. Labenz

Elisabeth Hospital, Essen, Germany

[1] INFAI, Bochum, Germany

[2] Institute of Pathology, Bayreuth, Germany*Purpose:* There seems to be a smaller subgroup of HP infected FD patients profitting of HP cure. The influence of HP cure on FD symptoms and gastric emptying is investigated in this study.*Methods:* 18 patients with FD have been enrolled. HP infection was assessed pretherapeutically by consisting results of culture and histology from gastric biopsies. The infection was cured in all patients by a one-week triple therapy comprising omeprazole, clarithromycin and amoxicillin as determined 4 weeks and 6 months posttherapeutically by urea breath test. Gastric emptying was measured by a previously validated ^{13}C-octanoic acid breath test pre- as well as 4–8 weeks and 6–7 months posttherapeutically.*Results:* 4–8 weeks (resp. 6–7 months) after HP cure, there was a major symptom relief stated by 9 (6) patients, a slight relief in 5 (8), no change in 3 (3) and worsening of symptoms in 1 (1) cases. Gastric half-emptying time (t1/2, min) data are given in the following *table:* Parameter: t1/2 Pre 4–8 weeks 6–7 monthsMean: 117.6 108.8 117.6Median: 115 114 120SD 35.1 33.3 33.3Minimum 64 56 72Maximum 181 163 200The differences were not significant in Wilcoxon test (p = 0.42 after 4–8 weeks, p = 0.97 after 6–7 months).*Conclusions:* Gastric emptying was delayed in FD patients with a wide interindividual variation. HP cure did not change consistently the t1/2 in the short or long term. Also, change of t1/2 was not closely related to symptom relief. Motility, specific: StomachOesophageal gastric duodenal disorders: Helicobacter Pylori }" "Delayed Gastric Emptying Unchanged after Cure of H. Pylori Infection (HP) in Functional Dyspepsia (FD)"

"P P 14 0383"P 14 0383**Chronic Dyspepsia and H. Pylori Infection**

*I. Jovanovic, T. Milosavljevic, M. Krstic, M. Micev, M. Ugljesic, D. Miletic, D. Popovic, P. Dugalic, R. Krstic, M. Bulajic

Institute of Digestive Diseases, Clinical Center of Serbia, Belgrade, YugoslaviaChronic dyspepsia was defined as a presence of one or more upper gastrointestinal symptoms over the preceding 6 months. Due to the present disputes over Helicobacter pylori infection causing chronic dyspeptic symptoms, we compared the prevalence of H. pylori infection in the patients with the upper gastrointestinal symptoms.Upper abdominal symptoms: epigastric pain, nausea, bloating, pyrosis, vomiting and belching were assessed by a questionnaire from 52 patients, (29 females and 23 males; mean age 48, range from 20 to 72) on a visual analog scale. The severity of each symptom was scored on a linear scale from 0 (absent) to 3 (unbearable). Patients taking NSAID and antibiotics or with the history of gastrointestinal disease, such us duodenal and gastric ulcers were excluded from the study group as well as patients with hepatobiliary or pancreatic diseases. In all patients we performed upper endoscopy. Macroscopic findings ranged from complete normal to focal redness and swollen mucosa of the stomach antrum. The presence of the H. pylori infection was diagnosed both with light microscopic examination and rapid ureasa test samples from stomach antral and body mucosa.H. pylori was found in 60% subject expressing dyspeptic symptoms since in 40% H. pylori was absent. According to the used scale, the severity of the symptoms in patients with and without H. pylori infection was equal. H. pylori infection was significantly associated with histological abnormalities, mainly superficial chronic gastritis and chronic atrophic gastritis.In the Yugoslav population, H. pylori infection is an important cause of dyspeptic symptoms in non-ulcer patients (60%). On the other hand, the severity of the symptoms does not differ in H. pylori positive and negative patients with dyspepsia. Oesophageal gastric duodenal disorders: GD disorders, acid pepticOesophageal gastric duodenal disorders: Helicobacter PyloriMotility, general: Functional GI disorders }"

"P P 14 0384"P 14 0384**The Density of Gastric H. Pylori Colonization is not Associated with the Occurrence of Dyspepsia**

*B. Braden, W.F. Caspary, B. Lembcke

Dpt. of Gastroenterology, University hospital Frankfurt Main, Germany*Purpose:* In most studies, the prevalence of *Helicobacter pylori* infection in patients with functional dyspepsia does not clearly differ from the prevalence in asymptomatic controls. However, the degree of *H. pylori* colonization might play a role for the occurrence and severity of dyspeptic symptoms.*Methods:* Between August, 1993, and July, 1994, we tested 1500 apparently healthy volunteers (1036 m, 464 w, 42 – 12 years) for *H. pylori* infection using the ^{13}C-urea breath test. The non-invasive urea breath test enables a semiquantitative assessment of the extent of *H. pylori* colonization in the stomach (Gastoenterology 1994; 106: A48; Z Gastoenterology 1993; 31: 312).*Results:* 526 (35.1%) of the 1500 volunteers complained about occasionally or frequently occurring dyspeptic symptoms. No difference was observed in the *H. pylori* prevalence between asymptomatic subjects (35.5%) and those with dyspeptic symptoms (35.9%; p > 0.95). A high density of *H. pylori* colonization in the gastric mucosa indicated by strongly increased { d}% values in the ^{13}C-urea breath test was not associated with a higher frequency of dyspepsia (p > 0.80). HP-negative. HP-positive < 5 { d}% 5–10 { d}% 10–20 { d}% > 20 { d}%Age [years] 40 – 12 44 – 13 45 – 12 45 – 14n 965 201 223 111Dyspepsianever 628 135 140 71n = 974 (65.1%) (67.2%) (62.8%) (64.0%)rarely 303 55 69 30n = 457 (31.4%) (27.4%) (30.9%) (27.0%)frequently 34 11 14 10n = 69 (3.5%) (5.5%) (6.3%) (9.0%)*Conclusion:* According to these findings an eradication therapy on the basis of dyspeptic symptoms alone can not be recommended as *H. pylori* is not a proven etiology of dyspepsia. "P P 14 0385"P 14 0385**H. Pylori Infection-Gastritis-Dyspepsia, Any Relation?**

*A. Goldis, N. Tudose, C. Vernic, V. Cleescu, R. Strain

Dept. of Gastroenterology, University of Medicine Timisoara, RomaniaThe purpose of our study was to investigate the relation between H. Pylori (HP) infection-chronic gastritis-dyspepsia and some possible risk factors.*Methods:* We prospectively investigated a batch of 59 NUD patients (37 F, 22 M) with amean age of 39.3 years (17–68). HP was evidenced by bacteriology and histology (2 biopsies each from the antrum, corpus and duodenum). Gradings from 0–3 were made for HP infection, chronic gastritis and its activity. Each patient was questionned for personal datas, dyspeptic complaints (epigastric pain, heartburn, belching/burping, nausea) and some possible risk factors.*Results:* HP was positive in 39 (66.1%) patients by bacteriology and in 41 (69.4%) by histology (95.1% concordance). In this study we considered the histology HP results and compaired the mean values for the following parameters (Student test) for the HP+/HP{ -} subjects: age-41.5 – 13.1/34.2 – 11.8 years (p = 0.0790-marginally significant), educational level-2.9/3.2 (p = NS), duration of dyspepsia-4.1/3.6 years (p = NS), dyspeptic symptoms (mean of the scores of the symptoms)-17.214.1 (p = NS), stress level-5.1/4.5 (p = NS), chronic gastritis-4.45 – 1.86/1.64 – 1.55 (p < 0.0001). From the 41 HP+ patients, we compared those with low, with those with high HP infection scores, but for age, educational level, dyspepsia duration and symptoms, stress level and chronic gastritis, the comparation of the mean values of these parameters in the 2 batches revealed p = NS.*Conclusions:* In our study only chronic gastritis was significantly correlated to HP infection (p < 0.0001). Age, educational level, duration and symptoms of Dyspepsia, as well as stress level did not correlate with HP infection. Oesophageal gastric duodenal disorders: Helicobacter PyloriOesophageal gastric duodenal disorders: GD disorders, acid peptic }" "H. Pylori Infection-Gastritis-Dyspepsia, Any Relation?"

"P P 14 0389"P 14 0389**Relationship between Helicobacter Pylori Infection and NSAID-Related Gastropathy in the Elderly**

*A. Pilotto, G. Leandro[1], L. Bozzola[2], M. Franceschi, F. Di Mario[3], S. Meli[2], G. Valerio

Dept. of Geriatrics, S. Bortolo Hospital Vicenza, Italy

[2] Clin. Pathol. Service, Vicenza, Italy

[1] Dept. of Gastroenterology, Castellana Grotte (BA)

[3] Dept. of Gastroenterology, University of Padova, ItalyWith the *aim* to evaluate the role of Hp infection on the prevalence and severity of NSAID-related upper G.I. lesions in the elderly we studied endoscopically 154 subjects NSAID-users with upper GI symptoms (62 males, 92 females; mean age: 80 years, range: 67–98). Patients were defined as ""NSAID-users"" if they took a drug of this class any time in the 7 days prior to endoscopy and by different use patterns they were separated in Occasional Users, Acute Users or Chronic Users. In 128 subjects HP infection was studied by histology (2 antral and 2 body gastric biopsies, Giemsa and H&E stains) and by the rapid urease test. Statistical analysis was performed by means of Student t test for unpaired data and the X^2 test. *Results:* 127/154 subjects (82.4%) presented gastro-duodenal damage: 6 pts (3.9%) were affected with erosive oesophagitis (OE), 46 pts (29.9%) with gastric ulcer (GU), 48 pts (31.1%) with duodenal ulcer (DU), 5 pts (3.2%) with both GU and DU and 22 pts (14.3%) with erosive gastritis (EG). 64/154 pts (41.55%) were affected with a bleeding lesion. 74/128 pts (57.8%) resulted HP-positive. HP-positive pts presented a statistically significant higher percentage of GU (68.4% vs 31.6%, $p < 0.0001$) and DU (67.4% vs 32.6%, $p < 0.0001$) and a lower percentage of oesophagitis (33.3% vs 66.7%, $p < 0.05$) and non gastro-duodenal lesions (38.1% vs 61.9%, $p = 0.01$). No significant differences were found between HP-negative (46%) and HP-positive (54%) subjects as regards bleeding lesions. No significant differences were observed as regards NSAID use patterns between HP-positive and HP-negative subjects: respectively occasional users: 55.4% vs 51.8%, acute users: 12.1% vs 14.2%, chronic users: 32.4% vs 35.1%. In *conclusion* 1) HP infection was associated with higher NSAID-related GU and DU in the elderly; 2) HP infection was not associated with a higher risk of bleeding in elderly NSAID-users. Oesophageal gastric duodenal disorders: GD disorders, acid pepticOesophageal gastric duodenal disorders: Helicobacter Pylori }" "Relationship between Helicobacter Pylori Infection and NSAID-Related Gastropathy in the Elderly"

"P P 14 0390"P 14 0390**High Prevalence of H. Pylori Infection among Patients with Functional Dyspepsia. Assessment with C_{13}-Urea Breath TestT. Pin\'f3s[1],**

*M. Barenys[2]

[1] CAP 2 Cerdanyola, L'Alian\'e7a de Sabadell, Barcelona

[2] Hospital de Viladecans, Barcelona*Introduction*Up to date, the majority of previous studies about the prevalence of H.P. infection were done by gastric mucosal biopsy (urease or culture) or by serologic tests.Breath urea tests, reported for the first time by Graham in 1987, are known to be highly specific and sensitive for the detection of active H. pylori infection, both almost 100%. This type of tests are based in H. pylori's efficient hydrolisis of urea. In this test the urea labeled with a carbon isotope is administered orally, and in infected individuals metabolized to ammonia and labeled carbon dioxide, that can be quantified in the breath.Because their sensitivity, specificity and simplicity breath tests are becoming the preferred method for the assessment of H. pylori infection in epidemiologic studies.*Aim of the Study:*To evaluate the prevalence of H. Pylori infection in patients with functional dyspepsia using $_{13}$C-urea breath test.*Methods:* We studied 67 consecutive patients with symptoms of dyspepsia with a duration longer than six months. None of them had a previous history of peptic ulcer disease or treatment with pump proton inhibitors. An upper gastrointestinal endoscopy was performed in all of them and if negative, we indicated a $_{13}$C-urea breath test. We employed the European Standard Method for the Urea Breath Test, which uses 4.2 gr of citric acid as a meal to delay gastric emptying and an oral dosage of urea of 75 mgr.*Results:*26 patients (38.8%) were and 41 (61.2%) female. Mean age of the patients with FD was 43.2 yearsThe $_{13}$C-urea breath test showed positivy in 50 patients and negative results were found in 19 patients.So, the presence of h. pylori infection is proved in 72.4% of the patients with functional dyspepsia.Mean age of H. pylori positive subjects was 44.16 – 15.65 and 40.35 – 13.15 for H. pylori negative subjects. (p = 0.372)*Remarking Conclusions:*Our study shows that patients with functional dyspepsia in our area have H. pylori infection in 72.4% of cases.These results are similar to figures found in patients with gastric ulcer (70–80%) and slightly inferior to prevalence of infection in the duodenal ulcer group (90–95%).In our opinion this high percentage of positive values in a functional dyspepsia group of patients, higher than that reported with other methods, may suggest minor pathogenetic relevance of H. pylori infection in peptic ulcer disease. Oesophageal gastric duodenal disorders: Helicobacter PyloriMotility, general: Functional GI disorders }"

"P P 14 0391"P 14 0391***Helicobacter Pylori (HP)* Antibodies Against CAG A Protein in Bleeding and Non-bleeding Gastric and Duodenal UlcersG. Illies, M. Nilius, J.E. Dominguez-Munoz, A. Hackelsberger, B. Pepperkok[1], P. Malfertheiner**

Dept. Gastroenterology, Hepatology and Infect. Diseases, Otto-von-Guericke-University Magdeburg, Medical Laboratory Dr. Limbach, Germany*Background:* Cag A is a recognized indicator for increased *H. pylori* virulence and is more frequently detected in strains from patients with ulcer disease and gastric malignancy. The prevalence of CagA producing H. pylori strains in bleeding ulcers is unknown. Aim of the study was therefore to evaluate the frequency of Cag A-antibodies in patients with bleeding and non-bleeding ulcers and chronic gastritis.*Methods:* 100 patients, 30 patients with non-bleeding, 30 patients with bleeding gastric (GU) and duodenal ulcer (DU) and 40 patients with activ chronic gastritis (CG) were included. All patients were examined for HP-infection by urease-test (HUT), histology, ^{13}C-UBT and serology. HP-serology was performed by a commercially available ELISA (BioWhittaker). Cag A determination was investigated by an ELISA, coated with recombinant Cag A protein (viva diagnostika) and by a comercial Western Blot (BAG-pylori-Blot).*Results:* 87/100 (87%) were HP-positive by at least 3 tests. HP-antibodies were detected in 81/100 ((81%) of the patients, 61/100 (61%) had also CagA antibodies in the CagA-ELISA. 80/100 (80%) had a positive Western-Blot result. The profile of CagA and VacA antibodies within the three different patient groups is summarized in the following table: Western-Blot BU NBU CGCag A 22/30 (73.3%) 23/30 (76.7%) 27/40 (67.5%)Vac A 11/30 (36.7%) 11/30 (36.7%) 19/40 (47.5%)CagA-ELISA 22/30 (73.3%) 20/30 (66.7%) 19/40 (47.5%)*Conclusion:* CagA-antibodies are detectable in about 2/3 of patients and are present as frequently in bleeding and non-bleeding ulcers and chronic gastritis. Antibodies against VacA seem to be higher in CG. However CagA as well as VacA are not useful indicators for predicting ulcer complications. "P P 14 0392"P 14 0392**The Relation of Malt with Helicobacter Pylori Associated Gastritis in Patients with Ulcer and Non-Ulcer Dyspepsia**

*N.Y. Bagatur, A.F. Celik, C. Davutoglu, A. Dobrucali, F. Hamsioglu, K. Bal, M. Tuncer, S. Goksel, A. Dirican, I. Yurdakul, H. Uzunismail, E. Oktay

University of Istanbul, Cerrahpasa Medical Faculty, Internal Medicine and Pathology Department, Turkey*Aim:* To determine the prevalence of mucosa associated lymphoid tissue (MALT) and its relation with age, sex, ulcer, non-ulcer dyspepsia, activity of gastritis and density of H. pylori in H. pylori positive patients. *Methods:* 110 consecutive, previously untreated patients underwent endoscopic examination and two biopsies were taken from both antrum and corpus. Only histologically H. pylori positive patients were included (only three patients out of 110 were H pylori negative). In grading the gastric biopsy specimens, Sydney system classification was used. *Results:* MALT was positive in 39 (35.5% – 19 females, 20 males, mean age: 41.3 + 3.1) and negative in 71 (64.5% – 45 females, 26 males, mean age: 40.1 + 3.1) patients and found more often in antral mucosa (89.7%) than in corpus (20.5%) ($p < 0.0001$)***. When both malt positive and negative patients were divided into groups by decades of age, the correspondent groups in malt positive and negative patients included similar percentage of individuals ($p < 0.05$).** Sex distribution, prevalence of duodenal ulcer, gastric ulcer, gastritis, gastroduodenitis and intestinal metaplasia were not different in MALT positive and negative groups ($p < 0.05$)**. There were also no significant differences with respect to both the severity of activity of gastritis (Mild, Moderate, Severe) and the density of H. pylori (Mild, Moderate, Severe) between MALT positive and negative groups ($p < 0.05$)**. *Conclusion:* Our results suggest that additional factors such as bacterial or host related ones are responsible for MALT rather than the severity of the activity of gastritis or the density of H. pylori.Comparisons made by using independent samples t-test*, chi-square** or fisher.*** Oesophageal gastric duodenal disorders: Helicobacter PyloriOesophageal gastric duodenal disorders: GD disorders, acid pepticOncology, specific: Lymphoma }" "The Relation of Malt with Helicobacter Pylori Associated Gastritis in Patients with Ulcer and Non-Ulcer Dyspepsia"

"P P 14 0393"P 14 0393**The Helicobacter Pylori Colonization in Gastroduodenal Mucosa and Immune Response in Patients with Acne Rosacea: Aspects of Etiopathogenesis and TreatmentL.E. Abrahamovych**

Medical Institute, Lviv, UkraineThe aim of our study was to determine Helicobacter pylori (H.P.) prevalence in gastroduodenal mucosa and its role in immune response and etiopathogenesis of acne rosacea (A.R.) and gastroduodenal pathology. The study was based on 160 patients (pts) with A.R. (64.4% women, 35.6% men; mean age 41.6 – 1.7 years). All pts underwent upper gastroduodenal endoscopy and biopsy samples were taken and studied for H.P. by both methods: microscopic – Giemsa staining and CLO – rapid diagnosis urease test. The cellular and humoral immune response was analysed by WHO demanded tests constellation (1981). The beginning of skin changes has been observed 3–4 years after the symptoms of the gastroduodenal pathology (Gastroduodenitis – 68.2%, duodenal ulcer – 30.6%) in 98.8% pts with A.R. The H.P. positive test was found in the majority of examined pts, among them 92.5% in the antrum, 93.28% in the duodenum, as well as immune inflammation in gastroduodenal mucosa. The extent of H.P. colonization in gastroduodenal mucosa was compared with cellular and humoral immune response in pts with A.R. Changes of immunology reactivity parameters were analogous in 4 stages of A.R. which is typical for hyperreactive T- and B-immunity systems dysbalance. High level of total T-E lymphocytes was accompanied by low level of active T-A lymphocytes with resulting low effector T-A/T-E index ($p < 0.01$). High receptor activity of T-E lymphocytes, T-A lymphocytes and T-helpers ($p < 0.001$) with concomitant high immunoregulatory index (T-H/T-S; $p < 0.01$), increased O-lymphocytes and leucocyte/O-lymphocyte index ($p < 0.001$), reflecting inflammation component of internal organs involvement, high receptor activity of B-lymphocytes ($p < 0.001$) and increased total circulatory immune complexes was also revealed. Thus, profound autoaggressive disorders of cellular and humoral immunity are baseful mechanisms for A.R. and gastroduodenal pathology development. The treatment by antihelicobacterial and immunoregulatory drugs gave the positive clinical results of gastroduodenal and cutaneous pathology in 99.37% pts (recovery in 66.25%, uncomplete clinical remission in 33.12%) with eradication of H.P. colonization.*Conclusions:* The established changes indicate the importance of H.P. infection with the autoaggressive immune response in the etiopathogenesis of acne rosacea as well as gastroduodenal pathology with corresponding treatment approaches. Oesophageal gastric duodenal disorders: Helicobacter PyloriOesophageal gastric duodenal disorders: GD disorders, acid pepticImmunology and microbiology: Host defense mechanisms }" "The Helicobacter Pylori Colonization in Gastroduodenal Mucosa and Immune Response in Patients with Acne Rosacea: Aspects of Etiopathogenesis and Treatment"

"P P 14 0394"P 14 0394**Helicobacter Pylori (H.P.) Infection in Gastric Stump Mucosa and Immunoreactivity in Patients (Pts) with Postgastroresectional Disease (PGRD): Aspects of Pathogenesis**

*O.O. Abrahamovych, M.P. Pavlovsky, E.S. Abrahamovych, M.O. Abrahamovych

Medical Institute, Lviv, UkraineThe aim of our study was to determine H.P. prevalence in pts in late terms (5–33 years) after partial gastrectomy for gastroduodenal ulcer (GDU), and its role in immunoreactivity and PGRD pathogenesis. The study was based on 250 pts (96% men, 4% women; aged range 31–74 years) who underwent gastric resection by Billroth-I (B-I; 48%) and Billroth-II (B-II; 52%) mode. Thirty pts with GDU, without gastric surgery, were used as control. All pts underwent upper gastrointestinal endoscopy and biopsy samples were taken and studied for H.P. by CLO – urease test. The cellular and humoral immunoreactivity was analysed by WHO demanded tests (1981). The H.P. positive test was found in 56% examined pts totally, among them in 24% in both gastric stump body (GSB) and anasthomosis (A), in 28% – only in the GSB and in 4% – only in the A, compared with 28 (93.5%) of 30 pts with GDU without gastric surgery ($p < 0.01$), as well as duodeno (jejuno) gastric reflux – in 97.1%, versus – 66.7% ($p < 0.01$). More often H.P. occured after partial gastrectomy by B-II than by B-I mode (1.2:1.0), after 1/2 gastric resection than 2/3 one (2.1:1.0), in pts who suffered from duodenal than gastric ulcer (1.7:1.0). Thus, H.P. prevalence in pts with partial gastrectomy is lower than in GDU pts without gastric surgery, indicating a potential inhibitory role of bile reflux on the development of the microorganism. The extent of H.P. colonization in gastric stump mucosa was compared with cellular and humoral immunoreactivity. The hyperreactive (autoaggressive) type of T- and B-immune systems was established. Blood T-lymphocytes were increased (59.7 – 0.9%, $p < 0.01$), effector index (T-A/T-E) -decreased (0.28 – 0.02, $p < 0.001$), immunoregulatory index (T-helpers/T-suppressors) – increased (5.52 – 1.19, $p < 0.001$), leucocytes/T-E index – increased (9.31 – 0.42, $p < 0.001$), reflecting inflammation component of internal organs involvement. B-lymphocytes were decreased (16.06 – 0.64, $p < 0.001$) with concomitant tendency to Ig and circulatory immunocomplexes (CIC) increase (total CIC – 392.6 – 19.7 IU, $p < 0.001$; small CIC – 548.45 – 33.5 IU, $p < 0.05$), pointing to activation of antibody formation by decreased number of B-lymphocytes, hyperreactivity of humoral immunity and autoimmune processes in pts with PGRD. Thus, the established changes indicate the importance of H.P. infection in gastric stump mucosa with the autoaggressive immune response in the PGRD pathogenesis, which must be taken into account in diagnostics, evaluation treatment results by antihelicobacterial and immunoregulatory drugs, and prognosis. Oesophageal gastric duodenal disorders: Helicobacter PyloriImmunology and microbiology: Host defense mechanismsOesophageal gastric duodenal disorders: GD disorders, acid peptic }" "Helicobacter Pylori (H.P.) "P P 14 0395"P 14 0395**Helicobacter Pylori in Patients with Resected Stomach**

*A. Nagorni, J. Milonovic, T. Tasic, V. Katic, V. Brzacki, S. Petrovic-Nagorni, I. Stamenkovic, V. Zivkovic

Clinic for gastroenterology and Clinic for pathology Faculty of Medicine Nis, YugoslaviaChronic gastritis and dysplasia of the resected stomach (adenomatous, cystic, microglandular, globoid, mixed) are common findings, especially ten and more years after gastric resection. These findings are more frequent after Billroth II resection. The aim of our study was to evaluate Helicobacter pylori (H. pylori) prevalence in patients after partial gastric resection for duodenal ulcer. We studied 42 partially resected patients, 30 men and 12 women, mean age 59.1 years, range 31 to 75 years. Twenty nine patients were with Billroth II procedure and 13 patients with Billroth I procedure. The mean time interval between the gastric resection and our study was 15.2 years (range 5 to 24 years) in Billroth II procedure group and 6.3 years (range 1 to 11 years) in Billroth I procedure group. All patients were underwent to proximal gastrointestinal endoscopy. Biopsy samples were taken from the mucosa in the surroundings of anastomosis. Biopsy samples were studied for histology and H. pylori by rapid urease test (bramio test). Forty patients with duodenal ulcer were used as a control group for H. pylori evaluation. Chronic gastritis of various types and stages of dysplasia was diagnosed in all patients with resected stomach. H. pylori was present in 13 (44.8%) patients of Billroth II group and in 8 (61.5%) patients of Billroth I group, compared with 34 (85%) patients of duodenal ulcer group ($p < 0.05$). *Conclusion:* The prevalence of H. pylori in patients with Billroth II resection is lower than in patients with Billroth I procedure, probably because of inhibitory role of bile reflux on the development of H. pylori infection. "P P 14 0396"P 14 0396***Helicobacter Pylori* Colonization and Ulcer Recurrence after Gastric Surgery in Duodenal Ulcer (DU) Patients**

*S.J. Konturek, E. Sito, T. Popiela

Inst Physiol and Dept Surg, Univ Sch Med, Krakow, Poland*Purpose:* The eradication on *Helicobacter pylori* (Hp) is known to reduce remarkably the recurrence of DU similarly as does gastrectomy but it is not clear what is the prevalence of Hp in DU patients undergoing gastrectomy or vagotomy. The purpose of this study was to evaluate the influence of gastrectomy or selective vagotomy with pyloroplasty on the prevalence of Hp.*Material:* 79 patients (35–73 yrs old) just before and 6–8 months after surgical interventions were included. ^{14}C-urea breath test and CLO-test and culture of Hp in the biopsy samples of antral mucosa obtained during endoscopy were used to detect Hp.*Summary of results:* Hp infection was detected in all patients before the surgery. Following distal gastric resection (antrectomy) with Billroth II anastomosis (N = 32) due to ulcer resistance to conservative therapy (N = 26) or pyloric stenosis (N = 6), Hp was only in 3 out of 32 operated patients) and no ulcer recurrence was observed. Following selective vagotomy and pyloroplasty (N = 43) or simple closure of perforated ulcer in DU patients (N = 4), Hp was found in all (100%) cases and ulcer relapse occurred in 7 vagotomized patients (16%).*Conclusions:* (1) disappearance of Hp is probably the major factor responsible for low ulcer recurrence after gastrectomy and (2) vagotomy should be avoided as the method of treatment of DU because of the high Hp prevalence rate and high ulcer recurrence after this procedure. Oesophageal gastric duodenal disorders: GD disorders, acid peptic }" "Helicobacter Pylori Colonization and Ulcer Recurrence after Gastric Surgery in Duodenal Ulcer (DU) Patients"

"P P 14 0397"P 14 0397**Epithelial Cells Proliferation in *Helicobacter Pylori* (HP) Associated Gastritis and in Operated Stomach**

*V.A. Isakov, L.E. Gurevitch, A.R. Zlatkina

Moscow Regional Research Clinical Institute (MONIKI), Moscow, RussiaThe increase of epithelial proliferation rate in HP-positive gastritis is considered as one of the initial steps in gastric carcinogenesis. The increased PCNA labeling index was reported in HP gastritis comparing with health controls. On the other hand, operated stomach, which usually lacks HP, is one of independent risk factors for the development of gastric carcinoma. The aim of the study was to evaluate epithelial proliferation rate in gastric mucosa of the patients with HP-gastritis and in patients with operated stomach using proliferating cell nuclear antigen labeling index (PCNA-LI). Multiple formalin-fixed gastric biopsies taken from the body of the stomach of 6 HP-negative patients (2–10 yrs after Billroth-II operation because of peptic ulceration) and from the body and antrum of the stomach of 4 patients with HP-positive gastritis were routinely stained with H&E and toluidine blue for the assessment of HP-status. PCNA was revealed by PAP immunostaining with PC-10 murine anti-PCNA monoclonal antibody, using microwave pretreatment technique for better antigen retrieval. *Results:* All 6 operated patients have type C gastritis with moderate/severe mucosal atrophy, five of them have focal incomplete intestinal metaplasia. All HP-positive patients have pangastritis with mild/moderate atrophy in antrum and corpus mucosa and two of them have intestinal metaplasia. Mean PCNA-LI of 6 operated patients was significantly higher (22.31 – 1.86) than in HP-positive patients (17.62 – 1.75) ($p < 0.01$). It indicates that in operated stomach epithelial cells experienced other proliferative stimuli, than in HP gastritis. In conclusion, there are at least two different ways for stimulation of epithelial cell's proliferation in the stomach that can independently induce the development of gastric carcinoma in HP associated gastritis and in operated stomach. "P P 15 0398"P 15 0398**Gastric Carcinoma (GC) Strains of *H. Pylori* (HP) Presents *vacA* Sequence that Allows to Differentiate Them from Duodenal Ulcer (DU) and Chronic Gastritis (CG) Strains**

*D.M.M. Queiroz, E.N. Mendes, G.A. Rocha, A.M.R. Oliveira, S.B. Moura, G.F. Lima Jr., C.A. Oliveira

Lab. Research in Bacteriology/FM/UFMG, BrazilHP is the major cause of human CG and is now considered a significant risk factor for the development of peptic ulcer and GC. The vacuolating cytotoxin, encoded by *vacA,* is an important virulence factor, being more frequently produced by HP strains associated with DU. Patients with GC also present antibodies to cytotoxin. Despite *vacA* can be detected in almost all strains, only about 50% of them induce vacuolation *in vitro.* It was demonstrated that *vacA* presents 3 signal (s1a and s1b, which are closely related, and s2) and 2 mid region sequences (m1 and m2). It was also observed that HP strains isolated from DU patients are more frequently type s1/m1, a sequence associated to cytotoxin and *cagA* positivity. We investigated the distribution of *vacA* genotypes in HP strains isolated from GC patients to verify if it is possible to differentiate them from CG and DU strains. We studied 48 HP isolates from GC, 33 from DU and 37 from CG patients. DNA was extracted by a phenol-chloroform method. Primers used for *vacA* homologues detection were previously published by Atherton *et al* (1995). GC patients presented 38 (79.1%) s1/m1, 9 (18.8%) s1/m2 and one (2.1%) s2/m2 strain. Most strains isolated from DU patients were also s1 (31 { -} 93.9%), but they were more frequently m2 (12 { -} 36.4%) than those isolated from GC patients (p = 0.06). On the other hand, 18 (48.6%) patients with CG presented s2/m2 strains, 9 (24.3%) s1/m1 and 10 (27.1%) s1/m2. In regard to signal sequences s1 and s2, there were significant differences between GC and CG isolates ($p < 10^{-6}$) and DU and CG strains ($p < 10^{-3}$) but no difference was observed between GC and DU isolates (p = 0.56). GC patients have also type m1 strains more frequently than CG patients ($p < 10^{-6}$). To better differentiate GC from DU strains we employed other primers to identify s1a and s1b signal sequences and we observed that 93.5% (29/31) strains from GC patients were type s1b and 80.0% (16/20) strains from DU patients were type s1a ($p < 10^{-8}$). In conclusion, GC patients present more frequently type s1b/m1 strains, DU patients types s1a/m1 and s1a/m2 strains and CG patients types s2/m2 and s1b/m2 strains. Supported by: CNPq, FINEP and FAPEMIG/Brazil. Oesophageal gastric duodenal disorders: Helicobacter PyloriOncology, specific: Stomach }" "Gastric Carcinoma (GC) Strains of H. Pylori (HP) Presents vacA Sequence that Allows to Differentiate Them from Duodenal Ulcer (DU) and Chronic Gastritis (CG) Strains"

"P P 15 0399"P 15 0399**Comparing the Presence of H. Pylori on the Unchanged Gastric Mucus Layer and within the Tumor Tissue in Patients with Gastric Carcinoma**

*T. Milosavljevic, M. Micev, M. Krstic, M. Ugljesic, I. Jovanovic, R. Krstic, P. Dugalic, V. Antic, D. Popovic, M. Bulajic

Institute of Digestive Diseases, Clinical Center of Serbia, Belgrade, YugoslaviaOne of the most controversial discussions in the resent studies has been the possible association between H. pylori infection and gastric cancer. The risk of the gastric cancer is 6 times increased by the presence of H. pylori, accounting for about a half of all the gastric cancers. The complicated interaction between gastric H. pylori infection, gastric acid secretion and gastric histology remains unraveled.The aim of our present study was to compare the presence of H. pylori in the tumor tissue and on the unchanged stomach mucosa surrounding the carcinoma. During the last two years we investigated 99 patients with endoscopically and hystologically confirmed stomach carcinoma (55 males and 44 females, age between 46 and 80). After the operation, we examined H. pylori presence in tumor tissue and surrounding stomach mucosa.In the 55 (55%) persons we found H. pylori in the surrounding mucosa, but in 13 patients we also found H. pylori in the tumor tissue (23.60% of all cases of gastric cancer). Majority of all patients with presence of H. pylori were males (12). Hystologically, the intestinal type of cancer was the most frequent one, counted 12 cases: macroscopically, the vegetant type was present in 9 cases and superficial, infiltrative and early cancer counted one case each.In addition to still present enigma of H. pylori infection role in gastric cancer pathogenesis, we conclude that Helicobacter pylori is not present on the surrounding mucus layer only. It can also be detected in tumor tissue in about 25% of patients with gastric cancer and concomitant H. pylori infection. Oesophageal gastric duodenal disorders: GD disorders, acid pepticOesophageal gastric duodenal disorders: Helicobacter PyloriOncology, specific: Stomach }" "Comparing the Presence of H. "P P 15 0401"P 15 0401**Gastric Epithelial Cell Proliferation and Helicobacter Pylori CagA-Positive Strains: Immunohistochemical Study in a High Gastric Cancer Risk Population**

*L. Baldini, F. Bonvicini, G. Epifanio, S. Pretolani, N. Figura[1], C. Fasanella, E. Mazzotta, F. Miglio[2], G. Gasbarrini[3]

I Patologia Medica, University of Bologna, Bologna, Italy

[1] Patologia Medica, University of Siena, Bologna, Italy

[2] Dept. Int. Med., Malp\'edghi Hospital, Bologna, Italy

[3] Dept. Int. Med., Catholic University, Rome, ItalyRecently, Helicobacter pylori was classified as Type I carcinogen. Many evidences in literature show that an increased cell proliferation can be an important step in carcinogenesis. The role of *H. pylori* on gastric epithelial cell proliferation is still debated. High prevalence of *H. pylori* CagA positive (Hp CagA+ve) strains was found in a representative sample of a population at high risk for gastric cancer (San Marino Study I – GUT 1995). *Aim:* to evaluate, in this population, the gastric epithelial cell proliferation, in order to find possible correlations with Hp infection and CagA-status. *Methods:* Thirty-six patients were studied, subdivided into 4 groups: Hp CagA+ve gastritis, Hp CagA { -} ve gastritis, Hp { -} ve gastritis and controls. Antral mucosal biopsies were incubated with PC 10 monoclonal antibody for the immunohistochemical detection of PCNA (avidin-biotin peroxidase technique). The following parameters were blindly evaluated by computerized image analysis system: Proliferative Zone index (PZ = number of cell included between the uppermost and lowest labelled cell), and Labelling index (LI = percentage ratio between total number of labelled cells and total number of cells in proliferative zone). Statistics: data were analysed with T-Student's test and linear regression. *Results:* Hp+ve gastritis shows a significant higher LI (33 – 8) and PZ index (70 – 9) with respect to normal mucosa (23 – 15; 50 – 16) and Hp { -} ve gastritis (13 – 3; 41 – 10). LI and PZ index are directly correlated with anti-CagA antibodies ($p < 0.01$). *Conclusions:* These data indicate that CagA+ve *Hp* strains induce a higher gastric cell proliferation, and support the role of this infection in gastric carcinogenesis. Oesophageal gastric duodenal disorders: Helicobacter PyloriOncology, general: Proliferation, carcinogenesis }"

"P P 15 0402"P 15 0402***Helicobacter Pylori* and Intestinal Type of Gastric Cancer**

*C. Mart\'edn de Argila, D. Boixeda, C. Redondo, R. Cant\'f3n, L. Moreno, J.P. Gisbert, L. Ruiz del Arbol

Gastroenterology, Pathology and Microbiology Departments, ""Ram\'f3n y Cajal"" Hospital, Madrid, SpainEpidemiological studies have consistently shown an association between infection with *H. pylori* and gastric cancer but different conclusions have been reported regarding its association with the intestinal and diffuse histologic types.*Aim:* To determine whether there is an association between *H. pylori* infection and gastric adenocarcinoma and its relationship with two histologic gastric cancer types: intestinal and diffuse.*Materials and Methods:* 48 (17 females; mean age: 68.7 – 11.5 yrs; range: 39–88 yrs) patients with histologically confirmed gastric adenocarcinoma were studied. No patient had received blood or blood derivatives. Gastric cancers were histologically classified as intestinal or diffuse type following Lauren classification. *H. pylori* infection status was assessed by determining IgG antibodies to this organism using an ELISA assay commmercial kit (Helico-G, Porton, Cambridge, UK). Titers > 10 U/ml were considered positive.*Results:* 31 (65%) of gastric cancers were classified as intestinal type, 12 (25%) as diffuse type and 5 unknown. Age and male/female distribution were similar in both groups. The overall *H. pylori* seroprevalence was 85.4%. *H. pylori* was found in 29 (93.5%) of the 31 intestinal-type cancer cases compared with 8 (66.7%) of the 12 diffuse-type cancer cases ($p < 0.05$).*Conclusions:* The overall *H. pylori* prevalence in cancer gastric patients was clearly higher than that reported in healthy people in Western developed countries. The prevalence of *H. pylori* in intestinal-type gastric cancer exceeded by far the prevalence of *H. pylori* in diffuse disease, thus suggesting that *H. pylori* may be a cofactor for the development of this histologyc gastric cancer type. "P P 15 0403"P 15 0403**Gastric Adenocarcinoma Location and *Helicobacter Pylori* Infection**

*C. Mart\'edn de Argila, D. Boixeda, C. Redondo, L. de Rafael, J.P. Gisbert, E.S. Villalobos, F. Hernandez Ranz

Gastroenterology, Pathology and Microbiology Departments, ""Ram\'f3n y Cajal"" Hospital Madrid, Spain*H. pylori* infection is recognized as a risk factor for gastric adenocarcinoma.*Aim:* To determine if there is an association between *H. pylori* infection and gastric cancer and its relationship according to tumor location.*Materials and Methods:* 48 (17 females; mean age: 68.7 – 11.5 yrs; range: 39–88 yrs) patients with histologically confirmed gastric adenocarcinoma were studied. None of patients had received blood or blood derivatives. Gastric cancers were assigned to the following groups according its location: antrum, corpus, and gastric fundus (near to cardia). *H. pylori* infection status was assessed by determining IgG antibodies to this organism using an ELISA assay commercial kit (Helico-G, Porton, Cambridge, UK). Titers > 10 U/ml were considered positive.*Results:* 13 (27%) of gastric cancers were located at gastric antrum, 12 (25%) at gastric corpus, and 5 (10.4%) at gastric fundus. In 18 (37.5%) patients the tumor extended to more than one of the described locations, thus preventing to accurately know the origin of the neoplasm. The overall *H. pylori* seroprevalence was 85.4%. *H. pylori* infection according tumor location yielded the following distribution: Tumor location *H. pylori* + *H. pylori {* -} TotalAntrum 13 (100%) 0 13Corpus 11 (91.7%)* 1 (8.3%) 12Fundus 2 (40%)$^{*@}$ 3 (60%) 5*p < 0.05 (compared with ""antrum); $^{@}$p = 0.052, almost significant (compared with ""corpus"").*Conclusions:* These results confirm the high prevalence of *H. pylori* infection in patients with gastric adenocarcinoma, much higher than that observed in healthy people in Western developed countries. The higher *H. pylori* prevalence observed in patients with antrum and corpus gastric adenocarcinoma supports a relationship between *H. pylori* infection and the noncardia gastric adenocarcinoma. "P P 15 0405"P 15 0405**Low-Grade Malt Lymphoma of the Stomach, Associated with *Helicobacter Pylori:* Russian Experience**

*V.A. Isakov, L.E. Gurevitch

Moscow Regional Research Clinical Institute (MONIKI), Moscow, RussiaDuring the last two years we have followed-up 6 patients with low-grade MALTomas of the stomach. There were 5 women and 1 man, the mean age was 51.8 years. There were one polypoid-like lesion, four ulcerated and one was presented as a bulk infiltration of 1/3 of the stomach with ulceration. The diagnosis was confirmed by histology and monoclonality of tumor cells was confirmed by immunohistochemistry with { k} and { l} light chains antibodies. All patients received triple therapy that consisted of CBS (De-nol) 120 mg qid, ampicillin 500 mg qid and methronidazole 250 mg qid during 14 days, one patient because of allergy for penicillins received tetracycline 500 mg qid instead of ampicillin. H. pylori was eradicated in 5 patients. In all these patients the regression of MALToma was progressively noted. It started with the decrease of density of infiltrate in lamina propria of gastric mucosa, then lympho-epithelial lesions disappeared. Nevertheless, at that period of time and up to the 8 month after treatment monoclonality of cells infiltrating lamina propria was revealed by immunohistochemistry with anti-{ k}-antibodies in two patients. Nine months after the cessation of the therapy the biological remission of low grade MALToma was achieved in all 5 patients in whom the H. pylori was successfully eradicated. During the follow-up period one patient relapsed after 8 months of biological remission with H. pylori reinfection and showed reappearance of all features of low-grade MALToma including lympho-epithelial lesions and mucosal ulceration. After the repetition of the triple therapy H. pylori was eradicated again and after 6 mo biological remission of MALToma was achieved.*In conclusion:* Eradication of H. pylori leads to histological and biological remission of low-grade MALToma of the stomach. Reinfection of H. pylori followed by rapid relapse of MALToma. "P P 15 0406"P 15 0406**Sequential Histological and Molecular Follow Up of Low Grade Gastric Malt Lymphoma after Eradication Therapy for *Helicobacter Pylori***

*D. Boixeda, C. Montalban, A. Manzanal, J.L. Calleja, M.G. Montero, C. Martin de Argila, I. Alvaez Baleriola, C. Bellas

Departments of Internal Medicine, Pathology, Gastroenterology, ""Ram\'f3n y Cajal"" Hospital and Hematology, ""Severo Ochoa"" Hospital, Madrid, Spain*H. pylori* infection is associated with low grade gastric MALT lymphoma, and available data support that the eradication of *H. pylori* can cause lymphoma regression. In this study, 10 untreated patients with low grade gastric MALT lymphoma were treated with amoxicillin, metronidazole and omeprazol for 14 days. In order to assess the response to *H. pylori* eradication and the evolution of the histological and molecular responses, patients were followed up with sequential endoscopy, mapping gastric biopsies and molecular studies with amplification of the IgH gene by PCR with Fr2 and Fr3 V-region primers with nested primers directed to the J-region. *H. pylori* was eradicated in all patients and reinfections were non demonstrated. In 8 of the 10 patients the lymphoma regressed both endoscopically and histologically; another patient achieved a partial histological regression. In 4 of the 8 histologically cured patients no clonal band was detected by PCR; in the remaining 4 patients, PCR demonstrated a clonal band, that disappeared in all patients after a mean of 7.2 – 6 months. All 8 patients have a persistent clinical and histological remission after a median follow up of 12.5 – 6 months.*Conclusions:* 1) *H. pylori* eradication can produce histological regression of low grade gastric MALT lymphoma. 2) *H. pylori* should be the initial therapy for stage I low grade gastric MALT lymphoma. 3) Despite histological regression of the lymphoma, a clonal population may persist in some cases. 4) The disappearance of this clonal population may be delayed for months. 5) Patients with histological regression of the lymphoma but with a persistent clonal population should no be treated unless a relapse can be histologically demonstrated. These observations suggests that gastric lymphoma can be effectively cured; still, long-term follow up studies are necessary to assess the ultimate outcome of these patients.

"P P 15 0407"P 15 0407**Precancerous Lesions in Patients HP Positive and Gastric Cancer Risk Index**

*E. Masci, E. Viale, M. Freschi, A. Tittobello

S. Raffaele Hospital, University of Milan, Italy*Background:* the follow-up of precancerous gastric lesions (PGL) is a controversial problem, because only few patients with chronic atrophic gastritis (CAG) and intestinal metaplasia (IM) develop cancer. Recently a simple score has been proposed to detect Hp infected patients with an increased risk for gastric cancer (GC). In this risk index histological criteria were evaluated in early gastric cancer patients in comparison with duodenal ulcer (DU) patients [1]. *Aim:* to compare two groups of patients, with DU and with CAG with type III IM, a well know PGL, both characterized by Hp infection and to assess if the only difference of lymphocytes/plasmacells and neutrophiles infiltration in corpus and antrum without considering metaplasia to discriminate the two groups of patients with different cancer risk. *Materials and methods:* we have drawed two biopsies from the antrum and two from the corpus of 41 patients with DU and 25 subjects with CAG and type III IM. The samples were histologically examined. *Results:* in subjects with CAG and type III IM samples from the gastric corpus, compared to those from the antrum, showed higher infiltration of lymphocytes and plasmacells. In addition, when compared with DU patients, they showed higher lymphocytic and neutrofiles, considered as 1 point of the score: DU type III IM pLymphocytes/plasmacells 14.63% (6) 40% (10) < 0.020Neutrophiles 14.63% (6) 44% (11) < 0.0082 vs 0 points: Odds – ratio = 5.71; 95% CI = 1.49–21.84*Conclusions:* in our preliminary study the degree of Hp gastritis and the activity, in the corpus, is more pronounced in subjects with CAG and type III IM than in DU patients. However, the overlapping of the results in the two groups of patients need further data in large group to confirm the usefulness of considering the two histological features in corpus as a predicting factor of risk of cancer, independently of IM.

"P P 16 0409"P 16 0409**Comparative Cytopathologic and Histologic Study of Benign Nonspecific Inflammation and Infections of Upper Alimentary Tract in Childhood**

*M.D. Georgieva-Shakola, M.V. Atanassova[1], I. Krasnaliev[2], I.M. Russeva

Dept. of Pediatrics, Medical University, Varna, Bulgaria

[1] Clin. of Gastroenterol., Medical University, Varna, Bulgaria

[2] Dept. of Pathology, Medical University, Varna, BulgariaThe aim of the study was to review the role of cytological abrasive biopsy in children upper endoscopy for establishing changes in gastric and esophageal epithelium & for detecting infectious agent (Helicobacter pylori-H.p.). In 1994/95 the examination covered 113 children and adolescents (57 girls and 56 boys) aged 6–18 years with upper dyspeptic syndrome. Each patient underlined gastroscopy with brush biopsy. Smears of 108 patients were stained with Giemsa. Sixty three of them was examined histologically and 26 with urease test. Twenty five patients with endoscopic diagnosis gastritis were examined for cytological changes of gastric epithelium & 5 patients with endoscopic diagnosis esophagitis – of epithelium of esophagus. H.p. was found in smears in 50.9%. Gastrospirillum hominis in 1.9% & Candida albicans in 0.9%. For detection of H.p. cytological method had (in comparison with histological) sensitivity 91%, specificity 46%, accuracy 62%, positive predictive value 48% and negative predictive value 91%. In comparison with histological and urease test, cytology had sensitivity 93%, specificity 92% and accuracy 92%, positive predictive value 93% and negative predictive value 92%. In patients with endoscopic gastritis cytological examination revealed minimal cell atypia 9/25, increased cellular exfolation 7/25 and nuclear hyperchromatism 9/25. Histological activity of gastritis was related with increased nuclear hyperchromatism & cellular exfoliation. Inflammatory cells and cells undergone intestinal metaplasia were not found cytologically. Established cytological changes in patients with endoscopic esophagitis were increased cellular exfoliation 2/5, minimal cellular atypia, inflammatory cells and Candida albicans – 1/5. In conclusion brush biopsy in childhood is a rapid and simple method for detection of H.p. infection. Cytological changes may suggest to inflammation of gastric and oesophageal mucosa. "P P 16 0410"P 16 0410**Recurrent Abdominal Pain (RAP) and Helicobacter (HP) Infection in Children: Effectiveness of Eradication TherapyA. Carroccio, F. Cavataio, C. Acierno,**

*G. Montalto, G. Li Voti, M. Soresi, S. Ippolito, P. Campagna, C. Magliarisi, G. Iacono

Cattedra di Med. Int. and Chir. Ped. Univ. di Palermo II Div. Ped., Osp. ""Di Cristina"" Palermo (Italy)A relationship between HP infection and RAP in children has been suggested but not clearly demonstrated. We evaluated the effectiveness of eradication treatment for HP infection in patients with RAP, selected from over 4,000 children in the general population. 180/4,000 subjects presented RAP, defined according to Apley's criteria. 77/180 were positive for serum anti-HP antibodies. After esophagogastroscopy (EGDS), 65 patients were randomly assigned to 3 treatment groups: Group A (omeprazole + clarithromycin), Group B (clarithromycin + bismuth citrate), Group C (amoxicillin + bismuth citrate), each including 23, 22 and 20 patients respectively. 35 HP-negative RAP patients were selected as controls and treated with placebo. A RAP severity score was determined at study entry and at 3 and 12 months after treatment. In the 3 eradication treatment groups, symptoms scores were significantly lower both at 3 and 12 months after treatment than at the entry. The percentage of completely cured patients at 3 months was significantly higher in Group A (22/23 subjects) than in Group B (13/22) and in Group C (10/20); At 12 months the number of cured patients was 17/23 in Group A, 12/22 in Group B and 9/20 in Group C. In general the frequency of cured RAP was significantly higher in the HP-positive patients than in controls both at 3 and at 12 months. Post treatment EGDS showed persistent HP in 14/20 patients who were still symptomatic after treatment and in 0/15 subjects considered cured ($p < 0.0001$). Eradication percentages were significantly higher in the subjects of Group A than in the other 2 treatment groups. We conclude that more than 1/3 of the RAP patients also have HP infection and that the eradication treatment is useful in curing RAP.

"P P 16 0411"P 16 0411**Gastric Mucous Inflammation at Childhood Upper Gut Disease**

*K. Marakhovsky, A. Zarubov, S. Zuk, Y. Marakhovsky

Minsk Diagnostic Centre for Child, Republican Gastroenterology Centre, Minsk, BelarusInflammatory reactions of the gastric mucous are accompanied with many upper gastrointestinal diseases. On the other hand, such widespread infectious factor, as H. pylori colonised gastric mucous and it associated with the mucous inflammation which has the adverse prognosis, especially in children. However, the frequency and feature of gastric mucous inflammatory reactions at the children are investigated not reasonably.*Aim of the study* Evaluate of gastric mucous inflammatory reactions (GMIR) at the various diseases of upper gastro intestinal tract and at different level of H. pylori colonisation in children's age.*Methods.* 2594 patients (pts) (F – 1413, M – 1181) in age from 2 to 15 years old was examined by upper endoscopy and mucous lesions was assessment by the OMED standards. Biopsies from antrum was evaluated by a degree of lymphoplasmacytic (LPC), polymorphonuclear (PMN) reactions and H.p. colonisation (HpCo) on Sydney system following for the descriptions of the histological parameters.*Results.* Group I – 1273 pts (49.07%) had gastritis with total HpCo-61.2%; group II – 69 (2.66%) pts had duodenal ulcer and H.p positive in 81.8%; group III – 154 (5.94%) pts with flat lesions of duodenal bulb mucous and HpCo-66.0%; group IV – 195 (7.52%) pts with flat stomach lesions and HpCo-67.7%.Following GMIR was detected: middle LPC > PMN in 29.3% from all cases; low grade LPC = PMN in 39.7%; LPC < PMN was found in only 21 cases (0.8%). High and middle HpCo is associated with severe GMIR in 68.7% pts.*Conclusion:* 1. Chilhood upper gastrointestinal diseases are provided with predominated chronic gastric mucous inflammatory reactions type. Severe grade of gastric mucous inflammatory reactions correlated with high gastric mucous H. pylory colonisation rate. Bologna

[1] Cesena

[2] Ferrara

[3] Mantova

[4] Pavia

[5] Torino

[6] Trieste*Background.* The ^{13}C-Urea Breath Test (^{13}C-UBT) is a simple non invasive highly accurate test for the detection of Helicobacter (H.) pylori infection in adults. Although the use of ^{13}C-labelled urea renders this test absolutely safe and thus undoubtely suitable for the detection of H. pylori infection in children, as yet a standardized ^{13}C-UBT protocol for children has not been formulated. In particular we have no information on the three fundamental components of the ^{13}C-UBT: the number of and time intervals for breath sample collection, the appropriate test meals to delay gastric emptying and doses of ^{13}C-Urea. *Purpose.* The aim of our study was to evaluate the accuracy of the ^{13}C-UBT in children using different types of test meal, doses of ^{13}C-Urea and breath sampling intervals. *Methods.* 98 children, recruited in our study (51 males, 47 females; age (yrs) range 2–16, mean – SE: 10.1 – 0.3; body surface area (m^2) range 0.5–1.7, mean – SE: 1.2 – 0.03) underwent routine upper GI endoscopy. 3 antral and 2 corpus-fundus biopsy specimens were taken for histological evaluation for the presence of H. pylori infection (Haematoxylin/Eosin; GIEMSA) and the quick Urease-test was performed. The ^{13}C-UBT was performed in each child after undergoing endoscopy, and was then repeated within three days modifying the test meal or the dose of the ^{13}C-Urea. 62 children were given a fatty test meal, Pulmocare (Abbott) 100 ml, and two different doses of ^{13}C-Urea, 100 and 50 mg respectively. 36 children were given the same dose of ^{13}C-Urea, 50 mg, but two different types of test meal, Pumocare 100 ml and 10 gr at 10% of Polycose (polymer of glucose) respectively. Breath samples were collected every 10 minutes for 60 minutes and analyzed by an Automated Breath ^{13}C Analyzer (ABCA Europa Scientific). The ""gold standard"" for the detection of H. pylori infection was defined as a concordant result on histology and quick urease-test. The cut-off value was calculated taking the mean of H. pylori { -}ve subjects – 3 SD and using a ROC curve. *Results.* According to the ""gold standard"" 48 children were considered H. pylori +ve and 44 H. pylori { -}ve. 100 mg Urea + Pulmocare 50 mg Urea + Pulmocare 50 mg Urea + Polycose T10 T20 T30 T40 T50 T60 T10 T20 T30 T40 T50 T60 T10 T20 T30 T40 T50 T60Sens (%) 96.3 100

"P P 16 0413"P 16 0413**Upper Gastrointestinal Mucosal Lesions Caused by Intensive Cytostatic Therapy in Children**

*J. Kokkonen[1], M. M\'f6tt\'f6nen[1], M. Lanning[1], T. Karttunen[2]

[1] Department of Paediatrics, University Hospital, Fin-90220 Oulu, Finland

[2] Department of Pathology, University Hospital, Fin-90220 Oulu, FinlandTo assess the degenerative effects of intensive cytostatic therapy on the upper gastrointestinal mucosa, we enrolled all new cases of children with malignant diseases older than 1 year of age in a six-week follow-up study with upper gastrointestinal endoscopy performed at four weeks. Eleven patients (7 males, 4 females, median age 6 yrs, range 1–15 years) were monitored clinically, and nine of them consented to endoscopy. – Five patients complained of mouth pains during eating and two developed mucosal ulcerations. Abdominal cramps, mostly during the first three weeks, were reported by three patients and two developed diarrhoea. A positive lactose challege test (increment > 20 ppm) was found in three patients out the nine who were able to do a breath test. Macroscopic findings at endoscopy were observed in five out of the nine patients, the most prominent feature being esophagitis. All the duodenal samples showed histological alterations (increased eosinophils in 5, crypt hyperplasia in 5 and mild villous atrophy in 3). Only one patient had inflammation of the antral mucosa and two others excessive lymphocytes in their esophageal samples.*Conclusion:* The most prominent histological changes attributable to cytostate therapy are in the jejunum, while the ventricle and esophagus are less affected.

"P P 16 0415"P 16 0415**Beta-Endorphin Levels in Children with Gastroduodenitis**

*L. Szewczyk, H. Jankowska, S. Zbaranska, A. Szewczyk

Department of Pediatry, Endocrinology and Adolescent Diseases, Medical Academy, Lublin, PolandThe experimental investigation indicate that opioid can regain a protective field in gatric and duodenal mucosa lesion prevention.In the group of 50 children (10–16 years old) suffering from chronic gastritis and duodenitis, which were confirmed by endoscopic examination, beta-endorphin ({ b}-E) levels in serum (RIA Kit Incstar Corp.) were determined. Afterwards, the results were compared to values of control group.In group of healthy children level was mean 8.43 – 1.41 pmol/L, however in group of sick children was significantly lower ($p < 0.01$) and it was mean 6.47 – 1.02 pmol/L.In group of 20 children, { b}-E level before and after monthly dietetic and drug treatment (Venter or Ventrisol) was determined. According to our data, mean beta-endorphin level before treatment { b}-E = 5.85 – 1.77 pmol/L was significantly lower ($p < 0.05$) than beta-endorphin level after the therapy { b}-E = 7.2 – 1.82 pmol/L. We also found, that in group of children, where ulcer formation were presented, { b}-E level was the lowest { b}-E = 4.2 – 1.2 pmol/L and increased after the treatment up to { b}-E = 6.5 – 1.6 pmol/L.Our conclusion is that in children with gastritis and duodentis, particularly in such cases where ulcer is accompanied, lowered opioid activity was observed. We paid attention to increased tendency during the therapy. Oesophageal gastric duodenal disorders: EGD disorders in children }" "Beta-Endorphin Levels in Children with Gastroduodenitis"

"P P 16 0416"P 16 0416**Serum Cholinesterase and Acetylocholinesterase Activity in Children with GastroduodenitisL. Szewczyk, S. Zbaranska, H. Lozowska,**

*D. Witkowski

Department of Pediatry, Endocrinology and Adolescent Diseases Medical Academy, Lublin, PolandThough its role has not been very well defined yet, serum cholinesterase (ChE) is said to play a role similar to acetylocholinesterase (AChE) in cholinergic activity regulation.Our investigation involved 35 healthy children and 35 children (25 girls and 10 boys aged 9.6–16.3) with gastroduodentis treated with Venter or Ventrisol. These children underwent endoscopy examinations because of epigastric pains.Urease test and histopatological examinations in 13 children confirmed Helicobacter pylori (Hp) infections; in 22 children these results were negative.In these children the AChE (colorimetric meth. f. Chemed) and ChE (Weber kinetic meth.) activity test was conducted twice.*Results:*ChE activity in children with digestive tract pathological changes (mean = 6129.16 – 1333 IU/L) was significantly lower ($t = 2.34$, $p < 0.05$) than in healthy children (mean = 6825.08 – 1135 IU/L). There were differences in ChE activity between children with positive and negative results of confirmed Hp presence investigations.Namely, the ChE activity in children with Hp infection (mean 5245 – 1118 IU/L) was significantly lower ($t = 2.73$, $p < 0.01$) than in children with negative bacteriological tests. (mean 6617.19 – 1607 IU/L). AChE levels behaved in the same way.AChE and ChE activity decrease may prolong acetylocholine action and cause secretory and motile changes in the upper part of digestive tract. This situation facilitates the bacterial factor penetration. [1] Clinica Pediatrica, Universita' di Torino, Catanzaro, Italy

[3] Servizio di Anatomia Patologia, Ospedale Pugliese, Catanzaro, Italy*Background/Aim:* Epidemiological studies suggest that in most populations *H. pylori* infection is commonly acquired in childhood. Serology is a sensitive and specific indicator of *H. pylori* infection also in pediatric population, provided that children's sera are used to standardize the assay. We have recently shown that salivary IgG to *H. pylori* paralleled specific circulating IgG and accurately detected *H. pylori* infection in adults (Am J Gastro 1995). In this study we validated our salivary test to diagnose *H. pylori* infection in children. *Methods:* 112 consecutive patients (55 M; median age: 11 yrs, range 2–18) attending for upper GI endoscopy were available for the study. Two antral and corpus biopsy specimens were taken for histology (Giemsa staining) and one antral biopsy for urease quick test. Assessments were made blinded to the final diagnosis. Where both evaluations were concordant this was taken as the gold standard *H. pylori* status for that patient. 1–2 ml of unstimulated saliva were collected from each patient before endoscopy and stored at { -}20\'b0C until tested. Saliva samples (working dilution 1:2) were assayed for *H. pylori* IgG by an in-house ELISA using a sonicate of a whole *H. pylori* strain as antigen. All samples were run in duplicate in the same assay. A cut-off of 2 SD above the mean of a standard reference pool of histologically *H. pylori* negative children's saliva was chosen. Results were expressed as mean optical density (OD) – SD. 95% CI were given. *Results: H. pylori* was identified in 57 (51%) patients. Salivary *H. pylori* IgG were significantly higher in *H. pylori* positive than negative patients (0.495 – 0.292 vs 0.150 – 0.131, $p < 0.001$). Based on a cut-off of 0.200 OD, we found that 4 *H. pylori* positive patients were saliva negative and 10 *H. pylori* negative were saliva positive. The sensitivity and specificity of salivary *H. pylori* IgG were 93% (83–98%) and 82% (70–91%) with positive and negative predictive values of 84% (73–92%) and 92% (80–98%), respectively, with an accuracy of 87.5% (80–93%). *Conclusion:* Salivary *H. pylori* IgG is an accurate indicator of gastric *H. pylori* colonization in pediatric population. It may offer practical advantages in children in both clinical and investigational settings. *L. Bak-Romaniszyn, K. Zeman, E. Malecka-Panas, E. Czkwianianc, T. Wozniakowska-Ģesicka

Dept. of Pediatrics Military Medical University and Polish Mother's Memorial Hospital, Dept. of Immunology Military Medical University, L\'f3dz, PolandThe study evaluates the frequency of *Helicobacter pylori (H. pylori)* infection, as well as systemic cellular immune response to *H. pylori* in duodenal ulcer (DU) in children.The study group comprised 60 children with DU, aged 6–17 (mean 13.3 – 2.5) *H. pylori* detection was based on urease test, histology, culture and serologic tests. Endoscopic and morphologic findings were analysed according to Sydney System criteria. In 16 children from the overmentioned group subsets of blood lymphocytes B and T (CD3, CD4, CD8, CD3/DR, CD19) and NK cells, some neutrophils functions (phagocytosis, chemiluminescence), phagocytes receptors (CD11B, Fc{ g} IIIRa), components C4, CH50 before and one month after *H. pylori* triple treatment were investigated.*H. pylori* infection was detected in 56 (93%) of the investigated children. In addition, pathologic examination revealed chronic gastritis and chronic duodenitis in 91% of them. In immunosystemic examination decreased percentage of CD8 lymphocytes, NK cells, increased CD4/CD8 ratio, decreased mitogen-induced response and changes of function and receptor expression of neutrophils were found. In addition the decrease of components C4, CH50 were found. After *H. pylori* eradication normalisation of immune parameters in children were shown.The results of our investigation indicate, that *H. pylori* infection and the changes in host immune response may plays an important role in the pathogenesis of duodenal ulcer in children. "P P 16 0419"P 16 0419**The Role of Endoscopy Procedures in Upper Gastrointestinal Anomalies Treatment in Infants**

*E. Czkwianianc, A. Chilarski, S. Nowak, E. Chruslinska

Deps. of Pediatrics, Pediatric Surgery, Intensive Neonatal Care, Pediatric Intensive Care, Polish Mother's Memorial Hospital, L\'f3dzThe aim of the paper is to assess the role of interventioned endoscopy in upper gastrointestinal anomalies treatment in newborn and infants, as a supplementary method to the surgical procedures. Dilatation of anastomotic strictures jkin two children, operated previously for different esophageal anomalies were performed, with Savary-Gilliard's method. The children underwent the dilatation procedures with different size of bougies used till the nr 6 (11 mm in diameter) several times at five days intervals. First case was a newborn with a congenital esophageal atresia. Because the distance between both ends of esophagus was very long (more than 4 cm) one step operation was impossible and the several steps treatment was applied. At the begining the upper esophageal end has been elongated under the endoscopy control, then by plastic probe. Under radiologic control both, upper and lower parts of esophagus were brought close to each other: upper end by probe and lower one endoscopically. As the proper condition for surgical treatment was confirmed, anastomosis was performed. No complications in the postoperative course were observed. Two months later the symptoms of esophageal stricture were seen clinically and were confirmed radilologically. After several dilatation procedures the significant improvement was seen. Next case was an infant with a slight esophageal stricture after the GERD surgical treatment. The dilatation procedures were performed and the symptoms of dysphagia were relived. In the third case, of a newborn with a single esophagotracheal fistula (so-called H-fistula), we tried to close it endoscopically using the submucosal fibrin adhesion technique. In the first stage the occlusion of the fistula was achieved, but the fistula reccurented seven months later. This time a successful surgical operation was performed. The sealing procedure with the fibrin glue allowed delay of the operation and to perform it in older child with better anatomical and physiological conditions. Those are some new possibilities of application of endoscopy procedures in congenital esophageal malformations in infants. Oesophageal gastric duodenal disorders: EGD disorders in childrenEndoscopy, general: Instrumentation, therapyEndoscopy, general: Endoscopy: children }" "The Role of Endoscopy Procedures in Upper Gastrointestinal Anomalies Treatment in Infants"

"P P 16 0420"P 16 0420**Triple Therapy with Omeprazole and Two Antibiotics in Children with *Helicobacter Pylori* GastritisG. Oderda, P. Lerro, P. Caristo, M. Kuvidi, M. Forni, N. Ansaldi, P. Martelli, E. Chiroboli, G. Monga, G. Bona**

Pediatric Gastroenterology, University of Turin & Novara, ItalyIn children with *Helicobacter pylori (Hp)* gastritis dual therapy regimens with antibiotics with or without bismuth salts usually reach eradication rates ranging from 70 to 80% and triple therapy has seldom been tried.*Aim:* to evaluate efficacy of triple therapy in childhood *Hp* gastritis with Omeprazole plus Clarithromicin and Amoxicillin or Metronidazole for one or two weeks.*Patients & Methods: Hp* gastritis was diagnosed by urease test and histology (*Giemsa* stain) in 79 children (M/F 44/35) median age 11 yrs (range 5 { -} 15). They were divided in two groups: a first one (*group A:* 45 children) was treated with a 2-week course of Omeprazole (1 mg/kg bid) + Clarithomicin (15 mg/kg bid) + Amoxicillin (50 mg/kg bid) a second one (*group B:* 34 children) was treated with an 1-week course of Omeprazole (0.5 mg/kg mane) + Clarithomicin (15 mg/kg bid) + Metronidazole (20 mg/kg bid). Six weeks after stopping treatment endoscopy was repeated and eradication proven by urease test, histology of both the antrum and the gastric corpus biopsies and ^{13}C-Urea breath test (UBT).*Results:* Six children refused repeated endoscopy and eradication was evaluated by UBT only. *Hp* was eradicated in 35 children of group A (77.7%) in 23 of group B (67.6%). Compliance was poor in 5 children of group A, and in 4 of group B.*Conclusions:* Triple therapy for 1 or 2 weeks, with Omeprazole given one or two times a day does not reach a better eradication rate than the average obtained with dual therapy for a poor patient compliance. "P P 16 0421"P 16 0421**Trace Elements (TE) and Metallothionein (MT) in Duodenal Mucosa of Wilson's Disease (WD)**

*C. Mestriner, R. D'Inc\'e0, P. Irato[1], M. Minotto, R. Naccarato, G.C. Sturniolo

Division of Gastroenterology, University of Padua, Italy

[1] Dept. of Biology, University of Padua, ItalyWilson Disease is due to an inherited disorder in copper (Cu) metabolism. Cu absorption involves intracellular carriers known as metallothionein (MT). Zinc (Zn) is the most relevant competetive antagonist for MT-dependent Cu absorption and storage. MT synthesis can be experimentally induced in duodenal mucosa by Zn administration. We measured MT and TE (Zn, Cu, Fe) in the duodenal mucosa of 6 WD patients (3 F, 3 M, range of age 26–31 years) and 8 controls (5 F, 3 M, range of age 28–34 years). 5 WD patients were on Zinc sulphate ($ZnSO_4$ 220 mg po tid) and Cu-deficient diet (less than 1.5 mg/day). One patient was examined any at diagnosis before treatment. Controls had negative endoscopy and did not take any drug. MT concentration was measured in the duodenal mucosa by the Ag-saturation haemolysate method. TE were assayed by Atomic Absorption Spectrophotometry (AAS).*Results:* Patients with WD treated with $ZnSO_4$ had significantly higher tissue levels of MT (434.4 – 337 ug/g wet wt) with respect to controls (41.56 – 16) ($p < 0.05$). The newly diagnosed WD patient before treatment had MT concentrations similar to controls (54.3 ug/g wet wt). Mucosal Zn concentrations were higher in WD patients than in controls (513 – 160 vs 119.5 – 64 ug/g dry weight) as were Iron (Fe) concentrations (202.34 – 67.5 vs 80.6 – 33.7 ug/g dry weight). Cu concentration was undetectable in the duodenal mucosa of both patients and controls.*Conclusion:* Zinc therapy increases Zn and MT concentrations in the duodenal mucosa. MT induction may bind Cu within the intestinal cells blocking its absorption although we did not find a direct evidence of increased Cu in the duodenal mucosa. Increased Fe concentration in the duodenal mucosa may also derive from MT induction. Liver and bile ducts, 1: Hepatotoxicity, ethanol }" "Trace Elements (TE) and Metallothionein (MT) in Duodenal Mucosa of Wilson's Disease (WD)"

*G.V. Papatheodoridis, A. Zizi-Serbetzoglou[1], M. Tzouvala, K. Triantafyllou, V. Xourgias, I. Elemenoglou[1], D.G. Karamanolis

Gastroenterology Dept., ""Tzaneion"" General Hospital, Piraeus, Greece

[1] Pathology Dept., ""Tzaneion"" General Hospital, Piraeus, GreeceHigh-grade and persistent low-grade dysplasia in ulcerative colitis (UC) are well established predisposing conditions for colorectal cancer, but the significance of indefinite dysplasia has not been completely clarified. Changes in p53 gene have been observed early in the histological progression of neoplasia in UC.The aim of this study was to evaluate the clinical significance of indefinite dysplasia in UC and its possible relation to p53 protein accumulation.Between January 1989 and December 1995, indefinite dysplasia was diagnosed in colon biopsies of 20 UC patients [12 M/8 F, mean age: 42 (range: 21–81) years]. Patients with indefinite probably negative dysplasia or with indefinite dysplasia not confirmed by both pathologists were excluded. Five (25%) patients had total and 15 (75%) left-sided UC and the duration of disease was longer than 8 years in 5 patients with left-sided colitis (13, 17, 18, 20 and 23 years) and less than 8 years in the remaining cases. Paraffin embedded microwaved tissue sections with indefinite dysplasia were retrospectively examined for p53 protein accumulation using the commercially available monoclonal antibody DO-7 (Biogenex).p53 Protein overexpression was not detected in any of the sections tested. The patients have been followed for a median of 26 (range: 10–40) months. Colon cancer has not been developed in any of the 20 patients. Ten of the patients underwent a second total colonoscopy approximately two years after the initial examination, where multiple biopsies were taken (2–3 specimens from each 10–15 cm of the total colon). Dysplasia was not detected in any of the last specimens.Our data support that indefinite dysplasia in UC: 1. is not a high risk condition for colon cancer and 2. is not related to p53 protein accumulation. Intestinal disorders: IBD diagnosis, monitoringOncology, general: Screening, prevention }" "Indefinite Dysplasia in Ulcerative Colitis: Clinical Significance and Possible Relation to p53 Protein"

*M.H.K. Leidenius[1], L.T. Risteli[2], J.P. Risteli[2], E.T. Taskinen[3], I.H. Kellokumpu[1], K.A.V. H\'f6ckerstedt[1]

[1] Fourth Department of Surgery, Helsinki University Central Hospital, Helsinki, Finland

[2] Departments of Medical Biochemistry and Clinical Chemistry, University of Oulu, Oulu, Finland

[3] Department of Oncology, Division of Pathology, Helsinki University Central Hospital, Helsinki, FinlandThe aim of the study was to determine the circulating concentrations of the aminoterminal propeptide of type III procollagen (S-PIIINP) in ulcerative colitis and associated hepatobiliary diseases and to estimate the usefulness of S-PIIINP in the screening for hepatobiliary diseases in patients with ulcerative colitis.S-PIIINP was measured in three patient groups: 69 patients with ulcerative colitis only, 14 with ulcerative colitis and elevated serum alkaline phosphatases but no radiological findings consistent with primary sclerosing cholangitis, and 20 patients with ulcerative colitis and primary sclerosing cholangitis.The median serum concentration of PIIINP was 3.1 \'b5g/l in UC only, 4.3 \'b5g/l in the patients with ulcerative colitis and minor hepatobiliary dysfunction and 8.9 \'b5g/l in those with ulcerative colitis and primary sclerosing cholangitis (reference interval 1.7–4.2 \'b5g/l). When the S-PIIINP cut off level was set at 5 \'b5g/l, 5% of the patients with ulcerative colitis only, 21% of those with minor hepatobiliary dysfunction, and 90% of the patients with primary sclerosing cholangitis had S-PIIINP values above that level.In conclusion, S-PIIINP above 5 \'b5/l in a patient with ulcerative colitis strongly suggests concomitant primary sclerosing cholangitis. Intestinal disorders: IBD diagnosis, monitoringLiver and bile ducts, 1: Cell biology, collagen, fibrosis }" "Aminoterminal Propeptide of Type III Procollagen (PIIINP) and Hepatobiliary Dysfunction in Ulcerative Colitis"

[1] Fourth Department of Surgery, Helsinki University Central Hospital, Helsinki, Finland

[2] Department of Pathology, Helsinki University Central Hospital, Helsinki, Finland

[3] Second Department of Medicine, Helsinki University Central Hospital, Helsinki, FinlandThe aim of the study was to evaluate, if the risk of colorectal dysplasia and carcinoma in ulcerative colitis (UC) is accentuated by concomitant primary sclerosing cholangitis (PSC).Thirty-two PSC patients with UC for 7 years or longer were examined for colorectal dysplasia and carcinoma in a case- control study. They were pair- matched with controls with extensive, longstanding UC but without PSC or even a history of elevated liver function tests. The matching factors included sex, the age at the onset of UC and the duration of UC. Also, if a PSC patient was operated on because of the intractable UC, we tried to find a control with the same history when possible.Biopsy specimens for assessing dysplasia and carcinoma were obtained in colonoscopy and/or colectomy. The median duration of UC was 16.5 years in PSC patients and 18.5 years in controls.Twelve PSC cases (38%) had colorectal neoplasia: 4 had carcinoma, 3 high grade dysplasia (HGD) and 5 had low grade dysplasia (LGD). Three controls with UC alone (9%) had neoplasia: one had carcinoma, one LGD and one HGD.Our results indicate that PSC is an additional risk factor for the development of colorectal dysplasia and carcinoma in UC. Intestinal disorders: IBD diagnosis, monitoringOncology, general: Screening, preventionOncology, specific: Colon, rectum }" "Primary Sclerosing Cholangitis and Colorectal Neoplasia in Ulcerative Colitis"

[1] Dept. for Nuclear Medicine, Markusovszky Teaching Hospital, Szombathely, Hungary

[2] Dept. of Pathology, Markusovszky Teaching Hospital, Szombathely, HungaryThe knowledge of the location and extent of bowel involvement is an important aspect in the management of patients with inflammatory bowel diseases. The simplest technique for imaging intestinal inflammation involves radiolabeling patients mixed white cells ex vivo with Tc99m which are then reinjected.*The purpose of the study:* to evaluate the clinical yield of Tc99m-HMPAO leukocyte scintigraphy in the estimation of inflammatory extension in patients with ulcerative colitis.*Methods:* 17 patients with active ulcerative colitis were investigated from 1993 to 1995 using total coloscopy with stepwise biopsies and Tc99m-HMPAO leukocyte scintigraphy. The interval between coloscopy and leukocyte scintigraphy was less than 12 (average: 5.5) days in all patients. Images were obtained at 30 min., 2 and 4 hours after injection of the labeled cells. For comparative evaluation colon was divided into 4 parts: recto-sigmoid, descending, transverse and ascending colon + coecum. 68 parts were analyzed for the extent of active inflammation. For comparison histology was used as reference.*Results:* By coloscopy there were 41 true-positive, 1 false-positive, 18 true-negative, 8 false-negative by leukocyte scintigraphy 45 true-positive, 6 false-positive, 13 true-negative and 4 false-negative cases.*Conclusion:* Tc99m HMPAO leukocyte scintigraphy a simple non-invasive test is an excellent technique for the assessment of diseases extent in ulcerative colitis, and is useful when total or partial coloscopy can not be performed. Intestinal disorders: IBD diagnosis, monitoringRadiology and ultrasound: Diagnosis }" "99m-Technetium-HMPAO Leukocyte Scintigraphy in the Assessment of Disease Extent in Ulcerative Colitis"

"P P 17 0427"P 17 0427**Effect of Oral Elemental Diet on Nutritional Status, Intestinal Permeability and Disease Activity Crohn's Patients**

*G. Zoli, M. Caré, F. Falco, M. Parazza, C. Span\'f2, G. Gasbarrini

I Patologia Medica, Centro Ricerche Nutrizione-Dip. Biochimica, University of Bologna, Italy

Ricerca in Medicina, Bologna, Italy

II Medicina Interna, Universit\'e0 Cattolica, Roma, ItalyElemental diet is considered an effective primary treatment for active Crohn's disease (CD), and it is usually administered enterally.Twenty patients (12 males, median age 30 years, range 18–60) with moderately active CD were enrolled in a randomized study in which the efficacy of elemental diet administered orally was compared to high dose corticosteroids in achieving clinical and laboratory remission. Ten patients were treated by oral elemental diet (Peptamen, Clintec) and ten received corticosteroids. Both treatment regimens lasted 2 weeks. The two groups were not different with respect to age, sex, body weight, location of disease, treatment and disease activity before the study. In all patients studied simple Crohn's disease activity index (SCDAI), nutritional status (evaluated with anthropometric and biolelectric measurements, expressed as body mass index (BMI), percentage of ideal body weight (% IBW), fat mass (FM, kg and %), fat free mass (FFM, kg and %) eritrocyte sedimentation rate (ESR), interleukin-6 (IL-6), intestinal permeability (expressed as permeability index (PI), prealbumin (PA), retinol binding protein (RBP), multiskin test (Multitest IMC), were evaluated before and after treatment.After two weeks of treatment, in the diet group there was a significant improvement of SCDAI (5.6 – 0.8 vs 2 – 1.4, $p < 0.01$), ESR (21.4 – 6 vs 16.7 – 6.7, $p < 0.05$), PI (4.9 – 5.3 vs 2.1 – 2, $p < 0.01$), BMI (18.5 – 3 vs 19.2 – 3.1, $p < 0.02$), PA (22.2 – 8 vs 23.5 – 7.8, $p < 0.01$), RBP (3.7 – 0.7 vs 4 – 0.8, $p < 0.02$), IMC test (4.2 – 2.1 vs 5.9 – 2.3, $p < 0.01$); no significant differences were found for the other parameters studied. In the corcosteroid group there was a significant improvement of SCDAI (4.5 – 0.7 vs 3.5 – 1.2, $p < 0.04$) and of FFM (kg) (45.9 – 10.5 vs 47.2 – 10.7, $p < 0.05$). These data suggest that, in the short term, oral elemental diet is at least as effective as steroids in inducing remission of mild-moderately active CD, but it may be more effective in improving nutritional status of these patients, probably through a more quickly restoration of intestinal permeability. Nutrition: Nutrients and gut function }" "Effect of Oral Elemental Diet on Nutritional Status, Intestinal Permeability and Disease Activity Crohn's Patients"

[1] II Servizio di Radiologia, IRCCS Ospedale Maggiore, Italy*Background:* Osteoporosis has been observed in about 40% of patients with inflammatory bowel disease but the series studied were unselected.*Aim:* To determine bone mineral density and body composition in a selected series of patients with ulcerative colitis.*Patients and method:* We enrolled 31 patients (12 M, mean age 36, range 21–49, and 19 F, mean age 36, range 23–45) with ulcerative colitis followed as outpatients and not currently treated with calcium, vitamin D, calcitonin or biphosphonates. All patients underwent total body bone, lean and fat mass measurement by dual X-ray absorptiometry (Hologic QDR-1000/W). The mean time from ulcerative colitis diagnosis was 8 yr (range 2–18). Disease was confined to the rectum in 2 cases and to the rectum and sigmoid colon in 12; 7 patients had left-sided colitis, 4 substantial colitis and 6 pancolitis. Previous total steroid intake in the patients' lifetime was computed and expressed in mg prednisone-equivalent. Osteocalcin, intact parathyroid ormone and fasting urinary hydroxyproline/creatinine excretion were determined. Healthy subjects matched for sex, age and body mass index served as controls. Statistical analysis was performed using the Wilcoxon and Spearman rank correlation tests.*Results:* Mean lifetime steroid intake in men was 3764 mg (range 0–13205) and in women 1556 mg (range 0–5964). No differences were found in bone mineral density and body composition between male patients and their controls, nor was there a correlation between steroid intake and bone density. In female patients, cortical bone density was significantly reduced compared to their controls (p = 0.01), and lean mass was significantly greater (p = 0.01). Bone formation and resorption markers did not differ significantly in the male and female patients and healthy subjects.*Conclusion:* We observed a significant decrease in cortical bone density in a selected group of women with ulcerative colitis. This finding warrants further investigation to delucidate the pathogenesis and the possible relation to fracture risk. Intestinal disorders: IBD diagnosis, monitoring }" "Decrease in Cortical Bone Density in Women with Ulcerative Colitis: A Controlled Study"

"P P 17 0429"P 17 0429**Ulcerative Colitis (UC): How Many Diseases?E.A. Belousova, N.A. Morozova, L.D. Serova, A.R. Zlatkina**

Moscow Regional Research Clinical Institute, Moscow, RussiaThe distribution of HLA antigens I and II classes (A, B, C, DR) was investigated in patients with UC in Moscow Region with 8000000 population to study HLA phenotype and genetic peculiarities and heterogeneity of the disease in UC of different extent and different age of onset. 149 patients were observed. The investigation was performed by standard method with histotypical serum kits. The positive association with HLA DR5 (x^2 = 10.25, RR = 2.36) and HLA Cw4 (x^2 = 3.88, RR = 2.4) was shown in whole UC group in compare with healthy population. The x^2 criterion and RR was the highest in the group with combination of DR5 and Cw4 (x^2 = 37.5, RR = 6.5). The negative association was found in this group with HLA Aw19 (x^2 = 7.48) and DR4 (x^2 = 5.94). Thus, HLA Aw19 and DR4 may play a role of defense antigens. Their absence enhances the ability of HLA DR5 and Cw4 realization and increases RR (relative risk of disease) threefold. The significant correlation between HLA DR5 and large forms of UC (total and left side) was found (x^2 = 7.21, RR = 2.58), but there was no difference in HLA frequency between distal colitis and healthy population. The peculiarity of phenotype was found in young UC patients group (HLA DR5 x^2 = 8.58, RR = 2.0 and Cw4 x^2 = 12.9, RR = 2.15) and in elderly patients (HLA DR3 x^2 = 16.4, RR = 5.64).*Conclusion:* The genetic heterogeneity of UC in Russia has been shown. Our data confirm the hypothesis about different pathogenesis of various UC forms and the possibility to exist few different UC. Intestinal disorders: IBD, etiology and genetics }" "Ulcerative Colitis (UC): How Many Diseases?"

"P P 17 0430"P 17 0430**Variation of p-ANCA over Time in Patients with Ulcerative Colitis (UC)G. Monteleone, R. Marasco, T. Parrello, P. Doldo, F. Luzza, F. Pallone**

Dipt Med. Sper. e Clin, Univ di Reggio Calabria, Catanzaro, Italy*Background.* ANCA exhibiting an immunofluorescence perinuclear pattern (p- or x-ANCA) are a subclinical marker of UC. Variations of ANCA status have been reported. *Aim.* To examine whether in UC patients p-ANCA may vary over time and to explore whether p-ANCA status is related to disease activity, extent, treatment, duration and extraintestinal manifestations. *Methods.* 75 patients (54 M and 21 F; mean age 39.5, range 13–72) with diagnosis of UC were followed for a median time of 24 months (range 12–36). 3–6 serum samples were obtained from each patient at regular intervals (4–6 months). ANCA status was tested by ELISA (1:100 serum dilution) and confirmed by indirect immunofluorescence. Only perinuclear pattern was considered for the purposes of this study. 20 healthy subjects were also considered as negative control group. *Results.* At entry p-ANCA were detected in 43/75 (57%) patients: 38/59 (63%) with active disease and 5/16 (33.3%) with inactive disease ($p = 0.036$). No relation was observed with the other disease clinical variables. Variation in the p-ANCA status occurred in 21/75 (28%) patients. 13 out of 15 sera initially p-ANCA positive became p-ANCA negative after that stable remission was achieved, whereas 7 sera initially p-ANCA negative reverted to positive during flare-up. In 1 patient ANCA status change did not seem to be apparently related to disease activity. In addition, 5/5 patients with stable remission and 11/13 with a ""non aggressive course"" (1–4 flares-up/1–3 years) were persistently negative for p-ANCA. In contrast, 11/11 patients with chronic active disease and 10/12 patients with aggressive course"" (> 4 flares-up/year) showed a persistent p-ANCA positivity over the follow-up study. All five patients p-ANCA positive with inactive disease at entry experienced > 4 flares-up per year in the subsequent follow-up and their p-ANCA status was persistently positive. *Conclusions.* Data suggest that p-ANCA in UC may help defining subgroups of patients with a more aggressive course and that disease activity may contribute to ANCA status. Intestinal disorders: IBD, etiology and geneticsIntestinal disorders: IBD diagnosis, monitoring }" "Variation of p-ANCA over Time in Patients with Ulcerative Colitis (UC)"

"P P 17 0431"P 17 0431**Interest of Flow Cytometry and of KI-*ras* Gene Mutation and p53 Gene Alteration Research in the Follow Up of Ulcerative Colitis**

*F. Gaetan[1], M.C. Gelineau[2], C. Mar\'e7ais[2], M. Cottier[4], S. Isaac[3], M. Rochet[3], A. Revol[2], L. Descos[1]

[1] Gastroenterology Department

[2] Biochimy and immunology laboratory

[3] Anatomopathology's laboratory, Centre Hospitalier Lyon Sud 69495 Lyon, France

[4] Histology's laboratory, Hospital Nord 42000 St Etienne, France*Aim:* to evaluate the degenerative potential of ulcerative colitis (UC) by studying Ki-*ras* and p53 genes as well as flow cytometry.*Method:* 38 patients (average age 44 years – 14) underwent a total colonoscopy during a reactivation stage or during the follow-up. In all these cases, the ulcerative colitis had been evolving for an average of 12 years – 7. In 5 cases, there was a longstanding total colitis; two of which had lasted more than 20 years. Systematic biopsies were carried out on the whole length of the colon. All the patients were submitted to a test for Ki-*ras* codon 12 mutation by hybridization; 7 patients with dysplasia, cancer, or an isolated Ki-*ras* mutation, were checked for an overexpression of p53 protein by immunohistochemistry and 32 patients were examined for DNA ploidy by flow cytometry.*Results:* histological examinations revealed 4 cases of dysplasia (2 low grade and 2 high grade) and 1 case of adenocarcinoma. Ki-*ras* gene mutation was found in 7 patients, 5 cases involving histological lesions (3 times in inflammatory mucosa, once in a low grade dysplasia, once in an adenocarcinoma) and 2 cases involving healthy mucosa. An overexpression of p53 protein was observed in only 1 patient with adenocarcinoma. Only 1 patient displayed a DNA aneuploidy, on an inflammatory non dysplastic mucosa.*Conclusions:* despite the lack of hindsight and a group with a feeble risk of degeneration, we can say that, out of 38 patients, 10 cases of potentially higher degeneration risk were identified, 4 presenting the usual histological anomalies (dysplasia) whereas the other 6 cases had either a Ki-*ras* codon 12 mutation or a DNA aneuploidy. The regular follow up of all these patients and the systematic search for overexpression of p53 protein must be undertaken in order to evaluate, along with the histological date, which patients can be considered members of a high risk group requiring more frequent colonoscopies. "P P 17 0433"P 17 0433**Efficacy of Association of Low-Doses of CsA-Steroids in Treatment of Ulcerative Colitis**

*G. Pia, L. Pascalis, G. Aresu

University Cagliari Italy20 patients with endoscopically and histologically diagnosed colite ulcerosa were treated with Cyclosporin A and low doses of fluocortolone, supplementary to standard medication (mesalazin or sulfasalazin) within the framework of a therapy trial during an acute attack. Inclusion criteria for patients: a therapy refractory condition after an at least 2-weeks treatment with prednisone at a dose of 1 mg/Kg body weight, which usually corresponded to 40–70 mg. However the onset of side effects not only made it impossible to use higher doses bat implicated a progressive reduction of the posoloy which led to a relaps of the clinical syndrome after 6–7 weeks.Cyclosporin A was administered: initial daily dose of 5 mg per Kg body weight (ideal weight in the case of overweight subjects). Blood levels of the drug were between 100 and 200 mcg/l by the third day of treatment. Fluocortolone was administered initially at a dose to control disease activity, that is, 80–70 mg/week on 5 days depending on the case, and then tapered in relation to the course of the disease down to a maintenance dose of 15 20 mg/week administered on 3 days. Fluocortolone administration was withdrawn in all patients (at 36 months) and treatment proceeded with CsA alone at dose of 5 mg/Kg per day administered 4 days a week. All patients were given a coloscopic before inclusion in the study to determine the degree of endoscopicactivity according to the Rachmilewicz scoring system, and their clinical activity index (CAI) was also calculated according to the Rachmilewicz evaluation. The criterium for clinical remission was a decline in the specified indications.*Results:* All patients presented a significant improvement of the clinical picture 7–15 days after onset of treatment and total remission of symptoms after 20–30 days whilst regression of the colonscopic and histomorphologic phenomena was observed 30 days after onset of treatment. In addition, the disease activity indexes normalized and remained normal for the rest of the follow-up period (60.18 – 9.15 months, range 69–50). No renal or hepatic toxicity was observed in any patient. Nine of them presented hypertrichosis, 4 iperplasia gengivale an one nausea. "P P 17 0434"P 17 0434**P53 Mutation Is a Genetic Marker on Ulcerative Colitis which Predicts the Clinical Responder to the Medical Treatment?**

*S.K. Chang, J.S. Chang, J.H. Do, C. Moon, H.J. Kim, J.K. Kim, S.M. Park

Division of Gastroenterology, Dept of Medicine, Chung-Ang Univ Hospital Seoul, Korea*Background/Purpose:* Long standing ulcerative colitis (UC) has known to increase the development of colorectal cancer. Although the molecular events demonstrate the frequent loss of p53 allele in carcinoma and their precursors dysplasia in UC, a rare incidence of p53 genetic alteration was also noted in indefinite dysplasia and long standing UC. Therefore we investigate the p53 point mutation in UC patients who did not show the evidence of dysplasia and cancer.*Methods;* Sixteen patients with UC had extensive disease of more than 8 years' duration were followed prospectively by colonoscopic surveillancec using mucosal biopsy sampling. P53 gene alterations in 16 UC by polymerase chain reaction single-strand conformation polymorphism analysis (PCR-SSCP) for exon 4–8 and immunohistochemical staining (IHCS) with anti-p53 antibody.*Results:* p53 mutations were detected in 4 (25%) out of 16 by PCR-SSCP in exon 4–8: 1, 1, 0, 2, and 0 mutations in exons 4, 5, 6, 7, and 8 respectively. The positive staining by IHCS was 5 (31%) out of 16. With regards to clinical characteristics these patients with p53 point mutation showed more frequent activation of underlying colitis, and not well respond to medical treatment (5-ASA, steroid, cyclosporin A). One of four patients undertaken total colectomy.*Conclusion:* These results suggest P53 point mutation is not an infrequent event in UC patiens who didn't show dysplasia and cancer, and this genetic alterations suggest that it plays a role as a possible genetic marker to evaluate the responsiveness to the medical treatment.

"P P 17 0435"P 17 0435**Early Prediction of IV Steroid Treatment Failure in Ulcerative Colitis**

*S. Lindgren, L. Flood, A. Kilander, R. L\'f6fberg, R. Sj\'f6dahl

Departments of Gastroenterology, University hospitals of Malm\'f6, Huddinge, G\'f6teborg and Link\'f6ping, Sweden*Purpose.* Early identification of patients with exacerbations of ulcerative colitis not responding to corticosteroids remains difficult and critical. We therefore scrutinized clinical and biochemical data in an effort to identify prognostic markers for steroid resistance and subsequent colectomy.*Methods.* The outcome of iv steroid treatment was analysed retrospectively in 97 patients with moderate and severe attacks of ulcerative colitis treated in 4 major Swedish hospitals 1988–1993. Basic clinical and biochemical data were obtained from patient record forms. Patients requiring colectomy within 30 days after admission were compared to those who did not.*Results.* Thirty days after admission 37 patients (38%) were in complete clinical and endoscopic remission while 33 (34%) had undergone colectomy. No association between steroid unresponsiveness and the extent of disease, duration of the acute exacerbation, number of previous attacks or maintenance treatment was observed. In contrast, short disease duration (mean 2.7 years vs 8.1 years, p = 0.0037), prior steroid treatment (70% vs 42%, p = 0.010) and particularly sustained increase of body temperature (mean 37.4\'b0 vs 36.9\'b0, p = 0.012), sustained diarrhea (mean 6.8/d vs 3.6/d, p < 0.0001), passage of blood (83% vs 42%, p = 0.0003) and CRP elevation (36.3 mg/L vs 18.0 mg/L, p = 0.007) after three days of treatment were identified as predictors of a poor response and a high risk for colectomy during the forthcoming month.*Conclusion.* Sustained elevation of body temperature, high stool frequency, passage of blood and increased CRP during the first three days of iv steroid treatment strongly predict steroid resistance, particularly in ulcerative colitis of short duration. In these patients more aggressive medical treatment or colectomy should be considered at an early stage.

"P P 17 0436"P 17 0436**Anti-Neutrophil Cytoplasmic Antibodies (ANCA) in Sera from Patients with Ulcerative Colitis**

*C.Z. Stachowiak, J. Zeromski, G. Dworacki, L. Hryniewiecki, K. Rzymski, J. Hasik

Departments of Gastroenterology, Immunopathology and Radiology University of Medical Sciences, Poznan, Poland*Aim of the study:* In the current study, an attempt was made to trace a correlation between the incidence of serum autoantibodies, predominantly ANCA, in various stages of UC activity.*Background:* Antibodies reacting with cytoplasmic components of human neutrophils (ANCA) manifested as diffuse staining of cytoplasm (c-ANCA) by immunofluorescence (IMF) have been found in several vascular diseases, especially in Wegener's granulomatosis. A variant of ANCA called p-ANCA, seen in fluorescence microscopy as a perinuclear rim of staining has been described in inflammatory bowel disease and especially in ulcerative colitis (UC).*Material and methods:* The study was performed in 48 UC patients (14 women and 34 men) aged from 17 to 61 years. In 17 UC patients p-ANCA were detected while in 25 patients the test came out negative. In 6 patients c-ANCA were found. P-ANCA+ group has been shown in 100% of cases to be in active phase of disease as demonstrated by rectosigmoidoscopy. Presence of p-ANCA correlated with extent of colon involvement. There was no relationship between p-ANCA positivity and mean age and mean duration of disease.ANCA were determined by indirect IMF on cytospin sediments of human (group O Rh+) neutrophils. In addition, organ autoantibodies have been evaluated by indirect IMF on rat tissue sections.*Conclusions:*1. Incidence of combined ANCA (p + c) in patients with UC is 68% of all cases2. pANCA-positive group shows correlation with activity of the disease as well as the extent of colon involvement3. No relationship could be established between pANCA positivity and mean age and mean duration of the disease4. Prevalence of some autoantibodies (esp. antinuclear antibodies) demonstrates the correlation between pANCA and disease activity5. Determination of pANCA may be of value in diagnosis and monitoring of UC patients Intestinal disorders: IBD, etiology and geneticsIntestinal disorders: IBD diagnosis, monitoringIntestinal disorders: IBD, therapy }" "Anti-Neutrophil Cytoplasmic Antibodies (ANCA) in Sera from Patients with Ulcerative Colitis"

"P P 17 0438"P 17 0438**Interleukin's Role in the Quantification of the Inflammation in Active Ulcerative Colitis**

*P. Vazquez, P. Conde, A. Olveira, R. Codoceo, F. Rebollo

Departament of Gastroenterology, University Hospital La Paz, Madrid, Espa\'f1aThe importance of the interleukins as a sign of the level of inflammation in the EII is disputed because some authors find them increased in the active phase of the disease, while others don't find significative differences with the control group.*Objectives:* To determine if the interleukin I.L-6, I.L-8 and the necrosis tumorals factor (TNF{ a}) can be used as an indicator as the grade of inflammation in the CU.*Methods:* We have carried out a case control study with endoscopychistologyc test on twenty patients with CU clasified with the Floren's index in Grade I (low affectation), G- II (moderated) and G- III (several) and we have compared them with ten controls. We have done a complete colonoscopy and biopsy on all the patients with a study of their 48 hour evacuations. We determinated the interleukins in the sample of biopsy and the faecal for enzimo-immunological analisys (Medgenix).*Results:* In the colonic biopsy we didn't find significative differences in I.L-6 and TNF{ a} levels between the controls; while the value of I.L-8 was clearly higher in patients with CU (120.6 ng/gr protein with a range of 4.95–433), in relation to the control group (16.3 ng/gr protein with a range of 0.5–66.2). In the faecal's study the patients with CU had a value of I.L-8 (39.523.8 gr/24 h of average with a range of 155–171.900) higher than the control group (4.204 gr/24 h with a range of 88–1.624). The determination of TNF{ a} also showed an average value distinctly higher in patients with CU (5.604 gr/24 h with a range of 884–20.526) in relation with control group, whose values were sensitively lower (774.5 gr/24 h, with a range of 44–1444).*Conclusion:* The determination of I.L-8 and TNF{ a} in the feacal of patients with CU shows the presence of inflammation, although it doesn't appear to be of use to determinate the intensity grade of inflammation or its extension, because despite of finding differences between the patients. "P P 17 0439"P 17 0439**Expression and Secretion of Annexin 1 in Biopsies of Patients with Ulcerative Colitis**

*N. Vergnolle, P. Pagés[1], D. Louvel[1], J. Escourrou[1], L. Bu\'e9no, C. Com\'e9ra

Dept of Pharmacology, INRA, Toulouse, France

[1] Dept of gastroenterology, CHU Rangueil, Toulouse, FranceAnnexin 1 is a 38-kDa protein, displaying pharmacological anti-inflammatory properties in several experimental models. We have previously shown that annexin 1 is selectively secreted in rats 1) by proximal colons inflamed by a TNBS-injection 2) by small intestine after a TNBS-treatment as well as after an infection with a nematode parasite: *Nippostrongylus brasiliensis.* Here, we studied the annexin 1 expression and secretion in biopsies of control and ulcerative colitis (UC) patients.Biopsies of inflamed tissues were collected by endoscopic examination in the colon of 10 patients (women: 4; men: 6; age: 29.8 – 10.5 years, range 19–47) with UC and 5 control patients (age 69.2 – 7.6: years, range 60–76). Using the Truelove classification, UC were divided in 3 groups (severe n = 6, moderate n = 2 and slight n = 2). In 7 UC patients (4 severe, 2 moderate and 1 slight), biopsies were also collected in unaffected parts of the colon. Five patients were treated by glucocorticoids (severe n = 3, moderate n = 2). Secretion of annexin 1 was identified by incubating colonic tissues in culture media for 30 min. at 37\'b0C. Annexin 1 was then detected by Western-blot analysis, in both colons and culture media.No major difference in annexin 1 expression was seen in biopsies of control, slight, moderate or severe UC patients and in unaffected biopsies of UC patients. Biopsies from 1) control patients 2) slight or moderate UC patients and 3) unaffected tissues of severe UC patients did not release annexin 1 into the culture media. In contrast, annexin 1 was secreted by all the inflamed samples from patients with severe UC. The glucocorticoid treatment did not seem to influence the mechanism of secretion of annexin 1 (in the severe group, annexin 1 secretion occurs in the presence or in absence of glucocorticoid-treatment).Because annexin 1 presents anti-inflammatory extra-cellular properties, this study suggests that annexin 1 is selectively involved in severe human intestinal inflammatory processes, possibly to reduce them. Annexin 1 appears to be a marker of severity of UC. "P P 17 0440"P 17 0440**Rifaximin in Patients with Moderate or Severe Ulcerative Colitis Resistant to Steroid-Treatment**

*F. Rizzello, P. Gionchetti, A. Venturi, S. Peruzzo, E. Raule, C. Brignola, M. Miglioli, M. Campieri

Ist. Clinica Medica e Gastroenterologia, University of Bologna, Italy*Aim:* Aim of this study was to evaluate the efficacy and the systemic absorption of Rifaximin, a non absorbable rifamycin antibiotic, in patients with moderate to severe, steroid resistant, ulcerative colitis.*Methods:* The study was an open-controlled trial. Patients were eligible if they had an histological confirmed diagnosis of ulcerative colitis and no response after 7–10 days of intravenous corticosteroid therapy (Methylprednisolone 1 mg/kg/day). Fourteen patients with moderate to severe steroid-resistant ulcerative colitis entered in the study and received rifaximin 400 mg tablets bid for ten days, in addition to the intensive standard intravenous steroid regimen. Clinical activity of disease was defined in accordance with Truelove and Witts criteria. Before the entry to the study and on the last day of treatment, serum and urine samples were taken to determine the systemic absorption of rifaximin.*Results:* Nine of 14 treated patients (64.3%) showed a substantial clinical and endoscopic improvement with a significant decrease of clinical activity score [mean – SD (2.14 – 0.36 vs 1.57 – 0.64)($p < 0.05$)]. Plasma concentrations of rifaximin were undetectable and the urinary excretion at the end of treatment was negligible.*Conclusions:* This preliminary study suggest that rifaximin, being practically not absorbed after oral administration, may be useful in patients with steroid-resistant ulcerative colitis. Intestinal disorders: IBD, therapy }"

[7] Department of Gastroenterology, Erasme Hospital, UZA, Brussels, Belgium*Introduction:* Cyclosporine (CsA) has been successfully administered in patients with acute severe ulcerative colitis (UC). The aim of this multicenter Belgian study was to determine parameters which may be important to predict successful outcome of CsA therapy.*Material & methods:* The study included 32 patients (median age: 33 y. (15–77 y.); 15 females and 17 males). The median duration of the disease was 4 y. (0.3 to 33 y.). According to Truelove's clinical score, UC was severe in 30 cases and moderate in 2 cases. Before initiating CsA, patients were unresponsive to treatment including iv corticosteroid, 5-ASA or salazopyrine, azathioprine or antibiotics. The iv mean dose was 4 mg/kg/day and adapted to blood CsA level.Patients were considered as responders to CsA when immediate colectomy was avoided. The following parameters before starting CsA therapy were studied: 1. age; 2. sex ratio; 3. duration of the disease; 4. mean hemoglobin level; 5. mean erythrocyte sedimentation rate; 6. location of the disease (left colon versus total colon).*Results:* Good outcome was observed in 23 patients (72%). Thus 9 patients were referred for subsequent colectomy. Patients with higher mean hemoglobin levels, lower mean erythrocyte sedimentation rate and longer history of the disease presented better immediate outcome. However, these differences were not significant (NS). There was no trend for other parameters.*Conclusion:* In patients with steroid refractory ulcerative colitis who received CsA, immediate colectomy was avoided in 72% of the cases. Among clinical and biochemical parameters which were studied, none of them was likely to predict a successful outcome of the treatment. Intestinal disorders: IBD, therapy }" "Are There Parameters Likely to Predict Successful Outcome in Patients with Severe Ulcerative Colitis Receiving Cyclosporine?"

CHU Liége, Department of Gastroenterology, Erasme Hospital, Brussels, Belgium

UZA, Department of Gastroenterology, Erasme Hospital, Brussels, Belgium*Introduction:* Cyclosporine (Csa) has been proposed in the management of patients with acute ulcerative colitis (UC) who failed standard therapy and were candidates for colectomy.*Material and Methods:* Seven academic hospitals contributed to this study that included 32 patients (median age: 33 y. (15–77 y.); 13 females and 17 males). The median duration of the disease was 4 y. (0.3 to 33 y.) According to Truelove's clinical score, UC was severe in 30 cases and moderate in 2 cases. The mean level (\'b1 SD) of Hb was 9.7 – 1.4 g/dl and ESR: 56 – 24 mm/H. Before initiating Csa, patients were unresponsive to treatment including – IV corticosteroid (n = 27), 5-ASA or Salazopyrine (n = 18), azathioprine (n = 3), antibiotics (n = 18), total parenteral nutrition (n = 3). The mode of Csa administration was intravenous (IV) (n = 15), IV + subsequently oral (n = 11), oral (n = 3). The IV mean dose was 4 mg/kg/day and adapted to blood Csa level. Concomitant treatment included corticosteroid (n = 27).*Results:* The mean duration of IV Csa administration was 13.2 – 8.1 days. At the end of Csa administration, a global improvement was described in 23 patients (72%) while a surgery had to be performed immediately in 8 patients (25%) because of exacerbation of symptoms (n = 7) or perforation (n = 1). One other patient died because of pneumocystis carinii infection. For the responders, maintenance therapy included: tapering dose of corticosteroid (n = 13), Azathioprine (n = 12), 5-ASA or Salazopyrine (n = 10), methotrexate (n = 1) or oral Csa (n = 11). The mean duration of follow-up was 14.3 – 12.9 months. Among the 23 responders, 9 (28%) were subsequently referred for colectomy either selectively (n = 3) or because of recurrence (n = 6).*Conclusion:* In patients with acute refractory UC who received Csa, the short-term efficacy (avoidance of immediate colectomy) was 72%. However, the overall success rate at a mean follow-up of 14 months was 44%. Intestinal disorders: IBD, therapy }"

"P P 17 0443"P 17 0443**Low-Dose Weekly Methotrexate Therapy in Remission Maintenance in Ulcerative ColitisM.D. Onuk,**

*S. Kaymakoglu, K. Demir, Y. \'c7akaloglu, G. Boztas, Z. Mungan, F. Besisik, U. \'c7evikbas[1], N. Erol, R. Sezer

Dept. of Gastroenterohepatology, Istanbul Medical Faculty, Istanbul, Turkey

[1] Dept. of Pathology, Istanbul Medical Faculty, Istanbul, TurkeyImmunosuppressive drugs have been commonly used in refractory cases with inflammatory bowel disease in the last years. Relapse rates are relatively high (25–40%) in patients with ulcerative colitis taking sulfasalazine (SFZN) for maintenance therapy. The purpose of this study was to evaluate whether long-term use of methotrexate (MTX) concurrent SFZN in patients with remission is effective to reduce relapse rate. The presence of ulcerative colitis was previously diagnosed by appropriate combinations of clinical, endoscopic, histological and radiological criteria. All patients were maintained in full remission on oral SFZN for at least 2 months at study entry. Twenty-six patients were randomly assigned to receive either MTX (15 mg per week, orally) plus SFZN (3 g per day, orally) or SFZN alone for 12 months. Fourteen patients (8 women, mean age: 36.6 – 7.4 yr., left-sided colitis in 6, pancolitis in 8) were in MTX group, and 12 patients (10 women, mean age: 36.3 – 10.7 yr., left-sided colitis in 9, pancolitis in 3) in SFZN group. Two groups were similar in regard to age, sex and the features of the disease. Clinical, biochemical, sigmoidoscopic and histological assessments were made initially, at 3, 6, 9 and 12 months. Relapse was accepted if endoscopic inflammatory score and histological activity index were grade 2 or higher, or if symptoms were present. Three patients (25%) relapsed in SFZN group over the study period, none in MTX group. Although the difference was insignificant, the success rate of MTX plus SFZN in maintaining remission appears to be better than SFZN alone. The relapse was severe in 2, and mild in 1 patients. Patient compliance was excellent and none was withdrawn because of treatment related intolerance or adverse effects in both groups. These findings suggest that MTX may have an important adjunctive therapeutic role for remission maintenance in patients with ulcerative colitis. Intestinal disorders: IBD, therapy }" "Low-Dose Weekly Methotrexate Therapy in Remission Maintenance in Ulcerative Colitis"

"P P 17 0444"P 17 0444**Disposition of 5-ASA by Olsalazine (Dipentum) and Mesalazine (Asacol) in Patients with Ulcerative Colitis in Remission****A. Archimandritis[1], G. Hatzis[1], A. Konstandinidis[2], K. Paraskeva[2], M. Tjivras[1], N. Skandalis[2]**

[1] Department of Pathophysiology, Medical School, University of Athens, Greece

[2] Gastroenterology Section, Laiko Gen Hospital and Gastroenterology Clinic, Gen State Hospital of Athens, Greece*Purpose:* To determine whether olsalazine (Dipentum) (1 g/d), gives a lower systemic uptake of 5-ASA and Ac-5-ASA at steady state, compared to mesalazine (Asacol) (1.2 g/d), when treating patients with ulcerative colitis in remission.*Patients and methods:* Eight male and 9 female patients, aged 19 to 69 years, with disease duration from 1–15 years were included in this open, randomized, cross-over study.Dipentum, 500 mg twice daily for 7 days or Asacol, 400 mg three times daily for 7 days, orally with food were given.Urine and plasma sampling at day 6 and 7 of each treatment period for the determination of 5-ASA and Ac-5-ASA at steady state were taken.*Results:* Nineteen patients were included and randomized to first week's treatment. Two patients withdraw from the study, one before starting treatment. Seventeen patients remained in remission, completed the study and were included into the statistical analysis. The systemic uptake of 5-ASA and Ac-5-ASA was significantly lower as reflected by urine and plasma data following treatment with Dipentum (1 g/d) compared to Asacol (1.2 g/d). Asacol showed, compared to Dipentum, 8.35 times higher levels of 5-ASA in urine. The treatment ratio (Asacol/Dipentum) was for Ac-5-ASA in plasma 3.3 with the 95% lower confidence limit equal to 2.56.One patient on olsalazine withdraw from the study due to diarrhea. No other serious adverse events were noted.*Conclusions:* This study demonstrates that mesalazine (Asacol), 1.2 g/d, causes higher levels, at steady state, compared to olsalazine (Dipentum), 1 g/d, of both 5-ASA and Ac-5-ASA in urine as well as in plasma. The low systemic load of 5-ASA provided by Dipentum thus reduces the potential risk of nephrotoxicity.

[1] U.O. Laboratorio Centrale, Azienda Ospedaliera di Careggi, Firenze, Italy

[2] Istituto di Anatomia e Istologia Patologica, Azienda Ospedaliera di Careggi, Firenze, ItalyThe risk of colorectal cancer is increased among patients with long-standing Ulcerative Colitis (UC), therefore identification of patients at high risk is a crucial point. Thirty patients with extensive UC and at least 15 years of disease have been selected for a prospective colonoscopic surveillance program. Each patient underwent a colonoscopy with multiple biopsies. Bioptic specimens were sampled from predetermined locations of the colon and rectum at regular intervals and from macroscopical lesions, when present. In our program specimens were assessed for dysplasia by histology and for DNA aneuploidy by Flow-Cytometry (FC). For DNA Index (DI) evaluation fresh samples were stained, after mechanical disaggregation, with propidium iodide and at least 20,000 nuclei analyzed on an Epics Elite cytofluorimeter (Coulter Co). We found 23 out of 30 patients with macroscopic lesions (polypoid lesions and/or lumen narrowing). Six patients showing macroscopical lesions at endoscopy revealed aneuploidy biopsies by FC (26.1%). Among the 6 patients with aneuploid biopsy: 2 were indefinite for dysplasia, 1 had low grade dysplasia, 1 was affected by colorectal cancer and the last 2 were negative for dysplasia. We found no patients with dysplasia without aneuploidy. Our results show the close correlation between aneuploidy and dysplasia. Moreover, the changes in nuclear DNA content could be earlier than dysplasia in the neoplastic progression of the UC colorectal mucosa. For this reason we propose FC as a selection technique in colonoscopic surveillance program for long-standing UC patients. The finding of aneuploidy in 25% of patients with endoscopic lesions confirms that FC could be a useful tool to select high risk patients and could reduce costs and improve effectiveness in screening programs. "P P 17 0446"P 17 0446**Prednisolone Enemas Improve Patients with Distal/Left Sided Ulcerative Colitis More Rapidly than Butyrate Enemas**

*J.M.D. Nightingale, K.P. West, B.J. Rathbone, J.F. Mayberry, A.C. Wicks

Leicester Royal Infirmary, Leicester, U.K.*Purpose:* Butyrate, a short chain fatty acid readily metabolised by colonocytes, has been used to treat diversion colitis and distal ulcerative colitis unresponsive to standard therapy. This study compares butyrate enemas with prednisolone enemas and with combined butyrate/prednisolone enemas,*Method:* 27 patients with active distal or left sided ulcerative colitis were randomly allocated into 3 groups of nine. The enemas (all 100 ml nocte for 6 weeks) were 20 mg prednisolone 21-phosphate, 100 mmol sodium butyrate or the same amount of prednisolone and butyrate mixed together as one enema.*Results:* After 2 weeks treatment median stool frequency fell significantly in the prednisolone group (pre-treatment: 9 stool/24 hr; 2 weeks: 3 stool/24 hr, $p < 0.02$) but not in those given butyrate enemas (pre-treatment: 7 stool/24 hr, 2 weeks; 6 stool/24 hr)). At 2 weeks 2 patients receiving butyrate showed no improvement in their colitis and withdrew from the trial. At 6 weeks 8 patients treated with prednisolone still had a reduction in stool frequency compared with 5 in the butyrate group. In both groups there was an improvement in urgency, incontinence, blood loss and sigmoidoscopic score, but not in histological appearance. 16 of 18 patients receiving butyrate alone or in combination complained of its unpleasant odour.*Conclusions:* Prednisolone enemas were successful in treating most patients with distal or left sided ulcerative colitis and the improvement was apparent at 2 weeks. Butyrate enemas, which were malodorous, improved some patients by 4 weeks. There was no additional advantage in combining both butyrate and prednisolone into one enema. Intestinal disorders: IBD, therapyNutrition: Nutrients and gut function }" "Prednisolone Enemas Improve Patients with Distal/Left Sided Ulcerative Colitis More Rapidly than Butyrate Enemas"

"P P 17 0447"P 17 0447**Combined Immune Modulation for Refractory Ulcerative Colitis. A Five-Year Study****R. Sostegni, G. Rocca, M. Pinna-Pintor[1],**

*G.C. Actis, M. Rizzetto

Dept of Gastroenterology, Ospedale Molinette, Turin, Italy

[1] Dept of Digestive Surgery, Ospedale Molinette, Turin, Italy*Background* Owing to the difficult management and the side effects, it has been recommended that the use of Cyclosporin (CsA) for refractory ulcerative colitis (UC) be restricted to tertiary care Centers. As one such Center, we have used this drug in a 5-year study.*Patients and Methods* The requirements for enrolment were the patient's eligibility for emergency colectomy after failure of his flared UC to respond to a 7-day course of full-dose parenteral steroids. On such criteria, 43 patients were enrolled in a 5-year time. There were 24 males, and 19 females, aged 17–72. They had sub-total or universal colitis, with a mean CAI score of 10 marks. In the 14-day acute phase, the steroids were tapered, and CsA was continuously infused at 2 mg/Kg/day (ref blood range 60–240 ng/ml). The responders (reducing the CAI score by 50%), received 6–8 mg/Kg/day oral CsA for the 6-month chronic phase.*Results* 14 (32%) patients worsened on IV CsA and had emergency colectomy. Further 10 (23%) although not improved avoided emergency surgery, but 7 of them had surgery in a year. The remaining 19 (44%) had a full response in 7 days and were discharged disease-free on oral CsA and tapering steroids. One of them dropped out, the remaining 18 were followed up for 1–60 months. Medication on leaving CsA included mesalamine in 12, and 1.5 mg/Kg azathioprine (AZA) in 6. Of the 12, 10 had an > 2 year follow-up. One has avoided surgery, for the other 9 the median time-to-colectomy was 23 months, with 5 keeping remission till the 3rd year; early relapse significantly ($p = 0.05$) associated to previous aggressive disease. In the same follow up, none of those on aza has needed surgery ($p = 0.02$). Side effects included cholestasis in the acute phase (7 cases), seizures (1 case); nephrotoxicity (2 cases). No infection was found at all.*Conclusion* Some half of the patients with severe refractory UC fully remit in one week of IV CsA; 40% of them delay surgery for > 2 years or may not need it at all after 4 years. This figure may be brought up to 60% combining aza to oral CsA. At the doses used no infection due to immune suppression was seen. We conclude that combined immune modulation for severe refractory UC is effective and safe, and its use should be encouraged at tertiary care Centers.

"P P 17 0448"P 17 0448**Role of Different Indirect Immunofluorescence Techniques in Detecting pANCA and Antinuclear Antibodies in Ulcerative Colitis**

*C. Papi, V. Pittoni[1], G. Valesini[1], A. Ciaco, M.L. Ciminelli, L. Pallotta, L. Capurso

Dpt Malattie Digestive & Nutrizionali Osp S Filippo Neri, Roma, Italy

[1] Clinica Medica I, Policlinico Umberto I, Roma, ItalyA distinct subset of antineutrophils cytoplasmic antibodies showing a perinuclear staining pattern (pANCA) on ethanol fixed neutrophils (EFN) have been detected in ulcerative colitis (UC) with a prevalence ranging from 50% to 70% [1]. In most studies the typical perinuclear pattern observed by indirect immunofluorescence (IIF) on EFN is considered diagnostic for pANCA. However also antinuclear antibodies (ANA) can give a similar pattern. In order to differentiate pANCA from ANA we have used two additional IIF techniques: IIF on formalin fixed neutrophils (FFN) and IIF on Hep2 cell. Formalin fixation prevents the redistribution of granular antigens to the perinuclear space rendering the staining as a cANCA one and Hep2 cell is a highly sensitive substrate for ANA. Sera from 47 UC patients were assayed for pANCA with conventional IIF using EFN as substrate. All positive sera were retested on FFN to confirm the presence of pANCA. Sera in which pANCA were not confirmed were assayed on Hep2 cell to detect the presence of ANA.Result are shown in the figure below: IIF on EFN (screening test) IIF on FFN IIF on Hep2Negative Positive (pANCA) (ANA)23/47 (49%) 24/47 (51%) 17/24 (71%) 7/24 (29%)

pANCA could be confirmed in 71% of sera showing a perinuclear staining pattern on EFN; in 29% the perinuclear pattern was due to ANA. Moreover ANA were detected in 3 additional patients showing a negative IIF on ETN and the coexistence of both antibodies occurred in 5 patients. The prevalence of pANCA and ANA in UC patients was 17/47 (36%) and 15/47 (32%) respectively. The lower prevalence of pANCA as compared to other studies can be explained by the fact that IIF on EFN alone overstimates the prevalence of pANCA of about 30% and can not rule out the presence of ANA. The use of the three IIF techniques is therefore warranted in assessing the true prevalence of pANCA in IBD.

"P P 17 0450"P 17 0450**Prevalence of Antineutrophil Cytoplasmic Antibody (ANCA), HLA DR2 and HLA DR4 in Patients with Ulcerative Colitis and in First Degree RelativesJ. Baranda,**

*F. Portela, H. Ribeiro, F. Cardoso, P. Amaro, M. Ferreira, P. Andrade, P. Ministro, A. Rosa, I. Pimenta, M.C. Leit\'e3o, A. Donato, D.S. Freitas

Department of Gastroenterology, Coimbra University Hospital, Coimbra, Portugal*Background:* xANCA (ANCA with perinuclear pattern but without reactivity against mieloperoxidase) is more frequent in ulcerative colitis (UC) than in other colitis and in controls. The prevalence of xANCA in first degree relatives (FDR) of patients (pts) with UC and its relationship with HLA DR2 and HLA DR4 is less well defined. *Aim:* 1) To compare the prevalence of xANCA between pts with UC and FDR. 2) To evaluate if there is preponderance of HLA DR2 in xANCA positive (pos) UC pts and if HLA DR4 is associated with xANCA negative (neg) UC. 3) To confront the frequence of HLA DR2 an HLA DR4 in UC pts and FDR with the one that occurs in a healthy population of Central Portugal (HPCP). *Methods:* xANCA, HLA DR2 and HLA DR4 status were determined in 29 UC outpatients and in 58 FDR without UC. The mean age was 44.7 – 18.1 yr; 58.6% were females. xANCA was searched by indirect immunofluorescence; mieloperoxidase was measured by an ELISA assay. HLA DR2 and HLA DR4 status were based on the microlymphotoxicity technic. Data from HPCP was given by Lusotransplante/Centro de Histocompatibilidade do Centro. Data analysis was made by { ?} 2 and Odds Ratio (OR) for a confidence interval (CI) of 95%. *Results:* xANCA was detected in 46.4% of UC pts and in 3.8% (2 cases) of FDR ($p < 0.0001$); these 2 cases were FDR of xANCA pos UC pts. We didn't find differences in the prevalence of DR2 and D0R4 status between UC pts and FDR (DR2: 25% vs 26.4%; DR4: 0% vs 3.7%; p NS). The frequence of DR2 status was 23.1% in xANCA pos UC pts and 28.6% in xANCA neg UC pts (p NS). DR4 status was never found in UC patients either xANCA pos or neg. DR2 status is slightly more prevalent in UC patients and FDR than in HPCP (25% and 26.4% vs 16.2%; p NS). There is a lower frequence of DR4 status in UC patients and FDR than in HPCP (UC – 0%; FDR – 3.8%; HPCP – 27.4%; OR = 0.067; CI: 0.016–0.28). *Conclusions:* 1) The prevalence of xANCA in FDR is no different from that expected in control groups. 2) We didn't find any association between xANCA pos UC patients and DR2 status neither between xANCA neg UC patients and DR4 status. 3) It seems to exist a strong negative association between DR4 status and UC in Central Portugal. Intestinal disorders: IBD, etiology and genetics }" "Prevalence of Antineutrophil Cytoplasmic Antibody (ANCA), HLA DR2 and HLA DR4 in Patients with Ulcerative Colitis and in First Degree Relatives"

P P 17 0451"P 17 0451**Autoimmune Haemolytic Anaemia and Coombs Positivity without Haemolysis Associated with Ulcerative Colitis**

*S. Potamianos, E. Giannadaki, M. Roussomoustakaki, A. Kapsoritakis, P. Skordilis, O.N. Manousos

Department of Gastroenterology, University Hospital of Crete, Greece*Objectives:* To estimate the frequency of autoimmune haemolytic anaemia and Coombs positivity without overt haemolysis in ulcerative colitis; to determine subsets of patients with ulcerative colitis susceptible to this complication; to assess the efficacy of the applied therapeutic modalities.*Patients:* 302 patients with ulcerative colitis treated at the University Hospital of Heraklion, Crete over a 6 years period were included. Within this group, a subgroup of 152 patients were studied prospectively for the presence of a positive direct Coombs test.*Results:* A diagnosis of autoimmune haemolytic anaemia was made in 5 of 302 patients with ulcerative colitis (1.7%). One more patient developed a Coombs positive haemolytic anaemia attributed to sulphasalazine. A positive Coombs test without evidence of haemolysis was found in 3 of 152 patients (2%). The mean age of all Coombs positive patients was 50.5 years and there was a definitive male preponderance (M/F: 2/1). In all cases autoimmune haemolytic anaemia occurred during active colitis.. The mean time between the onset of colitis and the diagnosis of autoimmune haemolytic anaemia was 17 months. 3 of 5 patients with autoimmune haemolytic anaemia (60%) and 7 of 9 of all Coombs positive patients (77.7%) had total colitis.All patients with autoimmune haemolytic anaemia were treated initially with corticosteroids. 3 of 5 (60%) had a good haematological response. One patient responded to the addition of azathioprine and one underwent splenectomy and proctocolectomy.*Conclusions:* In this study the frequency of autoimmune haemolytic anaemia associated with ulcerative colitis was higher than in previous reports. The complication occurred early in the course of colitis and was related to the disease activity and extent. In contrast to other studies a male preponderance was found. A Coombs test and a detailed investigation for possible haemolysis are proposed for all patients with ulcerative colitis and anaemia. Although immunosuppressive therapy is successful in most cases, sometimes surgery is required. Intestinal disorders: IBD diagnosis, monitoringClinical practice: Epidemiology (non cancer) }" "Autoimmune Haemolytic Anaemia and Coombs Positivity without Haemolysis Associated with Ulcerative Colitis"

"P P 17 0452"P 17 0452**A Five-Year Prospective Epidemiological Study of Ulcerative Colitis at Heraklion, Crete, Greece, 1990–1994E. Giannadcki,**

*I.A. Mouzas, M. Tzardi, P. Skordilis, I. Koutroumbakis, I. Vlachonikolis, O.N. Manousos

Gastroenterology Department, University Hospital, Heraklion, CreteThe *aim* of this descriptive epidemiological survey of ulcerative colitis (UC) in the Heraklion area (pop. 264.000 inh.) of the island of Crete was to obtain an accurate estimate of the incidence of UC in Crete and to compare the incidence rates with those of North and South Europe.*Methods:* The medical, pediatric and surgical departments of the two hospitals of the Heraklion area, health centers as well as private doctors of the area agreed to refer patients with symptoms suggestive of UC. All pharmacists were asked to screen medication specific for UC. All patients were seen at our Department and underwent a complete work-up including stool examinations, radiology and colonoscopy with biopsies. Standard criteria were taken into account in reaching the final diagnosis. Annual and average UC incidences were calculated. For the aggregated data age standardized incidences were calculated by the direct method using as standard the European population. Ninety-five per cent confidence intervals (CI) were calculated using the exact binomial variance.*Results:* The average incidence over the five year period was 8.9/100,000/year (CI 2–10.5), 11.6 for men and 6.3/100,000/y for women. There was an increasing trend of the incidence rates over the five years: 5.4–6.5–10.6–10.6–11.4/100,000 for the consecutive years 1990–1994. In regard to the incidences of UC by sex and residence, there was an incidence of 9.2/100,000 for the urban and 8.4/100,000 for the rural population. When incidences of UC by educational level were estimated, significant differences were found, with high incidences for high educational level (44.8) as opposed to middle (21.5) and low educational level (7.2/100,000). The average incidence of UC by age and sex revealed men to be more often affected than women, with two peaks of incidence at 35–44 years and 55–64 years respectively.*Conclusions:* UC in the Heraklion area of Crete is more common in men than women, in patients with higher rather than middle and lower educational level. There is no significant difference in incidence of UC between rural and urban areas. The overall incidence of UC in Heraklion, Crete is as high as in Central and Northern European countries. "P P 17 0453"P 17 0453**A Randomised Trial Comparing Mesazlazine and Prednisolone Foam Enemas in Patients with Active Distal Ulcerative Colitis**

*V. Mani, N.H.S. Wigan, N.H.S. Leigh

Trust Hospitals, Leigh Infirmary, Leigh, WN7 1HS, England*Background:* Mesalazine (5-ASA) foam enema has been shown to be superior to prednisolone foam enema in the treatment of relapse of distal ulcerative colitis (UC) at the end of 4 weeks. In this study we have compared the Clinical Research File (CRF) and diary data in the first two weeks of the same clinical trial.*Method:* In a multi-centre double-blind randomised study 295 eligible patients (range 18–88) received either 5-ASA 2 g (n = 147) or prednisolone foam enema 20 mg (n = 148) nocte for 4 weeks. Patients CRF (average no of stools per day, % of patients with blood in stools and mucus in stools) and diary cards (change in bowel frequency week 1–2, with number of days with blood, mucus and liquid stools) data were analysed.*Results:* Both groups were well matched with respect to age, sex, clinical history and base line sigmoidoscopic grades. In the first two weeks of the study, CRF data showed no difference between the treatment groups in the average number of stools per day. There was a significant difference in the percentage of patients with blood in the stools (14%) (CI: 3–24%) in favour of 5-ASA foam enemas (p = 0.014), but no significant difference noted with regard to mucus in stools. Diary data during the first two weeks indicated significantly fewer days with blood in stools (p = 0.007), as well as mucus in stools (p = 0.024) in the 5-ASA group. Prednisolone treated patients experienced significantly fewer days with liquid stools (p = 0.005) at two weeks.*Conclusion:* In this analysis, the time to onset of effect of 5-ASA foam enema has been shown to be clinically superior to prednisolone foam enema. This important aspect should be considered when treating acute relapses of distal ulcerative colitis. Intestinal disorders: IBD, therapy }" "A Randomised Trial Comparing Mesazlazine and Prednisolone Foam Enemas in Patients with Active Distal Ulcerative Colitis"

"P P 17 0454"P 17 0454**Interrelations between Trace Elements, Immunologic Markers and Acute Phase Response in Well-Nourished Patients with Ulcerative Colitis (UC)G.N. Dalekos[1], J. Savaidis[2], K.I. Seferiadis[2], E.V. Tsianos[1]**

[1] Division of Internal Medicine, School of Medicine, University of Ioannina, Greece

[2] Laboratoy of Clinical Biochemistry, School of Medicine, University of Ioannina, Greece*Purpose:* This study was conducted in an attempt to assess the trace elements status and the possible interrelation(s) between them and various immunologic markers, acute phase reactants or standard haematological parameters in the circulation of well-nourished patients with UC. *Methods:* The serum levels of zinc, copper, soluble interleukin-2 receptors (sIL-2Rs), interleukin-1{ b} (IL-1{ b}), interleukin-2 (IL-2) tumor necrosis factor-a (TNF-a), non-organ specific autoantibodies, CRP, C_{3C} and C_4 components of the complement system, cerulo-plasmin and haematological parameters, were determined in 75 consecutive, selected well-nourished patients with UC (32 patients with active and 43 with inactive UC) and in 33 healthy individuals. *Results:* We found autoantibodies of at least one specificity (AUBS) in 77.3% of patients. The mean levels of sIL-2Rs were significantly higher in active disease than in inactive UC ($p = 0.0001$) and in patients with ANA ($p < 0.05$), ANCA ($p = 0.01$) or AUBS ($p < 0.05$). None of the patients had detectable IL-1{ b}, IL-2, and TNF-a in their sera at least with the ELISAs used. The mean concentrations of zinc and copper were significantly higher (ANOVA, $p < 0.005$ and $p = 0.0001$, respectively) either in active or in inactive UC compared with healthy controls ($p < 0.05$). The copper was negatively correlated with haemoglobin (r = { -}0.22, $p < 0.05$) but positively with C_{3C} ($r = 0.41$, $p < 0.0005$), C_4 ($r = 0.38$, $p < 0.001$) and ceruloplasmin ($r = 0.44$, $p < 0.0005$) whilst, zinc was correlated with ESR ($r = 0.27$, $p < 0.01$) C_{3C} ($r = 0.32$, $p = 0.0005$) and ANA ($p = 0.01$). Zinc and copper were also correlated with sIL-2Rs but without statistical significance ($p < 0.10$). *Conclusions:* These findings indicate that in UC patients, zinc and copper are correlated either with haematological parameters of relapse of the disease or acute phase reactants and-although without statistical significance-with markers of immune cellular activation (sIL-2Rs). The high copper levels may be of relevance in perpetuating the inflammatory and immune processes in UC while an high zinc levels may indicate the increased zinc requirements to mantain the activity of the oxygen scanvenger enzyme, superoxide dismutase. Intestinal disorders: IBD, basic }" "Interrelations between Trace Elements, Immunologic Markers and Acute Phase Response in Well-Nourished Patients with Ulcerative Colitis (UC)"

"P P 17 0455"P 17 0455**The p-ANCA Titers of Ulcerative Colitis Patients May Vary with Change of the Disease Activity**

*S.-K. Yang, W.I. Oh[1], S.M. Park, M.H. Lee, H.-Y. Jung, H.R. Kim, W.-S. Hong, H.S. Chi[1], Y.I. Min

Dept of Internal Medicine, Asan Medical Center, College of Medicine, University of Ulsan, Seoul, Korea

[1] Dept of Clinical Pathology, Asan Medical Center, College of Medicine, University of Ulsan, Seoul, KoreaStudies have suggested that p-ANCA is an immunogenetic marker of ulcerative colitis (UC) and has no correlation with the disease activity. However, little information is available about the serial follow-up of p-ANCA titers in UC patients. *Aim:* We performed this study to test our hypothesis that p-ANCA titers may change with the disease activity. *Methods:* Of 71 Korean patients with UC (42 ANCA positive; 29 ANCA negative), 20 patients who were tested by indirect immunofluorescence for p-ANCA more than once (2–5 times) were analyzed for the change in p-ANCA titers. The disease activity was assessed according to L. Sutherland (Gastroenterol 1987; 92: 1894). The change in p-ANCA titers was defined as the change of the titer fourfold or more. *Results:* Titers of p-ANCA in 10 p-ANCA positive patients ranged from 1:80 to 1:2,560 (median 1:320) on initial check. On follow-up examination, 3 became p-ANCA negative and 4 showed a 4-fold decrease in titers after remission (n = 5) or improvement (n = 2). One patient who had demonstrated negative conversion after remission became positive after relapse of UC and showed a 4-fold decrease in the titer after improvement again. There was, however, no change in titers in 3 patients (two in remission, one with no change in activity). Of 10 patients who were initially p-ANCA negative, 9 remained p-ANCA negative after remission (n = 5), aggravation (n = 2) or no change (n = 2) in activity; one patient with mild disease on initial check became p-ANCA positive after remission. *Conclusion:* Our data suggest that, in some patients, although not in all, p-ANCA titers may have correlation with UC activity. We postulate that this apparent discrepancy may be partly due to heterogeneity of antigens involved in p-ANCA reaction. Intestinal disorders: IBD, etiology and geneticsIntestinal disorders: IBD diagnosis, monitoring }" "The p-ANCA Titers of Ulcerative Colitis Patients May Vary with Change of the Disease Activity"

"P P 17 0456"P 17 0456**Assessment of Ulcerative Colitis by Measurement of Superior Mesenteric Artery (SMA) Velocity with Doppler USN. Kalantzis[1], A. Antoniou[2], S. Tarazis[1],**

*C. Markoglou[1], D. Mourikis[2]

[1] Department of Gastroenterology, NIMTS Hospital; Athens, Greece

[2] Department of Diagnostic Radiology, Areteion Hospital, Athens University, Greece*Purpose:* To test the hypothesis that increased velocity in the superior mesenteric artery (SMA) reflects disease activity and extension in patients with Ulcerative colitis.*Materials and methods:* Duplex Doppler sonographic measurement of SMA velocity were obtained in 28 patients (18 male – 10 female, A_1: 13 patients with pancolitis, A_2: 5 patients with subtotal colitis and B: 10 patients with left sided colitis) and 50 healthy volunteers (control group). Disease activity was determined with clinical and endoscopic findings (indicators).*Results:* A marked increase in SMA velocity (peak systolic and end-diastolic velocity) was noted in patients with pancolitis group A_1 (U_{syst} = 3.64 – 0.18 m/sec and U_{diast} = 0.94 – 0.09 m/sec) compared with healthy volunteers (U_{syst} = 1.49 – 0.07 m/sec and U_{diast} = 0.38 – 0.04 m/sec), $p < 0.01$. A lower increase in SMA velocity was noted in patients with subtotal colitis group A_2 (U_{syst} = 2.06 – 0.14 m/sec and U_{diast} = 0.45 – 0.05 m/sec) compared with healthy volunteers $p < 0.01$. In patients of group B with left sided colitis the changes in SMA velocity (U_{syst} = 1.45 – 0.08 m/sec and U_{diast} = 0.36 – 0.03 m/sec) compared with healthy volunteers were not statistically significant $p < 0.05$.*Conclusion:* Activity (extension) of Ulcerative colitis causes a substantial increase in SMA velocity. Measurement of SMA velocity may be an important non invasive, readily available method that can be used to monitor Ulcerative colitis extension-activity. Intestinal disorders: IBD diagnosis, monitoring }" "Assessment of Ulcerative Colitis by Measurement of Superior Mesenteric Artery (SMA) Velocity with Doppler US"

"P P 17 0457"P 17 0457**Serum IgG Against Specific Tropomyosin (TM) Isoforms in Ulcerative Colitis Patients and Unaffected RelativesL. Biancone, R. Marasco, G. Monteleone, F. Pallone**

Dpt. Med. Sper., Universit\'e0 di R. Calabria, Catanzaro, Italy*Background.* Genetic susceptibility has been shown in IBD. IgG antibodies against a putative autoantigen related to TMs have been reported in Ulcerative Colitis (UC). UC mucosal lymphocytes release IgG and IgG1 against TMs, supporting an autoantigenic role of TMs in UC. TMs are cytoskeletal proteins with organ specific isoforms. The TM isoforms related to the putative autoantigen in UC are unknowm. *Aims.* 1. To investigate the human TM (hTM) isoforms recognized by serum IgG of UC patients. 2. To explore the immunorecognition of hTMs by serum IgG of healthy UC relatives. 3. To evaluate whether IgG immunoreactivity to hTMs is related to ANCA status. *Methods.* Source of serum samples: 33 UC patients, 21 Crohn's Disease (CD), 20 normal subjects (NS), 60 healthy UC relatives (39 1st degree and 21 nd) and 31 healthy CD relatives (20 1st degree and 11 2nd). IgG to hTMs were examined by ELISA using 4 recombinant hTM isoforms (hTM1, hTM2, hTM3, hTM5) as antigen. Sera were tested (1:100) using an A-P conjugated goat anti-human IgG. Data were expressed as Optical Density (OD) (m – SEM). p-ANCA were detected in sera (1:100) by ELISA followed by indirect immunofluorescence. 17/33 UC patients and 5/60 UC relatives were p-ANCA+ve. *Results.* Serum IgG reactivity to hTM1 and hTM5 was higher in UC patients than in CD and NS ($p < 0.01$; T-test). IgG immunoreactivity to hTM1 was higher ($p < 0.04$) in UC relatives than CD relatives and NS. Patients Relatives NShTM-IgG UC (n = 33) CD (n = 21) UC (n = 60) CD (n = 31) (n = 20)hTM1 OD 0.113 – 0.017 0.050 – 0.014 0.068 – 0.012 0.030 – 0.007 0.018 – 0.009hTM2 OD 0.105 – 0.018 0.084 – 0.019 0.061 – 0.014 0.046 – 0.010 0.073 – 0.011hTM3 OD 0.056 – 0.011 0.018 – 0.007 0.025 – 0.009 0.005 – 0.003 0.018 – 0.010hTM5 OD 0.117 – 0.015 0.044 – 0.014 0.014 – 0.003 0.014 – 0.006 0.011 – 0.016Using the mean OD + 2SD from NS as a cut off, 52% of UC sera were positive for hTM1 and 64% for hTM5, while 13/60 (21%) UC relatives were positive for hTM1. Less than 5% of controls were positive for the 4 hTMs tested. In UC patients reactivity to hTM5 was higher in the ANCA+ve than in ANCA{ -}ve group (OD 0.144 – 0.020 vs 0.082 – 0.018 p = 0.01). *Conclusions.* Circulating IgG against hTM1 and hTM5 represent a feature of UC. Immunoreactivity against hTM1 differentiates UC relatives from controls. ANCA status may influence immunoreactivity to hTMs. Results indicate an autoimmune response and a genetic susceptibility to specific hTM isoforms or related peptides in UC. Intestinal disorders: IBD, etiology and geneticsImmunology and microbiology: Host defense mechanismsClinical practice: Epidemiology (non cancer) }"

"P P 17 0458"P 17 0458**The Impact of Smoking Habit in Ulcerative Colitis Is Correlated with Sex Distribution**

*G. Riegler, M. Tartaglione, R. Marmo, R. Carratu', ""Gruppo Italiano Studio Colon-Retto – GISC"", R. D'Inc\'e0, M.I. Russo, D. Valpiani, C. Papi, M. Astegiano, V. Annese, A. Andreoli, M. Ingrosso, M. Vecchi, M.C. DiPaolo, M.A. Pelli, M.R. Garcea, C. Mansi, G. Novelli, D. Cantarini, P. Usai, D. Assisi

Seconda Universit\'e0 Di Napoli, via v. Mosca 39, Napoli 80129, ItalyData concerning clinical picture of Idiopathic Ulcerative Colitis (IUC) in relation to the different age of patients are scarce and controversial. In fact it is difficult to recruit so many IUC patients in old age to let a valuable comparison with younger IUC patients.1705 consecutive IUC patients (60.2% male, 39.8% female; mean age at diagnosis 38.5 – 16.04 years) were recruited in 17 clinics homogeneously distributed in our country. All patients were arranged in quartiles (0–25; 26–35; 36–50; = > 51 years of age) and the M/F ratios observed were respectively 1.13; 1.40; 1.79; 2.02 with a statistically significant difference ($p < 0.001$).The sex distribution was investigated with regard to clinical parameters: smoking habit; symptoms at onset; disease extension and activity. Only smoking habit was found to be strongly correlated (Figure).

The M/F ratio was found to be correlated with a more frequent ex-smoker status observed in older men. Intestinal disorders: IBD, etiology and geneticsIntestinal disorders: IBD diagnosis, monitoringClinical practice: Epidemiology (non cancer) }" "The Impact of Smoking Habit in Ulcerative Colitis Is Correlated with Sex Distribution"

"P P 17 0459"P 17 0459**Appendicectomy, Smoking and Ulcerative Colitis: A UK Case-Controlled StudyS. Jain,**

*H.H. Tsai

Gastroenterology Department, Castle Hill Hospital, Castle Road, Cottingham, E. Yorkshire, U.K. HU16 5JQThere is an inverse relationship between appendicetomy and ulcerative colitis (UC) in a Belgian study. This effect is not seen in a American study and has not yet been confirmed in the U.K. There is also a possibility that this relationship may be linked with smoking. This case-controlled, prospective study examines the frequency of appendicetomy and smoking in a stable U.K. population.*Methods:* A total of 228 patients with a definitive diagnosis of inflammatory bowel disease were prospectively interviewed by a standardised questionnaire. There were 112 patients with a diagnosis of ulcerative colitis and 116 patients with Crohn's disease. 112 controls were recruited from accidents and emergency department and were matched for age and sex.*Results:* The appendicectomy rates amongst patients with UC was 2.7% (3/112) which was significantly lower compared to 16.1% (18/112) amongst controls ($P < 0.005$, Odds ratio: 6.96, 95% C.I. 37.7–1.93). 2 patients with UC had their appendicetomy performed after diagnosis. Appendicectomy rates amongst patients with Crohn's disease was significantly greater than controls: 34% (18/112) vs. 16.1% (39/116), ($P < 0.01$; O.R. 2.65, 95% C.I. 5.31–1.34) but includes 9 patients who had appendicectomy as part of surgical intervention for Crohn's disease. The strong association of UC with non-smoking is confirmed (2% v 42%, $P < 0.001$, OR 35.6; 95% C.I. 308–8.68). However there appears to be no association between smoking and appendicetomy in all three groups.*Conclusion:* UC is associated with significantly lower appendicetomy rates than controls while appendicetomy rates in Crohn's disease is higher. This finding is independent of smoking. }" "Appendicectomy, Smoking and Ulcerative Colitis: A UK Case-Controlled Study"

"P P 17 0460"P 17 0460**The Role of Reactive Oxygen Metabolites in Ulcerative Colitis**

*\'dc. Dagli, M. Balk, D. Y\'fccel, A. \'dclker, H. \'d6ver, \'c7. Baysal, B. Sahin

Y\'fcksek Ihtisas Hospital, Ankara- TurkeyReactive oxygen metabolites (ROMs) contribute to tissue injury inflammatory bowel disease. The purpose of this study were (1) to determine the concentrations of malondialdehyde (MDA), superoxide dismutase (SOD) and myeloperoxidase (MPO) in intestinal mucosa of ulcerative colitis (UC) and to compare with the values in control mucosa, (2) to find out the relation between the disease activity and the concetrations of MDA, SOD and MPO.The study group consisted of 27 patients with UC (14 active, 13 quiescent) and 10 patients with anal disease as a control group. We measured the content of MDA, SOD and MPO in rectal biopsy. MDA was measured by thiobarbituric acid, SOD and MPO were measure with nitrobluetetrazolium and O-dianisidine as indicators. The Student t test was used to detect statistically significant differences between groups. Correlation data were analyzed using the Spearman random correlation method.The MDA, SOD and MPO tissue levels were found to be significantly different between the active UC, the patients with quiescent UC and the control subjects. A positive lineer correlation is found between the tissue concentrations of MDA, SOD and the disease activity (r: 0.809, r: 0.74 respectively). The SOD concentrations were significantly and negatively correlated with the disease activity (r: { -}0.574).These findings might indicate a decreased endogenous intestinal protection against oxygen derived radicals in UC which contribute to the pathogenesis of the disease. Intestinal disorders: IBD, basic }" "The Role of Reactive Oxygen Metabolites in Ulcerative Colitis"

"P P 17 0461"P 17 0461**Immune Response Level and Genetic Markers in Ulcerative Colitis**

*T.I. Boiko, N.M. Bereza, T.P. Shamshonkova, N.N. Vcherashnyaya

Ukrainian Scientific Research Institute of Gastroenterology, Dnepropetrovsk, UkraineUlcerative colitis (UC) is a disorder of unknoun aetiology and characterized by a variety of immunological abnormalities. It has become increasingly apparent that genetic factors play a major role in the development of vaious forms of IBD. HLA B5 and HLA B51 have been observed by ourselves to be genetic markers associated with UC in Ukrainian population.The aim of this study was to investigate a correlation between the frequency of HLA B5 and HLA B51, the level of immune response and severity of clinical manifestations of UC.*Materials and methods.* 107 patients with confirmed UC (60 males, 47 females, age range 18–65) were observed: mild – 4, moderate – 63, severe – 35. The identification of the MNC-genes was carried out in microlymphocytotoxic test according to Terasaky. In order to estimate the immune response level the amount of T- and B-cells in periphery blood was determined.*Results.* It has been founded that HLA B5 has positive association with severe UC, high level of B-cells in periphery blood and T-lymphopenia mainly decreased the number of T-helpers. An increased frequency of HLA B51 was observed in patients with mild and moderate UC and had a connection with normal or low level of B-cells and the normal number of T-cells and their sub-populations.*Conclusion.* The data obtained showed that the severity of disease and the level of immune response depends upon MNC-genes, that should provide new approaches to prognosis and therapy of UC. "P P 17 0462"P 17 0462**Is the Tc-99m HMPAO Lebelled Leukocyte Scinticraphy a Reliable Method for Assesment of Disease Activity and Localisation in Patients with Ulcerative Colitis?**

*A. Doburcali, K. S\'f6nmezoglu[1], M. Tuncer, F. Hamsioglu, A. \'c7elik, T. Cansiz[1], K. Bal, H. Uzunismail, \'c7. \'d6nsel, I. Yurdakul, E. Oktay, I. Din\'e7

Gastroenterology and Nuclear Medicine, Istanbul, Turkey

[1] Departments of Cerrahpasa Medical, Faculty of Istanbul University, Istanbul, TurkeyThe diagnosis of ulcerative colitis (UC) is based on endoscopy and histology. In the follow-up of UC patients, knowledge of current clinical activity and the extent of the involved bowel segments is necessary. The clinical activity can be determined on the basis of laboratory parameters or the UC activity index. The extent of inflammation can be investigated by means of colonoscopy and X-ray examination and labelled leukocyte scintigraphy (LS). Technetium-99m hexamethylpropylene amine oxime (99mTc-HMPAO) is a frequently used agent for in vitro leucocyte labelling. In this study, for the assesment of inflammatory activity and localisation, the grade of leukocyte accumulation was compared with the endoscopic, histologic findings and activity index. 17 patients (9 male and 8 female, mean age: 39) with known UC were enrolled the study. The inflammatory activity in 71 bowel segments of 17 patients was assessed by endoscopy, histology and 99mTc-HMPAO labelled LS using a numerical system. Sensitivity, specivity, diagnostic accuracy, positive and negative predictive values were 77%, 94%, 81%, 97% and 58% respectively. Scintigraphic activity score was significantly correlated with endoscopic, histologic and clinic activity scores ($r = 0.3612$, $p < 0.05$, $r = 0.6505$, $p < 0.05$ and $r = 0.7407$, $p < 0.05$ respectively). Our results suggested that 99mTc-HMPAO LS can be a reliable method for the assesment of severity and localisation of the inflammatory activity in UC. In new patients normal LS and rectosigmoidoscopy can be used to exclude UC and abnormal scans may enable further investigations to be efficiently targeted. [4] Institute of Virology, Slovak Academy of Sciences, Bratislava, Slovak RepublicCarbonic anhydrases (CAs) are enzymes which regulate the acid-base and water balance in several gastrointestinal tract epithelia and digestive glands. This report presents immunohistochemical comparison of the distributions of CA isoenzymes in the human intestine.*Small intestine:* CA I was found to be present in the deep crypts of Lieberk\'fchn of the jejunum and ileum. CA II appeared in the Brunner's glands of the duodenum and in the surface epithelium of duodenum and jejunum. Basolateral staining for MN/CA IX was found in the surface epithelial cells of the duodenum and jejunum, and in the deep crypts of the ileal mucosa.*Large intestine:* Intense cytoplasmic reactions for both CA I and II and strong mucosal brush border associated signal for CA IV were seen in the surface non-goblet epithelial cells throughout the large intestine. MN/CA IX gave a moderate reaction at the basolateral surfaces of the epithelium in the deep crypts of the caecum and ascending colon.The surface epithelial cells showed a positive staining for mitochondrial CA, CA V, in all segments of the gut. No signal for secretory CA VI was detected.The results indicate that CA isoenzymes are differentially expressed along the axis of the gastrointestinal canal. Several are expressed in small and large intestine where they likely form complementary systems that participate in electrolyte and water transport. Intestinal disorders, absorption: Enterocyte biologyIntestinal disorders, absorption: Epithelial transport }" "Distribution of Carbonic Anhydrase Isoenzymes I, II, IV, V, VI and MN/CA IX in the Human Intestine"

"P P 18 0464"P 18 0464**The Expression and Postnatal Development of Aquaporins in the Rat Small Intestine**

*L. Grahnquist, M. Yasui, E. \'d6stlund, Y. Finkel

Dept. of Woman and Child Health, Karolinska Institutet, Stockholm, Sweden*Background:* Intestinal water transport has for a long time been regarded as secondary to electrolyte or solute transport. Intestinal water transport in small children are more susceptible to osmotic changes and diarrhoeal diseases. Developmental changes in water transport has also been found in laboratory studies on rats. Aquaporins, a family of proteins responsible for the cellular transmembrane movement of water was discovered in 1993. So far 5 different aquaporins have been cloned. Different aquaporines are expressed in different organs and sites within the cell. The aim of this study was to the explore the expression of the mRNA of aquaporins in the proximal small intestine of infant and adult rat.*Methods:* We used 10 day old and 40 day old rats which corresponds to infant and adult respectively. Total RNA was extracted from the proximal small intestine. The expression of aquaporin 1–5 was evaluated with semi quantative PCR. { b}-actin was co-amplified as an internal control.*Results:* Our study showed that aquaporin 3 and 4 is present in the proximal small intestine of rats. Aquaporin 3 is weakly expressed in infant small intestine and increases dramatically in adult tissue. Aquaporin 1, 2, and 5 was not detected in the small intestine.*Conclusion:* Intestinal water absorption/secretion undergoes postnatal development and plays a great role during normal and pathological conditions. We have for the first time shown that aquaporin 3 and 4 are present in the small intestine and that aquaporin 3 undergoes postnatal development. The low expression of aquaporin 3 in the infant rat might explain some of the immaturity of the intestinal water transport. Intestinal disorders, absorption: Enterocyte biologyIntestinal disorders, absorption: Epithelial transport }" "The Expression and Postnatal Development of Aquaporins in the Rat Small Intestine"

*J. Hammer, K. Kletter[1], A. Gangl

General Hospital of Vienna, Abt. f. Gastroenterologie und Hepatologie, Austria

[1] Universit\'e4tsklinik f. Nuklearmedizin, AustriaThe terminal ileum -—but not the small intestine — discriminates, at times, liquids from solids (Hammer et al, Gut, 1993). *Aims:* To scintigraphically determine small intestinal and ileocecal transit of solids and liquids after infusion of various nutrients and non-caloric solutions. *Methods:* 28 healthy volunteers (age: 24 – 3 years; 7 F, 21 M) fasted for 6 hours and then swallowed a tube that was positioned with its distal end at the Ligament of Treitz. 1 gram Amberlite resin pellets, labeled with 100 \'b5Ci $^{111}InCl_3$, served as markers of the solid phase. They were injected and rinsed down the tube (infusion rate: 1 ml/min) by a fluid that was either 30 ml of Intralipid' 10% (1 kcal/ml), Albumin 10% (1 kcal/ml), NaCl 0.9% or an isoosmotic (Osm.) electrolyte solution (n = 7 each). Fluids were labeled with 2 mCi ^{99m}Tc-DTPA. { g}-camera images were obtained in 10 minute intervals until all radiolabels had entered the colon. A variable region of interest program quantified the arrival of radiolabels in the colon. *Results:* * = significant vs. protein ($p < 0.05$, after Bonferroni correction) Start of % Counts in Duration of colonic filling the colon colonic filling # of bolusesInfused (min) after 3 hours (min)fluid Tc = In Tc In Tc = In Tc InLipid 50 – 8* 99 – 3* 90 – 6* 131 – 7* 3 – 1^{NS} 2 – 1^{NS}Protein 176 – 16 30 – 14 29 – 14 67 – 12 2 – 1 2 – 1NaCl 123 – 2 58 – 11 71 – 9 97 – 7 3 – 1 3 – 1Osm. 96 – 21* 66 – 12 60 – 12 116 – 11 3 – 1 3 – 1After infusion of lipids the small intestine started to empty earlier compared to all other solutions. Duration of colonic filling, i.e. the period when colonic filling started until the time when all counts entered the colon, was significantly delayed after lipid infusion. Movement of solids and liquids was simultaneous. *Conclusion:* Lipids transit the small intestine faster compared to proteins, but the ICR significantly slower. Solids and liquids are transported simultaneously through the small intestine and the ICR. Ileal contents mainly are transported in boluses into the cecum independent of the caloric content of the solutions. Motility, specific: Small bowelNutrition: Nutrients and gut function }" "Transport of Various Nutrients through the Small Intestine and the Ileocecal Region (ICR)"

[3] Institute of Experimental Pathology, University of Ancona, Ancona, ItalyExcessive consumption of alcoholic beverages, may be associated with gastrointestinal symptoms such as dyspepsia and diarrhea. However, it remains controversial whether or not chronic alcohol ingestion damages the small intestinal mucosa. Aim of the study to investigate the effect of chronic alcohol abuse on the jejunal mucosa and, particularly, on its extracellular matrix (ECM) network. *Patients and Methods:* Jejunal biopsy specimens were obtained during upper gastrointestinal endoscopy from 50 chronic alcoholics without cirrhosis and 10 healthy subjects. Morphological studies were performed by routine histology, immunohistochemistry and electron microscopy. Morphometry of jejunal tissues was performed with a computerized image analyzer. *Results:* No significant jejunal epithelial changes were found in alcoholics despite an evident reduction in the enterocyte turnover. Myofibroblast-like cells were significantly increased in the villus stroma of alcoholics in comparison to controls. These cells stained positively for desmin, smooth muscle actin and for several ECM components. In alcohol abusers thickness of mucosal basement membrane was higher, and the staining for collagen I and III was enhanced both in the basement membrane and in the villus stroma. A higher expression of tenascin was also seen at the base of villi of alcoholics. *Conclusions:* These data indicate that chronic alcohol abuse may induce a fibrosis of jejunal villi which is associated with a transformation of villus iuxtaparenchymal cells into active subepithelial myofibroblast-like cells able to produce different ECM components. }" "Ethanol-Induced Alteration of Matrix Network in the Jejunal Mucosa of Chronic Alcohol Abusers"

"P P 18 0467"P 18 0467**Intestinal Permeability Assessment — Evidence Against the Solvent Drag Hypothesis**

*S.M. Gabe[1], R. Crane[2], I.S. Menzies[2], D.B.A. Silk[1], I. Bjarnasson[2]

[1] Dept Gastroenterology & Nutrition, Central Middlesex Hospital, London NW10 7NS

[2] Dept. Biochemistry, Kings College Hospital, London SE5 9RSIntestinal permeability tests are widely used for diagnostic screening and therapeutic monitoring. However, the precise pathways used by the probes are unknown. One suggestion is that villous tip osmolarity is the main determinant of small probe permeation rates by regulating the degree of solvent drag [1]. It is reported that the addition of sodium (66 mmol/L) and glucose (100 mmol/L) to a 100 ml test solution containing lactulose and mannitol increased the permeation of mannitol by 1.7 fold, reducing the lactulose/mannitol excretion ratio 1.4 fold.10 volunteers underwent a combined absorption-permeability test using lactulose (5 g), L-rhamnose (1 g), D-xylose (0.5 g) and 3-O-m-D-glucose (0.2 g) in 100 ml water as i) baseline, ii) with 66 mmol/L sodium and 100 mmol/L glucose and iii) 198 mmol/L sodium and 300 mmol/L glucose in an attempt to confirm the above results. The 5 hour urinary excretion (% dose) of the probes are below: Test substance Baseline sodium-glucose sodium-glucose 66, 100 mmol/L 198, 300 mmol/LLactulose 0.29 – 0.04 0.38 – 0.05 0.33 – 0.03L-rhamnose 11.65 – 1.09 10.77 – 0.91 10.22 – 0.60*D-xylose 33.59 – 1.56 31.42 – 2.91 29.56 – 1.61**3-O-m-D-glucose 51.92 – 2.60 55.37 – 4.04 41.67 – 2.20*Lactulose/L-rhamnose 0.029 – 0.005 0.035 – 0.004 0.035 – 0.004Differs significantly from baseline: *p = 0.03, **p < 0.01No significant changes were found with the low dose sodium-glucose whilst active and carrier mediated transport and the non-mediated permeation of L-rhamnose were reduced significantly with the higher dose of sodium-glucose. The lactulose/L-rhamnose ratio was not significantly altered.*Conclusion:* These results are contrary to the hypothesis that solvent drag is an important regulator of small-probe permeation across the small intestine. The changes observed with the higher dose of sodium and glucose are in fact contrary to expectations.

"P P 18 0468"P 18 0468**Intestinal Permeability in Systemic SclerosisM. Secondulfo[1], L. deMagistris[1], A. De Luca, E. Tirri, C. Valentini,**

*R. Carrat\'f9[1]

[1] Unit of Gastroenterology, Second University of Naples, Naples, Italy

Istitute of Internal Medicine and Rheumatology, Second University of Naples, Naples, ItalyIntestinal permeability has been recently reported to be increased in chronic rheumatic diseases such as rheumatoid arthritis, ankylosing spondylitis, psoriasis arthritis. No such data are available in Systemic Sclerosis.Here we report the results of a preliminary study on intestinal permeability in Systemic Sclerosis (SSc). Eleven patients with SSc, all of whom satisfying the preliminary ARA criteria for the classification of the disease (F = 10, M = 1, mean age – SD = 44.91 – 11.90; with a disease duration ranging from 3 to 28, mean – SD = 17.20 – 10.14) were enrolled in the study. All the patients were carefully investigated in order to define the subset of the disease and the exent of skin and internal organ involvement. No patients had gastrointestinal symptoms. Small intestinal permeability was evaluated by Cellobiose/Mannitol (CE/MA) test. Cellobiose (5 g) and Mannitol (2 g) were given as an oral isosmolar load in the fasting state and urine collected for consecutive 5 h. The CE/MA ratio of % urinary excretion was considered as an index of intestinal permeability. In 32 normal subjects the CE/MA was < 0.038.In N = 11 sclerodermic patients the CE/MA ratio resulted 0.009 – 0.006 (mean – SD), with no statistical significant difference vs normal subjects. No correlation was detected among intestinal permeability values and epidemiological or clinical features.SSc has long been known to affect intestinal wall in a quite high percentage of cases. Our data point out a lack of intestinal permeability alteration in a preliminary series of asymptomatic SSc patients Intestinal disorders, absorption: Malabsorption syndromesIntestinal disorders, absorption: Enterocyte biology }"

[2] Dip. Pediatria Universit\'e0 di Napoli ""Federico II"", Napoli

[3] Cattedra Pediatria Universit\'e0 di Catanzaro, Napoli

[4] Centro Endocrinologia e Oncologia Sperimentale del C.N.R., Napoli

[5] Dept. of Pediatrics, Sect. of Gastroenterology, University of Chicago*Aim of the study:* Nitric oxide (NO) is involved in the regulation of several physiological and pathophysiological processes. NO is produced by NO-synthase during the conversion of L-arginine to L-citrulline. The latter functions as an oxigen donor and transforms NO into NO_2. The endogenous synthesis of NO is specifically inhibited by the structural analogues of L-arginine and by carboxyphenyl-tetramethyl-imidazoline-oxyl-oxide (cPTIO). The role of the L-arginine-NO pathway in regulating the intestinal transport of water and electrolytes is still unclear and is the subject of the present study. *Methods:* Our approach was based on the *in vivo* perfusion of rat intestine. *Results:* The Table (column 1) shows the data obtained in the rat jejunum perfused with 10 mM L-arginine before and after the intraperitoneal injection of chlorpromazine (CPZ), an inhibitor of intestinal secretion. Increments indicate net water absorption from the intestinal lumen. L-arginine had a marked anti-absorptive effect. A dose-response curve indicated that the anti-absorptive effect was maximal at the concentration of 1 mMol/l. In order to assess the specificity of L-arginine, we measured the effect of another diamino acid, L-lysine, at the concentration of 10 mMol/l. The data in the Table (column 2) show that L-lysine does not modify the transport of water. In order to establish whether L-arginine exerted its effect after being converted to NO, cPTIO was added to the solution containing 1 mM L-arginine to be used for the perfusion experiment. The Table (column 3) shows that, in the presence of cPTIO, L-arginine had almost no effect. *Conclusion:* our data suggest that, in rat, NO is a mediator of the intestinal secretion of water and electrolytes. 1 2 3 H_2O H_2O H_2O (\'b5/l/min/g) (\'b5/min/g) (\'b5l/min/g)Control 25.3 Control 10.3 Control 11.21L-arg 11.2 L-lys 9.8 L-arg 4.99CPZ+ 16.5 L-arg+ 9.63L-arg cPTIO Intestinal disorders, absorption: Pathophysiology of diarrheaIntestinal disorders, absorption: Enterocyte biologyIntestinal disorders, absorption: Epithelial transport }" "In vivo Study of the Activity of L-Arginine and Nitric Oxide on Intestinal Secretion in Rat"

"P P 18 0470"P 18 0470**The Effects of Cardiopulmonary Bypass on Intestinal Absorption**

*\'dc Saritas, A. Saritas, O. Tarcan, N. Kantaroglu, T. \'c7etintas, S.F. Katircioglu, O. Tasdemir, B. Sahin, K. Bayazit

Y\'fcksek Ihtisas Hospital, Departments of Gastroenterology, Cardiovascular Surgery and Biochemistry, Ankara, TurkeyFollowing cardiac operations gastrointestinal complications are seen at a rate of %0.6–2 and their mortality is high (%15–65). Subclinical splanchnic damage is more common. In this prospective study, the effect of cardiopulmonary bypass (CPB) procedure on intestinal absorption is investigated on 44 patients.D-Xylose solution, that is containing 25 gr of D-Xylose in 100 ml of water, was given to the patients; and D-Xylose levels were measured in blood sample after 2 hours and in urine that was collected for 5 hours. This test was done 2 days before the operation, and on the first hour and third day postoperatively. Patients whose second hour blood D-Xylose was below 20 mg/dl and whose 5 hours' urine D-Xylose was below 5 gr were regarded as having defective intestinal absorption. Intestinal absorption was compared with clinical, laboratory and hemodynamic data.Intestinal absorption was defective in 30 patients (%68.18). Except one of the patients blood and urine D-Xylose levels were at normal levels on the third postoperative day. The patient with defective intestinal absorption on the third postoperative day was died due to multiple organ failure. Twenty-four of the 30 patients with defective intestinal absorption, had abdominal symptoms. The most commonly encountered symptoms were abdominal pain and nausea. There was no statistically significant correlation between absorption defect and age, sex, adjunctive treatment, body weight, cardiac output, hematocrit, intraoperative hypothermia, hypotension, central venous pressure, CPB time, cross clamp time and period of mechanical ventilation. The relation with cardiac index was marginally significant (p = 0.0633); and the relation with coronary artery bypass grafting was statistically significant (p = 0.044). There was no statistical relation between absorption defect and the period of intensive care unit or postoperative hospital stay.In conclusion, CPB procedure damages the intestinal absorption reversibly. This damage is more significant in patients who undergone coronary artery bypass grafting and whose cardiac index is low. This should be remembered when oral drug therapy or enteral feeding is to be started immediately after CPB. If absorption defect continues, it may cause endotoxemia and multiple organ failure leading to death; as was seen in one of our patients. Intestinal disorders, absorption: Malabsorption syndromes }" "The Effects of Cardiopulmonary Bypass on Intestinal Absorption"

"P P 18 0471"P 18 0471**Effect of (R){ a}-Methylhistamine on Duodenal Bicarbonate Secretion in the Rat**

*G. Coruzzi, G. Bertaccini

Institute of Pharmacology, University of Parma, ItalyPrevious studies from our laboratory showed that the histamine H_3 receptor agonist (R){ a}-methylhistamine (MHA) is able to protect the gastric mucosa against the damaging effects of different noxious stimuli (absolute ethanol, aspirin and stress). Electron microscopy studies revealed that both adherent and intracellular mucus are increased by MHA. In order to investigate other possible mechanisms, the effect of MHA on alkaline secretion was studied in the anaesthetized rat, in comparison with PGE_2, cholinergic agents and intraluminal 10 mM HCl. Under urethane anaesthesia a duodenal loop was perfused with oxygenated saline at 37\'b0C and the alkaline output was measured by titration at pH 6 with 10 mm HCl. MHA (3–30 \'b5mol/kg i.v.) induced a dose-dependent increase in bicarbonate secretion, with a maximum effect of 0.8 \'b5Eq $HCO_3^{\{-}$}/10 min. MHA at 100 \'b5mol/kg i.v. did not cause any effect. The novel H_3 receptor agonist immepip (3–100 \'b5mol/kg i.v.) induced negligible and variable effects, being the basal secretion slightly increased or decreased. The stimulatory effect of MHA 30 \'b5mol/kg i.v. was greatly enhanced (2.15 \'b5Eq $HCO_3^{\{-}$}/10 min) in the presence of the { $a\}_2$ adrenoceptor antagonist, yohimbine 100 \'b5/kg/h; moreover this compound unmasked a stimulatory effect of MHA 100 \'b5mol/kg i.v., indicating that high doses of MHA can activate { $a\}_2$ adrenoceptors with consequent inhibition of bicarbonate secretion. These data indicate that MHA can influence bicarbonate secretion from the rat duodenum by opposite mechanisms: the involvement of histamine H_3 receptors in the stimulatory effect of MHA is still unclear; whereas the activation of inhibitory { $a\}_2$ adrenoceptors seems to be established. Oesophageal gastric duodenal disorders: GD disorders, acid pepticOesophageal gastric duodenal disorders: Secretion: mechanism, regulationHormones and receptors: Receptor characterization }" "Effect of (R)alpha-Methylhistamine on Duodenal Bicarbonate Secretion in the Rat"

"P P 18 0472"P 18 0472**Plasma Post-Absorptive Citrulline as a Biochemical Marker of Enterocyte Mass**

*P. Crenn, C. Coudray-Lucas[1], L. Cynober[1], B. Messing

INSERM U290, Hospital St-Lazare, Paris, France

[1] Biochimie A, Hospital St-Antoine, Paris, FranceIn animals models citrulline, an amino acid (AA) not incorporated into proteins, is specifically produced by enterocytes from glutamine (pyrroline 5 carboxylate synthase pathway); then citrulline is metabolized into arginine by the kidney (J Biol Chem 1994, 269, 32667). *Aim:* To test the hypothesis that plasma citrulline concentration give an index of enterocyte mass in non-clinically stressed short bowel (SB) patients on free oral diet, not on steroids and without visceral deficiency other than severe small bowel disease. *Methods:* Plasma venous AA concentrations were analyzed in post-absorptive state by ion exchange chromatography (\'b5mol/l: mean – SD) in SB patients submitted to Parenteral Nutrition (PN) for more than 6 months with standard glutamine and citrulline-free AA solutions (n = 37), in SB patients without PN (n = 8), and-in controls (n = 57); in addition 16 SB patients on PN had simultaneous plasma venous and arterialized AA determination. Enterocyte mass was evaluated on a *in vivo* one dimension measurement of small bowel length (SBL) by opisiometer on X-ray films. *Results:* Plasma citrulline was 17 – 9* in SB patients on PN, 33 – 15 in SB patients without PN, and 42 – 13 in controls. Plasma arginine concentration was decreased in SB patients (45 – 21* *vs* 75 – 16 in controls) (*p < 0.05 *vs* controls). Plasma citrulline concentration was not related to PN duration, to body mass index, to presence of colon, to AA solution and to site (venous *vs* arterial) of sampling but was related to albuminemia (p < 0.01) and to SBL (p < 0.0001). In multivariate analysis plasma citrulline remained only related to remnant SBL (p < 0.0001, r = 0.85) while presence of PN and albuminemia became non significant. *Conclusion:* Decrease of plasma citrulline in short bowel patients is compatible with the concept of a decrease in citrulline production due to the reduction of enterocyte mass. These data suggest that post-absorptive plasma citrulline is, independently of nutritional status, a biochemical marker of enterocyte mass. Nutrition: MetabolismIntestinal disorders, absorption: Malabsorption syndromesClinical practice: Management strategy }" "Plasma Post-Absorptive Citrulline as a Biochemical Marker of Enterocyte Mass"

"P P 18 0473"P 18 0473**Luminal Administration of Omeprazole Increases Human Proximal Duodenal Mucosal Bicarbonate Secretion**

*J. Hillings\'f8, A. Mertz-Nielsen, K. Bukhave, J. Rask-Madsen

Depts. of Gastroenterology and Clinical Physiology, Hvidovre Hospital, University of Copenhagen, Denmark

Dept. of Biochemistry and Nutrition, Technical University of Denmark, DenmarkWe have previously demonstrated that suprapharmacological doses of the proton pump inhibitor, omeprazole [1] (OME), used for acid suppression of the stomach, result in higher than normally observed rates of proximal duodenal mucosal bicarbonate secretion (PDMBS) in healthy volunteers. Apparently, the effect was independent of gastric acid secretion. To study whether OME itself, rather than a sulfenamide, may act on the duodenal mucosa we have assessed the effects of duodenal perfusion with half-maximum inhibitory concentrations or higher of OME for inhibition of *in vitro* stimulated human gastric glands [2].*Methods:* A 3-cm segment of proximal duodenum was isolated by occluding balloons and continuously perfused (2 ml/min, 154 mM NaCl, 10 \'b5Ci/L ^{51}CrEDTA), simultaneously with the stomach (5 ml/min, 154 mM NaCl, phenol red), in 12 healthy volunteers for a 1 h basal period followed by a 1 h test period. In the test period 3.45 mg/100 ml (n = 5) or 34.5 mg/100 ml (n = 7) OME was added to the perfusion solution. HCO_3 was determined in the duodenal effluents using a method corresponding to the back-titration method. Determination of phenol red, ^{51}CrEDTA and trypsin served as markers for recovery or contamination.*Results:* Duodenal perfusion with OME did not affect gastric pH or acid output. No significant change in PDMBS was observed after perfusion with OME 3.45 mg/100 while 34.5 mg/100 ml caused an increase in HCO_3 secretion from 130 – 14 \'b5mol/h cm to 190 – 17 \'b5mol/h cm (mean – SEM) (p = 0.008; t-test).*Conclusions:* These results demonstrate that intraduodenally administered OME, in doses insufficient to inhibit gastric acid secretion, causes a prompt increase in PDMBS. Thus, epithelial, glandular or heterotopic parietal cells lining the duodenal wall may be the site of proton pump inhibition.

"P P 18 0474"P 18 0474**Mechanism of the Inhibitory Effect of Peptide YY on VIP-Stimulated Jejunal Fluid Secretion in Rats**

*A. Souli, O. Presset, A. Tsocas, J. Chariot, C. Roz\'e9

INSERM U410, Facult\'e9 de M\'e9decine X. Bichat, BP 416, 75870 Paris, FranceThe hormonal peptide YY (PYY) potently inhibits net electrolyte and water secretion in the intestine in humans and in different animal species. In vitro data suggest a direct effect on enterocytes while some in vivo results suggest an indirect nervous mechanism. The aim of the present work was to study the mechanisms of the inhibitory effect of PYY on VIP-stimulated jejunal fluid secretion in rats.*Methods.* Net jejunal fluid secretion was studied in vivo in pentobarbital-anesthetized rats equipped with a closed jejunal loop. A proximal jejunal loop (20 cm long) was tied off and filled at time zero with 2 ml 0.9% saline. Jejunal secretion was stimulated by i.v. infusion of VIP (30 \'b5g/kg.h for 30 min). After 30 min, the rats were sacrificed, the loop harvested, and the amount of absorbed or secreted fluid was calculated by weighing the full and empty loop. PYY (3–100 pmol/kg) was i.v. injected 15 min before time zero. Pharmacological antagonists were i.v. injected 5 min before PYY. In one group of animals, bilateral truncal cervical vagotomy was carried out 30 min before time zero.*Results.* 1. PYY inhibited VIP-stimulated jejunal net water flux in a dose-related manner (ID 50 # 6 pmol/kg). 2. The inhibitory effect of PYY (10 pmol/kg) was suppressed by tetrodotoxin, hexamethonium, and decreased (46%) by vagotomy. 3. The inhibitory effect of PYY was suppressed by BMY 14802, a specific antagonist of sigma receptors, and decreased (75%) by idazoxan, an antagonist of alpha-2 adrenoreceptors and imidazoline-1 receptors. 4. Devazepide, a CCK_A antagonist, and L-NAME, a NO synthase inhibitor, did not modify the effect of PYY.*Conclusions.* 1. PYY prevents VIP stimulation of jejunal net water flux in rats. 2. This effect is mediated by a neural cholinergic nicotinic pathway, mediated in part by the vagus nerves. It involves sigma and/or alpha-2 receptors. 3. NO and CCK_A receptors are not implicated in this effect. Intestinal disorders, absorption: Enterocyte biologyIntestinal disorders, absorption: Epithelial transport }" "Mechanism of the Inhibitory Effect of Peptide YY on VIP-Stimulated Jejunal Fluid Secretion in Rats"

"P P 18 0475"P 18 0475**Five-Hydroxytryptamine Receptor Antagonist Reduces Salmonella-Induced Net Fluid Accumulation in Porcine Small Intestine**

*M.B. Hansen, M.L. Gr\'f8ndahl, G.M. Jensen, C. Nielsen, J.E. Olsen, E. Skadhauge

Departments of Anatomy & Physiology and Microbiology, The Royal Veterinary and Agricultural University, Copenhagen, Denmark*Background and purpose.* The pathophysiological mechanism(s) of Salmonella is not clear but seems to involve the release of a cholera toxin (CT)-like enterotoxin. Five-hydroxytryptamine (5-HT) is released locally in the intestine by CT and acts as a neurotransmitter and paracrine secretagogue in the small intestine in most species. Accordingly, 5-HT_3 receptor antagonists are potent inhibitors of CT-induced intestinal secretion. We *hypothesize,* that Salmonella induces intestinal secretion through a CT-like mechanism with a concomitant release of 5-HT. The purpose of the study was to evaluate the effect of a 5-HT_3 receptor antagonist on Salmonella typhimurium (St)-induced fluid accumulation.*Materials and methods.* 9 weeks old female Danish Landrace/Yorkshire pigs were used. Total anaesthesia was achieved by intravenous infusion of propofol (induction), continuous inhalation of isoflurane and cutaneous infiltration with bupivacaine. Supporting treatments included continuous intravenous infusion of Ringer-acetate liq. and artificial controlled respiration. Jejunal and ileal ligated loops were either unfilled (U), filled with 10 ml of Argenzio-4 test solution alone (T) or filled with test solution containing St phag. T123389-1 in 10^{10} colony forming units. Loops were removed from the peritoneal cavity after 8 hrs and the net amount accumulated fluid was determined. Ondansetron (Glaxo-Wellcome, UK) is a 5-HT_3 antagonist and was injected subcutaneously (200 \'b5g {\'b4} kg$^{\{-}$1}) before surgery and 6 hrs later. Results are expressed as means – SEM. N represents number of animals, and n the number of loops. Data were analyzed by Student's unpaired t-test. P < 0.05 as significant level (*).*Results.* U and T loops accumulated no significant net amounts of fluid in any experiments (data not shown). Data for loops exposed to St accumulated the following amounts (mg fluid pr. mg dry loop weight): Controls (N = 5) Ondansetron-treated (N = 5)Jejunum 5.2 – 0.6 (n = 12) 3.1 – 0.4 (n = 30)*Ileum 3.8 – 0.8 (n = 10) 2.2 – 0.3 (n = 29)**Conclusion.* These data *demonstrate* that ondansetron reduces the net fluid accumulating effect of ST by about one third in porcine small intestine. Furthermore, the results *suggest* the release of 5-HT and the activation of 5-HT_3 receptors in the secretory pathway of St, supporting the hypothesis of St inducing secretion partly via a CT-like mechanism. "P P 18 0476"P 18 0476**Comparison of the Antisecretory Effect of Endogenous Forms of Peptide YY on Fed and Fasted Rat Jejunum**

*B. Eto, M. Boisset, J.F. Desjeux

CNAM and INSERM U290, Hospital Saint-Lazare, 75010 Paris, FranceIts is intringuing that the antisecretory peptide YY is present in plasma in two forms PYY1-36 during fasting and PYY3-36 in fed state. In addition PYY3-36 has been found in human and rabbit blood within 30 min at the beginning of the meal, when the peak of water and electrolytes secretion occurs in the duodeno-jejunum. The aim of this study was therefore 1) to compare the antisecretory effect of PYY1-36 and PYY3-36 in fed and fasted rat jejunum 2) to assess the effect of PYY3-36 on secretion induced by different intestinal peptides. The variations in short-circuit current ({ D}Isc) due to the modification of ionic transport across jejunum were assessed *in vitro,* using Ussing chambers. In fasted rats, both PYY1-3- and PYY3-36 at 2 {\'b4} 10{ -7} M in serosal medium induced a similar decrease in Isc ({ -}19 – 2.36 versus { -}16.6 – 1.44 \'b5A/cm^2, p < 0.001 for PYY3-36 and 1.32 \'b5Eq/hr.cm^2, p < 0.001 for PYY1-36). In addition, when a second stimulation with 10{ -7} M PYY3-36 was performed 30 min after a previous challenging exposure at 10{ -8} M, the decrease in Isc was smaller than the one obtained after 60 min ({ -}11.64 – 2.64 versus { -}24 – 3 \'b5A/cm^2, p < 0.05), suggesting a tachyphylaxis phenomenon. The increase in Isc induced by 2 {\'b4} 10{ -7} M gastrin I, motilin, pancreatic polypeptide, peptide Histidine Isoleucine, secretin, helodermin, substance P, atrial natriuretic factor (1–28), and vasointestinal peptide was abolished by 2 {\'b4} 10{ -7} M PYY3-36 in fasted rat (p < 0.001). In fed animals, PYY3-36 had no significant effect on Isc (+1.65 – 2.36 \'b5A/cm^2), and the antisecretory effect of PYY1-36 was present but blunted ({ -}10 – 1.01 \'b5A/cm^2). Net chloride secretion was also reduced bu PYY1-36 to 0.71 \'b5Eq/hr.cm^2 p < 0.05, whereas PYY3-36 had no effect ({ -}0.07 \'b5Eq/hr.cm^2, p > 0.05). In fasted rats, this study confirms the antisecretory effect of PYY1-36, and shows that the endogenous form PYY3-36, dispays a similar effect. In addition, PYY3-36, reversed secretion induced by various intestinal peptides. In fed rats, PYY3-36 the major form of postprandial circulating PYY has no antisecretory effect *in vitro.*This finding indicate that the 2 circulating forms of PYY does not display the same activity in fed animals. Although 3-36 PYY has an antisecretory effect against secretory peptides in fasted rats, the jejunal epithelium of fed rats does not respond to 3-36 PYY until 60 min after challenge. Intestinal disorders, absorption: Pathophysiology of diarrheaIntestinal disorders, absorption: Epithelial transportHormones and receptors: Receptor characterization }"

"P P 18 0477"P 18 0477**Pentoxifylline (PTX) Inhibits Cytokine Secretion by Peripheral Mononuclear Cells (PBMC) and Intestinal Biopsies in Inflammatory Bowel Diseases (IBD)**

*J.M. Reimund, B. Duclos, S. Dumont[2], C.D. Muller[4], R. Baumann[1], P. Poindron[2]

[1] Depts of Gastroenterology, Hopital de Hautepierre, Strasbourg, France

[3] INSERM U 381, Strasbourg, France

[2] Dept of Immunology, Immunopharmacology and Pathology, University of Strasbourg, France

[4] CNRS U491, University of Strasbourg, FranceInflammatory cytokines are involved in the pathogenesis of IBD. In recent studies PTX has been shown to decrease tumor necrosis factor-{ a} (TNF) secretion by normal PBMC *in vitro* and *in vivo;* on the other hand, anti-TNF antibodies were shown to be efficient in a pilot study of Crohn's disease therapy. Therefore we studied the effects of PTX upon TNF, interleukin (IL)-1{ b} (IL1), IL6 and IL8 secretions of PBMC and intestinal biopsies in Crohn's disease (CD) and ulcerative colitis (UC) patients.*Methods:* PBMC of 11 CD and 7 UC patients were separated by mean of a Ficoll density gradient and cultured in standard medium over a 24 hour period (10^6 cells/well, 95% air, 5% CO2, 37\'b0C) with or without PTX (1, 10, 100 \'b5g/ml). Biopsies from inflamed (CD: 11, UC: 5) and morphologically (macroscopically and microscopically) normal CD intestinal mucosa (n = 6) underwent the same procedure. Supernatants were collected, filtered and frozen ({ -}70\'b0C) until cytokine assays (ELISA using 2 monoclonal antibodies, J.S. Kenney, Antibody Solutions, Half Moon Bay, CA, USA).*Results:* 1) PTX inhibited significantly and in a dose-dependent manner the TNF production by PBMC of IBD patients (79% of basal production at 1 \'b5g/ml of PTX, 66% at 10 \'b5g/ml and 46% at 100 \'b5g/ml). There was no difference between CD and UC. 2) IL8, 6, 1 and TNF concentrations in organ culture supernatants were increased for both involved and non-involved biopsies compared to normal subjects. 3) PTX (1, 10 and 100 \'b5g/ml) significantly decreased basal IL1 and TNF secretions (approximately { -}40%) by involved CD or UC, and unaffected CD mucosa. This effect was not different between CD and UC inflamed mucosa or between CD affected and unaffected mucosa. IL6 and 8 were less modified by PTX.*Conclusion:* PTX decreased TNF and IL1 secretions of inflamed intestinal mucosa organ cultures from CD and UC, whereas only TNF secretion by PBMC was affected. Interleukin-6 and IL8 secretions were less modified. In addition PTX decreased the raised TNF, and in a lower degree IL1, productions of biopsies from endoscopically and microscopically normal intestinal areas. These effects indicate a potential interest for PTX or related compounds in IBD therapy. "P P 18 0478"P 18 0478**Apical Effect of Diosmectite on the Alteration in Intestinal Epithelial Barrier Induced by Basal TNF{ a}**

*L. Mahraoui[1], M. Heyman[1], O. Plique[2], M.T. Droy-Lefaix[2], J.F. Desjeux[1]

[1] INSERM U290 Hospital St Lazare 107, rue du Fg St Denis 75010 Paris, France

[2] IPSEN 24, rue Erlanger 75016 Paris, FranceIn many digestive diseases, including infectious diarrhea, inflammatory bowel diseases and food allergy, the intestinal barrier is weakened by the release of proinflammatory cytokines due to the abnormal activation of the epithelial cells and underlying immune system.This study investigate the protective effect of apical mucosal diosmectite on the intestinal dysfunction induced by the proinflammatory cytokine TNFa. Filter-grown monolayers of the intestinal cell line HT29-19A, were incubated, for 48 h, in the presence of 10 ng/ml TNFa and 5 U/ml IFNg, in the basal medium. Afterward, diosmectite (1, 10 or 100 mg/ml) was placed in the apical medium during 1 hour. The intestinal function was then assessed in Ussing chambers by measuring the ionic conductance (G), and apico-basal fluxes of ^{14}C-mannitol fluxes (J_{man}) and intact horseradish peroxidase (J^{HRP}). In control intestinal monolayers, diosmectite did not modify significantly G, J_{man} and J^{HRP}. After incubation with TNFa and IFNg, the intestinal function was altered as attested by an increase in G (22.8 – 3.7 vs 9.6 – 0.5 mS/cm^2), J_{man} (33.8 – 7.5 vs 7.56 – 0.67 \'b5g/h.cm^2) and J^{HRP} (1.95 – 1.12 vs 0.14 – 0.04 \'b5g/h.cm^2) compared to control values. G and J_{man} were highly correlated suggesting that the increase in permeability was paracellular. Treatment with diosmectite (optimal concentration 10 mg/ml) restored all the parameters to values not statistically different from control values. In conclusion, these results confirm that basal TNFa disrupt the intestinal barrier at the tight junctional level, and further indicate that apical diosmectite fully counteract such deleterious effect. Intestinal disorders: IBD, basicImmunology and microbiology: InflammationIntestinal disorders, absorption: Pathophysiology of diarrhea }" "Apical Effect of Diosmectite on the Alteration in Intestinal Epithelial Barrier Induced by Basal TNFalpha"

"P P 18 0480"P 18 0480**Neuronal Activity and CRF Receptor Gene Transcription in the Brain of Rats with TNBS-Induced Colitis**

*B. Bonaz, J. Fournet, C. Feuerstein

Lab. Neurophysiology and Dept. of Gastroenterology, 38043 Grenoble cedex 09, FranceColitis induced in rats by trinitrobenzene sulfonic acid (TNBS) is an immune challenge [1]. The immune-, endocrine- and central nervous systems communicate each other through cytokines, steroids and neuropeptides [2]. Brain CRF is one of these neuropeptides and acts through CRF receptors (CRF-R). *Purpose:* to study in the rat brain 1) neuronal pathways activated by TNBS-induced colitis using c-fos mRNA as a marker of neuronal activation, 2) the transcription of the genes encoding CRF-R1 [3] and CRF-R2alpha [4], 3) the localization of these transcripts in CRF perikarya in the paraventricular nucleus (PVN) of the hypothalamus, the main source for CRF in the brain. *Methods:* TNBS (30 mg in 50% ethanol, Sigma 5% weight/vol) or saline was administered in the colon of conscious fasted rats chronically fitted with a colonic catheter (10 cm proximal to the anus). Rats were fixed 1, 2, 3, 4, 6, 12 and 24 h later. Coronal frozen sections of the brain and spinal cord were cut and the rat c-fos, CRF-R1 and CRF-R2alpha mRNAs were assayed by *in situ* hybridization (ISH) using ^{35}S-labeled riboprobes [5]. Localization of these transcripts in CRF perikarya of the PVN was determined using a combination of immunocytochemistry and ISH [5]. *Results:* in TNBS-induced colitis 1) c-fos mRNA was expressed in the spinal cord, nucleus tractus solitarius, area postrema, lateral reticular nucleus, parabrachial nucleus, locus coeruleus, thalamus, arcuate nucleus, suprachiasmatic nucleus, supraoptic and PVN, amygdala, subfornical organ, bed nucleus of the stria terminalis. This expression peaked at 1 h to 3 h, then progressively decreased to completely vanish after 12–24 h. 2) CRF-R1 mRNA appeared at 2 h in the parvo-PVN, was highly expressed at 3–6 h, decreased at 12 h and totally vanished at 24 h. 3) No change of the CRF-R2alpha mRNA was observed in the limbic structures, 4) In the PVN, numerous CRF perikarya expressed c-fos and CRF-R1 transcripts. *Conclusions:* TNBS-induced colitis is followed by a neuronal activation in brain nuclei involved in autonomic and stress responses. CRF pathways are selectively activated in the PVN mainly through CRF-R1 receptors.

"P P 18 0481"P 18 0481**Differential Effects of Superoxide and Hydrogen Peroxide on Transepithelial Permeability and Heat Shock Expression in Cultured Intestinal CellsJ. Ries, C. Walter, B. Gebhardt, A. Schmitt, W.F. Caspary, J. Stein**

II. Department of Internal Medicine, Div. of Gastroenterology, J.W. Goethe-University, 60590 Frankfurt/Main, Germany*Background:* Reactive oxygen metabolites (ROM) are implicated in various pathologies in the GIT, such as inflammation or the ischemia-reperfusion syndrome. To improve our understanding of how oxidate stress affects intestinal cell function, we compared the effects of the hypoxanthine-xanthine oxidase system (X-XO) and that of H_2O_2 on transepithelial permeability and heat shock protein expression in the cultured intestinal cell line CaCo-2.*Methods:* Cells were grown in permeable supports and mounted in Ussing chambers. Apically added FITC-Dextran 4400 D was used for measuring epithelial permeability. Data were expressed as FITC-dextran basolateral concentration as a percent of apical concentration after 240 min. Potential difference (PD) and short-circuit current (I_{sc}) were monitored and transepithelial resistance (TER) was calculated by Ohm's law. Results are given as percent of the baseline resistance. To establish optimal HSP induction ^{35}S-methionine incorporation was assessed. Western analysis and 2-dimensional electrophoresis confirmed induction of HSP-70. LDH-release was measured photometrically.*Results:* Basolateral FITC-Dextran progressively accumulated even under control conditions (0.057 – 0.012), TER decreased slightly (88.2 – 4.1). The addition of 0.02 U or 0.2 U XO + 1 mM xanthine showed a dose dependent increase in transepithelial permeability (0.141 – 0.077%; $p < 0.05$/0.908 – 0.330%; $p < 0.001$), but only at higher concentrations a decrease of TER (89.4 – 5.3%; $p > 0.05$/68.2 – 2.8%, $p < 0.001$), compared with controls.In contrast addition of H_2O_2 led to a significantly decrease of TER both at 0.05 mM (61.5 – 6.1; $p < 0.01$) and 0.1 mM (60.4 – 3.4; $p < 0.01$), while transepithelial permeability showed only a moderate increase (0.228 – 0.026; $p < 0.05$/0.374 – 0.094; $p < 0.05$. Compared to controls only exposure to XO (0.2 U/ml) showed a significantly (6-fold; $p < 0.05$) induction of HSP70 synthesis. In contrast LDH release was significantly (2.6-fold; $p < 0.01$) increased after H_2O_2 (0.1 mM) exposure (0.2 U XO: 1.3-fold; $p < 0.05$).*Conclusion:* This study shows differential effects of superoxide and hydrogen peroxide on transepithelial permeability and heat shock protein expression in cultured intestinal cells implicating differential mechanism of ROM as mediators of epithelial dysfunction and injury. }" "Differential Effects of Superoxide and Hydrogen Peroxide on Transepithelial Permeability and Heat Shock Expression in Cultured Intestinal Cells"

"P P 18 0482"P 18 0482**Induction of GST-PI by Short Chain Fatty Acids in the Intestinal Cell Line Caco-2O. Schr\'f6der, G. Oremek[2], M. Lorenz[1], W.F. Caspary,**

*J. Stein

Division of Gastroenterology, J.W. Goethe-University of Frankfurt

[1] Division of Surgery, J.W. Goethe-University of Frankfurt

[2] Division of Clin. Chemistry, J.W. Goethe-University of FrankfurtGlutathione S-transferases (GSTs) are a multigene family of detoxification and metabolising enzymes, which have been linked with the susceptibility of tissues to environmental carcinogens. Beside their role as the main energy source in the colonic mucosa, short chain fatty acids (SCFAs) were found to act as potent anti-proliferative and differentiating agents in various cancer cell lines. The objective of this study was to evaluate the effects of SCFAs on the induction of GSTpi in the intestine as a possible new anticarcinogenic mechanism of SCFAs. Studies were performed in Caco-2 cells, a cell line resembling functionally-normal enterocytes. Cells, cultured in DMEM supplemented with 10% fetal calf serum, were studied from day 0 dpc (days post confluence) until 21 dpc and culture. SCFAs (acetate, propionate, butyrate) were added to give a final concentration of 5 mmol/L. At 0, 3, 6, 9, 15, and 21 dpc, protein, lactate dehydrogenase (LDH), alkaline phosphatase (aP) and GSTpi were measured. Butyrate supplementation significantly (p {\'a3} 0.01) increased GSTpi levels compared to controls in a concentration dependent manner. The effect was detectable within 3 dpc with a maximum at 14 dpc. In contrast to butyrate, the other SCFAs tested had no (acetate) or little effect (propionate). In *conclusion* our data suggests that the anticancer effect of butyrate in part may based on the induction GSTpi activity resulting in an enhanced detoxification capacity of the gut. }" "Induction of GST-PI by Short Chain Fatty Acids in the Intestinal Cell Line Caco-2"

"P P 18 0483"P 18 0483**Conditionally Immortalized Rat Fetal Intestinal Epithelial Cell Line (2/4/A1): A Model for Studying Enterocyte Differentiation**

*V. Milovic[1], G. Ocklind[1], S. Olsson[1], J. Hochman[2], E.C.A. Paul[3], P. Artursson[1]

[1] Department of Pharmaceutics, Uppsala University, Sweden

[2] Merck Research Laboratories, West Point, PA, USA

[3] School of Biological Sciences, University of Manchester, U.K.

Gastroenterology Unit, Guy's Hospital, UMDS of Guy's and St Thomas's Hospitals, London, U.K.*Background.* Intestinal epithelial cell culture models originate from either tumour cells or immature crypt cells. They maintain malignant and/or non-differentiated phenotype and do not express all features of the intestinal epithelial cell differentiation. 2/4/A1 cells, isolated from rat fetal intestinal epithelium and transfected with thermolabile SV40 large T antigen (pzipSV40tsa58 mutant), proliferate at 33\'b0C, but eliminate the antigen, cease proliferating and undergo apoptotic cell death after being switched to 39\'b0C. *Aim.* We evaluated proliferation and differentiation of 2/4/A1 cells, seeded at the permissive (33\'b0C), intermediate (37\'b0C) and non-permissive temperature (39\'b0C), in order to establish a cell culture model which will follow the events from proliferation to terminal differentiation and apoptosis, similar to normal enterocytes. *Methods.* 2/4/A1 cells were maintained under serum-free conditions. Proliferation was assessed by thymidine incorporation assay, and differentiation was examined by brush border enzyme assays, transmission electron microscopy, and immunocytochemistry. Apoptosis was evaluated by staining with DAPI (diamino-phenylindole hydrochloride) and fluorescence microscopy. *Results.* 2/4/A1 cells grown at permissive temperature proliferated rapidly, forming multilayers consisting of immature enterocytes. The cells grown at 37\'b0C and 39\'b0C required extracellular matrix in order to attach and avoid rapid apoptotic death. Laminin-containing matrices enabled prolonged cell survival at these temperatures, and were significantly more efficient than collagens I and IV and fibronectin in either cell attachment and in delaying apoptosis at 39\'b0C. At 37\'b0C 2/4/A1 cells formed polarized monolayers with differentiated tight and adherence junctions; their tight junctions had functional integrity similar to that of the human small intestine. The activities of brush border enzymes increased significantly at 37 and 39\'b0 in comparison to 33\'b0C, indicating a considerable degree of the apical membrane differentiation. *Conclusion.* 2/4/A1 cell line might be a suitable model to study the factors involved in enterocyte differentiation Oncology, general: Proliferation, carcinogenesisIntestinal disorders, absorption: Enterocyte biologyOncology, specific: Small bowel }" "Conditionally Immortalized Rat Fetal Intestinal Epithelial Cell Line (2/4/A1): A Model for Studying Enterocyte Differentiation"

"P P 18 0484"P 18 0484**Are Mutation of the Human Ileal Sodium-Dependent Bile Acid Transporteur (HISBT) Gene Implicated in the Genetic Susceptibility to Crohn's Disease (CD)?D. Heresbach, M. Alizadeh, M. Pagenault, M. Gosselin, B. Genetet, G. Semana, J.F. Bretagne**

Department of Gastroenterology and University Laboratory of Immunology, 35033 RennesRecent studies have shown a single C to T transition resulting in a proline to serine substitution (P 290 S) at HISBT cDNA and genomic level in a CD patient. The inheritance of this mutation in the proband's family was confirmed by DNA sequencing; moreover, taurocholate uptake activity was abolished in HISBT (P 290 S)-transfected COS cells. An increased faecal excretion of taurine congugates has been described in patients with inflammatory bowel disease in the active phase and in children during clinical remission.*The aim* of our study was to determine the frequency of this mutation (P 290 S) in a population of CD patients.*Patients and methods:* One hundred forty one CD patients and ethnically matched controls were included in this study: 8 patients with ulcerative colitis (UC) with age at onset below 16 years were also analyzed. DNA was isolated from peripheral blood leucocytes using salting out method. HISBT polymorphism was analyzed after DNA amplication by PCR using a sense primer 5{\'a2}ACACGCAGCTATGTTCCACCATCG3' corresponding to HISBT nucleotides 915-939 and a antisense primers 5{\'a2}TGAAATCGGATTGGCATGATTCCT3' corresponding to the flanking intron. After an initial denaturation step at 94\'b0C for 5 min, PCR amplification was performed with 100 ng of genomic DNA for 30 cycles using an annealing temperature of 64\'b0C. Brs-B1 digestion resulted in fragments that either remained untact (P at position 290 = allele 1) or were cut in two fragments (S at position 290 = allele 2). Fragments were analyzed by electrophoresis on 3% agarose gels containing 0.1% ethidium bromide.*Results:* Only one control, and 2 CD patients presented the HISBT mutation at position 290. All this 3 individuals were heterozygous for this gene. None of the UC patients or of CD patients with age at onset of symptoms below 16 years harbor the mutation.*Conclusions:* HISBT (P 290 S) was rare in controls and CD patients whatever age at onset of CD. These data argue against HISBT in pathogenesis of CD. Intestinal disorders: IBD, etiology and genetics }" "Are Mutation of the Human Ileal Sodium-Dependent Bile Acid Transporteur (HISBT) Gene Implicated in the Genetic Susceptibility to Crohn's Disease (CD)?"

"P P 19 0485"P 19 0485**The Amelioration of Acute Pancreatitis Using a TNF-Metalloproteinase Inhibitor**

*A.N. Kingsnorth, P. Skaife, M. Wood[1], N.S. Kulkarni[2]

Department of Surgery, University of Liverpool

[2] Department of Pathology, University of Liverpool

[1] British Biotechnology LaboratoriesTumour necrosis factor (TNF) is a potent pro-inflammatory cytokine that has been shown to be an important mediator in the development of both local and systemic sequelae associated with severe acute pancreatitis.The effect of a TNF metalloproteinase inhibitor BB1101, known to be active at the post-translational step in TNF production, was studied in the microvascular ischaemic model of acute pancreatitis in male Wistar rats. Administration of BB1101 (3 mg/kg), given as a single intraperitoneal dose 30 minutes *after* induction of acute pancreatitis, significantly reduced (p = 0.01) the rise of serum amylase (mean 2083; range 1646–2843) in treated animals *vs* controls (mean 2623; range 2071–3058), the pancreatic weight (p = < 0.005), (mean 1.16 g; range 0.84–1.4 g) *vs* controls (mean 1.75 g; range 0.96–2.23 g), and the histology score was also significantly reduced (p = < 0.001), (mean 8.25; range 5–11) *vs* control pancreata (mean 17; range 14–20).Pancreatic tissue levels of TNF are increased in experimental acute pancreatitis. Treatment with a TNF metalloproteinase inhibitor can ameliorate the disease progression and this may represent a new therapeutic strategy. "P P 19 0486"P 19 0486**Pancreatic Ischemia and Tissue Concentrations of IMIPENEM in Acute Experimental Pancreatitis****K. Kotzampassi, E. Eleftheriadis, V. Siarkou[1], A. Hrodotou, P. Skepastianos[1], N. Harlaftis, N. Gougleri**

Dept of Surgery, Faculty of Medicine, Univ. of Thessaloniki, Greece

[1] Dept of Microbiology, Faculty of Veter. Medicine, Univ. of Thessaloniki, GreeceIt is accepted that during the course of acute experimental pancreatitis pancreatic ischemia occurs; since Imipenem is considered as a well penetrating antibiotic into pancreatic tissue we decide to investigate its bioavailability in acute experimental pancreatitis in 72 Wistar rats subjected to sodium taurocholate pancreatitis or served as controls. Imipenem [Primaxin, Merck] was injected intravenously in a dose of 12.5 mg/100 g BW, while pancreatic microcirculation was monitored by laser Doppler flowmetry. At 30, 60 and 120 min, respectively, blood and pancreatic tissue were sampled for Imipenem concentration assessment by the thin layer diffusion on agar using the E. coli ATCC 25922 strain.

We conclude that in this model the pancreatitis induced reduction in pancreatic microcirculation lead to a diminution in pancreatic tissue concentrations; however Imipenem levels are higher than those of minimum inhibitory concentration for this strain of E. coli. }" "Pancreatic Ischemia and Tissue Concentrations of IMIPENEM in Acute Experimental Pancreatitis"

"P P 19 0487"P 19 0487**A Prospective Study of Hyperamylasemia and Post Pump Pankreatitis after Cardiopulmonary Bypass = Incidence, Significance and Risk Factors**

*\'dc Saritas, A. Saritas, O. Tarcan, N. Kantaroglu, A. Serin, O. Tasdemir, B. Sahin, K. Bayazit

Y\'fcksek Ihtisas Hospital, Departments of Gastroenterology, Cardiovascular Surgery and Biochemistry, Ankara, TurkeySevere acute pancreatitis is a rare but well defined complication of cardiac surgery performed under cardiopulmonary bypass (CPB). Hyperamylasemia is seen more frequently. In this prospective study, clinical importance and incidence of hyperamylasemia and post pump pancreatitis that develop after CPB and risk factors that have effects on these are investigated.Thirty-seven patients who had a cardiac operation under CPB between June 1995 and November 1995 are included in this prospective study. Serum amylase and lipase levels are measured 2 days before the operation and on the first hour and third day postoperatively. Patients with amylase levels above 220 U/L and lipase levels above 190 U/L are evaluated as post pump pancreatitis. Clinical, laboratory and hemodynamic parameters of these patients are compared with the drugs used, calcium chloride, blood transfusions and the amount of cardioplegia.Ten (%27.02) of 37 patients had high levels of amylase and lipase. All the patients had abdominal symptomps. One of the patients who had severe pancreatitis was dead on the 63. postoperative day due to multiple organ failure. There was no statistically significant correlation between post pump pancreatitis and age, sex, body weight, cardiac pathology, cardiac output, cardiac index, adjunctive treatment, accompanying diseases (diabetes mellitus, hypertension), intraoperative hypothermia, hypotension, central venous pressure, hematocrit and period of mechanical ventilation. CPB time and cross clamp time were significantly ($p = 0.0283$, $p = 0.05$) longer in the pancreatitis group. The amount of calcium chloride used intraoperatively and the amount of blood transfused were marginally significant ($p = 0.0667$, $p = 0.0908$). The correlation between the amount of cardioplegia and pancreatitis was highly significant ($p = 0.007$). There was no correlation between the time of intensive care unit and pancreatitis; but the correlation with time of postoperative hospital stay was significant ($p = 0.0274$).In conclusion, post pump pancreatitis is a common complication of CPB procedure, but severe pancreatitis is rare. It is a fatal condition when seen together with multiple organ failure. Long CPB and cross clamp times, excessive amounts of calcium chloride, cardioplegia and blood transfusions increase the risk of post pump pancreatitis. They increase the postoperative morbidity. Post pump pancreatitis that is frequently overlooked, remain undiagnosed and treated lately should be remembered in patients who have abdominal symptoms following cardiac operations; and the risk factors should be tried to be decreased. Intestinal disorders, absorption: Malabsorption syndromes }" "A Prospective Study of Hyperamylasemia and Post Pump Pankreatitis after Cardiopulmonary Bypass = Incidence, Significance and Risk Factors"

"P P 19 0488"P 19 0488**Necrotizing Pancreatitis with Sterile Percutaneous Aspiration: Clinical and Bacteriological Outcome**

*F. Paye, N. Rotman, A. Salvat, M. Julien, P.L. Fagniez

Centre Hospitalo-Universitaire Henri-Mondor, 94010 Cr\'e9teil, FranceDiagnosis of necrosis infection is a crucial point in the management of necrotizing pancreatitis. Infection of necrosis requires surgical drainage but the treatment of sterile necrosis is still debated. In order to evaluate the significance of sterile necrosis on the outcome, we studied 17 patients with initially sterile percutaneous aspiration of pancreatic necrosis.Seventeen patients, hospitalized for necrotizing pancreatitis with signs of sepsis, had a first sterile CT- guided aspiration. Eight patients underwent a simultaneous percutaneous drainage of the punctured collection. A supportive therapy was carried on, unless severe bioclinical deterioration or secondary infection of necrosis proven by iterative percutaneous aspiration indicated surgical necrosectomy and drainage.Among the 8 patients drained percutaneously, one died of septic shock, one was cured without sequellae and one had a pseudocyst treated by cystogastrostomy. Five patients were operated on and one died. Four of them had infected necrosis. Among the 9 patients who underwent only percutaneous aspiration, 7 were operated on, 2 had infected necrosis and 3 died. Secondary infection of necrosis was observed in 2 among 9 patients who had only fine needle aspiration of the collection (22%) and in 7 out of the 8 patients drained percutaneously (88%) (p = 0.03). Hospital mortality rate reached 29% and was not affected by the bacteriological status of necrosis.Initial sterile aspiration of collections in severe acute pancreatitis did not warrant a favourable course and secondary infection of necrosis was observed in 65% of the patients. Percutaneous drainage of sterile collections favours secondary infection of necrosis and is not recommended. Pancreas: Pancreatitis, acute }" "Necrotizing Pancreatitis with Sterile Percutaneous Aspiration: Clinical and Bacteriological Outcome"

"P P 19 0489"P 19 0489**Relationship between Neopterin Serum Levels and Severe Outcome of Acute Pancreatitis**

*G. Uomo, S. Misso[1], G. Manes, O. Spada[2], B. Feola[1], A. Minerva[1], M. Laccetti, P.G. Rabitti

[1] Pancreas Unit, Immunohaematology, City Hosp., Caserta, Italy

[2] Pancreas Unit, Haematology, Cardarelli Hospital Napoli, Caserta, Italy*Aim:* of this study was to estimate neopterin (N), a useful *in vivo* marker of macrophages activation, in the prognostic assessment of acute pancreatitis (AP). Serum levels of N (mmol/ml), interleukin-6 (IL-6; pg/ml) and tumor necrosis factor (TNF; pg/ml)) were measured in the 1st and 7th days of hospital admission in mild AP (n = 24) and severe AP (n = 17) – Atlanta classification-. Statistical analysis was performed by means of 2-way ANOVA, nonparametric tests and Spearman's correlation method.*Results:* N was significantly higher in severe AP (day 1: 42.9 – 30,; day 7: 111.3 – 46.7) than in mild AP (day 1: 28.6 – 10.2; day 7: 21.4 – 7.6); both groups showed higher values than controls (12.1 – 4.4) at admission, while at 7th day only values of patients with severe disease were significantly higher than controls. Considering intragroups data (severe and mild AP) N serum levels were significantly higher ($p < 0.0001$) in the 7th than in the 1st day in patients with severe forms only. Cutoff level of 40 mmol/ml reached a specificity and sensitivity of 92% in discriminating mild from severe AP at 7th day. No difference was observed as concerns TNF values. IL-6 at admission was significantly higher in severe *vs* mild AP and controls; in the severe AP, IL-6 serum levels at 1st day were significantly higher than values at 7th day. No correlation was found between N and IL-6 serum level.*Conclusions.* Initially enhanced N and IL-6 serum levels reflect the severity of the disease; N may be considered a reliable prognostic parameter also at a distance of AP onset, because it increases during the first week of AP in patients with severe forms only. Pancreas: Pancreatitis, acute }" "Relationship between Neopterin Serum Levels and Severe Outcome of Acute Pancreatitis"

"P P 19 0490"P 19 0490**Role of Cell Calcium Overload in the Course of Conversion of Edematous to Necrotizing Pancreatitis: Effects of Verapamil on Cytosolic Free Calcium of Rat Pancreatic Acini**

*J. Shen, Z.P. Wu, H. Xiao, Y.H. Song, M. Liu

Department of Surgery, Sichuan Continuing Education College of Medical Sciences, Chengdu 610041, P. R. ChinaSince calcium channel blockades could improve the pancreatic circulation, limit the prostaglandin imbalance and influence the development of acute pancreatitis (AP), the influx of calcium ions may play an essential role in the pathophysiology of AP. Acute experimental pancreatitis was inducted by biliopancreatic retrograde injection of 4.5% sodium taurocholate solution (0.1 ml/30 s/100 g) in 140 SD rats. In the treated group, a dose of 0.1 mg (0.25 ml/100 g) verapamil was given intraperitoneally at 5 min after induction of AP. Morphological alterations of the pancreas were monitored by histological and ultrastructural techniques, the intracellular free calcium concentration ((Ca2+)i) of pancreatic acinar cells was measured with Shimazu 5000-RF fluorescence spectrophotometer in the three groups.The results demonstrated that a characteristic feature of early phase of acute necrostic-haemorrhagic pancreatitis was at 2 and 3 hrs following induction of AP. After induced AP, the pancreatic acinar cell (Ca2+)i was increased from sham-operated control (163.04 – 13.39 nM) to its highest (402.75 – 17.54 nM) at 2 hrs after induced AP in the AP group ($P < 0.001$). In the treated group, the pancreatic acinar cell (Ca2+)i was lower than that in AP group significantly ($P < 0.001$). The correlation between the pancreatic acinar cell (Ca2+)i and the severity of pancreatic damages was significant ($r_s = 0.9227$, $P < 0.001$) in the AP group. The verapamil treated rats exhibited significant increase in the survival rate and survival time. They also showed decrease in the severity of pancreatic heamorrhage and necrosis, and reduced the damages to the pancreatic cellular ultrastructures. These data suggest that in the early stage of AP, the cell calcium overload maybe a key role in the pathophysiology of bile-induced acute experimental pancreatitis in rats and prevent the cell calcium overload is a important role in therapeutic pathogenesis of calcium channel blockades treated AP. Pancreas: Acinar, duct cell functionPancreas: Pancreatitis experimentalPancreas: Pancreatitis, acute }" "Role of Cell Calcium Overload in the Course of Conversion of Edematous to Necrotizing Pancreatitis: Effects of Verapamil on Cytosolic Free Calcium of Rat Pancreatic Acini"

"P P 19 0491"P 19 0491**Early Indicators of the Need of Parenteral Nutrition in Acute Pancreatitis**

*P. Lage, J. Reis, M.E. Camilo, A. Figueiredo, A. Coutinho, P. Alexandrino, M. Carneiro Moura

Servi\'e7o de Medicina II, Hospital Santa Maria, Lisbon, Portugal*Background:* The institution of parenteral nutrition (PN) in acute pancreatitis (AP) is controversial. It is an useful adjuvant therapy when treating AP complications but there are no clinical/laboratory indices for early PN. In a previous retrospective study it was found that persistence of ileus at the 5th day, serum albumin < 2.9 g/dl, 20% reduction of Hb or hypocalcemia < 1.78 mmol/l at 72 hrs could be early indicators of the need of PN. *Aims:* To prospectively evaluate the previous indices as predictors for early institution of PN, according to a protocol. *Patients and methods:* Between 1991–6, were admitted, to our ICU, 179 patients with AP. PN was prescribed in 45 (25%) patients: 25 male and 20 female with an mean age of 54 (19–76) years. The pancreatitis aetiology was biliary in 20 (44%), alcohol in 18 (40%) and other in 7 (16%) patients. We have prospectively evaluated Ranson criteria, clinical and laboratory indices that were considered indicators for PN, morbidity and mortality. *Results:* The mean Ranson criteria was 4.6 – 2.1 (0–8), 42/45 (93%) patients developed complications, which were local in 7, systemic in 1 and both in the remaining 34 patients and the mean hospital stay was 24.7 – 16.8 (6–100) days. Early PN was started in 24 patients (group I), 4 with ileus and 20 with at least one of the previous laboratory parameters; all patients with albumin < 2.9 g/dl or a 20% reduction of Hb at 72 hrs developed local complications. In 14 patients (group II) PN was prescribed because local complications developed although none of the previous early indicators were present. The protocol was not followed in 7 patients (group III): in 4 of them early laboratory and/or clinical indicators were present but early PN was not prescribed, while in the remaining 3 patients there was no clear evidence for the need of PN. Mean time for PN onset was 4.5 – 1.4, 7.9 – 5.6, 9.4 – 4.5 days (p = 0.003) and its mean duration was 14 – 12.9, 9.4 – 4.3, 7.4 – 4.7 days (p = 0.2) in group I, II and III, respectively. Severe hypocalcemia was associated with mortality (p = 0.008). *Conclusion:* The proposed laboratory indices are associated with a more severe clinical course and proved to be useful as early indicators for the need of PN. "P P 19 0493"P 19 0493**A New Prognostic Scoring System for Patients with Acute Biliary Pancreatitis**

*T.A. Marek, A. Nowak, E. Nowakowska-Dulawa, R. Kaczor

Department of Gastroenterology, Silesian Medical Academy, Katowice, Poland*Background:* The use of urgent endoscopic sphincterotomy (ES) for acute biliary pancreatitis (ABP) decreases the efficiency of presently used prognostic scoring systems (PSS). None of presently used systems includes the influence of ES. Construction of the new system, overcoming this problem, was the aim the study.*Material and methods:* The study comprised 150 consecutive patients with ABP treated by urgent ES from May 1993 through September 1995. The outcome was graded as mild (74%), complicated (19%) or fatal (7%). Clinical and laboratory factors significantly different in mild (uncomplicated) and severe (complicated and fatal) ABP, with specific cut-off points, were selected. The set of factors for the new system was chosen by the stepwise logistic regression. Sensitivity, specificity, accuracy, and Youden's index were used to compare the efficiency of the new and presently used PSS.*Results:* Nine-factor system (called ""Katowice"") was found to have the best prognostic efficiency. The system includes: interval between onset of ABP and ES (> 48 h), C-reactive protein (> 240 mg/L), heart rate (> 115/min), WBC (> 11 G/L), glucose (> 130 mg/dL), creatinine (> 1.6 mg/dL), p_aO_2 (< 70 mmHg), total protein (< 5.9 g/dL), and calcium (< 8.2 mg/dL). For all factors the worst result during first 48 hours in the hospital is evaluated; 4 or more positive factors predicts severe ABP. Table presents the comparison between ""Katowice"" and other PSS: Ranson Glasgow AP II CT KatowiceSensitivity 46% 67% 69% 54% 92%Specificity 92% 87% 79% 88% 93%Accuracy 80% 82% 77% 79% 93%Youden's index 0.38 0.54 0.49 0.42 0.85*Conclusion:* New system ""Katowice"" appears to be more efficient in the prediction of severity in ABP, especially in ES-treated patients. "P P 19 0494"P 19 0494**Oxygen Free Radicals and Complications of Acute Biliary PancreatitisA. Dziurkowska-Marek,**

*T.A. Marek, A. Nowak, T. Kacperek-Hartleb, E. Sierka, E. Nowakowska-Dulawa

Department of Gastroenterology, Silesian Medical Academy, Katowice, Poland*Background:* Oxygen-derived free radicals (OFR) are generated in the early phase of acute pancreatitis. The degree of oxidant-antioxidant balance changes reflects the outcome of the disease. The aim of the present study was the evaluation of relationship between type of complications and the intensity of OFR generation.*Material and methods:* The study comprised 74 consecutive patients with ABP, treated from October 1994 through September 1995. Plasma levels of malonyldialdehyde (MDA; 56 patients) and sulfhydryl groups (SH; 73 patients) were chosen as the indicators of OFR generation and antioxidant capacity of the organism, respectively.*Results:* Uneventful recovery (RC) was observed in 47 (63%) patients. Systemic complications (SC) alone developed in 14 patients (19%), whereas pancreatic complications (PC) were found in 13 (11 with systemic also) cases (18%). 3 patients with pancreatic complications (1 – sterile, 2 – infected necrosis) died (DE). Table presents the selected levels of plasma MDA and SH in above three groups of patients: RC SC PC DE *p, ANOVA*MDA no of pts. 36 10 7 3 admission 9.5 10.8 8.8 12.4 0.0045mean maximum 11.7 13.6 12.7 16.2 0.0009[nmol/mL] increase (%) 24.6 26.3 47.4 32.2 0.0152SH no of pts. 46 14 10 3 admission 311.4 289.9 295.3 326.7 0.6426mean minimum 230.3 206.0 194.2 166.3 0.0011[nmol/mL] decrease (%) 24.4 27.4 33.0 50.4 0.0015*Conclusion:* The generation of oxygen-derived free radicals seems to be more prominent when local (pancreatic) complications of ABP are present. "P P 19 0495"P 19 0495**A 21 Years Experience in Surgical Management of Acute Necrotizing Pancreatitis (ANP)**

*Zhang Sheng-Dao, Zhang Chen-Lie, Tang Yao-Qing

Dept. of Surgery Rui-Jin Hospital, Affiliated to Shanghai 2nd Medical University, Shanghai, ChinaFrom 1974 to 1995, 243 patients with ANP proved by operation or CT scanning were hospitalized. The severity of the disease had been evaluated by CT scoring system. The overall survival rate of this group was 70.4%.During 21 years basing on the understanding of the development of ANP by degrees, combining with our own experimental work, we changed the strategy in the surgical treatment of ANP twice.In the First stage (1974 – 1987), the strategy of treatment was resection of the necrosis as radical as possible, as early as possible, and the main type of operation was subtotal pancreatectomy. The survival rate of this period was 61.3% (49/80).In the second stage (1988 – 1991) inspired by our own experimental work, we recognized the importance of infection. And the strategy of the treatment had been changed into ""Individualization"" which means ""In case of the pancreatic necrosis sterile, the conservative treatment is the first choice. In case of pancreatic necrosis infected, necrosectomy is performed early."" In this period, the survival rate of conservative treatment was 85.7% (6/7); that of operative treatment was 67.1% (57/85) and overall survival rate of this period was 68.5% (63/92).In the third stage (1991 – 1994), we insisted: 1. late operation for the patient with necrosis infected; 2. comprehensive management for all patients with ANP. The survival rate of conservative treatment of this period was 100% (11/11); that of operative treatment was 80% (48/60), and overall survival rate of this stage was 83.1% (59/71).We conclude that comprehensive management combined with late operation for the patients with necrosis infected is a better strategy for the treatment of ANP. Pancreas: Pancreatitis, acute }" "A 21 Years Experience in Surgical Management of Acute Necrotizing Pancreatitis (ANP)"

"P P 19 0496"P 19 0496**Gabexate Mesilate (FOY’) Inhibits Sphincter of ODDI Motility in Patients with Acute Recurrent Pancreatitis**

*V. Di Francesco, G. Angelini, P. Bovo, A. Castagnini, M. Filippini, B. Vaona, L. Frulloni, L. Rigo, M.P. Brunori, G. Borsini, G. Cavallini

Gastrointestinal Unit, University of Verona, ItalyGabexate Mesilate (GM), is an anti-protease drug which has been shown to be effective in the treatment of acute pancreatitis and recently also in the prevention of post-ERCP pancreatitis. GM action on sphincter of Oddi (SO) motility has not been investigated so far. Aim of our study was to verify SO motor response to an acute administration of GM in a group of patients with the same indication for SO manometry. Eight patients (5 M, 3 F, mean age 46 – 8 years), who had suffered from recurrent attacks of acute pancreatitis at least 3 months before the examination, entered the study. After an overnight fast they were sedated with diazepam 10 mg i.v. an then submitted to SO manometry. The procedure was performed endoscopically by using a perfusion system, connected to a computerized system (Polygram Synectis, Sweden) and a triple lumen modified catheter, with two recording and one aspirating channel (Wilson-Cook, USA). After a stable basal registration at least 1 min long was obtained, GM 100 mg i.v. was infused and the registration repeated. Intraduodenal pressure was taken as zero reference and then basal SO pressure, amplitude and frequency of phasic contractions (PC), area under the curve were calculated before and after GM administration. Wilcoxon Rank Test for paired data was used for statistical analysis.*Results:* two patients showed a picture of SO stenosis without any evident phasic activity. In these cases GM infusion did not affect manometric findings. In the other 5 patients with normal basal pressure, with a latency of about 1 min, GM administration caused a reduction of phasic sphincter activity, both in terms of PC amplitude and frequency (Table: value expressed as mean – SE). Before GM After GM PBasal pressure (mmHg) (n = 8) 39.5 – 2.8 36.5 – 10.5 0.061PC amplitude (mmHg) (n = 6) 196 – 68 89 – 37 0.021PC frequency (n/min) (n = 6) 5.5 – 1.1 3.75 – 1 0.021Area (mmHg {\'b4} 1 min) (n = 8) 6205 – 2495 3173 – 621 0.014In conclusion our preliminary data suggest that 1) GM induces SO motility inhibition and this action may be important in the treatment and prevention of pancreatitis; 2) GM affect manometric results, thus it must be avoided during SO manometry or, when GM prophylactic infusion is indicated, this must start after manometry. Pancreas: Pancreatitis, acute }" "Gabexate Mesilate (FOY®) Inhibits Sphincter of ODDI Motility in Patients with Acute Recurrent Pancreatitis"

"P P 19 0498"P 19 0498**Monitoring of Neutrophil Function and Inflammatory Mediators in Acute Pancreatitis**

*I. G\'e1l, E. Ro˝th, J. Lantos[1], J. Nagy[1]

Department of Surgery, Bugat Pal Hospital, Gy\'f6ngy\'f6s, Hungary

[1] Department of Experimental Surgery, University Medical School of P\'e9cs, HungaryAlthough it is generally accepted, that inflammatory mediators and polymorphonuclear leukocytes (PMN) play important role in acute pancreatitis the inflammatory response reaction seems to be less investigated in the clinical practice. The current experiments were designed, to evaluate the stimulated state of neutrophils, to detect the changes of acut phase protein in patients suffering from acute pancreatitis. Peripheral venous blood samples were collected from 14 patients to measure the following markers: superoxide radical generation capacity of isolated neutrophils, enzyme level of myeloperoxidase (MPO), and PMN-elastase in the plasma, C-reactive protein (CRP) in the sera. The observation period started on the day of hospital admission and ended on the 20th day. All patients were treated conservatively because of their uncomplicated disease. Our results showed that superoxide radical production of isolated PMN was depleted alredy on the first day and the lowest value was registered on the 8-10th days (3.72 – 0.92 and 3.05 – 1.19 nmolO^2/min/1.5 {\'b4} 10^6 PMN respectively). The normal O^2 production of PMN was detected only at the end of observation period (13.14 – 1.98 nmolO^2/min/1.5 {\'b4} 10 PMN). In contrast MPO activity increased until the 6th day/1.23 – 0.28 to 2.50 – 0.61 OD/ml respectively) reaching the normal value after 2 weeks (0.84 – 0.19 OD/ml). There was an elevation of PMN-elestase at the time of hospital admission (65.8 – 10.8 ng/ml), comparing to the reference value (35.1 – 2.4 ng/ml), which persisted during the first week and was followed by a continuous fall towards the normal value on day 20. Measurement of CRP revealed that at the time of patients admission it was much higher than normal (83.4 – 32.2 mg/l) and remained on this level during the first 4 days. Mean values of CRP normalised on the 8–10th day (0–10 mg/l) and remained within this range during the further observation period.Our results suggest that functional state of neutrophils and C-reactive protein are in close correlation with the improvement of clinical outcome during the course of acute pancreatitis. The continuous monitoring of these parameters may give useful information to the clinical state and help to set up therapeutic strategies.

"P P 19 0499"P 19 0499**The Relationship between Polyamines Metabolism and Phospholipase D Activity in Isolated Pancreatic Acini and during Regeneration after Acute Pancreatitis in Rats***

*G. Rydzewska, G. Jurkowska, A. Gabryelewicz

Gastroenterology Dept. Medical School, Bialystok, PolandRecently we have shown the involvement of phospholipase D activity and the importance of polyamines metabolism in pancreatic recovery after AP. The aim of the present study was to evaluate possible relationship between polyamines metabolism and PLD activity during caerulein (Cae) induced AP and *in vitro* in isolated pancreatic acini. *Methods:* The AP was induced by sc. injections of Cae in gelatin (12 \'b5g/kg). Rats were then divided into six treatment groups: control + saline (C), control + ornithine decarboxylase inhibitor (ODC) { a}-difluoromethylornithine (DFMO) (C + DFMO), AP + saline (AP), AP + DFMO, AP + putrescine (AP + P), AP + DFMO + P, and treated for 2, 7 and 14 days. DFMO was given: 3 {\'b4} 300 mg/kg b.w. i.p. during the first 3 days (1 day before and during 2 days of Cae injections) and during 2, 7 and 14 days of treatment, and additionally as 2% solution in drinking water during the first 3 days in C + DFMO, AP + DFMO and AP + DFMO + P groups. Putrescine was given 4 mg/kg b.w. i.p. tid. After the treatment, rats were sacrificed and pancreatic acini were prepared and loaded with ^{3}H myristic acid to measure ^{3}H phosphatidic acid (PA), a marker of PLD activity. *In vitro:* Pancreatic acini from healthy rats were prepared, loaded with ^{3}H myristic acid, preincubated 30 min. with 1 mM DFMO and stimulated with 500 pM Cae. After 30 min. of stimulation ^{3}H PA was separated and counted. *Results:* PLD activity was significantly elevated after 2 days and returned to control value after 7 and 14 days of AP. Treatment with DFMO significantly increased PLD activity in control animals and partially prevented the increase of PLD activity after 2 days of AP; DFMO did not influence PLD activity after 7 and 14 days of AP. Putrescine intake did not change PLD activity after 2 and 7 days, but increased this activity after 14 days of treatment. After 2 days in AP + DFMO + P group PLD activity was also comparable to AP; DFMO did not prevent the influence of putrescine. *In vitro* pretreatment with DFMO did not change Cae stimulated PLD activity in pancreatic acini. *In vivo* study suggests that inhibition of polyamines synthesis rather stimulates PLD activity in control and AP groups (except 2nd day of AP). However *in vitro* pretreatment of acini with DFMO did not change basal and Cae stimulated PLD activity. *Conclusions:* Inhibition of polyamines synthesis does not directly influence PLD activity in rat pancreatic acini *(in vitro* study), and modulation of this activity observed *in vivo* is dependent rather on indirect effects of polyamines metabolism on intracellular signaling pathways. It seems that polyamines metabolism and PLD activation are separated pathways leading to pancreas growth.* partly supported by the grant KBN 4 S402 0306 Pancreas: Acinar, duct cell functionPancreas: Pancreatitis experimentalPancreas: Pancreatitis, acute }" "The Relationship between Polyamines Metabolism and Phospholipase D Activity in Isolated Pancreatic Acini and during Regeneration after Acute Pancreatitis in Rats*"

"P P 19 0500"P 19 0500**The Role of Transforming Growth Factor { b}s in Human Acute Pancreatitis: Repair Mechanism?**

*H. Friess, L. Zhao, E. Riesle, A. Zimmermann, L.I. Gold, M. Korc, M.W. B\'fcchler

Department of Visceral and Transplantation Surgery and Institute of Pathology, University of Bern, Switzerland

Department of Pathology, New York, University Medical Center, USA

Departments of Medicine and Biological Chemistry, University of California Irvine, USATransforming growth factor (TGF)-{ b}1, -{ b}2, and -{ b}3 are multifunctional polypeptides that have been implicated in the regulation of cell growth and the formation of extracellular matrix and fibrosis. Upregulation of TGF-{ b} transcription has been reported in several in vivo models of tissue injury and repair. In the present study we examined the expression of TGF-{ b}1, TGF-{ b}2, TGF-{ b}3 in relation to changes in collagen expression during the course of pancreatic remodeling process following acute pancreatitis (AP) in humans and in an experimental model of AP.*Design:* Pancreatic tissue samples were obtained from 13 patients (median ranson score: 6 (range 1–9)) with a median age of 65 years (range: 37–77 years) with necrotizing AP undergoing necrosectomy. Operation was performed on day 5.5 (range 4–17) after the onset of AP. Tissues obtained from 12 previously healthy organ donors (median age: 43 years) served as controls.In male rats (body weight 240–260 g) AP was induced by cerulein infusion (10 \'b5g/kg body weight/h) for 4 hours. 4, 8, 24 hours, 2, 3, 4, 5, 6, and 7 days following AP induction the rats were sacrificed and the pancreas was removed.*Methods:* The expression of TGF-{ b}1, -{ b}2, -{ b}3, amylase and collagen was analyzed by Northern blot analysis. In addition, immunohistochemical analysis using TGF-{ b} isoform-specific polyclonal antibodies was performed.*Results:* By Northern blot analysis there was a marked increase in TGF-{ b}1, and TGF-{ b}3 and a slight increase in TGF-{ b}2 mRNA expression in the human AP samples. In contrast, amylase mRNA expression was markedly decreased and collagen mRNA was increased in human AP. Immunohistochemistry demonstrated intense TGF-{ b}1–3 immunoreactivity in the remaining acinar and ductal cells in human AP.Induction of AP in rats led to a biphasic peak pattern of TGF-{ b}1–3 mRNA expression with a marked increase between day 1 to 3 and again at day 5 to 7. Immunostaining revealed moderate to strong TGF-{ b}1–3 immunoreactivity in the pancreatic acinar cells after induction of AP whereas only weak TGF-{ b} immunoreactivity was present in a few cells of the normal pancreas.*Conclusion:* Overexpression of TGF-{ b}s might play an important role in pancreatic repair and remodeling after AP. The enhanced levels of TGF-{ b}s might contribute to the changes in the extracellular matrix and to the repair process which occurs after pancreatic damage. Support: SNF grant 32-39529. "P P 19 0501"P 19 0501**Effects of CCK-A Receptor Antagonist (Devazepide) and Nitric Oxide Synthase Inhibitor (L-Name) on Acute Pancreatitis in Rats**

*H. Yamada, D. Chen, K. Kimura, R. Hakanson

Department of Pharmacology, University of Lund, Lund, Sweden*Background/aim:* Although the pathogenesis of acute pancreatitis is poorly understood, CCK is thought to play a role. The purpose of the study was to examine possible protective effects of a CCK-A receptor antagonist (devazepide) and a nitric oxide synthase inhibitor (L-NAME) on two types of acute pancreatitis.*Methods:* Male Sprague-Dawley rats weighing 200–300 g were used. Acute pancreatitis was induced as follow: (1) Caerulein (CR)-induced pancreatitis; CR (5.0 \'b5g/kg/h) was infused intravenously for 4 hrs. (2) Taurocholate (TC)-induced pancreatitis; 200 \'b5l of 4.0% sodium taurocholate was injected retrogradely into the pancreatic duct. Devazepide (60 \'b5g/kg) and L-NAME (N^G-nitro-L-arginine methyl ester, 60 mg/kg) were given by intravenous bolus injection 30 min before the administration of CR and TC. Controls received 0.9% NaCl. Body weight, pancreatic wet weight, serum amylase levels and plasma CCK concentration were measured.*Results:* (1) Serum amylase levels, plasma CCK concentration and pancreatic wet weight were increased after CR administration. The increase in serum amylase levels and pancreatic wet weight was prevented by devazepide or L-NAME. (2) Serum amylase levels, plasma CCK concentration and pancreatic wet weight were increased after TC administration. Devazepide or L-NAME was without effect.*Conclusions:* Devazepide and L-NAME prevented caerulein-induced pancreatitis, but failed to inhibit taurocholate-induced pancreatitis. "P P 19 0502"P 19 0502**Effect of Early Jejunal Feeding on Septic Complications in Acute Pancreatitis: A Prospective, Randomized Study**

*A. Ol\'e1h, G. Pardavi, Gy. Varga, T. Bel\'e1gyi

Petz Alad\'e1r County Hospital, Dept. of Surgery, Gyo˝r, Hungary*Purpose of study:* The necrotized tissue of pancreas is colonized by bacteria mainly from the colon which may lead to abscess or infected necrosis. Our purpose was to prove, that early jejunal feeding — preventing the atrophisation of mucosa and disruption of mucosal mechanical barrier, preventing the increased permeability and bacterial translocation, decreasing the paralytic condition and distension of colonic wall and preserving the normal colonic bacterial flora — can reduce the rate of septic complications.*Patients and method:* The study included 64 patients admitted to our department in 1995 with acute, non-biliary pancreatitis, randomizing into two groups. In group ""A"" (n = 30) jejunal feeding was started in the first 24 hours (Survimed OPD). In group ""B"" (n = 34) conventional parenteral nutrition was applied. Between the two groups neither in the male:female ratio (23:7 and 30:4), nor in the average age (47.2 and 43.8 years) nor in the etiology (21 and 25 alcoholic; 9 and 9 idiopathic) were significant difference found.*Results:* Necrosis developed altogether in 20 patients (31.3%). In group ""A"" two infected necrosis, one abscess and five sterile necrosis were detected. In group ""B"" five infected necrosis, five abscess and two sterile necrosis were found. Septic complication due to bacterial contamination developed so in 3 cases in group ""A"" (10%) and in 10 cases in group ""B"" (29.4%). Statistical difference is marginally significant (p = 0.09; Fisher-test). In group ""A"" five patients, in group ""B"" ten patients underwent operating procedure. The difference in the mortality rate was not significant between the two groups (2 and 4 patients; p = 0.42).*Conclusion:* Our results suggest that early jejunal feeding in the treatment of acute pancreatitis can reduce the rate of bacterial contamination of necrotized pancreatic tissue, mainly in the later phase of disease, after the first week. Pancreas: Pancreatitis, acute }" "Effect of Early Jejunal Feeding on Septic Complications in Acute Pancreatitis: A Prospective, Randomized Study"

"P P 19 0503"P 19 0503**Experimental Study on the Usefulness of Hemodiafiltration in Decreasing Contrast Medium of the Therapy of Severe Acute Pancreatitis**

*M. Sogabe, T. Okahisa, S. Hayashi, S. Taoka, H. Matunaga, Y. Ohkita, A. Tsutsui, T. Fukuda, N. Muguruma, M. Yasuda, T. Yokoi, S. Okamura, H. Shibata, S. Ito

Second Department of Internal Medicine, School of Medicine, The University of Tokushima, Tokushima, Japan*Purpose:* Contrast-enhanced computed tomography (CECT) is used to detect poorly perfused areas in severe acute necrotizing pancreatitis. However, intravenous contrast media increase acute renal failure. We studied the efficacy of Hemodiafiltration (HDF) in decreasing contrast medium in the blood in *in vitro* bovine blood models.*Methods:* HDF was performed for 6 hrs (blood flow; 100 ml/min, dialisate flow; 10 ml/min, filtrate flow; 10 ml/min) using a polysulfone filter (PS filter CF, surface area; 0.7 m^2, Kuraray Co. Ltd., Japan). The extracorporeal circuit was anticoagulated with nafamostat mesilate (Torii Co. Ltd., Japan) at 30 mg/hr. After the start of HDF, 200 ml of contrast medium (Iomeprol 300, 300 mgI/ml, MW 777, Eizai Co. Ltd., Japan) was added to the 5 L of blood in the tank. Iomeprol was measured in blood and ultrafiltrate with HPLC. Clearance (CL), half-life time (t1/2) and elimination rate (ER) were calculated.*Results:* The clearance was 18.1 ml/min. The half-life time was 1.8 hrs. After 6 hrs, 89.3% of IPM was eliminated in ultrafiltrate by HDF (ER 1 hr = 24.4%, ER 2 hrs = 46.1%, ER 4 hrs = 75.4%, ER 6 hrs = 89.3%).*Conclusion:* Iomeprol was easily filtrated by HDF. If HDF is applied to severe acute pancreatitis at the time of CECT, the risk of renal failure will be decreased. Pancreas: Pancreatitis, acute }" "Experimental Study on the Usefulness of Hemodiafiltration in Decreasing Contrast Medium of the Therapy of Severe Acute Pancreatitis"

"P P 19 0504"P 19 0504**Treatment of Severe Acute Pancreatitis Using Continuous Venovenous Hemodiafiltration**

*T. Okahisa, M. Sogabe, S. Hayashi, S. Taoka, H. Matunaga, Y. Ohkita, A. Tsutsui, T. Fukuda, N. Muguruma, M. Yasuda, T. Yokoi, S. Okamura, H. Shibata, S. Ito

Second Department of Internal Medicine, School of Medicine, The University of Tokushima, Tokushima, Japan*Purpose:* Although the effectiveness of continuous hemodiafiltration (CHDF) in treating severe acute pancreatitis has been reported, its efficacy has not yet been adequately studied. We evaluated whether CHDF leads to extraction of chemical mediators, which are related to the increase of multiple organ failure, from circulation of patients with severe acute pancreatitis and explored the optimum method of using CHDF to in treat severe acute pancreatitis.*Methods:* We used CHDF in 4 cases of severe acute pancreatitis. CHDF was performed for a mean of 13.5 days (range, 1–43 days) using a polysulfone filter (PS filter CF, surface area; 0.7 m^2, Kuraray Co. Ltd., Japan). The flow rate of CHDF was as follows; blood flow = 100 ml/min, dialisate flow = 10 ml/min, filtrate flow = 10 ml/min. The extracorporeal circuit was anticoagulated with nafamostat mesilate (Torii Co. Ltd., Japan) at 30 mg/hr. Cytokines (TNF { a}, IL-6 and IL-8), endotoxins and pancreatic enzymes (Trypsin, Phospholipase A2, Trypsin like activity) were measured in blood and ultradiafiltrate. Their clearance (CL) and elimination rate (ER) were calculated.*Results:* CHDF resulted in elimination of cytokines (ER (IL-8) = 5.8%/hr, ER (IL-6) = 1.7%/hr) and endotoxins (ER (endotoxin) = 1.2%/hr) into the filtrate and adsorption of these factors onto the filter. In addition, pancreatic enzymes suppressed by nafamostat mesilate (an anti-coagulant used during CHDF)(ER (TLA) = 1.3%/hr).*Conclusion:* CHDF leads to extraction of chemical mediators, which are related to the increase of multiple organ failure. At present, the principal role of CHDF is thought to be to control water and electrolytes in cases of sever acute pancreatitis complicated by renal failure. But if CHDF is used in the early stages of severe acute pancreatitis, the prognosis of this disease may be improved. "P P 19 0505"P 19 0505**Local Therapy with Octreotide (Sandostatin) in Acute Necrotic Pancreatitis and Pancreatic Pseudocysts**

*N. Grigorov, A. Mendisova

Clinical Centre of Gastroenterology, University Hospital ""Queen Joanna"", Sofia, Bulgaria*Aim.* Control and results of the local therapy in acute necrotic pancreatitis and pancreatic pseudocysts. *Clinical material and method:* 12 patients with acute necrotic pancreatitis (7 – in acute and 5 – in subacute stage) and 9 patients with formed pancreatic pseudocysts have been treated locally with Sandostatin applied 0.2 mg once or several times. This treatment has been performed on a background of the perceived by us as a routine percutaneous drainage and lavage under US-control and Sandostatin (0.1–0.3 mg daily s.c.). *Results:* The combined parenteral and local treatment coupled with percutaneous drainage reduces the healing period significantly, compared with that one from our previous studies (16/21 – 76.4%). This effect is also confirmed by the fact, that in 7 patients, who did not have a significant improvement (US and CT control) from the perceived until now basic therapy, the additional local application (via the catheter) of Sandostatin sharply improved the clinical state and shortened the healing period. *Discussion:* The pathogenic mechanism is probably connected with a direct influence on difficulty closing fistulas, which complicate this mechanism and make ineffective the basic procedures. With the exception of one patient (transitory flush and slight dyspepsia), the other did not show side effects. *Conclusion:* The local application of Sandostatin can be added to the therapeutic approach in acute necrotic pancreatitis and pancreatic pseudocysts, especially in protracted cases.

"P P 19 0506"P 19 0506**Pancreatic Elastase I in Serum: Low Sensitivity for Detection of Acute Pancreatitis**

*N. Teich, F. Fiedler, W. Hartig, G. Thiele, J. M\'f6ssner, V. Keim

Medizinische Klinik II, Universit\'e4t Leipzig, Germany

Inst. f. Anaesthesie Mannheim, Universit\'e4t Heidelberg, GermanyFor diagnosis of acute pancreatitis measurement of serum elastase is thought to offer the highest sensitivity. Due to its long half life in serum it is also assumed, that pancreatitis can still be detected by elastase measurement several days after onset of the disease. This was controlled in a series of 253 patients admitted to hospital due to acute abdominal pain.*Methods:* Samples were taken at admission, after 3–4 and 6–7 days. Concentrations of amylase, lipase (kinetic assay), elastase (Elisa), and C-reactive protein were measured. Further samples from 14 patients with proven acute pancreatitis were taken daily and the parameters noted above were analysed.*Results:* The main final diagnosis were acute cholecystitis (42 patients), ulcer (33), and acute pancreatitis (30). Serum elastase was elevated above control value (3.5 ng/mL) in only 23 of the patients 33 patients with acute pancreatitis (Sensitivity 73%) and in 7 of the remaining 220 patients without evidence for pancreatitis (specificity 97%). The sensitivity of lipase (97%) and amylase (82%) were higher whereas the specificity of both enzymes was 81 and 84%. In most patients with elevated elastase, the enzyme concentration was already normal after 4 days. Consequently, the sensitivity of elastase after 3 days was lower (20%) than for lipase (80%) or amylase (50%). Furthermore, serum samples from 14 separate patients with acute pancreatitis were taken daily and elastase, lipase, and amylase were measured. Amylase or lipase was elevated in all patients, whereas elastase was negativ in one. Highest values were measured at admission. Half life of amylase, lipase or elastase in serum was below 2 days. Sensitivity of elastase was 70% after two and only 25% after 3 days.*Conclusion:* Contrary to published data we found that for primary diagnosis of acute pancreatitis serum elastase is not superior to lipase and may also not be helpful in the later stage of the disease. "P P 19 0507"P 19 0507**Serum Pancreatic Elastase-1 in Acute Pancreatitis**

*C. Millson, K. Charles, P. Poon, J. MacFie, C.J. Mitchell

Combined Gastroenterology Service, Scarborough Hospital, United KingdomThe pathophysiology of acute pancreatitis (A. P) is complex, involving ischaemic injury, neutrophil infiltration and enzyme activation. Pancreatic Elastase 1 (PE-1) has been shown to play a key role in the consequent destructive inflammatory process and might therefore provide a useful marker to predict severity. We have used an ELISA method [Schebo Tech, Germany] to evaluate serum PE-1 in 25 patients with acute pancreatitis.Twenty-five patients (11 M, 14 F aged 29–93) with AP were studied. The diagnosis of AP was based on clinical criteria, a 3.5-fold rise in serum amylase and either CT or ultrasound scans. The aetiology of the AP was gallstones in 13, alcohol 2, idiopathic 6, and miscellaneous 4, and was graded as mild in 20 and severe in 5.. AP was graded using the Glasgow criteria. Serial measurements of CRP, amylase and PE-1 were evaluatedThere was no significant difference between PE-1 levels in mild (median 34, range 2–40) and severe (median 35, range 0–176) pancreatitis. The same was true for CRP and amylase. The serial levels of PE-1 were not significantly different in patients developing complications, in patients with mild and severe pancreatitis and in those patients who died. The correlation coefficient of PE-1 levels with amylase was 0.74 ($p < 0.001$).In this study, serum PE-1 correlated closely with serum amylase activity, but did not provide further prognostic information with respect to mortality or morbidity. "P P 19 0508"P 19 0508**Serum Pancreatic Elastase-1 as a Diagnostic Test for Acute Pancreatitis: A Prospective Evaluation**

*C. Millson, K. Charles, P. Poon, J. MacFie, C.J. Mitchell

Combined Gastroenterology Service, Scarborough Hospital, United KingdomThe proteolytic enzyme Pancreatic elastase 1 (PE-1) is an important marker of pancreatic pathology, however it has yet to be evaluated prospectively as a diagnostic test. This study examined the diagnostic value of serum PE-1 in all patients in whom acute pancreatitis was suspected.Over a 3 month period, all requests for amylase tests received in the laboratory were also tested for PE-1 using an ELISA test (ScheboTech, Germany). Patients with pancreatitis were identified by standard diagnostic criteria.Requests for amylase were made on 566 patients, (mean age 56.4 years, range 4–98). A diagnosis of pancreatitis was made in 25 (4%) patients Other diagnoses included non-specific abdominal pain 220 (39%), surgical intra-abdominal emergencies 63 (11%), biliary tract disease 39 (7%), carcinoma of pancreas 11 (2%) and chronic pancreatitis 7 (1%).. The sensitivity and specificity of PE-1 were 72% and 91% respectively. Diagnostic efficiency was 90%. This compares with sensitivity of 84% and specificity of 99% for serum amylase (using a cut-off of 3.5 {\'b4} normal).Measurements of serum PE1 as a diagnostic test for acute pancreatitis in patients presenting with abdominal pain confers no benefit above the use of the cheaper and widely available measurement of serum amylase. "P P 19 0509"P 19 0509**Role of Non Esterified Fatty Acids in Necrotizing Pancreatitis: An Experimental Study**

*F. Paye[1], J. Chariot, C. Roz\'e9

[1] Dept. of digestive surgery Hospital Saint Antoine, Paris, France

INSERM U410 Facult\'e9 X., Bichat, Paris, FranceNon-esterified free fatty acids (NEFA) released by pancreatic lipase are supposed to favor tissue necrosis by their detergent properties. The aims of this work were to determine if NEFA are released in blood stream and peritoneal cavity in a rat model of taurocholate-induced pancreatitis, and to precise their action on the necrotic process, using a specific covalent inhibitor of pancreatic lipase, injected intra-peritoneally (i.p.).Three groups of male anaesthetized Sprague-Dawley rats were studied. The first group (control, n = 5) was submitted to a sham laparotomy. In the second group (T, n = 10), a retrograde infusion of 0.3 ml/100 g of 5% taurocholate induced a necrotizing pancreatitis, followed by 4 i.p. injections of saline at 6 hrs intervals. The third group (T + THL, n = 10) received both the retrograde taurocholate and 4 i.p. injections of 1 mg of the lipase inhibitor tetrahydrolipstatin (THL). The animals were sacrificed after 24 hours by aortic puncture, preceded by a last saline i.p. injection. Ascitis was harvested, macroscopic lesions were scored, and the pancreas was removed for histological examinationThe taurocholate retrograde infusion induced pancreatic necrosis, extra-pancreatic fat necrosis, ascitis and pancreatic \'9cdema, absent in the control group. The raise of plasma and ascitis lipase levels was significantly less pronounced in the T + THL group than in the T group. Plasma NEFA levels were comparable in the 3 groups, whereas the raise of NEFA levels in the ascitis, observed in the T and T + THL groups compared to control, was significantly less pronounced the T + THL group than in the T group (0.31 – 0.02 mmol/l vs 0.75 – 0.1 mmol/l p < 0.01). Fat necrosis was also significantly less extended the T + THL group than in the T group.No measurable release of NEFA occurred in circulation in this experimental necrotizing pancreatitis. But a NEFA release by pancreatic lipase occurred in the abdominal cavity and could play a role, locally promoting fat tissue necrosis.

"P P 19 0510"P 19 0510**Early Microvascular Damage in Caerulein Induced Acute-Pancreatitis in the Rat**

*C.A. Hern\'e1ndez, C. Emparan, Z.G. Zhou, R. Jover-Clos, L. Bisaro, E. Hliba, S.D. Fahimi, N. Senninger

University of Cordoba, Universit\'e4tsklinikum Heidelberg*Introduction:* edematous acute pancreatitis induced by caerulein is a well known model used in experimental pancreatitis. In order to see the events produced in early steps of acute pancreatitis a model of subcutaneous injection of caerulein has been used.*Material and Methods:* 200 g. Wistar male rats were fasted overnight and were treated with: A) a volume of saline similar to that used in treatment groups (n = 6). B) subcutanaeously injected caerulein (5, 5, and 7.5 microg/kg weight) at the beginning of the experiment, hour 1 and hour 2 (n = 12). Four hours after the beginning of the experiment blood samples were collected, and tissue samples of the pancreas were taken for optic and electronic microscopy studies. In group B two different techniques were used for obtaining tissue samples 6 animals were fixed in glutaraldehyde, while the other six were perfused intaraortically with Ringer's lactate prior to introduce the glutaraldehyde and fixed the pancreatic tissue.*Results:* macroscopic findings of acute pancreatitis were found in caerulein treated group. Blood amylases were higher ({\'b4} 2) in caerulein treated groups in a similar way to the presented in the first 20–30 minutes of i.v. caerulein induced acute pancreatitis. Under optic microscopy vacuoles were shown in pre-sphinteric interlobular arteriolae, this damage was correlated with a great amount of vacuoles and early mitochondrial damage in endothelial and smooth muscle cells of pancreatic arterioles, and macrovasculature.*Conclusions:* subcutaneous induced acute pancreatitis correlates with early steps of other experimental designs such as i.v perfusion. In the early steps of acute pancreatitis vascular damage in endothelial and smooth muscle cells can be demonstrated, and are probably related with N.O. activity. "P P 19 0511"P 19 0511**Changes of Hormones in Pancreatico-Duodenal Vein in Acute Experimental Pancreatitis**

*A. Gidayatov, V. Gidayatova

Azerbaijan Medical University Baku, AzerbaijanIn the present study we investigated the levels of insulin (l), Glucagon (G), Somatostatin (SS) in pancreatico-duodenal vein (PDV) in acute experimental pancreatitis (AEP). The experiments were carried out on 10 dogs. The biliary pancreatitis was induced in 5 dogs. The other 5 dogs made up a control group. The blood for the studies was taken from PDV prior to the inducing of AEP and on the 3-rd day (at the height of pancreatitis development) relaparotomy was carried out and the blood was taken prior to the administration of Pancreozymin (PZ) (2 u/kg), at 20-th and 40-th min. after the PZ administration.*Methods.* The levels of hormones were determined by RIA.*Summary of the results.* The I level in PDV prior to the inducing of AEP was 99.4 – 4.7 \'b5u/ml; on the 3-rd day after the inducing of AEP the I level was reduced two-fold: to 40.5 – 6.2 \'b5u/ml ($p < 0.05$). The G concentration in PDV was 129.6 – 12.8 ng/ml; on the 3-rd day the hormone level was markedly increased up to 253.5 – 16.8 ng/ml ($p < 0.05$). The SS level was also considerably increased in AEP (from 60.9 – 7.6 pg/ml to 116.5 – 9.4 pg/ml; $p < 0.05$). The PZ administration in dogs with AEP caused the rise of the I level by 31%, as compared with the initial one; in control animals the I level was increased by 105% following the PZ administration. The G content in AEP in response to PZ was increased by 12%; while in control group the content of G was increased by 77%. The SS level in PDV the animals with AEP after the PZ administration, was increased by 30%. This index in the control group was 70%.*Conclusion.* The results of the present investigations showed that in AEP: 1) hypoinsulinemia, hyperglucagonemia and hypersomatostatinemia are observed in PDV; 2) the response reaction of hormones to the stimulus is markedly decreased. "P P 19 0512"P 19 0512**C-Reactive Protein in Comparison with Haptoglobin and Amylase as Indicators of Necrosis in the Early Phase of Experimental Acute Pancreatitis**

*Z.P. Wu, J. Shen, H. Xiao, Y.H. Song, M. Lui

Department of Surgery and Pancreatology Laboratory, Sichuan Continuing Education College of Medical Sciences, Chengdu 610041, P. R. ChinaTo clarify the relationship between changes in serum C-reactive protein (CRP) and pathological changes in pancreatic parenchyma, this study was performed by using dog model with acute pancreatitis (AP). The models were induced by intrapancreatoductal injection of fresh trypsin and trypsinbile mixture respectively for acute edematous and necrotizing pancreatitis (AOP and ANP) in 24 dogs. CRP, heptoglobin (HPT) and amylase levels in the serum were determined for 2 and 4 hrs after the development of AP.At 2 hrs after the development of AP, amylase level rose directly in both pancreatitis groups (P < 0.01), CRP and HPT levels in ANP group rose markedly (P < 0.001), but only CRP level was significant difference between either of the pancreatitis groups (P < 0.001). At 4 hrs after the development of AP, amylase and CRP levels were increased in two pancreatitis group, only HPT rose in dogs of ANP group (p < 0.01). On the other hand, CRP level in ANP group was higher than that in AOP group (p < 0.001). In the three parameters, only the correlation between the serum CRP level and the severity of pancreatic damages was significant (r_s = 0.7964, P < 0.001 and r_s = 0.8246, P < 0.001) respectively at 2 and 4 hrs after induced AP in ANP group. Dogs with lethal outcome (83.3% mortality) had markedly elevated initial serum CRP level (from 34.64 – 2.66 to 148.77 – 7.25 mg/dl) at 2 hrs after AP (P < 0.001) in ANP group. These results suggest that serum CRP levels is reliable parameter with a high detection rate for pancreatic necrosis and available for the prognostic evaluation of AP in the early phase of acute necrotizing pancreatitis. "P P 19 0513"P 19 0513**Retrospective Analysis of Etiology of Acute Pancreatitis**

*A. Ol\'e1h, G. Pardavi, T. Bel\'e1gyi, A. Petz

County Hospital, Dept. of Surgery, Gyo˝r, Hungary*Purpose of study:* It is well-known that alcoholic etiology of acute pancreatitis is outstanding high in Hungary. In most of European countries the rate of this etiologic factor is much lower. The aim of our retrospective study was to analyse the etiology of our patients and the relationships between etiology and morbidity, mortality rates.*Patients and method:* Between 1990 and 1994 altogether 374 patients were admitted in our surgical department with acute pancreatitis. This enormous great number doesn't include a lot of mild cases which were hospitalized in departments of internal medicine. Diagnosis was based on clinical signs, elevation of serum enzymes and imaging studies (US, CT, ERCP). Necrosis was detected by contrast enhanced CT scan or by surgery.*Results:* In the whole group 220 pts had alcoholic, 115 pts had biliary and 39 pts had other (postoperative, traumatic or hyperlipidaemic) etiology. More than 60% of alcoholic pts consumed > 60 gr/day/> 5 years. Necrosis developed in 127 pts. The rate of alcoholic etiology was 80.3% in this group (102 pts) and only 7.9% of the biliary lithiasis (10 pts). Fifteen pts had other etiology (11.8%). In the oedematous group (247 pts) the rate of alcoholic and biliary etiology was about same (47.7% and 42.5%). Overall mortality was 5.8% (22 pts) and 15% (19 pts) of the necrotizing group. According to etiology we lost 14 pts from the alcoholic (6.4%), 3 pts from the biliary (2.6%) and 5 pts from the other — mostly hyperlipidaemic — group (33.3%).*Conclusion:* Our data support that in Hungary about 80% of the cases of necrotizing pancreatitis have alcoholic etiology with significantly worse prognosis. "P P 19 0514"P 19 0514**Serum Interleukin 10 in Human Acute Pancreatitis**

*P. Billi, R. Miniero, R. Pezzilli

Emergency Department and Central Laboratory, St. Orsola Hospital, Bologna, ItalyInterleukin 10 (IL-10) recently emerged as an anti-inflammatory cytokine which inhibits the secretion of proinflammatory cytokines by monocytes and/or macrophages and the release of free oxygen radicals. It has been reported that treatment with IL-10 decreases the severity of experimental pancreatitis, mainly by inhibiting cellular necrosis. We did the present study because there are no data about serum levels of IL-10 in human acute pancreatitis. Forty-five patients with acute pancreatitis (25 M, 20 F, mean age 60 years, range 20–82) were studied; the diagnosis was based on characteristic abdominal pain associated with a two-fold increase of serum lipase, and it was confirmed by imaging techniques. Acute pancreatitis was of biliary origin in 30 patients, due to alcohol abuse in 10, due to pancreas divisum in 1, and of unknown origin in the remaining 4. According to the Balthazar criteria, 19 patients had scores less or equal to 2 points and 26, had scores greater than 2 points. Twelve healthy subjects were also studied as controls. Serum IL-10 was determined in all subjects on admission, and in acute pancreatitis patients also daily for the subsequent 4 days using a commercial kit (Predicta Human Interleukin-10 kit, Genzyme Co., USA). Healthy subjects had no detectable serum levels of IL-10. In acute pancreatitis patients, serum IL-10 levels peaked on the first day of the disease (mean – SE: 193 – 171 pg/ml) and subsequently, decreased significantly (mean – SE: 137 – 96 pg/ml on the 2nd day of illness, 117 – 18 pg/ml on the 3rd day, 2.4 – 1.4 pg/ml on the 4th day and 2.5 – 1.0 pg/ml on the 5th day; P < 0.01 vs. the first day of the disease). On the first day of the acute pancreatitis, patients with the Balthazar scores less or equal to 2 points had serum levels of IL-10 (mean – SE: 424 – 389 pg/ml) significantly higher than those with scores greater than 2 points (mean – SE: 15 – 6 pg/ml) (P < 0.05). In the subsequent 4 days serum IL-10 levels decreased in both groups of patients in a similar fashion. The results of our study demonstrated that in patients with acute pancreatitis there is a secretion of IL-10 on the first day of the illness which is more marked in patients with mild acute pancreatitis than in those with the severe form of the disease. In the subsequent days there is a significant decrease of IL-10 secretion in both groups of patients. In patients with acute pancreatitis, especially those having the severe form of the illness, the administration of IL-10 should be considered in order to explore its potential therapeutic effect. Pancreas: Pancreatitis, acute }" "Serum Interleukin 10 in Human Acute Pancreatitis"

"P P 19 0515"P 19 0515**Does Inhibition of Polyamines Synthesis Affect the Pancreas Regeneration after Acute Pancreatitis. Ultrastructural and Biochemical Study**

*G. Jurkowska, G. Rydzewska, A. Andrzejewska[1], A. Gabryelewicz

Gastroenterology Dept., Medical School, Bialystok, Poland

[1] Pathomorphology Dept., Medical School, Bialystok, PolandThe factors involved in pancreas regeneration after acute pancreatitis (AP) are poorly clarified. The importance of polyamines in tissue growth and regeneration was shown.*The aim* of the present study was to evaluate the effect of polyamines synthesis inhibition on pancreas regeneration after AP.*Methods:* AP was induced in male Wistar rats by s.c. injections of caerulein (12 mg/kg) for 2 days t.i.d. with control (C) receiving saline. After AP induction rats were treated with inhibitor of polyamines synthesis a-difluoromethylornithine (DFMO) or saline for 2, 7 or 14 days. DFMO was given 3 {\'b4} 300 mg/kg bw i.p. during three treatment periods and additionally for the first 3 days (1 day before and during 2 days of caerulein injections as: i.p injections and 2% solution in drinking water). Pancreatic weight (PW), total protein, enzymes, DNA, RNA contents were evaluated and ultrastructural examination of tissue specimens was performed.*Results:* Two days after AP induction the interstitial edema, inflammatory infiltration and destruction of some acinar cells were observed. The mitosis of acinar cells were seen in both AP groups. After 14 days nearly complete recovery of pancreas ultrastructure in AP untreated rats was observed. DFMO treatment of AP animals (especially after 7 and 14 days) was connected with more pronounced injury of acinar cells. They showed the signs of RER lesion accompanied with large, dilated cisterns of Golgi apparatus. The amount of zymogen granules and condensing vacuoles were lowered after 7 and 14 days of treatment with DFMO when compared to untreated AP-rats and C. The evident polymorphism of mitochondria was also seen in AP rats treated with DFMO. Concurrently to morphological changes the biochemical parameters showed, that pancreas injury occurred 2 days after AP induction. The spontaneous recovery was observed after 14 days in both AP groups, however, in DFMO treated rats PW and RNA content still remained significantly lower than in C.*Conclusion:* These results suggest that the inhibition of polyamines synthesis delay the spontaneous regeneration after acute pancreatitis.Supported from the grant KBN 4 S402 03 06 Pancreas: Pancreatitis experimental }" "Does Inhibition of Polyamines Synthesis Affect the Pancreas Regeneration after Acute Pancreatitis. "P P 19 0516"P 19 0516**The Role of Oxidative Stress in Acute Pancreatitis**

*A. Gabryelewicz, U. Wereszczynska-Siemiatkowska, M. Jedynak

Department of Gastroenterology, Medical School, Bialystok, PolandThe oxidants/antioxidants imbalance as an important pathway in experimental acute pancreatitis (AP) has been found. The *aim* of this study was to evaluate the impairment of oxidants/antioxidants balance in the serum and urine of patients with AP. *Methods.* The studies were performed in 44 patients with mild (n = 16), moderate (n = 11), and severe (n = 17) AP. The serum and urine malondialdehyde (MDA) concentration as an index of oxidant-mediated lipid peroxidation, and sulfhydryl groups (SH) – major nonenzymatic antioxidant were measured at admission and at 2, 5, 10-th day of disease. The statistical analysis was performed using Wilcoxon and Mann-Whitney U tests. *Results.* Serum phospholipase A_2 (PLA_2) at admission was increased by 31%, 40%, 54% in mild, moderate and severe AP respectively ($p < 0.01$). Serum MDA concentration in severe AP was elevated by 44% ($p < 0.01$) at admission and 50% ($p < 0.01$) after 10 days in comparison to mild AP and by 27% ($p < 0.01$) and 34% ($p < 0.05$) in comparison to moderate AP, respectively. The highest urine MDA concentrations in severe AP in 2 day (by 38% $p < 0.01$), 5 day (by 45% $p < 0.05$) in comparison to admission values were observed. In this time in mild and moderate AP urine MDA concentration was significantly lower in comparison to severe AP. Serum SH concentration in severe AP was lowered after 2, 5, 10 days by 18% ($p < 0.01$), 22% ($p < 0.001$), 23% ($p < 0.001$) respectively, while in moderate AP after 10 days by 31% ($p < 0.01$) in comparison to admission; in mild AP slight differences were found. In acute pancreatitis the increase of serum and urine MDA concentration was associated with decrease of serum and urine SH groups concentration. The disturbance of oxidants/antioxidants balance coexists with the increase of serum phospholipase A_2 activity. *Conclusion.* An association of oxidants/antioxidants imbalance with severity of acute pancreatitis suggest an important role of oxidative stress in pathogenesis of acute pancreatitis.Partly supported by grant nr 513777. Pancreas: Pancreatitis, acute }" "The Role of Oxidative Stress in Acute Pancreatitis"

"P P 19 0517"P 19 0517**Factors Influencing Outcome in Pancreatic Necrosis**

*P.C. Leeder, I.G. Martin, M.J. McMahon

Department of Surgery, The General Infirmary at Leeds, UK144 patients with acute pancreatitis were treated consecutively over a seven year period by one consultant (MJM). 70 were admitted from our local population and 74 were transferred from other hospitals. The median age was 54 years (17–91) and 90 patients were male (1.7:1.0). The aetiology was thought to be ethanol in 44 patients, gallstones in 51, idiopathic in 33 and due to other causes in 16 patients.Dynamic CT imaging was performed in 99 patients. Pancreatic necrosis was diagnosed in 54 patients on CT. In 24 of these patients (44%), infection was demonstrated within the necrosis either by fine needle aspiration or subsequently at operation. 1 patient was found to have infected pancreatic necrosis which was not diagnosed at CT. The majority of organisms were of gut origin, with a number of staphylococci and yeasts grown.Of the 54 patients, 26 were managed conservatively and 28 had operation. Of these, 22 patients required pancreatic debridement. Surgery was carried out a median of 22 days after presentation.Overall 26 of the 144 (18%) patients died from their pancreatitis. The best predictor of overall mortality was the APACHE II score on admission ($p < 0.001$). 14 (56%) patients with infected pancreatic necrosis died compared with only 6 (20%) of those with demonstrated sterile pancreatic necrosis. 70% of patients undergoing pancreatic debridement died, a mean of 68 days from onset of their attack.The tertiary referral group had a significantly higher mortality following pancreatic debridement, compared to those presenting locally ($p < 0.03$). This we feel is due to both a delay in referral and transfer of patients to a specialist centre, exacerbated by a lack of intensive care beds. Patients with pancreatic necrosis should therefore be referred earlier to a specialist unit where optimum diagnostic and therapeutic services are available to deal with this difficult condition. [3] Center of Internal Medicine, University of G\'f6ttingen, Germany

[4] Center of Surgery, University of G\'f6ttingen, GermanySurveys on morbidity and mortality of acute pancreatitis date back a few decades. Newer studies concentrate mainly on the treatment of severe acute pancreatitis, i.e. only on a special aspect of the disease. Our retrospective study aimed to obtain more up-to-date data based on a substantial number of patients diagnosed and treated for acute pancreatitis during the last 15 years.*Patients and Methods.* The course of the disease was studied in 602 patients who were admitted between 1/1/1980 and 30/9/1993 to the University Hospital of G\'f6ttingen (n = 417) and between 16/11/1986 and 30/6/1994 to the Municipal Hospital of L\'fcneburg (n = 185).*Results.* Etiologies were biliary tract disease in 227 (37.7%), alcohol abuse in 177 (29.4%), unknown in 133 (22.1%), and other in 65 (10.8%) patients. Mean hospital stay was 27.9 – 24 days (x – SD), median 23 days. Within the first 48 hours, respiratory insufficiency was observed in 63.2% patients (of 204 patients undergoing arterial blood gas analysis) as well as renal insufficiency in 32.6% of all 602 patients. Artificial ventilation was indicated in 12.5% and dialysis in 7% patients. Pancreatic pseudocysts developed in 14.3% patients and surgical treatment was necessary in 11.1%. Mortality rate was 6.1% and did not differ between the university and the non-university hospital. However, mortality rate significantly correlated with respiratory and renal insufficiency, artificial ventilation and dialysis procedures ($p < 0.001$). Mortality rate was significantly higher in patients secondarily admitted as compared to patients primarily admitted to hospital (12.1 vs. 4.6%; $p < 0.005$).*Conclusion.* Mortality rate was distinctly lower than those reported in the last 3 decades of 10% to 25%. The higher mortality rate of secondarily admitted patients indicates the need for early transfer of patients with severe acute pancreatitis to specialized hospitals. "P P 19 0519"P 19 0519**Predictors of the Etiology of Acute Pancreatitis**

*D. Stimac, T. Lenac, Z. Marusic[1], D. Kovac, A. Vcev, M. Rubinic

Internal Clinic, Gastroenterology Division, Clinical Hospital Centre Rijeka, Rijeka, Croatia

[1] Central bureau of Statistics, Zagreb, CroatiaThe purpose of the study was to identify which laboratory parameter or combination of parameters predicts alcoholic or non alcoholic acute pancreatitis.A hundred and sixty-seven patients were divided into groups A (alcoholic pancreatitis) and NA (non alcoholic pancreatitis). Group NA consisted of groups B (biliary pancreatitis) and NANB (non alcoholic, non biliary pancreatitis). The values of serum amylase, lipase, aspartate aminotransferase (AST), alanine aminotransferase (ALT), alkaline phosphatase (ALP), gamma glutamyl transferase (GGT), bilirubin, lipase/amylase (L/A) ratio, erythrocyte means corpuscular volume (MCV) and urine amylases were analysed.Univariate analysis (Wilcoxon rank sum test) showed significant differences in serum amylase, ALT, AST, ALP, L/A ratio, MCV and urine amylase between the groups A and NA.Multivariate analysis (logistic regression) showed that three variables were simultaneously significant predictors of alcoholic or non alcoholic pancreatitis: L/A ratio ($p < 0.001$), MCV ($p = 0.023$) and ALP ($p = 0.071$). Resulting mathematical model for these three parameters has higher sensitivity (87.5%), specificity (97.8%) and diagnostic efficiency (95.8%) than any individual parameter analysed by univariate analysis.We conclude that L/A ratio, MCV and ALP are the most significant variables for the prediction of alcoholic versus non alcoholic pancreatitis. Pancreas: Pancreatitis, acute }"

"P P 19 0520"P 19 0520**The Effect of SMS 201–995 on Rats Pretreated with L-AsparaginaseAhmet G\'f6rg\'fcl,**

*Kayhan Bur\'e7ak, Kayhan Basak, Mentes B\'fclent

G\'dcTF, Ankara, T\'fcrkiyeThe aim of the study was to investigate the effect of SMS 201–995 on L-asparaginase induced hyperamylasemia and/or pancreatitis in rats.*Materials and methods:* 60 Wistar albino rats were into 5 groups. In the first group 100 \'b5g SMS 201–995 (ip) was administered 6 times with 2 hours intervals. The second group received a single dose of 5000 IU L-asparaginase (ip). In the third group, first 0.5 cc caerulein (ip) 2 times with 2 hours intervals and then 5000 IU L-asparaginase were given (ip). In the fourth group; we added 100 \'b5g SMS 201–995 (ip) 6 times with 2 hours intervals to the third group's treatments. The last group received 5000 IU L-asparaginase (ip) and 100 \'b5g SMS 201–995 (ip) 6 times with 2 hours intervals. Twelve hours after the first treatment doses, rats were killed with the withdrawal of 5 cc blood and the pancreatic tissue was removed. We compared both EC 3.2.1 amylase and EC 3.1.1.3 lipase levels. The pancreatic tissue samples were evaluated by two blinded pathologist.*Results:* We scored the severity of pancreatitis in all groups. According to the scoring system, group 1 lacked any evidence of pancreatitis. Groups 2 and 4 had mild or moderate pancreatitis; group 3 had severe pancreatitis; and group 5 had mild pancreatitis. EC 3.1.1.3 lipase activities were all with in normal ranges in all groups, but EC 3.2.1 amylase activities were significantly increased in all groups except for group 1.*Conclusion:* SMS 201–995 did not inhibit hyperamylasemia in rats induced by L-asparaginase. On the other hand, the microscopical findings of pancreatic injury induced by caerulein, L-asparaginase, or both of them were prevented by SMS 201–995, within the time limits of this study. Pancreas: Pancreatitis experimental }" "The Effect of SMS 201-995 on Rats Pretreated with L-Asparaginase"

"P P 19 0521"P 19 0521**Acute Pancreatitis in Cholesterolosis: Preliminary Results of a Prospective Study**

*M. Ventrucci, D. Festi, G.M. Ubalducci, A. Sangermano, A. Colecchia, E. De Vergori, P. Fusaroli, M. Orsini, P. Simoni, E. Roda

Dept of Gastroenterology, University of Bologna, Italy

Dept of Physiopathology, University of Chieti, ItalyThe etiological role of cholesterolosis in acute pancreatitis remains unclear. The presence of supersaturated bile with formation and migration of cholesterol crystals, impaction of detached cholesterol polyps at the sphincter of Oddi and biliary dysmotility have been suggested as putative factors. The aim of this study was to look for evidence of pancreatic damage in cholesterolosis and investigate its pathophysiology. *Methods:* 72 pts with ultrasonographic evidence of cholesterolosis were studied for follow-up periods ranging from 1 to 4 years. The presence of this condition was confirmed at repeat ultrasonography (within 12 months) performed by another examiner. Serum pancreatic isoamylase and lipase were determined in each patient. Biliary lipid analysis and crystal detection by microscopy were performed in the duodenal bile of 22 pts. Gallbladder motility was evaluated by ultrasound after a standard liquid meal in 40 pts. *Results:* During the follow-up period acute edematous pancreatitis occurred in 2 pts (3%) and mild abdominal pain not typical of acute pancreatitis was reported in 23 (32%). Abnormal pancreatic findings by ultrasound were observed only in one patient who had acute pancreatitis prior and during the study. Significant elevation (> 2 times the upper normal limit) of serum pancreatic amylase and lipase was detected in only one patient with nonpancreatic. abdominal pain. Supersaturated bile was found in 14/22 pts (64%), two of them with acute pancreatitis. Cholesterol and/or calcium bilirubinate crystals were seen in 12/22 (54%), two of whom with acute pancreatitis. Gallbladder motility, evaluated by both fasting and residual volumes and emptying, was normal in all pts. *Conclusion:* These preliminary results confirm the existence of a relationship between cholesterolosis and acute pancreatitis. The presence of supersaturated bile and of cholesterol or calcium bilirubinate crystals may be a factor in the pathophysiology of acute pancreatitis in this condition. *A. Pfeiffer, V. Keim[1], O. Kuntzen, F. Fiedler[2], H. Kaess

Dep. of Gastroenterology, Hospital Bogenhausen, Munich, Germany

[1] II. Med. Klinik, University of Leipzig, Germany

[2] Dep. of Anesthesiology, University of Mannheim, GermanyA raised serum lipase activity has been demonstrated in 22% of patients with acute gastroenteritis who had neither clinical nor sonographic signs of pancreatitis (GE 1995: 108 A 384). The underlying mechanism is still unknown. An increase in the intestinal permeability (IP) and not an inflammation of the pancreas has been proposed to be responsible for the hyperlipasemia in salmonella enteritis (Schw Med Wochenschr 1993; 123: 1482–86). As a highly specific marker of acute pancreatitis the pancreatitis associated protein (PAP) has recently been described (J Clin Invest 1992: 90, 2284–91). The aim was to investigate the relationships between a raised serum lipase and the IP and the serum PAP concentrations.*Methods:* 33 consecutive patients (20 women, 20–85 years) hospitalized for acute gastroenteritis participated in the study. IP was assessed by cellobiose (C) mannitol (M) ratio measured in urin collected during 5 hours, serum PAP concentration was determined by a competitive ELISA with a monoclonal antibody, and serum lipase activity was measured by a clinical routine method.*Results:* (Mean – SEM) Lipase (< 190 U/l) Lipase (> 190 U/l)Normal PAP (< 100 ng/ml) 20 1Elevated PAP (491 – 53 ng/ml) 2 10Normal IP (C/M 0.004 { -} 0.03) 11 4Elevated IP (C/M > 0.03) 9 9Using chi-square test with Yate's correction, there was a significant relationship between the elevation of lipase activity and PAP concentration ($p < 0.0005$), but not between lipase and IP.*Conclusion:* The association between the increased lipase activity and PAP concentration suggests a pancreatic damage in some patients with acute gastroenteritis. Lipase elevation in acute gastroenteritis is not due to an increased IP. Pancreas: Pancreatitis, acuteImmunology and microbiology: GI infections in adults }" "Pancreatitis in Acute Gastroenteritis"

*J. Jaworek, J. Bilski, A. Dembinski, Z. Warzecha, S.J. Konturek

Institute of Physiology, Collegium Medicum, Jagiellonian University, Krak\'f3w, PolandThe effects of calcitonin gene-related peptide (CGRP) and stimulation of pancreatic sensory nerves (SN) on secretory activity of isolated pancreatic acini in the course of caerulein-induced pancreatitis (CIP) were investigated in intact and capsaicin-denervated rats. CIP was produced by infusion of caerulein (10 \'b5g/kg-h {\'b4} 5 h) to the conscious rats. To stimulate duodenal sensory nerves 0.5 mg/kg of capsaicin (CP) was given intraduodenally (i.d.). To inactivate sensory nerves 100 mg/kg of CP was given s.c. over 3 days. CGRP (2 {\'b4} 10 \'b5g/kg s.c.) was injected before and during infusion of caerulein and in control tests. CIP significantly diminished the volume of isolated pancreatic acini (by 75%), and maximal secretion of amylase from these acini produced by caerulein or urecholine (by 45% and 40%, respectively) whereas basal enzyme release and pancreatic weight increased (both by 30%). Deactivation of sensory nerves by CP aggravated the changes produced by CIP. These harmful effects of ablation of sensory nerves on CIP were completely reversed by administration of CGRP into the CP-denervated rats. In intact rats treatment with CGRP, or stimulation of sensory nerves by CP, significantly attenuated all changes produced by CIP. Deactivation of sensory nerves and (or) administration of CGRP did not affect significantly all parameters tested. *Conclusion:* Administration of CGRP, or stimulation of pancreatic sensory nerves, attenuated the damage of pancreatic acini produced by CIP. "P P 20 0525"P 20 0525**Hepatic Arterial Chemoembolization with Streptozotocin in Patients with Liver Metastases of Endocrine Digestive Tumors**

*S. Dominguez[1], A. Denys[2], V. Vilgrain[2], Y. Menu[2], P. Bernades[1], P. Ruszniewski[1]

[1] Federation of Hepato-Gastroenterology, 92118 Clichy Cedex, France

[2] Radiology, Hospital Beaujon, 92118 Clichy Cedex, FranceHepatic arterial chemoembolization (CE) with doxorubicin is an effective palliative treatment for progressive liver metastases of endocrine digestive tumors. Systemic chemotherapy with streptozotocin (STZ) is the drug of choice for the treatment of these tumors; STZ has not been used for the CE so far. *Patients and methods:* 8 consecutive patients (pts), mean 58 years old, were included prospectively between July 1993 and February 1995. All had progressive liver metastases (histological confirmation: 6/8): 6 carcinoid tumors, 1 pancreatic gastrinoma, 1 non-secreting endocrine pancreatic tumor. The metastases were synchronous to the primary tumor in 6 pts, metachronous in 2, diffuse in 5 pts. Systemic chemotherapy had been ineffective in 3 pts. STZ was administered under general anaesthesia at a dose of 1.5 g/sqm in emulsion with iodized oil (LUF) before embolization with gelatine sponge. 2 to 6 sessions (median: 3) were performed in 6 pts (1 session in 2 pts). The modifications in size of liver metastases were evaluated by tomodensitometry or MRI according to WHO criteria. The median follow-up was 16 months (3–27). *Results:* An objective response (> 50% decrease in tumor size) was observed in 4 pts (50%) during 10, 12, 20 and 24 months, respectively. A tumoral stabilization was observed in 1 pt during 10 months. Progression was noted in 3 (37.5%) pts. One patient died in relation with tumoral progression after 9 months. Minor side effects of CE were nausea, fever and abdominal pain. An acute and reversible tubular necrosis attributed to CE was observed in 1 pt with previous nephrectomy. Bleeding peptic ulcer was recorded in one patient. *Conclusion:* STZ could be more effective than doxorubicin in palliative treatment of liver metastases of endocrine digestive tumors. The high specificity of STZ for endocrine tumors could account for these better results. Comparative studies with doxorubicin are necessary. "P P 20 0526"P 20 0526**Effect of Alpha-Interferon in Combination with Octreotide on Metastasized Gastroentero-Pancreatic Endocrine Tumours**

*M. Frank, U. Kajdan, K. Ehlenz, R. Arnold

Department of Gastroenterology, Philipp University, Marburg, Germany*Objective:* The first prospective German Sandostatin multicentre phase II trial demonstrated a longlasting antiproliferative effect of octreotide in 37% of patients with progressive metastatic endocrine gastroenteropancreatic (GEP) tumours (Arnold et al, Gut 1996). From case reports and a few prospective studies it has been suggested that the combination of octreotide and alpha-interferon (IFN) exhibits synergistic antiproliferative properties in patients unresponsive to octreotide alone. *Patients:* 20 patients (10 carcinoid syndromes, 6 non-functioning tumours, 3 gastrinoma, 1 vipoma) with tumour progression during octreotide treatment were enrolled in this open prospective trial. The patients received 200 \'b5g octreotide thrice daily plus 5 million IU IFN thrice weekly. *Results:* Effect of therapy Regression Standstill ProgressionPatients 1 (5%) 11 (55%) 8 (40%)Duration of response 36 months 20 monthsInhibition of 5-HIAA 8 (73%) 3 (28%)An inhibition of tumour growth (regression, standstill) was observed in 60% of patients with progressive GEP tumours. A hormonal response was observed in 73% of patients with carcinoid syndrome. No correlation between tumour size response and patient's characteristics could be detected. In 11 patients (55%), side effects (fever, weight loss, diarrhoea) developed, however benign and transitory. Five patients died of their metastatic disease.*Summary:* In conclusion, the combination of alpha-interferon and octreotide can be recommended as an antiproliferative strategy in patients with tumour progression during octreotide monotherapy. Oncology, specific: EndocrineOncology, general: Therapy }" "Effect of Alpha-Interferon in Combination with Octreotide on Metastasized Gastroentero-Pancreatic Endocrine Tumours"

"P P 20 0527"P 20 0527**Clinical Role of Somatostatin Receptor Scintigraphy in Patients with Neuroendocrine Gastro-Entero-Pancreatic Tumors**

*P. Tomassetti, M. Migliori, S. Fanti, E. Del Vecchio, R. De Giorgio, B. Bellanova, N. Monetti, A. Chiti, E. Bombardieri

Department of Internal Medicine and Gastroenterology, Nuclear Medicine Dpt., S. Orsola Malpighi University of Bologna

Nuclear Medicine Div. National Institute of Tumors, Milano-ItalySomatostatin receptor scintigraphy (SRS) is a validated method for non-invasive imaging of primary and metastatic gastroenteropancreatic neuroendocrine tumors. The aim of this study was to evaluate the role of SRS in the clinical management of patients with these lesions.Eighty patients with known or suspected GEP tumors were studied with SRS: planar and SPECT images were taken at 4 and 24 hours after injection of 200–250 MBq of 111-In-Pentatreotide. In addition to SRS, all patients were studied with at least one other imaging method: computed tomography (CT) in 65 patients, ultrasonography (US) in 63, and other procedures in 50. Results are detailed in the table: SRS CT USPrimary tumors 21/26 (81%) 13/21 (62%) 11/19 (58%)Metastases 33/38 (87%) 25/37 (68%) 22/31 (71%)Of the 80 patients studied, a total of 66 were eventually diagnosed with GEP tumors, all of which were confirmed by histology and distinguished as follows: 38 carcinoids, 9 gastrinomas, 2 insulinomas, 1 glucagonoma, 1 PPoma, 1 somatostatinoma, 14 non-functioning pancreatic tumors. In 17/66, SRS was the only imaging procedure able to correctly identify lesions; in the remaining 14, no evidence of tumor was found by SRS or the other studies performed. Regarding the role in clinical management, SRS supported the findings of other diagnostic modalities in all cases, and in 16 of the 66 GEP-positive patients the therapeutic approach was modified. *Conclusions:* our results confirm that SRS is a highly valid means of detecting GEP tumors and, consequently, has an important role in their management; it should be considered an essential procedure for all patients in whom these tumors are suspected. [1] Dept. Gastroenterology, Surgery, Univ. La Sapienza Rome, Italy

[2] Dept. Radiology, Univ. La Sapienza Rome, Italy

[3] Dept. of Pathology, Univ. La Sapienza Parma, Italy*Background:* Prognosis and management of patients with gastrinoma tumors depends by the tumors mass, extension and localizations. We and others authors have demonstrated the potential value of preoperative staging of tumors by combining ^{111}In Octreotide-""Octreoscan"" Scintigraphy and Magnetic Resonance (MR). The lack of data on the ""clinical outcome"" after such procedures plus surgical therapy led us to aim a study to investigate such aspects.*Methods:* 15 pts (8 M, 7 F mean age 49.1 yrs; range 11–74), 13 ZES, 2 MEN-I, (10 with multiple and 5 with single Presumable Tumor Lesion: PTL) underwent imaging studies: Octreoscan-scintigraphy (Images-plus SPET: Single Photon Emission Tomography-taken at 4 and 24 hours after radionuclide injection) and MR (Gyroscan T5, 5 mm thickness contiguous scans, 256 {\'b4} 256 matrix, T1 and T2 weighted spin echo and stir sequence), and were electively sent to surgery and operated on by the same surgeon in blind. The imaging studies were repeated 1 year after surgery. The follow-up of pts was prolonged at least at 24 mos. *Results:* Combined pre-surgical diagnostic procedures (Octreoscan plus MR) identified 48 PTL. At surgery 72.9% (35/48) were removed. 30 of them were histologically confirmed be tumors (62%; 30/48). At the post-surgery (1 year) imaging combined procedures 19 PTL were still detected. Two pts were cured (symptoms and PTL free 13.3%). The need of Omeprazole-therapy were reduced by 30%. The gastrin values were also decreased by 80% (pre vs post surgery values: $p < 0.001$). *Conclusions:* Even if the preoperative combined imaging (Octreoscan plus MR) increase the ability to detect more PTL and the debulking of tumor mass decreases significatively the values of circulating serum gastrin and improves the clinical symptoms but the rate of cured pts remains poor. "P P 20 0529"P 20 0529**P53 in Endocrine Tumors of Pancreas**

*L.E. Gurevitch, I.A. Kazantseva, A.P. Kalinin

Moscow Regional Research Clinical Institute (MONIKI), Moscow, RussiaAccurate diagnosis, treatment and prognosis of endocrine tumors of pancreas (ETP) are extremely difficult due to their morphological heterogeneity and variability in peptides are secreted by the tumor's cells. There is no universal approach for the evaluation of malignant potential in ETP that can be important for the choice of postoperative treatment regime and prognosis. The aim of our study was to determine the criteria for the evaluation of malignant potential in ETP using proliferating cell nuclear antigen (PCNA) and p53 protein. The expression of PCNA (clone P-10) and p53 (clone BP53-12) was revealed by immunohistochemistry, using microwave pretreatment in 10 surgical formalin fixed specimens of ETP. The hormonal profile of each tumor was determined by PAP technique with monoclonal antibodies against insulin, proinsulin, glucagon, gastrin, somatostatine, VIP, serotonin, calcitonin, chromogranine A. According PCNA and p53 expression 3 groups of tumors were revealed: Group I – with low proliferative rate (PCNA < 10% of tumor cells), p53 low/negative staining (3); Group II – with moderate proliferative rate (PCNA in 10–30% tumor cells), p53 positive (5); Group III – with high proliferative rate (PCNA > 30% tumor cells), p53 negative (2). Group III tumors were associated with poor prognosis and have clear morphological features of high malignancy: tumors' cell atypia, vessel invasion, and in one case liver metastasis. Group I tumors were associated with multihormonal profile and better prognosis. The data were found show that highly malignant ETP can be the result of mutation totally deleting p53 gene and so, they were usually associated with high proliferative and invasion rates. In contrast, moderately malignant ETP can be the result of mutation that partially deletes p53 gene (wild type expressed), and associated with moderate proliferative rate.*In conclusion:* Coexistence of high PCNA labeling and p53 negative staining found in ETP can be the markers of highly malignant potential of the tumor. OT4 0530 **Does Tumor Necrosis Factor (TNF) Microsatellite Define a Crohn's Disease-Associated Haplotype on Chromosome 6 in a French Population?D. Heresbach, A. Bourienne, M. Alizadeh, A. Dabadie, N. Leberre-Heresbach, B. Genetet, M. Gosselin, G. S\'e9mana, J.F. Bretagne**

Depts of Gastroenterology and University Laboratory of Immunology, 35033 RennesSome HLA class II association with Crohn's disease (CD) or ulcerative colitis (UC) may be due to their critical role in antigen presentation or act as markers for other closely linked genes on chromosome 6. Among the non HLA candidate genes the TNF locus is located in the MHC region centromeric to class I and telomeric to class II alleles. Furthermore, genetic polymorphisms at the TNF locus correlate with differences in TNF production as exhibited in CD or UC. Recently, five (a, b, c, d, e) microsatellites (MS) have been identified within the human TNF locus with 13, 7, 2, 5 and 4 alleles respectively.*The aim* of the study was to compare TNF MS allele frequencies at 5 loci in french populations of CD and UC patients with an ethnically matched control population.*Patients & Methods:* 60 UC and 100 CD patients are included in this study and compared to 65 ethnically matched controls (C) (distribution of age and sex was comparable between patients and controls). Genomic DNA (isolated from peripheral blood leucocytes) was amplified using a two-step PCR; 2 \'b5l of the first PCR reaction were amplified separately with specific primers pairs for each MS locus. Comparison of allele frequencies were tested by chi_2 test and corrected (p_c) according to multiple comparison.*Results:* Allele frequencies at the 5 TNF microsatellite loci are not significantly different between CD or UC patients and C. Haplotypes, defined as 5 loci allelic combinations previously identified were also analysed: there is no significant difference between patients and controls, especially for a_2 b_1 c_2 d_4 e_1 haplotypes (24% in CD, 23% in UC and 20% in C). Despite a non significant increase of this latter in CD patients receiving azathioprine (32% vs 16%, $p < 0.05$) compared to patients who reponded to first line treatment (ie, steroid or 5-ASA therapy) no haplotype association could be described according to clinical criteria.*Conclusions:* Our data did not support any association between TNF MS haplotypes and CD, particularly considering a_2 b_1 c_2 d_4 e_1 which have been previously reported associated with CD. OT4 0531 **Inhibition of Lamina Propria Cell Derived TNF-{ a} Synthesis by IL-10 in Inflammatory Bowel Disease**

*C. Gasche, S. Bakos, C. Dejaco, W. Tillinger, W. Reinisch, A. Gangl

Dept. Gastroenterology, University of Vienna, Austria*Aim:* Because of its anti-inflammatory properties, IL-10 is currently studied in the treatment of IBD. This trial was performed to investigate the inhibitory effect of IL-10 on mucosal TNF-{ a} synthesis in vitro. *Methods:* Lamina propria mononuclear cells were isolated from colonoscopic biopsies which were taken from both inflamed (i) and non-inflamed (ni) mucosa of patients with CD, UC or controls. Cells were cultured without (w/o) or with PHA (1% v/v) and with the addition of IL-10, IL-4 or IL-13, all at 10 ng/ml. After a 24 h incubation, supernatants were harvested and assayed for TNF-{ a} by a specific ELISA (values given in ng/ml or % of PHA stimulation). *Results:* Unstimulated TNF-{ a} production did not differ between groups. After PHA stimulation, TNF-{ a} levels increased significantly. Compared to controls, CD-i and UC-i but also CD-ni showed a lower TNF-{ a} synthesis. The addition of IL-10 inhibited TNF-{ a} production by { @} 30% in all groups. IL-4 decreased TNF-{ a} levels in UC-ni only (10%). IL-13 showed a similar inhibition in CD-i, CD-ni and UC-ni. CD-i CD-ni UC-i UC-ni Controlw/o (ng/ml) 0.05 – 0.03 0.2 – 0.2 0.2 – 0.06 0.08 – 0.03 0.1 – 0.03+PHA (ng/ml) 2.2 – 0.5** 4.5 – 0.9* 2.3 – 0.3** 7.1 – 1.7 10.5 – 1.4"" +IL-10 (%) 74 – 3$^{\#\#}$ 68 – 5$^{\#\#}$ 68 – 4$^{\#\#}$ 60 – 4$^{\#}$ 70 – 12$^{\#}$"" +IL-4 (%) 95 – 2 102 – 5 99 – 3 90 – 5$^{\#}$ 96 – 6"" +IL-13 (%) 94 – 3$^{\#}$ 89 – 4$^{\#}$ 103 – 5 88 – 2$^{\#\#}$ 92 – 5**p < 0.001, *p < 0.01, compared to control (by Wilcoxon Test). $^{\#\#}$p < 0.01, $^{\#}$p < 0.05, compared to PHA alone (by paired T-Test)*Conclusion:* PHA induced TNF-{ a} production is markedly decreased in inflamed mucosa. The decrease in TNF-{ a} production of macroscopic non-inflamed CD mucosa might reflect sampling of CD microlesions. IL-10 has the best inhibitory effect on TNF-{ a} synthesis which is preserved in inflamed mucosa. IL-10 is therefore a reasonable candidate for the treatment of IBD. OT4 0532 **Interleukin-1{ b} Converting Enzyme (ICE) is Expressed by Macrophages in the Lamina Propria of Active Inflammatory Bowel Disease (IBD) Mucosa**

*M.E. McAlindon, C.J. Hawkey, Y.R. Mahida

Division of Gastroenterology University Hospital, Nottingham, U.K.Interleukin-1{ b} (IL-{ b}) is a pro-inflammatory cytokine which is produced as an inactive pro-IL-1{ b} and processed by ICE to mature, active IL-1{ b}. We have recently shown that lamina propria cells isolated from active IBD mucosa produce mature IL-1{ b} and the active form of ICE (as assessed by Western blot analysis). Normal colonic lamina propria cells produced only pro-IL-1{ b} and the inactive form of ICE (Gastroenterology 1996; 110: A961). In this study, we have identified cells in the lamina propria that express ICE.Lamina propria cells were isolated from normal (3) and active IBD (7) mucosal samples. ICE expression and macrophages were studied in cytospin preparations and cryostat sections by immunohistochemistry using anti-ICE and anti-CD68 antibodies. Isolated IBD lamina propria cells were also incubated with opsonized zymosan for 1 h and cytospin preparations labelled with anti-ICE antibody.Using the anti-ICE antibody, scattered, weakly positive lamina propria cells with the morphology of macrophages were seen in tissue sections of normal intestinal mucosa. In IBD tissue, strong ICE-expressing cells, with the morphology of macrophages, were seen in the lamina propria and submucosa. Studies on isolated cells confirmed that the ICE-expressing cells were macrophages as demonstrated by the presence of numerous ICE-positive mononuclear cells that had phagocytosed opsonized zymosan. Median 63.5% (range 20–100%) of macrophages (CD68+ve) isolated from IBD mucosa expressed ICE. Of the other cell types, there was weak staining of lymphocytes and eosinophils in some cytospin preparations.*Conclusion.* In active IBD mucosa, cells strongly positive for ICE are present in the lamina propria and submucosa. As previously shown for IL-1{ b}, ICE is expressed predominantly by macrophages.* Supported by the British Digestive Foundation.
